## Chapter 4

## Process Variables

## INTRODUCTION

The authors originally considered the title "State, Physical, and Chemical Properties" for this chapter. However, since these three properties have been used interchangeably and have come to mean different things to different people, it was decided to employ the title "Process Variables." The three aforementioned properties were therefore integrated into this all-purpose title and eliminated the need for differentiating between the three.

This chapter provides a review of some basic concepts from physics, chemistry, and engineering in preparation for material that is covered in later chapters. All of these topics are vital in some manner to mass transfer operations. Because many of these topics are unrelated to each other, this chapter admittedly lacks the cohesiveness of chapters covering a single topic. This is usually the case when basic material from widely differing areas of knowledge such as physics, chemistry, and engineering are surveyed. Though these topics are widely divergent and covered with varying degrees of thoroughness, all of them will find use later in this text. If additional information on these review topics is needed, the reader is directed to the literature in the reference section of this chapter.

## ILLUSTRATIVE EXAMPLE 4.1

Discuss the traditional difference between chemical and physical properties.

SOLUTION: Every compound has a unique set of properties that allows one to recognize and distinguish it from other compounds. These properties can be grouped into two main categories: physical and chemical. Physical properties are defined as those that can be measured without changing the identity and composition of the substance. Key properties include viscosity, density, surface tension, melting point, boiling point, and so on. Chemical properties are defined as those that may be altered via reaction to form other compounds or substances. Key chemical properties include upper and lower flammability limits, enthalpy of reaction, autoignition temperature, and so on.

[^0]These properties may be further divided into two categories-intensive and extensive. Intensive properties are not a function of the quantity of the substance, while extensive properties depend on the quantity of the substance.

The remainder of the chapter addresses a variety of process variables.

## TEMPERATURE

Whether in the gaseous, liquid, or solid state, all molecules possess some degree of kinetic energy, i.e., they are in constant motion-vibrating, rotating, or translating. The kinetic energies of individual molecules cannot be measured, but the combined effect of these energies in a very large number of molecules can. This measurable quantity is known as temperature, which is a macroscopic concept only and as such does not exist on the molecular level.

Temperature can be measured in many ways; the most common method makes use of the expansion of mercury (usually encased inside a glass capillary tube) with increasing temperature. (However, in most industrial systems, thermocouples or thermistors are more commonly employed.) The two most commonly used temperature scales are the Celsius (or Centigrade) and Fahrenheit scales. The Celsius scale is based on the boiling and freezing points of water at 1 atm pressure; to the former, a value of $100^{\circ} \mathrm{C}$ is assigned, and to the latter, a value of $0^{\circ} \mathrm{C}$. On the older Fahrenheit scale, these temperatures correspond to $212^{\circ} \mathrm{F}$ and $32^{\circ} \mathrm{F}$, respectively. Equations (4.1) and (4.2) show the conversion from one temperature scale to the other:

$$
\begin{align*}
{ }^{\circ} \mathrm{F} & =1.8\left({ }^{\circ} \mathrm{C}\right)+32  \tag{4.1}\\
{ }^{\circ} \mathrm{C} & =\left({ }^{\circ} \mathrm{F}-32\right) / 1.8 \tag{4.2}
\end{align*}
$$

where $\quad{ }^{\circ} \mathrm{F}=$ a temperature on the Fahrenheit scale

$$
{ }^{\circ} \mathrm{C}=\mathrm{a} \text { temperature on the Celsius scale }
$$

Experiments with gases at low-to-moderate pressures (up to a few atmospheres) have shown that, if the pressure is kept constant, the volume of a gas and its temperature are linearly related (Charles' law, see later section) and that a decrease of $0.3663 \%$ or $(1 / 273)$ of the initial volume is experienced for every temperature drop of $1^{\circ} \mathrm{C}$. These experiments were not extended to very low temperatures, but if the linear relationship were extrapolated, the volume of the gas would theoretically be zero at a temperature of approximately $-273^{\circ} \mathrm{C}$ or $-460^{\circ} \mathrm{F}$. This temperature has become known as absolute zero and is the basis for the definition of two absolute temperature scales. (An absolute scale is one that does not allow negative quantities.) These absolute temperature scales are known as the Kelvin (K) and Rankine ( ${ }^{\circ} \mathrm{R}$ ) scales; the Kelvin scale is defined by shifting the Celsius scale by $273^{\circ} \mathrm{C}$ so that 0 K is equal to $-273^{\circ} \mathrm{C}$. Equation (4.3) shows the relationship described above:

$$
\begin{equation*}
\mathrm{K}={ }^{\circ} \mathrm{C}+273 \tag{4.3}
\end{equation*}
$$

The Rankine scale is defined by shifting the Fahrenheit scale $460^{\circ}$, so that

$$
\begin{equation*}
{ }^{\circ} \mathrm{R}={ }^{\circ} \mathrm{F}+460 \tag{4.4}
\end{equation*}
$$

The relationships among the various temperature scales are shown in Figure 4.1.

Figure 4.1 Temperature scales.

## ILLUSTRATIVE EXAMPLE 4.2

Perform the following temperature conversions:
1 Convert $55^{\circ} \mathrm{F}$ to (a) Rankine, (b) Celsius, and (c) Kelvin
2 Convert $55^{\circ} \mathrm{C}$ to (a) Fahrenheit, (b) Rankine, and (c) Kelvin

## SOLUTION:

1 (a) ${ }^{\circ} \mathrm{R}={ }^{\circ} \mathrm{F}+460=55+460=515$
(b) ${ }^{\circ} \mathrm{C}=\frac{5}{9}\left({ }^{\circ} \mathrm{F}-32\right)=\frac{5}{9}(55-32)=12.8$
(c) $\mathrm{K}=\frac{5}{9}\left({ }^{\circ} \mathrm{F}+460\right)=\frac{5}{9}(55+460)=286$

2 (a) ${ }^{\circ} \mathrm{F}=1.8\left({ }^{\circ} \mathrm{C}\right)+32=1.8(55)+32=131$
(b) ${ }^{\circ} \mathrm{R}=1.8\left({ }^{\circ} \mathrm{C}\right)+492=1.8(55)+492=591$
(c) $\mathrm{K}={ }^{\circ} \mathrm{C}+273=55+273=328$

## PRESSURE

Molecules possess a high degree of translational kinetic energy in the gaseous state, which means they are able to move quite freely throughout the body of the gas. If the gas is in a container of some type, the molecules are constantly bombarding the walls of the container. The macroscopic effect of this bombardment by a tremendous number of molecules-enough to make the effect measurable-is called pressure. The natural units of pressure are force per unit area. In the example of the gas in a container, the unit area is a portion of the inside solid surface of the container wall and the force, measured perpendicularly to the unit area, is the result of the molecules hitting the unit area and losing momentum during the sudden change of direction.

There are a number of different methods used to express a pressure measurement. Some of them are natural units (i.e., based on a force per unit area) and include pound (force) per square inch (abbreviated $\mathrm{lb}_{\mathrm{f}} / \mathrm{in}^{2}$ or psi ) and dyne per square centimeter (dyn/ $\mathrm{cm}^{2}$ ). Others are based on a fluid height such as inches of water (in $\mathrm{H}_{2} \mathrm{O}$ ) or millimeters of mercury ( mm Hg ). These latter units are convenient when the pressure is indicated by a difference between two levels of a liquid as in a manometer or barometer. Barometric pressure and atmospheric pressure are synonymous and measure the ambient air pressure. Standard barometric pressure is the average atmospheric pressure at sea level, $45^{\circ}$ north latitude at $32^{\circ} \mathrm{F}$. It is used to define another unit of pressure called the atmosphere (atm). Standard barometric pressure is 1 atm and is equivalent to 14.696 psi and 29.921 in Hg . As one might expect, barometric pressure varies with weather and altitude.

Measurements of pressure by most gauges indicate the difference in pressure either above or below that of the atmosphere surrounding the gauge. Gauge pressure is the pressure indicated by such a device. If the pressure in the system measured by the gauge is greater than the pressure prevailing in the atmosphere, the gauge pressure is expressed positively; if lower than atmospheric pressure, the gauge pressure is a negative quantity; the term vacuum designates a negative gauge pressure. Gauge pressures are often identified by the letter " g " after the pressure unit, e.g., psig (pounds per square inch gauge) is a gauge pressure in psi units.

Since gauge pressure is the pressure relative to the prevailing atmospheric pressure, the sum of the two yields the absolute pressure, indicated by the letter "a" after the unit, e.g., psia (pounds per square inch absolute):

$$
\begin{equation*}
P=P_{\mathrm{a}}+P_{\mathrm{g}} \tag{4.5}
\end{equation*}
$$

where $\quad P=$ absolute pressure ( psia )

$$
\begin{aligned}
& P_{\mathrm{a}}=\text { atmospheric pressure }(\mathrm{psia}) \\
& P_{\mathrm{g}}=\text { gauge pressure }(\mathrm{psig})
\end{aligned}
$$

The absolute pressure scale is absolute in the same sense that the absolute temperature scale is absolute, i.e., a pressure of zero psia is the lowest possible pressure theoretically achievable-a perfect vacuum.

## ILLUSTRATIVE EXAMPLE 4.3

Consider the following pressure calculations.
1 A liquid weighing 100 lb held in a cylindrical column with a base area of $3 \mathrm{in}^{2}$ exerts what pressure at the base in $\mathrm{lb}_{\mathrm{f}} / \mathrm{ft}^{2}$ ?
2 If the pressure is 35 psig (pounds per square inch gauge), what is the absolute pressure?

## SOLUTION:

1 Refer to Chapter 3.

$$
\begin{aligned}
F & =m g / g_{\mathrm{c}}=100 \mathrm{lb}\left(1 \mathrm{lb}_{\mathrm{f}} / \mathrm{lb}\right) \\
& =100 \mathrm{lb}_{\mathrm{f}}
\end{aligned}
$$

As discussed in Chapter 3, $g_{\mathrm{c}}$ is a conversion factor equal to $32.2 \mathrm{lb} \cdot \mathrm{ft} / \mathrm{lb}_{\mathrm{f}} \cdot \mathrm{s}^{2}$; $g$ is the gravitational acceleration, which is equal, or close to, $32.2 \mathrm{ft} / \mathrm{s}^{2}$ on Earth's surface. Therefore,

$$
\begin{aligned}
P & =F / S=100 \mathrm{lb}_{\mathrm{f}} / 3 \mathrm{in}^{2} \\
& =33.33 \mathrm{lb}_{\mathrm{f}} / \mathrm{in}^{2} \\
& =4800 \mathrm{lb}_{\mathrm{f}} / \mathrm{ft}^{2}
\end{aligned}
$$

where $S=$ surface area onto which force is applied.

$$
\begin{aligned}
2 P & =P_{\mathrm{a}}+P_{\mathrm{g}}=14.7+35 \\
& =49.7 \mathrm{psia}
\end{aligned}
$$

## MOLES AND MOLECULAR WEIGHT

An atom consists of protons and neutrons in a nucleus surrounded by electrons. An electron has such a small mass relative to that of the proton and neutron that the weight of the atom (called the atomic weight) is approximately equal to the sum of the weights of the particles in its nucleus (the protons and neutrons). Atomic weight may be expressed in atomic mass units (amu) per atom or in grams per gram atom. One gram atom contains $6.02 \times 10^{23}$ atoms (Avogadro's number). The atomic weights of the elements are available in the literature. ${ }^{(1,2)}$

The molecular weight (MW) of a compound is the sum of the atomic weights of the atoms that make up the molecule. Units of atomic mass units per molecule (amu/ molecule) or grams per gram mole ( $\mathrm{g} / \mathrm{gmol}$ ) are used for molecular weight. One gram mole (gmol) contains an Avogadro's number of molecules. For the English system, a pound mole ( lbmol ) contains $454 \times 6.023 \times 10^{23}$ molecules.

Molal units are used extensively in mass transfer calculations as they greatly simplify material balances where chemical reactions are occurring. For mixtures of substances (gases, liquids, or solids), it is also convenient to express compositions in mole fractions or mole percentages instead of mass fractions. The mole fraction is

## 24

the ratio of the number of moles of one component to the total number of moles in the mixture. Equations (4.6)-(4.9) express these relationships:

$$
\begin{align*}
\text { moles of } \mathrm{A} & =\frac{\text { mass } \mathrm{A}}{\text { molecular weight of } \mathrm{A}} \\
n_{\mathrm{A}} & =\frac{m_{\mathrm{A}}}{(\mathrm{MW})_{\mathrm{A}}}  \tag{4.6}\\
\text { mole fraction } \mathrm{A} & =\frac{\text { moles } \mathrm{A}}{\text { total moles }} \\
y_{\mathrm{A}} & =\frac{n_{\mathrm{A}}}{n}  \tag{4.7}\\
\text { mass fraction } \mathrm{A} & =\frac{\text { mass } \mathrm{A}}{\text { total mass }} \\
w_{\mathrm{A}} & =\frac{m_{\mathrm{A}}}{m}  \tag{4.8}\\
\text { volume fraction } \mathrm{A} & =\frac{\text { volume } \mathrm{A}}{\text { total volume }} \\
v_{\mathrm{A}} & =\frac{V_{\mathrm{A}}}{V} \tag{4.9}
\end{align*}
$$

The reader should note that, in general, mass fraction (or percent) is NOT equal to mole fraction (or percent).

## ILLUSTRATIVE EXAMPLE 4.4

A $55-\mathrm{gal}$ tank contains 20.0 lb of water.
1 How many pound moles of water does it contain?
2 How many gram moles does it contain?
3 How many molecules does it contain?
SOLUTION: The molecular weight of the water is

$$
\begin{aligned}
\mathrm{MW} & =(2)(1.008)+(15.999)=18.015 \mathrm{~g} / \mathrm{gmol} \\
& =18.015 \mathrm{lb} / \mathrm{lbmol}
\end{aligned}
$$

$\mathbf{1}(20.0 \mathrm{lb})\left(\frac{\mathrm{lbmol}}{18.015 \mathrm{lb}}\right)=1.11 \mathrm{lbmol}$ water
$2(20.0 \mathrm{lb})\left(\frac{453.593 \mathrm{~g}}{1 \mathrm{lb}}\right)\left(\frac{\mathrm{gmol}}{18.015 \mathrm{~g}}\right)=503.6 \mathrm{gmol}$ water
$3(503.6 \mathrm{gmol})\left(\frac{6.023 \times 10^{23} \text { molecules }}{1 \mathrm{gmol}}\right)=3.033 \times 10^{26}$ molecules

## MASS, VOLUME, AND DENSITY

The density $(\rho)$ of a substance is the ratio of its mass to its volume and may be expressed in units of pounds per cubic foot ( $\mathrm{lb} / \mathrm{ft}^{3}$ ), kilograms per cubic meter $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$, etc. For solids, density can be easily determined by placing a known mass of the substance in a liquid and determining the displaced volume. The density of a liquid can be measured by weighing a known volume of the liquid in a volumetric flask. For gases, the ideal gas law, to be discussed later in this chapter, can be used to calculate the density from the pressure, temperature, and molecular weight of the gas.

Unlike gases, the densities of pure solids and liquids are relatively independent of temperature and pressure and can be found in standard reference books. ${ }^{(1,2)}$ The specific volume $(v)$ of a substance is its volume per unit mass $\left(\mathrm{ft}^{3} / \mathrm{lb}, \mathrm{m}^{3} / \mathrm{kg}\right.$, etc.) and is therefore the inverse of its density.

Two key densities that the practicing engineer should be familiar with are that for air and water. Although the effect of temperature and pressure can be obtained directly from the ideal gas law, the following equation can be used to estimate the density of air at atmospheric conditions ${ }^{(1)}$ :

$$
\begin{equation*}
\rho_{\text {air }}\left(\mathrm{kg} / \mathrm{m}^{3}\right)=1.30-4.68 \times 10^{-3}(T)-1.40 \times 10^{-5}(T)^{2} ; \quad T \equiv{ }^{\circ} \mathrm{C} \tag{4.10}
\end{equation*}
$$

As one might expect, the effect of temperature on liquid water is negligible. However, the following equation may be employed to account for any temperature variation ${ }^{(1)}$ :

$$
\begin{align*}
\rho_{\mathrm{H}_{2} \mathrm{O}}\left(\mathrm{~kg} / \mathrm{m}^{3}\right)= & 999.85+6.1474 \times 10^{-2}(T)-8.3633 \times 10^{-3}(T)^{2} \\
& +6.6805 \times 10^{-5}(T)^{3}-4.3869 \times 10^{-7}(T)^{4} \\
& +1.3095 \times 10^{-9}(T)^{5} ; \quad T \equiv{ }^{\circ} \mathrm{C} \tag{4.11}
\end{align*}
$$

The reader should note that the density of a gas is denoted by $\rho, \rho_{\mathrm{V}}$, or $\rho_{\mathrm{G}}$ in this text. The term $\rho$ will generally be employed, but the other notations appear in certain situations for clarity. In addition, the density of a liquid is represented as $\rho_{\mathrm{L}}$.

## VISCOSITY

Viscosity is a property associated with a fluid's resistance to flow. More precisely, this property accounts for energy losses that result from shear stresses occurring between different portions of the fluid which are moving at different velocities. ${ }^{(3-5)}$ The absolute viscosity $(\mu)$ has units of mass per length $\cdot$ time; the fundamental unit is the poise $(\mathrm{P})$, which is defined as $1 \mathrm{~g} / \mathrm{cm} \cdot \mathrm{s}$. This unit is inconveniently large for many practical purposes and viscosities are frequently given in centipoises ( 0.01 poise), which is abbreviated to cP . The viscosity of pure water at $68.6^{\circ} \mathrm{F}$ is 1.00 cP . In English units, absolute viscosity is expressed either as pounds (mass) per foot $\cdot$ second ( $\mathrm{lb} / \mathrm{ft} \cdot \mathrm{s}$ ) or pounds per foot $\cdot$ hour ( $\mathrm{lb} / \mathrm{ft} \cdot \mathrm{h}$ ). The absolute viscosity depends primarily on temperature and to a lesser degree on pressure. The kinematic viscosity $(v)$ is the absolute viscosity divided by the density of the fluid and is useful in certain fluid
flow problems. The units for this quantity are length squared per time, e.g., square foot per second $\left(\mathrm{ft}^{2} / \mathrm{s}\right)$ or square meters per hour $\left(\mathrm{m}^{2} / \mathrm{h}\right)$. A kinematic viscosity of $1 \mathrm{~cm}^{2} / \mathrm{s}$ is called a stoke (S). For pure water at $70^{\circ} \mathrm{F}, v=0.983 \mathrm{cS}$ (centistokes). Because fluid viscosity changes rapidly with temperature, a numerical value of viscosity has no significance unless the temperature is specified.

Liquid viscosity is usually measured by the amount of time it takes for a given volume of liquid to flow through an orifice. The Saybolt universal viscometer is the most widely used device in the United States for the determination of the viscosity of fuel oils and liquid wastes. It should be stressed that Saybolt viscosities, which are expressed in Saybolt seconds (SSU), are not even approximately proportional to absolute viscosities except in the range above 200 SSU; hence, converting units from Saybolt seconds to other units requires the use of special conversion tables. As the time of flow through a viscometer decreases, the deviation becomes more marked. In any event, viscosity is an important property because of possible flow problems with viscous liquids.

The viscosities of air at atmospheric pressure and water are presented as functions of temperature in Tables 4.1 and 4.2, respectively. Viscosities of other substances are available in the literature ${ }^{(6)}$ and the Appendix. Several simple equations for directly calculating viscosities are presented below.

Equation (4.12) is used to calculate the viscosity of air:

$$
\begin{equation*}
\mu_{\text {air }}\left(\mathrm{N} \cdot \mathrm{~s} / \mathrm{m}^{2}\right)=1.71 \times 10^{-5}+5.0 \times 10^{-8} T ; \quad T \equiv{ }^{\circ} \mathrm{C} \tag{4.12}
\end{equation*}
$$

Regarding the viscosity of water, Equation (4.13) applies when the temperature is greater than $0^{\circ} \mathrm{C}$ and less than or equal to $20^{\circ} \mathrm{C}$ :

$$
\begin{align*}
\log \mu_{\mathrm{H}_{2} \mathrm{O}}(\mathrm{~kg} / \mathrm{m} \cdot \mathrm{~s})= & \frac{1301}{998.333+8.1855(T-20)+5.85 \times 10^{-3}(T-20)^{2}} \\
& -1.30233 ; \quad T \equiv{ }^{\circ} \mathrm{C} \tag{4.13}
\end{align*}
$$

This equation may be rearranged to give

$$
\begin{equation*}
\mu_{\mathrm{H}_{2} \mathrm{O}}=10\left[\frac{1301}{998.333+8.1855(T-20)+5.85 \times 10^{-3}(T-20)^{2}}\right]-1.30233 \tag{4.14}
\end{equation*}
$$

Table 4.1 Viscosity of Air at 1 Atmosphere ${ }^{a}$

| $T\left({ }^{\circ} \mathrm{C}\right)$ | Viscosity, micropoise $(\mu \mathrm{P})$ |
| :--- | :---: |
| 0 | 170.8 |
| 18 | 182.7 |
| 40 | 190.4 |
| 54 | 195.8 |
| 74 | 210.2 |
| 229 | 263.8 |

${ }^{a} 1 \mathrm{P}=100 \mathrm{cP}=10^{6} \mu \mathrm{P} ; 1 \mathrm{cP}=6.72 \times 10^{-4} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{s}$.

Table 4.2 Viscosity of Water

| $T\left({ }^{\circ} \mathrm{C}\right)$ | Viscosity, centipoise (cP) |
| :--- | :---: |
| 0 | 1.792 |
| 5 | 1.519 |
| 10 | 1.308 |
| 15 | 1.140 |
| 20 | 1.000 |
| 25 | 0.894 |
| 30 | 0.801 |
| 35 | 0.723 |
| 40 | 0.656 |
| 50 | 0.594 |
| 60 | 0.469 |
| 70 | 0.406 |
| 80 | 0.357 |
| 90 | 0.317 |
| 100 | 0.284 |

The viscosity of the water in the $20^{\circ} \mathrm{C}-100^{\circ} \mathrm{C}$ range may be calculated from Equation (4.15)

$$
\begin{equation*}
\log \left(\frac{\mu_{\mathrm{H}_{2} \mathrm{O} @ T}}{\mu_{\mathrm{H}_{2} \mathrm{O} @ 20^{\circ} \mathrm{C}}}\right)=\frac{1.3272(20-T)-1.053 \times 10^{-3}(T-20)^{2}}{T+105} ; T \equiv{ }^{\circ} \mathrm{C} \tag{4.15}
\end{equation*}
$$

The reader should note that, as with density, the viscosity of a gas is denoted by $\mu, \mu_{\mathrm{V}}$, and $\mu_{\mathrm{G}}$ in this text. In addition, the viscosity of a liquid is represented as $\mu_{\mathrm{L}}$.

## ILLUSTRATIVE EXAMPLE 4.5

What is the kinematic viscosity of a gas whose specific gravity ( $\mathrm{SG}=\rho / \rho_{\mathrm{H}_{2} \mathrm{O}}$ ) and absolute viscosity are 0.8 and 0.02 cP , respectively?

## SOLUTION:

$$
\begin{aligned}
\mu=\left(\frac{0.02 \mathrm{cP}}{1}\right)\left(\frac{6.720 \times 10^{-4} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s}}{1 \mathrm{cP}}\right) & =1.344 \times 10^{-5} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s} \\
\rho & =(\mathrm{SG})\left(\rho_{\mathrm{ref}}\right)=(0.8)\left(62.43 \mathrm{lb} / \mathrm{ft}^{3}\right)=49.94 \mathrm{lb} / \mathrm{ft}^{3} \\
\nu & =\mu / \rho=\left(1.344 \times 10^{-5} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s}\right) /\left(49.94 \mathrm{lb} / \mathrm{ft}^{3}\right) \\
& =2.691 \times 10^{-7} \mathrm{ft}^{2} / \mathrm{s}
\end{aligned}
$$

## ILLUSTRATIVE EXAMPLE 4.6

Calculate the viscosity of water at $10^{\circ} \mathrm{C}$.

SOLUTION: Equation (4.13) can be used over the temperature range of $0^{\circ} \mathrm{C}$ to $20^{\circ} \mathrm{C}$. Since the desired temperature is $10^{\circ} \mathrm{C}$,

$$
\begin{equation*}
\log \mu_{\mathrm{H}_{2} \mathrm{O}}=\frac{1301}{998.333+8.1855(T-20)+5.85 \times 10^{-3}(T-20)^{2}}-1.30233 \tag{4.13}
\end{equation*}
$$

Substituting $T=10^{\circ} \mathrm{C}$,

$$
\begin{aligned}
\log \mu_{\mathrm{H}_{2} \mathrm{O}} & =\frac{1301}{998.333+8.1855\left(10^{\circ} \mathrm{C}-20\right)+5.85 \times 10^{-3}\left(10^{\circ} \mathrm{C}-20\right)^{2}}-1.30233 \\
& =0.11633 \\
\mu_{\mathrm{H}_{2} \mathrm{O}} & =1.307 \text { centipoise } \\
& =1.307 \times 10^{-3} \mathrm{~kg} / \mathrm{m} \cdot \mathrm{~s}
\end{aligned}
$$

## REYNOLDS NUMBER

The Reynolds number, Re, is a dimensionless number that indicates whether a fluid flowing is in the laminar or turbulent flow regime. Laminar flow is characteristic of fluids flowing slowly enough so that there are no eddies (whirlpools) or macroscopic mixing of different portions of the fluid. (Note: In any fluid, there is always molecular mixing due to the thermal activity of the molecules; this is distinct from macroscopic mixing due to the swirling motion of different portions of the fluid.) In laminar flow, a fluid can be imagined to flow like a deck of cards, with adjacent layers sliding past one another. Turbulent flow is characterized by eddies and macroscopic currents. In practice, moving gases are generally in the turbulent region. ${ }^{(5)}$ For flow in a pipe, a Reynolds number above 2100 is an indication of turbulent flow.

The Reynolds number is dependent on the fluid velocity, density, viscosity, and some length characteristic of the system or conduit; for pipes, this characteristic length is the inside diameter:

$$
\begin{equation*}
\operatorname{Re}=D v \rho / \mu=D v / v \tag{4.16}
\end{equation*}
$$

where $\operatorname{Re}=$ Reynolds number

$$
\begin{aligned}
D & =\text { inside diameter of the pipe }(\mathrm{ft}) \\
v & =\text { fluid velocity }(\mathrm{ft} / \mathrm{s}) \\
\rho & =\text { fluid density }\left(\mathrm{lb} / \mathrm{ft}^{3}\right) \\
\mu & =\text { fluid viscosity }(\mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s}) \\
\nu & =\text { fluid kinematic viscosity }\left(\mathrm{ft}^{2} / \mathrm{s}\right)
\end{aligned}
$$

Any consistent set of units may be used with Equation (4.16).

## ILLUSTRATIVE EXAMPLE 4.7

Calculate the Reynolds number for a fluid flowing through a 5-inch diameter pipe at 10 fps (feet per second) with a density of $50 \mathrm{lb} / \mathrm{ft}^{3}$ and a viscosity of 0.65 cP . Is the flow turbulent or laminar?

SOLUTION: By definition

$$
\begin{equation*}
\operatorname{Re}=D v \rho / \mu \tag{4.16}
\end{equation*}
$$

Substitution yields

$$
\begin{aligned}
\mathrm{Re} & =\left(\frac{50 \mathrm{lb}}{\mathrm{ft}^{3}}\right)\left(\frac{10 \mathrm{ft}}{\mathrm{~s}}\right)\left(\frac{5 \mathrm{in}}{1}\right)\left(\frac{1 \mathrm{ft}}{12 \mathrm{in}}\right)\left(\frac{1}{0.65 \mathrm{cP}}\right)\left(\frac{1 \mathrm{cP}}{6.720 \times 10^{-4} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s}}\right) \\
& =\left(50 \mathrm{lb} / \mathrm{ft}^{3}\right)(10 \mathrm{ft} / \mathrm{s})(5 / 12 \mathrm{ft}) /\left(0.65 \times 6.72 \times 10^{-4} \mathrm{lb} / \mathrm{ft} \cdot \mathrm{~s}\right) \\
& =477,000
\end{aligned}
$$

The Reynolds number is $>2100$; therefore, the flow is turbulent.

## pH

An important chemical property of an aqueous solution is pH . The pH measures the acidity or basicity of a solution. In a neutral solution, such as pure water, the hydrogen $\left(\mathrm{H}^{+}\right)$and hydroxyl $\left(\mathrm{OH}^{-}\right)$ion concentrations are equal. At ordinary temperatures, this concentration is

$$
\begin{equation*}
C_{\mathrm{H}^{+}}=C_{\mathrm{OH}^{-}}=10^{-7} \mathrm{gmol} / \mathrm{L} \tag{4.17}
\end{equation*}
$$

where $\quad C_{\mathrm{H}^{+}}=$hydrogen ion concentration
$C_{\mathrm{OH}^{-}}=$hydroxyl ion concentration

In all aqueous solutions, whether neutral, basic, or acidic, a chemical equilibrium or balance is established between these two concentrations, so that

$$
\begin{equation*}
K_{\mathrm{eq}}=C_{\mathrm{H}^{+}} C_{\mathrm{OH}^{-}}=10^{-14} \tag{4.18}
\end{equation*}
$$

where $K_{\text {eq }}=$ equilibrium constant.
The numerical value for $K_{\text {eq }}$ given in Equation (4.18) holds for room temperature and only when the concentrations are expressed in gram mole per liter ( $\mathrm{gmol} / \mathrm{L}$ ). In acid solutions, $C_{\mathrm{H}^{+}}>C_{\mathrm{OH}^{-}}$; in basic solutions, $C_{\mathrm{OH}^{-}}$predominates. The pH is a direct measure of the hydrogen ion concentration and is defined by

$$
\begin{equation*}
\mathrm{pH}=-\log C_{\mathrm{H}^{+}} \tag{4.19}
\end{equation*}
$$

Thus, an acidic solution is characterized by a pH below 7 (the lower the pH , the higher the acidity), a basic solution by a pH above 7 , and a neutral solution by a pH of 7 . It should be pointed out that Equation (4.19) is not the exact definition of pH but is a close approximation. Strictly speaking, the activity of the hydrogen ion, $a_{\mathrm{H}^{+}}$, and not the ion concentration belongs in Equation (4.19). For a discussion of chemical activities, the reader is directed to the literature. ${ }^{(2,6)}$

## ILLUSTRATIVE EXAMPLE 4.8

Calculate the hydrogen ion and the hydroxyl ion concentrations of an aqueous solution if the pH of the solution is 1.0.

SOLUTION: For a pH of 1.0, apply Equation (4.19):

$$
\begin{aligned}
\mathrm{pH} & =-\log \left(C_{\mathrm{H}^{+}}\right) \\
C_{\mathrm{H}^{+}} & =10^{-\mathrm{pH}}=10^{-1}=0.1 \mathrm{gmol} / \mathrm{L} \\
C_{\mathrm{H}^{+}} \times C_{\mathrm{OH}^{-}} & =10^{-14} \\
C_{\mathrm{OH}^{-}} & =\frac{10^{-14}}{C_{\mathrm{H}^{+}}}=\frac{10^{-14}}{10^{-1}} \\
& =10^{-13} \mathrm{gmol} / \mathrm{L}
\end{aligned}
$$

## ILLUSTRATIVE EXAMPLE 4.9

Process considerations require pH control in a 50,000 -gal storage tank used for incoming waste mixtures (including liquid plus solids) at a hazardous waste incinerator. Normally, the tank is kept at neutral pH . However, the operation can tolerate pH variations from 6 to 8 . Waste arrives in 5000 -gal shipments.

Assume that the tank is completely mixed, contains 45,000 gal when the shipment arrives, the incoming acidic waste is fully dissociated, and that there is negligible buffering capacity in the tank. What is the pH of the most acidic waste shipment that can be handled without the need for neutralization?

SOLUTION: The pH of the most acidic waste shipment that can be handled without neutralization is calculated as follows: 5000 gal of waste with a $\left[\mathrm{H}^{+}\right]=X$ is diluted by $45,000 \mathrm{gal}$ at $\mathrm{pH}=7$ or $\left[\mathrm{H}^{+}\right]=10^{-7}$. The minimum pH of 6 that can be tolerated is equivalent to a $\left[\mathrm{H}^{+}\right]=10^{-6}$. From an ion balance:

$$
\begin{aligned}
{\left[\mathrm{H}^{+}\right] } & =10^{-6}=(5000 / 50,000) X+(45,000 / 50,000)\left(10^{-7}\right) \\
X & =\left(\frac{50,000}{5000}\right)\left[10^{-6}-\frac{45,000\left(10^{-7}\right)}{50,000}\right] \\
& =9.1 \times 10^{-6} \\
\mathrm{pH} & =5.04
\end{aligned}
$$

## VAPOR PRESSURE

Vapor pressure is an important property of liquids, and, to a much lesser extent, of solids. If a liquid is allowed to evaporate in a confined space, the pressure in the vapor space increases as the amount of vapor increases. If there is sufficient liquid present, a point is eventually reached at which the pressure in the vapor space is exactly equal to the pressure exerted by the liquid at its own surface. At this point, a dynamic equilibrium exists in which vaporization and condensation take place at equal rates and the pressure in the vapor space remains constant. The pressure exerted at equilibrium is equal to the vapor pressure of the liquid. The magnitude of this pressure for a given liquid depends on the temperature, but not on the amount of liquid present. Solids, like liquids, also exert a vapor pressure. Evaporation of solids (sublimation) is noticeable only for those with appreciable vapor pressures. This is reviewed in more detail in Chapter 6.

## IDEAL GAS LAW(7)

Observations based on physical experimentation often can be synthesized into simple mathematical equations called laws. These laws are never perfect and hence are only an approximate representation of reality. The ideal gas law (IGL) was derived from experiments in which the effects of pressure and temperature on gaseous volumes were measured over moderate temperature and pressure ranges. This law works well in the pressure and temperature ranges that were used in taking the data; extrapolations outside of the ranges have been found to work well in some cases and poorly in others. As a general rule, this law works best when the molecules of the gas are far apart, i.e., when the pressure is low and the temperature is high. Under these conditions, the gas is said to behave ideally, i.e., its behavior is a close approximation to the so-called perfect or ideal gas: a hypothetical entity that obeys the ideal gas law perfectly. For engineering calculations, the ideal gas law is often assumed to be valid since it generally works well (usually within a few percent of the correct result) up to the highest pressures and down to the lowest temperatures used in many industrial applications.

The two precursors of the ideal gas law were Boyle's and Charles' laws. Boyle found that the volume of a given mass of gas is inversely proportional to the absolute pressure if the temperature is kept constant:

$$
\begin{equation*}
P_{1} V_{1}=P_{2} V_{2} \tag{4.20}
\end{equation*}
$$

where $V_{1}=$ volume of gas at absolute pressure $P_{1}$ and temperature $T$ and $V_{2}=$ volume of gas at absolute pressure $P_{2}$ and temperature $T$.

Charles found that the volume of a given mass of gas varies directly with the absolute temperature at constant pressure:

$$
\begin{equation*}
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}} \tag{4.21}
\end{equation*}
$$

where $V_{1}=$ volume of gas at pressure $P$ and absolute temperature $T_{1}$ and $V_{2}=$ volume of gas at pressure $P$ and absolute temperature $T_{2}$.

Boyle's and Charles' laws may be combined into a single equation in which neither temperature nor pressure need be held constant:

$$
\begin{equation*}
\frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}} \tag{4.22}
\end{equation*}
$$

For Equation (4.22) to hold, the mass of gas must be constant as the conditions change from $\left(P_{1}, T_{1}\right)$ to $\left(P_{2}, T_{2}\right)$. This equation indicates that for a given mass of a specific gas, $P V / T$ has a constant value. Since, at the same temperature and pressure, volume and mass must be directly proportional, this statement may be extended to

$$
\begin{equation*}
\frac{P V}{m T}=C \tag{4.23}
\end{equation*}
$$

where $m=$ mass of a specific gas and $C=$ constant that depends on the gas.
Moreover, experiments with different gases showed that Equation (4.23) could be expressed in a far more generalized form. If the number of moles ( $n$ ) is used in place of the mass $(m)$, the constant is the same for all gases:

$$
\begin{equation*}
\frac{P V}{n T}=R \tag{4.24}
\end{equation*}
$$

where $R=$ universal gas constant.
Equation (4.24) is called the ideal gas law. Numerically, the value of $R$ depends on the units used for $P, V, T$, and $n$ (see Table 4.3). Other useful forms of the ideal gas law are shown in Equations (4.25) and (4.26). Equation (4.25) applies to gas flow rather than to gas confined in a container ${ }^{(7)}$ :

$$
\begin{equation*}
P q=\dot{n} R T \tag{4.25}
\end{equation*}
$$

where $q=$ gas volumetric flow rate $\left(\mathrm{ft}^{3} / \mathrm{h}\right), P=$ absolute pressure (psia), $\dot{n}=$ molar flow rate $(\mathrm{lbmol} / \mathrm{h}), T=$ absolute temperature $\left({ }^{\circ} \mathrm{R}\right)$, and $R=10.73 \mathrm{psia} \cdot \mathrm{ft}^{3} /$ lbmol $\cdot{ }^{\circ} \mathrm{R}$.

Equation (4.26) combines $n$ and $V$ from Equation (4.25) to express the law in terms of density:

$$
\begin{equation*}
P(M W)=\rho R T \tag{4.26}
\end{equation*}
$$

where $M W=$ molecular weight of the gas $(\mathrm{lb} / \mathrm{lbmol})$ and $\rho=$ density of the gas ( $\mathrm{lb} / \mathrm{ft}^{3}$ ).

Volumetric flow rates are often not given at the actual conditions of pressure and temperature but at arbitrarily chosen standard conditions (STP, standard temperature and pressure). To distinguish between flow rates based on the two conditions, the letters "a" and "s" are often used as part of the unit. The units acfm and scfm represent actual cubic feet per minute and standard cubic feet per minute, respectively. The ideal gas law can be used to convert from standard to actual conditions, but,

Table 4.3 Values of $R$ in Various Units

| $R$ | Temperature scale | Units of $V$ | Units of $n$ | Units of $P$ | $\begin{aligned} & \text { Units of } P V \\ & \text { (energy) } \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 10.73 | R | $\mathrm{ft}^{3}$ | lbmol | psia | - |
| 0.7302 | ${ }^{\text {R }}$ R | $\mathrm{ft}^{3}$ | lbmol | atm | - |
| 21.85 | ${ }^{\text {R }}$ | $\mathrm{ft}^{3}$ | lbmol | in Hg | - |
| 555.0 | ${ }^{\text {R }}$ R | $\mathrm{ft}^{3}$ | lbmol | mm Hg | - |
| 297.0 | ${ }^{\text {R }}$ R | $\mathrm{ft}^{3}$ | lbmol | in $\mathrm{H}_{2} \mathrm{O}$ | - |
| 0.7398 | ${ }^{\text {R }}$ R | $\mathrm{ft}^{3}$ | lbmol | bar | - |
| 1545.0 | ${ }^{\text {R }}$ | $\mathrm{ft}^{3}$ | lbmol | psfa | - |
| 24.75 | ${ }^{\text {R }}$ R | $\mathrm{ft}^{3}$ | lbmol | ft $\mathrm{H}_{2} \mathrm{O}$ | - |
| 1.9872 | ${ }^{\text {R }}$ | - | lbmol | - | Btu |
| 0.0007805 | ${ }^{\text {R }}$ | - | lbmol | - | $\mathrm{hp} \cdot \mathrm{h}$ |
| 0.0005819 | ${ }^{\text {R }}$ | - | lbmol | - | $\mathrm{kW} \cdot \mathrm{h}$ |
| 500.7 | ${ }^{\text {R }}$ | - | lbmol | - | cal |
| 1.314 | K | $\mathrm{ft}^{3}$ | lbmol | atm | - |
| 998.9 | K | $\mathrm{ft}^{3}$ | lbmol | mm Hg | - |
| 19.32 | K | $\mathrm{ft}^{3}$ | lbmol | psia | - |
| 62.361 | K | L | gmol | mm Hg | - |
| 0.08205 | K | L | gmol | atm | - |
| 0.08314 | K | L | gmol | bar | - |
| 8314 | K | L | gmol | Pa | - |
| 8.314 | K | $\mathrm{m}^{3}$ | gmol | Pa | - |
| 82.057 | K | $\mathrm{cm}^{3}$ | gmol | atm | - |
| 1.9872 | K | - | gmol | - | cal |
| 8.314 | K | - | gmol | - | J |

since there are many standard conditions in use, the STP being used must be known. Standard conditions most often used are shown in Table 4.4. The reader is cautioned on the incorrect use of acfm and/or scfm. Employing standard conditions is a convenience; when predicting the performance of or designing equipment, the actual conditions must be employed. Designs based on standard conditions can lead to disastrous results, with the unit usually underdesigned. For example, for a gas stream at

Table 4.4 Common Standard Conditions

| System | Temperature | Pressure | Molar volume |
| :--- | :---: | :---: | :---: |
| SI | 273 K | 101.3 kPa | $22.4 \mathrm{~m}^{3} / \mathrm{kmol}$ |
| Universal scientific | $0^{\circ} \mathrm{C}$ | 760 mm Hg | $22.4 \mathrm{~L} / \mathrm{gmol}$ |
| Natural gas industry | $60^{\circ} \mathrm{F}$ | 14.7 psia | $379 \mathrm{ft}^{3} / \mathrm{lbmol}$ |
| American engineering | $32^{\circ} \mathrm{F}$ | 1 atm | $359 \mathrm{ft}^{3} / \mathrm{lbmol}$ |
| Environmental industry | $60^{\circ} \mathrm{F}$ | 1 atm | $379 \mathrm{ft}^{3} / \mathrm{lbmol}$ |
|  | $70^{\circ} \mathrm{F}$ | 1 atm | $387 \mathrm{ft}^{3} / \mathrm{lbmol}$ |

$2140^{\circ} \mathrm{F}$, the ratio of acfm to scfm (standard temperature $=60^{\circ} \mathrm{F}$ ) is 5.0. Equation (4.27), which is a form of Charles' law, can be used to correct flow rates from standard to actual conditions:

$$
\begin{equation*}
q_{\mathrm{a}}=q_{\mathrm{s}}\left(\frac{T_{\mathrm{a}}}{T_{\mathrm{s}}}\right) \tag{4.27}
\end{equation*}
$$

where $q_{\mathrm{a}}=$ volumetric flow rate at actual conditions $\left(\mathrm{ft}^{3} / \mathrm{h}\right), q_{\mathrm{s}}=$ volumetric flow rate at standard conditions $\left(\mathrm{ft}^{3} / \mathrm{h}\right), T_{\mathrm{a}}=$ actual absolute temperature $\left({ }^{\circ} \mathrm{R}\right)$, and $T_{\mathrm{s}}=$ standard absolute temperature ( ${ }^{\circ} \mathrm{R}$ ).

The reader is again reminded that absolute temperatures and absolute pressures must be employed in all ideal gas law calculations.

In engineering practice, mixtures of gases are more often encountered than single or pure gases. The ideal gas law is based on the number of molecules present in the gas volume; the kind of molecules is not a significant factor, only the number. This ideal law applies equally well to mixtures and pure gases alike. Dalton and Amagat both applied the ideal gas law to mixtures of gases. Since pressure is caused by gas molecules colliding with the walls of the container, it seems reasonable that the total pressure of a gas mixture is made up of pressure contributions due to each of the component gases. These pressure contributions are called partial pressures. Dalton defined the partial pressure of a component as the pressure that would be exerted if the same mass of the component gas occupied the same total volume alone at the same temperature as the mixture. The sum of these partial pressures equals the total pressure:

$$
\begin{equation*}
P=p_{a}+p_{b}+p_{c}+\cdots+p_{n}=\sum_{i=1}^{n} p_{i} \tag{4.28}
\end{equation*}
$$

where $P=$ total pressure, $n=$ number of components, and $p_{i}=$ partial pressure of component $i$.

Equation (4.28) is known as Dalton's law. Applying the ideal gas law to one component ( $A$ ) only,

$$
\begin{equation*}
p_{A} V=n_{A} R T \tag{4.29}
\end{equation*}
$$

where $n_{A}=$ number of moles of component $A$.
Eliminating $R, T$, and $V$ between Equations (4.24) and (4.29) yields

$$
\frac{p_{A}}{P}=\frac{n_{A}}{n}=y_{A}
$$

or

$$
\begin{equation*}
p_{A}=y_{A} P \tag{4.30}
\end{equation*}
$$

where $y_{A}=$ mole fraction of component $A$.

## ILLUSTRATIVE EXAMPLE 4.10

What is the density of air at $75^{\circ} \mathrm{F}$ and 14.7 psia? The molecular weight of air is 29 .

SOLUTION: This example is solved using the ideal gas law:

$$
\begin{gathered}
P V=n R T=\frac{m}{(M W)} R T \\
\frac{P(M W)}{R T}=\frac{m}{V}=\rho
\end{gathered}
$$

or

$$
\begin{equation*}
\rho=\frac{P(M W)}{R T} \tag{4.26}
\end{equation*}
$$

Substituting,

$$
\begin{aligned}
\rho & =\frac{(14.7 \mathrm{psia})(29 \mathrm{lb} / \mathrm{lbmol})}{\left(10.73 \mathrm{ft}^{3} \cdot \mathrm{psi} / \mathrm{lbmol} \cdot{ }^{\circ} \mathrm{R}\right)(75+460)} \\
& =0.0743 \mathrm{lb} / \mathrm{ft}^{3}
\end{aligned}
$$

## ILLUSTRATIVE EXAMPLE 4.11

The exhaust gas flow rate from an absorber is 1000 scfm . All of the gas is vented through a small stack that has an inlet area of $1.0 \mathrm{ft}^{2}$. The exhaust gas temperature is $300^{\circ} \mathrm{F}$. What is the velocity of the gas through the stack inlet in feet per second? Assume standard conditions to be $70^{\circ} \mathrm{F}$ and 1.0 atm . Neglect the pressure drop across the stack.

SOLUTION: Note that since the gas is vented through the stack to the atmosphere, the pressure is 1.0 atm . Calculate the actual flow rate, in acfm, using Charles' law:

$$
\begin{equation*}
q_{\mathrm{a}}=q_{\mathrm{s}}\left(\frac{T_{\mathrm{a}}}{T_{\mathrm{s}}}\right) \tag{4.27}
\end{equation*}
$$

Substituting

$$
\begin{aligned}
& =1000\left(\frac{460+300}{460+70}\right) \\
& =1434 \mathrm{acfm}
\end{aligned}
$$

Calculate the velocity of the gas:

$$
\begin{aligned}
v & =\frac{q_{\mathrm{a}}}{S}=\frac{1434}{1.0} \\
& =1434 \mathrm{ft} / \mathrm{min}
\end{aligned}
$$
