- c) To allow further reduction of furosemide dose (target dose for furosemide during maintenance phase: 1–2 mg/kg PO q24–48h): Spironolactone dose varies between 0.5 mg/kg PO once daily (aldosterone blockade, weak diuretic effect) to 2 mg/kg twice daily (stronger diuretic effect). (de Madron 2004)

For treating ascites:

- a) Using the fixed dose combination with hydrochlorothiazide (*Aldactazide*®): The empirical dosage, based on the spironolactone component, is 0.5–1 mg/kg PO twice daily. (Trepanier 2008)
- b) Attempt at treating underlying abnormality. When ascites is caused by right-sided heart failure: Be sure owner is administering medication properly and the prescription is correct. Increase furosemide to 4–6 mg/kg PO q8h (generally speaking dose should be increased until all the abnormal accumulated fluid is eliminated or unacceptable azotemia develops). Optimize ACE inhibitor dose. Restrict dietary sodium. Add spironolactone at 1–2 mg/kg PO q12h. Initially (3 times weekly) substitute one of the oral furosemide doses with a SC dose. Consider adding hydrochlorothiazide initially at 2 mg/kg PO every other day. (Connolly 2006)

For adjunctive treatment of hypertension:

- a) 1–2 mg/kg PO q12h (Stepian 2006)
- b) As a fourth step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after **1**) enalapril/benazepril (0.5 mg/kg q12h); **2**) amlodipine (0.1 mg/kg q24h); **3**) amlodipine (0.2 mg/kg q24h); **4**) spironolactone (1–2 mg/kg twice daily); **5**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

#### ■ CATS:

As a diuretic in CHF:

- a) When furosemide and ACE inhibitors alone do not control fluid accumulation in refractory CHF: 1–2 mg/kg PO q12h (Ware & Keene 2000)
- b) 1 mg/kg q12h PO when serum potassium is low (Bonagura 1989)

For adjunctive treatment of hypertension:

- a) 1–2 mg/kg PO q12h (Stepian 2006)
- b) As a 3rd step drug when systolic BP >160 mmHg, diastolic >120 mmHg: **1**) amlodipine (0.625 mg per cat q24h; if cat greater than 6 kg, 1.25 mg/cat q24h), add ACE inhibitor if proteinuric; **2**) ACE inhibitor (benazepril/enalapril 0.5 mg/kg q12h); **3**) spironolactone (1–2 mg/kg twice daily); **4**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

For adjunctive treatment of primary hyperaldosteronism:

- a) If potassium supplementation alone does not control clinical signs: 1–2 mg/kg PO twice daily. (Caney 2009)

### Monitoring

- Serum electrolytes, BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema/ascites; patient weight, if indicated

### Client Information

- Notify veterinarian if GI symptoms (e.g., vomiting, diarrhea, anorexia), lethargy, or other CNS effects are severe or persist

### Chemistry/Synonyms

A synthetically produced aldosterone antagonist, spironolactone occurs as a cream-colored to light tan, crystalline powder with a faint mercaptan-like odor. It has a melting range of 198°–207°, with decomposition. Spironolactone is practically insoluble in water and soluble in alcohol.

Spironolactone may also be known as: espironolactona, SC-9420, spiro lactone, spironolactonum; many trade names are available.

### Storage/Stability

Spironolactone tablets should be stored at room temperature in tight, light-resistant containers.

### Compatibility/Compounding Considerations

An extemporaneously prepared oral suspension can be prepared by pulverizing commercially available tablets and adding cherry syrup. This preparation is reportedly stable for at least one month when refrigerated.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN LABELED PRODUCTS:**

## HUMAN PATIENTS:

Spirolonactone Oral Tablets: 25 mg, 50 mg & 100 mg; **Aldactone®** (Searle); generic; (Rx)

Spirolonactone/Hydrochlorothiazide Oral Tablets: 25 mg/25 mg & 50 mg/50 mg; **Aldactazide®** (Searle, generic); (Rx)

## STANOZOLOL

(*stah-no-zo-lahl*) Winstrol®-V

ANABOLIC STEROID

**Prescriber Highlights**

- **Anabolic steroid; FDA-approved products no longer marketed in USA**
- **Contraindications: Pregnant animals, breeding stallions, food animals. Extreme Caution: Cats, hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, & during the nephrotic stage of nephritis. Caution: Cardiac & renal dysfunction with enhanced fluid & electrolyte monitoring.**
- **Adverse Effects: Potentially high incidence of hepatotoxicity in cats. Other possible effects: sodium, calcium, potassium, water, chloride, & phosphate retention; hepatotoxicity, behavioral (androgenic) changes, & reproductive abnormalities (oligospermia, estrus suppression)**
- **Category “X” for pregnancy; teratogenicity outweighs any possible benefit**
- **Controlled substance in the USA**
- **Drug Interactions; lab interactions**

## Uses/Indications

Labeled Indications for the previously marketed veterinary stanozolol product *Winstrol®-V* (Winthrop/Upjohn) included “... to improve appetite, promote weight gain, and increase strength and vitality ...” in dogs, cats and horses. The manufacturer also stated that: “Anabolic therapy is intended primarily as an adjunct to other specific and supportive therapy, including nutritional therapy.” In a review of the evidence supporting anabolic steroid use in horses, the authors conclude: “Level 1 evidence for the efficacy of anabolic steroids in horses for therapeutic uses is not found in the biomedical literature. Evidence in other species exists for the efficacy of anabolic steroids in treating anemia and increasing muscle mass after illness or injury, but that evidence is not unequivocal, and the applicability to horses has not been demonstrated. There is little evidence in other species for the efficacy of anabolic steroids for increasing appetite.” (Fajt & McCook 2008)

Like nandrolone, stanozolol has been used to treat anemia of chronic disease. Because stanozolol has been demonstrated to enhance fibrinolysis after parenteral injection, it may be efficacious in the treatment of feline aortic thromboembolism or thrombosis in nephrotic syndrome; however, clinical studies and/or experience are apparently lacking for this indication at present.

## Pharmacology/Actions

Stanozolol possesses the actions of other anabolic agents but it may be less androgenic than other anabolics that are used in veterinary medicine. Refer to the discussion in the boldenone monograph for more information.

## Pharmacokinetics

No specific information was located for this agent. It is generally recommended that the injectable suspension be dosed on a weekly basis in both small animals and horses.

## Contraindications/Precautions/Warnings

Stanozolol is contraindicated in pregnant animals and in breeding stallions and should not be administered to horses intended for food purposes. Because of reported hepatotoxicity associated with this drug in cats, it should only be used in this species with extreme caution.

The manufacturer recommends using stanozolol cautiously in patients with cardiac and renal dysfunction with enhanced fluid and electrolyte monitoring.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, benign prostatic hypertrophy, during the nephrotic stage of nephritis, and in selected patients with breast carcinoma.

## Adverse Effects

The manufacturer (Winthrop/Upjohn) lists as adverse effects in dogs, cats, and horses only “mild androgenic effects” and then only when used with excessively high doses for a prolonged period of time.

One study in cats, demonstrated a very high incidence of hepatotoxicity associated with stanozolol use and the authors recommended that this drug not be used in cats until further toxicological studies are performed.

Potentially (from human data), adverse reactions of the anabolic agents in dogs and cats could include: sodium, calcium, potassium, water, chloride, and phosphate retention, hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (oligospermia, estrus suppression).

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *X* for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *D* (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, use in nursing patients with extreme caution.

## Overdosage/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving stanozolol and may be of significance in veterinary patients:

- **ANTICOAGULANTS (heparin, warfarin):** Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR/PT<sup>s</sup> and dosage adjustment, if necessary, of the anticoagulant are recommended
- **CORTICOSTEROIDS:** Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN:** Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements

## Laboratory Considerations

## Laboratory Considerations

- Concentrations of protein bound iodine (PBI) can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important. Androgen/anabolic agents can decrease amounts of thyroxine-binding globulin and decrease **total T<sub>4</sub>** concentrations and increase resin uptake of **T<sub>3</sub> and T<sub>4</sub>**. Free thyroid hormones are unaltered and there is no evidence of dysfunction.
- Both **creatinine** and **creatinine** excretion can be decreased by anabolic steroids.
- Anabolic steroids can increase the urinary excretion of **17-ketosteroids**.
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress **clotting factors** II, V, VII, and X.
- Anabolic agents can affect **liver function tests** (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase).

## Doses

### ■ DOGS:

As an anabolic agent per labeled indications:

a) Small Breeds: 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly.

Large Breeds: 2–4 mg PO twice daily; or 50 mg deep IM, may repeat weekly.

Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

For anemia secondary to chronic renal failure:

a) 1–4 mg PO once daily (Ross *et al.* 1989)

b) For anemias secondary to uremia: 2–10 mg PO twice daily (Maggio-Price 1988)

As an anabolic/appetite stimulant:

a) 1–4 mg PO twice daily (Weller 1988)

b) 1–2 mg PO twice daily or 25–50 mg IM weekly (Bartges 2003; Macy & Ralston 1989)

For canine cognitive dysfunction:

a) 2 mg/kg IM for 4–6 weeks with 1–2 mg (total dose) PO once daily for dogs less than 23 kg and 4 mg (total dose) PO once daily for dogs greater than 23 kg. If drug has some positive effect, maintain oral dosing and gradually reduce injections to every 3–4 weeks. (Hoskins 1999)

### ■ CATS: NOTE: SEE WARNINGS ABOVE

As an anabolic agent per labeled indications:

a) 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly. Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

### ■ FERRETS:

a) 0.5 mg/kg PO or SC twice daily; use with caution in hepatic disease (Williams 2000)

### ■ RABBITS, RODENTS, SMALL MAMMALS:

a) Rabbits: As an appetite stimulant: 0.5–2 mg PO once (Ivey & Morrissey 2000)

### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

As an anabolic agent per labeled indications:

a) 0.55 mg/kg (25 mg per 100 pounds of body weight) IM deeply. May repeat weekly for up to and including 4 weeks. (Package Insert; *Winstrol®-V*—Winthrop/Upjohn)

### ■ SHEEP & GOATS:

For acute or subacute aflatoxicosis in ruminants:

a) Stanozolol 2 mg/kg IM (plus activated charcoal 6.7 mg/kg as a 30% w/v slurry in M/15, pH 7 phosphate buffer). Do not combine with oxytetracycline therapy. (Hatch 1988)

### ■ BIRDS:

As an anabolic agent to promote weight gain and recovery from disease:

a) 0.5–1 mL/kg (25–50 mg/kg) IM once or twice weekly. Use with caution in birds with renal disease. (Clubb 1986)

### ■ REPTILES:

For most species post-surgically and in very debilitated animals:

a) 5 mg/kg IM once a week as needed (Gauvin 1993)

## Monitoring

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- RBC count, indices, if indicated
- Weight, appetite

## Client Information

- Tablets may be crushed and administered with food
- Because of the potential for abuse of anabolic steroids this agent is a controlled drug; it should be kept in a secure area and out of the reach of children

## Chemistry/Synonyms

An anabolic steroid, stanozolol occurs as an odorless, nearly colorless, crystalline powder that can exist in two forms: prisms that melt at approximately 235°C, and needles that melt at about 155°C. It is sparingly soluble in alcohol and insoluble in water.

Stanozolol may also be known as: androstanazole, estanozolol, methylstanazole, NSC-43193, stanozololum, win-14833, *Menabol®*, *Neurabol®*, *Stanol®*, *Stromba®*, *Strombaject®* and *Winstrol®*.

## Storage/Stability

Stanozolol tablets should be stored in tight, light-resistant packaging, preferably at room temperature.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

*Winstrol®-V* (Pfizer) tablets and injection were previously available. Stanozolol may be available from compounding pharmacies.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

## STAPHYLOCOCCAL PHAGE LYSATE

(*staf-loe-kok-al faje lye-sate*) Staphage Lysate (SP)<sup>®</sup>, SPL

### IMMUNE STIMULANT

#### Prescriber Highlights

- **Injectable immune stimulant used to treat dogs with recurrent, idiopathic, staphylococcal pyodermas**
  - **May cause hypersensitivity (local or systemic)**
- 

## Uses/Indications

Staphylococcal phage lysate (SPL) is labeled for treatment of canine pyoderma and related staphylococcal hypersensitivity, or polymicrobial skin infections with a staphylococcal component. Veterinary dermatologists use SPL most commonly to treat recurrent, idiopathic, staphylococcal pyodermas in combination (at least initially) with an appropriate antibiotic.

## Pharmacology/Actions

SPL apparently enhances cell-mediated immunity. It stimulates the production of tumor necrosis factor, interleukin-6, interleukin- $\gamma$ , and  $\gamma$ -interferon.

## Pharmacokinetics

No information was located.

## Contraindications/Precautions/Warnings

The label states that “there are no known contraindications to the use of *SPL*<sup>®</sup> except that in highly allergic patients, reduced desensitizing doses may be indicated.” However, use with extreme caution, if at all, in patients with prior systemic hypersensitivity reactions to it or documented hypersensitivity reactions to beef products (contains unfiltered beef heart infusion broth).

Avoid administering subsequent doses at the same injection site.

The product contains no preservative so it must be handled aseptically. It is recommended to use the entire contents when the vial is opened.

## Adverse Effects

Adverse effects reported for SPL include post vaccine-type reactions (fever, malaise, etc.) and injection site reactions (redness, itching, swelling) that may occur in 2–3 hours after injection and persisting up to 3 days. If these effects are excessive, the manufacturer recommends dosage reduction.

Systemic hypersensitivity reactions are thought to occur rarely. Signs could include weakness, vomiting, diarrhea, severe itching, rapid breathing, and/or fatigue/lassitude. Should an anaphylactic-type reaction occur, treat supportively; the manufacturer recommends epinephrine and atropine as antidotes.

## Reproductive/Nursing Safety

Studies performed in rats and rabbits demonstrated no impaired fertility or fetal harm.

No information was located on safety during nursing, but it is unlikely to be of concern.

## Overdosage/Acute Toxicity

No specific information was located. Other than an increased risk for local or systemic hypersensitivity reactions, significant morbidity appears unlikely.

## Drug Interactions

■ **CELL-MEDIATED IMMUNOSUPPRESSIVE DRUGS (e.g., corticosteroids, cyclosporine):** These drugs may reduce the efficacy of SPL.

## Laboratory Considerations

■ No significant concerns noted.

## Doses

### ■ DOGS:

a) For labeled indications: Highly allergic patients: Skin test with 0.05–0.1 mL intradermally. Therapy: Initially, 0.2 mL SC, then incremental increases of 0.2 mL once a week to 1 mL (a total of 5 injections). Then continue at 1 mL SC weekly for approximately 10–12 weeks.

For non-allergic patients: 0.5 mL SC twice weekly for 10–12 weeks, then 0.5–1 mL every 1–2 weeks.

Concomitant antibiotic therapy is recommended for an initial 4–6 week period.

Maximum dose should be decreased in small dogs and can be increased cautiously, if necessary, in large dogs to 1.5 mL. This dose is continued until improvement is demonstrated then the interval may be lengthened gradually to the longest interval that maintains adequate clinical control. (Label information; *Staphage Lysate (SPL)*<sup>®</sup>—Delmont Labs)

b) For idiopathic, recurrent pyoderma: Typically given 0.5 mL SC twice weekly for 10–12 weeks, then tapered to effect. This agent is rarely needed, because in most cases, an underlying cause can be identified and treated. (Gram 2005)

c) For chronic recurrent idiopathic pyoderma: Pyoderma needs to be under control as this product is not a substitute for antibiotics. Injections are administered twice weekly (0.5 mL) and slowly reduced to 0.5 mL every 2 weeks. (Waisglass 2009)

## Monitoring

- Clinical efficacy
- Local and systemic reactions (see adverse effects)

## Client Information

- This medication should ideally be administered at a veterinary practice where suitable treatment can be instituted should a serious adverse effect (e.g., anaphylaxis) occur
- Report to veterinarian any adverse effects noted (e.g., local effects at injection site, itching, change in behavior or activity level, difficulty or unexplained rapid breathing, vomiting, diarrhea)

## Chemistry/Synonyms

SPL is prepared by lysing cultures of *Staphylococcal aureas* (Cowan serologic types I & III; human strains) by a staphylococcal bacteriophage. Pre-lysed cell counts (120–180 CFU/mL) are used to standardize the product; ultrafiltration achieves bacteriologic sterility. The prepared solution contains *Staphylococcal aureas* components (protein A extracts), bacteriophage, and unfiltered beef heart infusion.

## Storage/Stability

SPL should be stored in the refrigerator (2–7°C); do not freeze.

Unopened, properly stored vials and ampules have an average expiration date of one year past the shipment date. The product contains no preservative and must be handled aseptically. It is recommended using the entire contents of the vial after opening. Do not use if contents are cloudy.

## Compatibility/Compounding Considerations

Do not mix with other drugs or solutions prior to administration.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Staphylococcal Phage Lysate (serotypes I & III): in 1 mL ampules (box of 10) and 10 mL multi-dose vials (no preservative added and manufacturer recommends using entire contents when opened); *Staphage Lysate (SPL)*® (Delmont Labs); (Biologic OTC)

**Note:** This product is a USDA-licensed biologic and is not an FDA-approved product.

**HUMAN-LABELED PRODUCTS:** None

## STREPTOZOCIN

(strep-toe-zoe-sin) Zanosar®

ANTINEOPLASTIC

### Prescriber Highlights

- Antineoplastic used primarily for treating recurrent insulinoma in dogs
  - May be nephrotoxic, myelotoxic, hepatotoxic
  - Vomiting after treatment may occur
  - To reduce nephrotoxicity, must give saline diuresis during administration
- 

## Uses/Indications

At present the primary purpose for streptozocin use in veterinary medicine is as a treatment for insulinomas in dogs, particularly those with refractory hypoglycemia and when tumors are non-resectable or have metastasized. Streptozocin potentially could be used for other oncologic conditions as well.

## Pharmacology/Actions

While streptozocin has activity against gram-positive and gram-negative bacteria, its cytotoxicity prevents it from clinical usefulness for this purpose. While its antineoplastic activity is not well understood, streptozocin is considered an alkylating agent and it inhibits DNA synthesis, probably by inhibiting precursor incorporation into DNA.

Streptozocin also exhibits a species-specific (in dogs, not humans) diabetogenic effect via reducing nicotinamide adenine dinucleotide (NAD) concentration in pancreatic beta cells. This effect is usually irreversible in animals with preexisting normal beta cell function.

## Pharmacokinetics

Streptozocin must be administered IV. Its distribution characteristics are not well known, but the drug does distribute to most tissues; concentrations in the pancreas are higher than those found in plasma. Streptozocin is metabolized, probably in the liver. Both unchanged and metabolized drug are excreted in the urine.

## Contraindications/Precautions/Warnings

Should be used for recurrent insulinoma only in dogs that have undergone previous surgery in which all of the tumor could not be resected. Confirmed histologic diagnosis is mandatory.

Streptozocin must be used with extreme caution in patients with decreased renal, bone marrow, or hepatic function.

## Adverse Effects

The primary concern when used for treating insulinomas in dogs is the potential for the development of serious, permanent renal toxicity. Aggressive saline diuresis during drug administration appears to reduce this concern. Additionally, GI effects (vomiting/nausea) often occur and can be severe or protracted. Less commonly, hematologic changes (mild myelosuppression) and increases in liver enzymes can occur. Injection site reactions (including severe necrosis) may occur if the drug extravasates.

## Reproductive/Nursing Safety

Streptozocin has been shown to be teratogenic in rats; use during pregnancy when the benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether streptozocin is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if used in nursing patients.

## Overdosage/Acute Toxicity

Severe toxicity may result if acutely overdosed (see Adverse Effects); calculate dosages carefully.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving streptozocin and may be of significance in veterinary patients:

- **DOXORUBICIN:** Streptozocin may prolong the half-life of doxorubicin; dosage adjustment may be required
- **MYELOSUPPRESSIVE DRUGS, OTHER:** When streptozocin is used with other myelosuppressive drugs (*e.g.*, **carmustine**) additive or synergistic myelosuppression may occur
- **NEPHROTOXIC DRUGS, OTHER (aminoglycosides, amphotericin B, cisplatin, etc.):** May cause additive nephrotoxicity when used with streptozocin
- **NIACINAMIDE (nicotinamide):** Can block the diabetogenic effects of streptozocin without altering its antineoplastic activity; this may be beneficial or detrimental depending on the reason for use

## Doses

### ■DOGS:

- For “investigational” treatment of recurrent insulinoma after surgery: Begin saline diuresis: Give normal saline at 18–20 mL/kg/hour for 7–8 hours. Over the 4th–5th hour, give streptozocin in the saline solution at a dose of 500 mg/m<sup>2</sup> IV. Give an antiemetic (e.g., butorphanol) at the end of the 7-hour period. (Meleo & Caplan 2000)
- Normal saline is given IV at 18.3 mL/kg/hr for 3 hours, then streptozocin is administered at 500 mg/m<sup>2</sup> over two hours with the saline diuresis continuing. After streptozocin infusion completed, continue saline diuresis for another 2 hours. Butorphanol is administered as an antiemetic immediately after streptozocin. May repeat at 3 week intervals until evidence of tumor progression, recurrence of hypoglycemia, or drug toxicity. Monitor for myelosuppression and nephrotoxicity. (Moore *et al.* 2002)

## Monitoring

- Blood glucose (efficacy)
- Baseline renal function tests (including urinalyses) and after treatment
- CBC
- Baseline liver function tests and before retreatment
- Hydration status (especially for the first few days after treatment or if vomiting a problem).

## Client Information

- Clients should understand the “experimental” nature of this treatment and the potential risks for serious adverse effects; follow-up monitoring is essential.

## Chemistry/Synonyms

Streptozocin is an antineoplastic antibiotic produced by *Streptomyces achromogenes*, although the commercial product is prepared synthetically. It occurs as an ivory colored, crystalline powder. It is very soluble in water and has a pKa of 1.35.

Streptozocin may also be known as: NSC-85998, streptozotocin, U-9889 and *Zanosar*®.

## Storage/Stability

The lyophilized powder for injection should be stored in the refrigerator and protected from light. It is stable for at least 3 years after manufacture. If stored at room temperature, it is stable for at least one year after manufacture.

After reconstitution, the lyophilized powder for injection has a pH of 3.5–4.5. Dextrose 5% or 0.9% sodium chloride are used to reconstitute the solution. Citric acid is added to buffer the solution at a concentration of 22 mg/mL. The solution is stable for 48 hours at room temperature and 96 hours if refrigerated, but as no preservative is added the manufacturer recommends using the drug within 12 hours of mixing.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Streptozocin Powder for Injection: 1 gram (100 mg/mL) in vials; *Zanosar*® (Genesia Sicor); (Rx)

## SUCCIMER

(*suc-i-mer*) Chemet®, DMSA, Dimercaptosuccinic acid

ANTIDOTE; CHELATOR

[Prescriber Highlights](#)

- **Oral heavy metal chelator**
  - **Appears to be safe & effective despite limited experience**
  - **Most likely adverse effects noted are GI in nature; may also cause increased liver enzymes, rash**
  - **High doses may be fatal in birds**
  - **Unpleasant odor of capsules; may give feces, urine, saliva, etc. a very unpleasant smell**
  - **Cost is an issue**
- 

## Uses/Indications

In veterinary medicine, succimer may be useful for the oral treatment of lead poisoning in small animals (including birds). Potentially, it also may be of benefit for the treatment of other toxic heavy metals such as arsenic or mercury, but more research must be done before this can be recommended.

## Pharmacology/Actions

Succimer physically chelates heavy metals such as lead, mercury, and arsenic. These water-soluble chelates are then excreted via the kidneys.

## Pharmacokinetics

No veterinary information was located. In humans, the drug is rapidly absorbed after oral ingestion, but only incompletely. Absorbed drug is excreted primarily through the kidneys into the urine. Half-life in humans is about 2 days.

## Contraindications/Precautions/Warnings

Succimer is contraindicated in patients hypersensitive to it. Chelation therapy should only be attempted if the source of lead is removed to prevent further exposure.

## Adverse Effects

Most common adverse reactions reported in humans are GI related effects (vomiting, diarrhea, etc.) or “flu-like” symptoms (body aches, fatigue, etc.). Increases in liver enzymes and rashes have also been reported.

## Reproductive/Nursing Safety

It is unknown if succimer is safe to use during pregnancy. At high doses it was fetotoxic and teratogenic in mice. Mothers are discouraged from nursing when taking succimer. In humans, the FDA categorizes this drug as

category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no adequate studies in humans; or there are no adequate studies in humans.*)

It is not known whether this drug is excreted in breast milk. Discourage mothers requiring therapy from nursing their infants.

### Overdosage/Acute Toxicity

In toxicology studies, doses of up to 200 mg/kg per day in dogs did not cause overt toxicity. Doses of 300 mg/day did cause fatalities in dogs; primarily kidney and GI tract lesions were seen. Doses of 80 mg/kg, PO q12h did cause a significant number of fatalities in Cockatiels (but 40 mg/kg q12h did not). If an overdose situation is encountered, standardized gut evacuation with subsequent activated charcoal protocols are recommended.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succimer and may be of significance in veterinary patients:

■ **CHELATING AGENTS, OTHER (CaEDTA, dimercaprol, trientine, penicillamine, etc.):** Concomitant use with other chelating agents is not recommended in humans

### Laboratory Considerations

■ False positive **urine ketones** can be reported when using nitroprusside reagents (*e.g.*, as in *Ketostix*®)

■ Falsely low measurements of **CPK** or serum **uric acid** can be caused by succimer

### Doses

#### ■ DOGS:

For lead poisoning:

a) 10 mg/kg PO q8h for 10 days. Succimer has a good therapeutic index, few side effects, spares most other elements from being chelated and does not cause enhanced lead uptake from the gut. Blood lead levels should be rechecked a few days following the last dose of succimer; a second round of chelation therapy may be necessary to reduce the lead load. (Talcott 2008)

b) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

#### ■ CATS:

For lead poisoning:

a) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

b) See the dog dose referenced to Talcott above.

#### ■ BIRDS:

For lead poisoning:

a) 15–35 mg/kg PO twice daily for 5 days (Calvert & Mieurs 2000)

b) 30 mg/kg PO twice daily for a minimum of 7 days. If severe neurologic signs, may supplement with one dose of CaEDTA (edetate calcium disodium; <50 mg/kg of body weight IM) (Hoogesteijn *et al.* 2003)

### Monitoring

■ Blood lead

■ GI adverse effects

■ Liver enzymes (AST, ALT)

### Client Information

■ Capsules may have an unpleasant odor; this is no problem with the drug, but unpleasant odor may be transferred to saliva, urine, feces

■ Contents of capsules may be sprinkled on soft food

■ Animals must be adequately hydrated as the lead chelates are excreted in the urine

### Chemistry/Synonyms

A heavy metal chelating agent also known as meso-2,3 dimercaptosuccinic acid (DMSA), succimer is an analog of dimercaprol. It has an unpleasant odor.

Succimer may also be known as: meso-2,3 dimercaptosuccinic acid, dimercaptosuccinic acid, DIM-SA, DMSA, *Chemet*® or *Succicaptal*®.

### Storage/Stability

Unless otherwise labeled, store succimer capsules in tight containers at room temperature. Protect from light.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Succimer Capsules: 100 mg; *Chemet*® (Ovation); (Rx)

---

## SUCCINYLCHOLINE CHLORIDE

(*suks-sin-i-mil-koe-leen*) Anectine®

NEUROMUSCULAR BLOCKING AGENT

### Prescriber Highlights

- **Depolarizing neuromuscular blocking agent**
- **Contraindications:** Severe liver disease, chronic anemias, malnourishment, glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, & increased CPK values with resultant myopathies
- **Extreme Caution:** Traumatic wounds or burns, receiving quinidine or digoxin therapy, hyperkalemia or electrolyte imbalances
- **Caution:** Pulmonary, renal, cardiovascular, metabolic or hepatic dysfunction
- **Adverse Effects:** Muscle soreness, histamine release, malignant hyperthermia, excessive salivation, hyperkalemia, rash, & myoglobinemia/myoglobinuria. Cardiovascular effects, (bradycardia

tachycardia, hypertension, hypotension, or arrhythmias)

- **Specific recommendations for use in horses (see Contraindications below)**
  - **No analgesic or anesthetic effects**
- 

### Uses/Indications

Succinylcholine chloride is indicated for short-term muscle relaxation needed for surgical or diagnostic procedures, to facilitate endotracheal intubation in some species, and reducing the intensity of muscle contractions associated with electro- or pharmacological-induced convulsions. Dogs, cats, and horses are the primary veterinary species where succinylcholine chloride has been used. Its use has been largely supplanted by newer agents (*e.g.*, atracurium) with fewer adverse effects.

### Pharmacology/Actions

An ultrashort-acting depolarizing skeletal muscle relaxant, succinylcholine bonds with motor endplate cholinergic receptors to produce depolarization (perceived as fasciculations). The neuromuscular block remains as long as sufficient quantities of succinylcholine remain, and is characterized by a flaccid paralysis. Other pharmacologic effects are discussed in the precautions and adverse effects sections.

### Pharmacokinetics

The onset of action, with complete muscle relaxation, after IV administration is usually within 30-60 seconds. In humans, this effect lasts for 2-3 minutes and then gradually diminishes within 10 minutes. The very short duration of action after a single IV dose is thought to occur because the drug diffuses away from the motor end plate. If multiple injections or a continuous infusion is performed, the brief activity is a result of rapid hydrolysis by pseudocholinesterases at the site of action. After IM injection, the onset of action is generally within 2-3 minutes and may persist for 10-30 minutes. Dogs exhibit a prolonged duration of action ( $\approx$  20 minutes); this species appears unique in this idiosyncratic response.

Succinylcholine is metabolized by plasma pseudocholinesterases to succinylmonocholine and choline; 10% is excreted unchanged in the urine. Succinylmonocholine is partially excreted in the urine and may accumulate in patients with impaired renal function. Succinylmonocholine has approximately  $1/20$  th the neuromuscular blocking activity of succinylcholine, but if it accumulates, prolonged periods of apnea may result.

### Contraindications/Precautions/Warnings

Succinylcholine is contraindicated in patients with severe liver disease, chronic anemias, malnourishment (chronic), glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, and increased CPK values with resultant myopathies. As succinylcholine can exacerbate the effects of hyperkalemia, it should be used with extreme caution in patients who have suffered traumatic wounds or burns, are receiving quinidine or digoxin therapy, or have preexisting hyperkalemia or electrolyte imbalances as arrhythmias or cardiac arrest may occur. It should be used with caution in patients with pulmonary, renal, cardiovascular, metabolic, or hepatic dysfunction.

Succinylcholine should not be used if organophosphate agents have been given or applied recently.

Succinylcholine chloride does not have analgesic effects; and should be used with appropriate analgesic, sedative, and anesthetic agents.

In horses, The American Association of Equine Practitioners have made the following additional recommendations:

- 1) Inform the owner that succinylcholine chloride is to be used as a restraining agent, not as an anesthetic.
- 2) Obtain history before use; do not use in horses if within 30 days they have received, an antibiotic ending in "mycin", organophosphate insecticides or anthelmintics, any other cholinesterase inhibitor, or procaine.
- 3) Do not use in debilitated, excited, or exhausted horses.
- 4) If possible, withhold food for 4-6 hours before use.
- 5) Dosage of 0.088 mg/kg IV may be used to paralyze skeletal muscles without causing respiratory depression. Higher doses may cause apnea and death without respiratory support. Lower doses may be possible if used with a preanesthetic agent.
- 6) After administration, have someone hold the horse that is familiar with the actions of succinylcholine chloride so that the animal does not fall forward on its nose. Be prepared to administer oxygen and artificial respiration.
- 7) If death occurs, a necropsy should be performed.

### Adverse Effects

Succinylcholine chloride can cause muscle soreness, histamine release, malignant hyperthermia, excessive salivation, hyperkalemia, rash, and myoglobinemia/myoglobinuria. Cardiovascular effects can include bradycardia, tachycardia, hypertension, hypotension, or arrhythmias.

### Reproductive/Nursing Safety

It is unknown if succinylcholine can cause fetal harm. The drug does cross the placenta in low concentrations and a newly delivered neonate may show signs of neuromuscular blockade if the mother received high doses or prolonged administration of the drug prior to delivery. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *B* (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

It is not known whether this drug is excreted into milk; exercise caution when succinylcholine is administered to a nursing patient.

### Overdosage/Acute Toxicity

Inadvertent overdoses, or standard doses in patients deficient in pseudocholinesterase may result in prolonged apnea. Mechanical ventilation with O<sub>2</sub> should be used until recovery.

Repeated or prolonged high dosages may cause patients to convert from a phase I to a phase II block.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succinylcholine and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** May increase succinylcholine's effects by causing electrolyte imbalances
- **DIGOXIN:** Succinylcholine may cause a sudden outflux of potassium from muscle cells, thus causing arrhythmias in digitalized patients
- **OPIATES:** Potential for increased incidences of bradycardia and sinus arrest
- **THIAZIDE DIURETICS:** May increase succinylcholine's effects by causing electrolyte imbalances

The following drugs/drug classes may increase or prolong neuromuscular blockade if used concurrently with succinylcholine:

- **AMINOGLYCOSIDES**
- **ANESTHETICS, INHALATION (ISOFLURANE, DESFLURANE)**
- **ANTIARRHYTHMICS (QUINIDINE, LIDOCAINE, PROCAINAMIDE)**
- **BETA-ADRENERGIC BLOCKERS**
- **CHLOROQUINE**
- **CLINDAMYCIN**
- **CORTICOSTEROIDS**
- **CYCLOPHOSPHAMIDE**
- **MAGNESIUM SALTS**
- **MAO INHIBITORS**

- Give on empty stomach if possible

- Drug Interactions

## Uses/Indications

Sucralfate has been used in the treatment of oral, esophageal, gastric, and duodenal ulcers. It has also been employed to prevent drug-induced (*e.g.*, aspirin) gastric erosions, but efficacy for this is somewhat sporadic.

Sucralfate has been used in human patients with hyperphosphatemia secondary to renal failure and potentially could be useful for this in animals as well. In a study done in six healthy cats, sucralfate did not significantly change serum or urine phosphorus levels (Quimby & Lappin 2008).

## Pharmacology/Actions

While the exact mechanism of action of sucralfate as an antiulcer agent is not known, the drug has a local effect rather than a systemic one. After oral administration, sucralfate reacts with hydrochloric acid in the stomach to form a paste-like complex that will bind to the proteinaceous exudates that generally are found at ulcer sites. This insoluble complex forms a barrier at the site and protects the ulcer from further damage caused by pepsin acid, or bile. Sucralfate can inactivate pepsin and bind bile acids.

Sucralfate may have some cytoprotective effects, possibly by stimulation of prostaglandin E2 and I2. Sucralfate also has some antacid activity, but it is believed that this is not of clinical importance.

Sucralfate does not significantly affect gastric acid output, or trypsin or pancreatic amylase activity. It may decrease the rate of gastric emptying.

As an aluminum salt, sucralfate can bind to gastrointestinal phosphorus.

## Pharmacokinetics

Animal studies have indicated that only 3–5% of an oral dose is absorbed which is excreted in the urine unchanged within 48 hours. By reacting with hydrochloric acid in the gut, the remainder of the drug is converted to sucrose sulfate, which is excreted in the feces within 48 hours. The duration of action (binding to ulcer site) may persist up to 6 hours after oral dosing.

## Contraindications/Precautions/Warnings

There are no known contraindications to the use of sucralfate. Because it may cause constipation, it should be used with caution in animals where decreased intestinal transit times might be deleterious.

## Adverse Effects

Adverse effects are uncommon with sucralfate therapy. Constipation is the most prominent adverse effect reported in humans (2%) and dogs receiving the drug. Vomiting has been reported in cats.

## Reproductive/Nursing Safety

It is unknown if sucralfate crosses the placenta and whether it may definitively be used safely during pregnancy. In rats, dosages up to 38 times those used in humans caused no impaired fertility and doses up to 50 times normal caused no symptoms of teratogenicity. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

It is not known whether this drug is excreted in milk, but it is unlikely to be of concern.

## Overdosage/Acute Toxicity

Overdosage is unlikely to cause any significant problems. Laboratory animals receiving up to 12 grams/kg orally demonstrated no incidence of mortality.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sucralfate and may be of significance in veterinary patients:

Sucralfate may impair the oral absorption of the following medications; separate dosing by at least 2 hours to minimize this effect:

### ■AZITHROMYCIN

■CIPROFLOXACIN/ENROFLOXACIN (assume other **oral fluoroquinolones** as well)

### ■DICLOFENAC

### ■DIGOXIN

### ■DOXYCYCLINE

### ■ERYTHROMYCIN

### ■KETOCONAZOLE

### ■LEVOTHYROXINE

### ■PENICILLAMINE

### ■TETRACYCLINE

### ■THEOPHYLLINE

### ■VITAMINS (fat soluble)

### ■WARFARIN

## Doses

### ■DOGS:

- For esophagitis: 0.5–1 gram PO three times a day. Suspensions are more therapeutic than intact tablets. (Washabau 2000)
- For large dogs: 1 gram PO q8; for smaller dogs: 0.5 gram PO q8h (Zerbe & Washabau 2000)
- 0.5–1 gram PO 2–4 times a day; patients with severe GI blood loss give an initial loading dose of 3–6 grams and then resume lower dose. If also using an H<sub>2</sub> blocker, administer sucralfate 30–60 minutes later. (Hall 2000)
- For eliminating *Helicobacter* gastritis infections: Using triple therapy: Metronidazole 33 mg/kg once daily, amoxicillin 11 mg/kg q12h and either sucralfate (0.25–0.5 grams q8h) or omeprazole 0.66 mg/kg once daily (Hall 2000)
- In patients with severe hematemesis and anemia we sometimes give a loading dose of 3–6 grams initially and then decrease to 1 gram PO three to four times a day. May not always work in vomiting dogs. Suspensions may have less tendency to be vomited up in these patients. (Willard 2006)
- For gastric ulcers, esophagitis: 0.5–1 gram PO per dog q8–12h (Sellon 2007)
- For GI ulcers/esophagitis associated with acute renal failure: 1 gram per 30 kg body weight PO q6h (Waddell 2007)

### ■CATS:

- 0.25–0.5 grams PO q8–12h (Zerbe & Washabau 2000)
  - Empirical dosage of sucralfate is ¼ of a 1 gram tablet per cat PO three to four times a day. (Trepanier 2010)c
- For gastric ulcers, esophagitis: 0.25–0.5 grams PO per cat PO q8–12h (Sellon 2007)

### ■FERRETS:

- 75 mg/kg PO q4–6h; give 10 minutes prior to feeding (Williams 2000)

a) 75 mg/kg PO q4-6h; give 10 mg/kg PO to receding (Williams 2009)

## HORSES:

- For adjunctive treatment (used with acid suppressive drugs) for preventing stress-induced ulcers in foals: 10–20 mg/kg PO q6–8h (Sanchez 2004)
- For treating equine gastric ulcer syndrome: 20–40 mg/kg PO q8h (Sanchez 2004), (Nadeau & Andrews 2003)
- Sucralfate alone may not be beneficial in treatment of equine gastric ulcer syndrome, but can be used in conjunction with acid-suppressive therapy and may be more suited for treatment of right dorsal colitis (colonic ulcers) at a dose of 22 mg/kg PO q6–8h. (Videla & Andrews 2009)

## REPTILES:

- For GI irritation in most species: 500–1,000 mg/kg PO q6–8h (Gauvin 1993)

## Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.

## Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; clinical signs may reoccur if dosages are missed
- Unless otherwise instructed, give this medication to animal having an empty stomach (1 hour before feeding or 2 hours after) and at bedtime

## Chemistry/Synonyms

A basic, aluminum complex of sucrose sulfate, sucralfate occurs as a white, amorphous powder. It is practically insoluble in alcohol or water.

Sucralfate is structurally related to heparin, but does not possess any appreciable anticoagulant activity. It is also structurally related to sucrose, but is not utilized as a sugar by the body.

Sucralfate is also known as aluminum sucrose sulfate, basic and *Carafate*®.

## Storage/Stability

Store sucralfate tablets in tight containers at room temperature.

## Compatibility/Compounding Considerations

A sucralfate 200 mg/mL suspension can be extemporaneously prepared. To make 100 mL: crush twenty (20) sucralfate 1 gram tablets and add sufficient quantity of distilled water to bring the volume to 100 mL. Suspending agents such as acacia or tragacanth should not be used, as they can bind to sucralfate and make it inactive. Label “shake well” and “refrigerate.” When refrigerated it is stable for 14 days.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS: None

### HUMAN-LABELED PRODUCTS:

Sucralfate Tablets: 1 gram; *Carafate*® (Axcan Sandipharma); generic; (Rx)

Sucralfate Suspension: 1 gram/10 mL in 10 mL unit dose cups & 415 mL; *Carafate*® (Axcan Scandipharma); generic (Precision Dose); (Rx)

## SUFENTANIL CITRATE

(*suo-fen-ta-nil*) Sufenta®

OPIATE AGONIST

### Prescriber Highlights

- Injectable, extremely potent opiate that may be useful for adjunctive anesthesia or epidural analgesia
- Marginal veterinary experience & little published data available to draw conclusions on appropriate usage in veterinary species
- Dose-related respiratory & CNS depression most likely adverse effects
- Class-II controlled substance; expensive when compared to fentanyl

## Uses/Indications

An opioid analgesic, sufentanil may be useful as an anesthesia adjunct or as an epidural analgesic. In humans, it has been used as the primary anesthetic in intubated patients with assisted ventilation, and as a post-operative analgesic.

## Pharmacology/Actions

Sufentanil is a potent *mu* opioid with the expected sedative, analgesic, and anesthetic properties. When comparing analgesic potencies, 0.01–0.04 mg of sufentanil is equivalent to 0.4–0.8 mg of alfentanil, 0.1–0.2 mg of fentanyl, and approximately 10 mg of morphine, when all are injected IM. Like fentanyl, sufentanil appears to have less circulatory effects than does morphine. Sufentanil has a rapid onset of action (1–3 minutes) and a faster recovery time than fentanyl.

## Pharmacokinetics

No information on the pharmacokinetics of sufentanil in domestic animals was located. In humans, the drug has rapid onset of action (1–3 minutes) after intravenous injection. The drug is highly lipid soluble and has volume of distribution in the central compartment of 0.1 L/kg. Approximately 93% is bound to plasma proteins; plasma concentrations rapidly decline due to redistribution. Terminal elimination half-life is about 2.5 hours. Plasma clearance has been reported to be 11.8 mL/min/kg. Sufentanil is metabolized primarily in the liver and small intestine via O-demethylation and N-dealkylation. The parent drug and these metabolites are excreted primarily in the urine. While the manufacturer states to use with caution in patients with impaired renal of hepatic function, limited pharmacokinetic studies in these patients, rarely showed any drug accumulation.

## Contraindications/Precautions/Warnings

Sufentanil is contraindicated in patients hypersensitive to it or other opioids. It should be used with caution in debilitated or geriatric patients and those with severely diminished renal or hepatic function.

Because of the drug's potency and potential for significant adverse effects, it should only be used in situations where patient vital signs can be continuously monitored. Initial dosage reduction may be required in geriatric

Because of the drug's potency and potential for significant adverse effects, it should only be used in situations where patient vital signs can be continuously monitored. Initial dosage reduction may be required in geriatric or debilitated patients, particularly those with diminished cardiopulmonary function.

### Adverse Effects

Adverse effects are generally dose related and consistent with other opiate agonists. Respiratory depression and/or CNS depression are most likely to be encountered.

In humans, bradycardia that is usually responsive to anticholinergic agents can occur. Dose-related skeletal muscle rigidity is not uncommon, and neuromuscular blockers are routinely used. Sufentanil has rarely been associated with asystole, hypercarbia and hypersensitivity reactions.

Respiratory or CNS depression may be exacerbated if sufentanil is given with other drugs that can cause those effects.

### Reproductive/Nursing Safety

In humans, the FDA categorizes sufentanil as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) While sufentanil is indicated for epidural use (mixed with bupivacaine ± epinephrine) in women for labor/delivery, it should not be administered systemically to a mother close to giving birth as offspring may show behavioral alterations (hypotonia, depression) associated with opioids.

The effects of sufentanil on lactation or its safety for nursing offspring is not well-defined, but sufentanil milk levels approximate those found in serum. This coupled with its low oral bioavailability, make it unlikely to cause significant effects in nursing offspring.

### Overdosage/Acute Toxicity

In dogs, the LD50 of intravenous sufentanil is 10.1–19.5 mg/kg. Intravenous severe overdoses may cause apnea, circulatory collapse, pulmonary edema, seizures, cardiac arrest and death. Treatment is a combination of supportive therapy and administration of an opiate antagonist such as naloxone. Although sufentanil has a fairly rapid half-life, multiple doses of naloxone may be necessary. Because of the drug's potency, the use of a tuberculin syringe to measure dosages less than 1 mL, with a dosage calculation and measurement double-check system is recommended.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sufentanil and may be of significance in veterinary patients:

- **BETA-ADRENERGIC BLOCKERS:** May increase bradycardia and hypotension
- **CALCIUM-CHANNEL BLOCKERS:** May increase bradycardia and hypotension
- **CNS DEPRESSANTS, OTHER:** Additive effects can occur if sufentanil is used concurrently with other drugs that can depress CNS or respiratory function (*e.g.*, **barbiturates**, etc.)
- **NITROUS OXIDE:** Can cause cardiovascular depression if used with high dose sufentanil

### Laboratory Considerations

- Because opiates can increase biliary tract pressure and raise serum **amylase** and **lipase** values, these values may be unreliable for 24 hours after sufentanil is administered.

### Doses

**Note:** In very obese patients, figure dosages based upon lean body weight.

#### ■ DOGS:

- a) As a pre-med: 3 micrograms/kg IV. As a combination for induction: Sufentanil 3 micrograms/kg IV first, then diazepam or midazolam 0.2–0.5 mg IV. (Banyard 2004)
- b) For epidural analgesia: 0.7–1 micrograms/kg diluted to a volume of 0.26 mL/kg with sterile saline. Onset of action in 10–15 minutes; duration 1–4 hours. (Otero 2006b)
- c) Acute pain relief in an emergency: 0.75–2 micrograms/kg IV; constant rate infusion of 1–2 micrograms/kg/hour. (Otero 2006a)
- d) For surgical pain: 5 micrograms/kg IV prior to a CRI. Duration of effect: 2–6 hours. CRI (post-operative) of 0.1 micrograms/kg/hour. (Ogilvie 2004)

#### ■ CATS:

- a) Acute pain relief in an emergency: 0.1–0.5 micrograms/kg IV; constant rate infusion of 0.5–1 micrograms/kg/hour. (Otero 2006a)

### Monitoring

- Anesthetic and/or analgesic efficacy
- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia

### Client Information

- Sufentanil is a very potent opiate that should only be used by professionals in a setting where adequate patient monitoring is available.

### Chemistry/Synonyms

A phenylpiperidine derivative opiate related to fentanyl, sufentanil citrate occurs as a white or almost white powder that is soluble in water, sparingly soluble in alcohol, acetone, or chloroform. The commercially available injection has a pH (adjusted with citric acid) of 3.5–6.

Sufentanil citrate may also be known as: R-33800, sufentanili citras, fentathienel citrate, sufentanyl citrate, sulfentanil citrate, *Fastfen*®, *Fentaientel*® and *Sufenta*®.

### Storage/Stability

Unless otherwise labeled, sufentanil injection should be stored protected from light at room temperature. Sufentanil citrate is hydrolyzed in acidic solutions.

### Compatibility/Compounding Considerations

Sufentanil citrate is reportedly **compatible** with D5W and bupivacaine. For Y-site injection it is **compatible** with solutions containing: atropine, dexamethasone sodium phosphate, diazepam, diphenhydramine, etomidate, metoclopramide, midazolam, phenobarbital, and propofol. It is **incompatible** with lorazepam, phenytoin and thiopental.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Sufentanil Citrate Injection: 50 micrograms/mL (as base) in 1 mL, 2 mL & 5 mL amps; *Sufenta*® (preservative free) (Taylor); generic; (Rx, C-II).

## SULFACHLORPYRIDAZINE SODIUM

(sul-fa-ktor-pye-rid-a-zen) Vetsulid®

SULFONAMIDE ANTIMICROBIAL AGENT

- **Contraindications:** Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
  - **Caution:** Diminished renal or hepatic function, or urinary obstruction
  - **Adverse Effects:** Can precipitate in the urine (especially with high dosages for prolonged periods, acidic urine or highly concentrated urine); Dogs: Keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting, & nonseptic polyarthritis possible
  - **Potentially teratogenic; weigh risk vs. benefit**
  - **Too-rapid IV injection may cause muscle weakness, blindness, ataxia, & collapse; SC or IM injection may cause tissue irritation**
- 

### Uses/Indications

Sulfachlorpyridazine is indicated for the treatment of diarrhea caused or complicated by *E. coli* in calves less than one month of age or colibacillosis in swine. It is also used parenterally as a general-purpose sulfonamide in adult cattle and other species.

### Pharmacology/Actions

Sulfonamides are usually bacteriostatic agents when used alone. They are thought to prevent bacterial replication by competing with para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfas.

Microorganisms that are usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *C. perfringens*, and many strains of Nocardia. Sulfas have *in vitro* activity against some gram-negative species, including some strains of Shigella, Salmonella, *E. coli*, Klebsiella, Enterobacter, Pasturella, and Proteus. Sulfas also have activity against some rickettsia and protozoa (Toxoplasma, Coccidia). Unfortunately, resistance to sulfas is a progressing phenomenon and many strains of bacteria that were once susceptible to this class of antibacterial are now resistant. The sulfas are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

### Pharmacokinetics

Very limited information is available on the specific pharmacokinetics for this agent. In general, sulfonamides are readily absorbed from the GI tract of non-ruminants, but absorption can vary depending on the drug, species, disease process, etc. Food delays the rate, but usually not the extent of absorption. Peak levels occur within 1–2 hours in non-ruminant (and young pre-ruminant) animals. Adult ruminants may have significant delays before the drug is absorbed orally.

Sulfas are well distributed throughout the body and some reach significant levels in the CSF. Levels of the drugs tend to be highest in liver, kidney, and lung, and lower in muscle and bone. The sulfas can be highly bound to serum proteins, but the extent of binding is species and drug dependent. When bound to proteins the sulfa is not active.

Sulfonamides are both renally excreted and metabolized. Renal excretion of unchanged drug occurs via both tubular secretion and glomerular filtration. Protein bound drug is not filtered by the glomeruli. Metabolism is performed principally in the liver, but extra-hepatic metabolism is also involved. Mechanisms of metabolism are usually acetylation and glucuronidation. The acetylated metabolites may be less soluble and crystallization in the urine can occur with some sulfonamides, particularly at lower pH. The serum half-life of sulfachlorpyridazine is approximately 1.2 hours in cattle.

### Contraindications/Precautions/Warnings

Sulfonamides are contraindicated in patients hypersensitive to them, thiazides, or sulfonylurea agents. They are also considered contraindicated in patients with severe renal or hepatic impairment and should be used with caution in patients with diminished renal or hepatic function, or urinary obstruction.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

### Adverse Effects

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH's. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but it also decreases the amount available for tubular reabsorption. Crystalluria can usually be avoided with most of the commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

Too rapid intravenous injection of the sulfas can cause muscle weakness, blindness, ataxia, and collapse.

In dogs, keratoconjunctivitis sicca has been reported with sulfonamide therapy. In addition, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported in dogs.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

### Reproductive/Nursing Safety

Sulfas cross the placenta and may reach fetal levels of 50% or greater those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk. Safe use during lactation cannot be assumed; use with caution.

### Overdosage/Acute Toxicity

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfachlorpyridazine and may be of significance in veterinary patients:

■ **ANTACIDS:** May decrease the oral bioavailability of sulfonamides if administered concurrently

### Laboratory Considerations

■ Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

### Doses

#### ■ CATTLE:

In calves for labeled indications: 33–49.5 mg/kg PO, or IV twice daily for 1–5 days; suggest initiating therapy with intravenous preparation and then changing to oral if possible (Package insert; *Vetisulid*®—Fort Dodge)

#### ■ SWINE:

For labeled indications: 44–77 mg/kg PO per day (divide dose and give twice daily if treating individual animals) for 1–5 days (Package insert; *Vetisulid*®—Fort Dodge)

#### ■ BIRDS:

For enteric bacterial infections:

a) Using the oral powder: Mix ¼ teaspoonful per liter of water and use as only supply of drinking water for 5–10 days. May be effective for many *E. coli* enteric infections. (Clubb 1986)

b) Using the oral powder: Mix ¾ teaspoonful per 2 quarts of water. Fairly effective for enteric infections, particularly *E. coli*. Reserved for clients who are unable to give other medications by mouth or parenterally. (McDonald 1989)

c) For pigeons: 1200 mg per gallon of drinking water. Very effective for *E. coli* and it is a good coccidiostat. (Harlin 2006)

pharmacokinetic parameters (absorption, distribution, elimination) in each species. Since different organisms may have different MIC values and the optimal ratio of trimethoprim to sulfamethoxazole differs from organism to organism, this problem is exacerbated.

There is considerable controversy regarding the frequency of administration of these combinations. The veterinary product, trimethoprim/sulfadiazine is labeled for once daily administration in dogs and horses, but many clinicians believe that the drug is more efficacious if given twice daily, regardless of which sulfa is used.

### Contraindications/Precautions/Warnings

The manufacturer states that trimethoprim/sulfadiazine should not be used in dogs or horses showing marked liver parenchymal damage, blood dyscrasias, or those with a history of sulfonamide sensitivity. It is not for use in horses (or FDA-approved for other animals) intended for food.

Doberman pinschers appear to be very susceptible to sulfonamide-induced poly-systemic immune complex disease and most believe that these drugs are contraindicated in them.

This combination should be used with caution in patients with pre-existing hepatic or renal disease.

Because of its potential for crystallization in the urine, it may be wise to avoid the use of sulfadiazine in dogs known to have uroliths, at increased risk for developing uroliths or known to have highly concentrated (dehydration) or acidic urine.

### Adverse Effects

Adverse effects noted in dogs include: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria and cholestasis. Potentiated sulfonamides may cause hypothyroidism in dogs, particularly with extended therapy. Acute hypersensitivity reactions manifesting as Type I (anaphylaxis) or Type III reaction (serum sickness) can be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers may possibly be more susceptible to this effect than other breeds. Other hematologic effects (anemias, agranulocytosis) are possible, but are fairly rare. TMP/Sulfa has rarely been noted to cause an idiosyncratic, moderate to severe hepatic necrosis. TMP/Sulfa may be a risk factor for developing acute pancreatitis, but cause and effect have not been definitively shown.

Adverse effects noted in cats may include anorexia, leukopenias and anemias.

In horses, transient pruritus has been noted after intravenous injection. Oral therapy has resulted in diarrhea in some horses, but incidence is relatively low. Previous administration of potentiated sulfas has been implicated in increasing the mortality rate of associated with severe diarrhea. If the 48% injectable product is injected IM, SC, or extravasates after IV administration, swelling, pain and minor tissue damage may result. Hypersensitivity reactions and hematologic effects (anemias, thrombocytopenia, or leukopenias) may also be seen; long-term therapy should include periodic hematologic monitoring.

Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic urine or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction.

### Reproductive/Nursing Safety

Safety of trimethoprim/sulfa has not been clearly established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported. Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Use TMP/sulfa products in nursing animals with caution. TMP-SMZ is not recommended for human use in the nursing period as sulfonamides are excreted in milk and may cause kernicterus. Premature infants and infants with hyperbilirubinemia or G-6-PD deficiency are also at risk for adverse effects.

### Overdosage/Acute Toxicity

Manifestations of an acute overdosage can include clinical signs of GI distress (nausea, vomiting, diarrhea), CNS toxicity (depression, headache, and confusion), facial swelling, bone marrow depression and increases in serum aminotransferases. Oral overdoses can be treated by emptying the stomach, (following usual protocols), and initiating symptomatic and supportive therapy. Acidification of the urine may increase the renal elimination of trimethoprim, but could also cause sulfonamide crystalluria, particularly with sulfadiazine containing products. Complete blood counts (and other laboratory parameters) should be monitored as necessary. Bone marrow suppression associated with chronic overdoses may be treated with folic acid (leucovorin) if severe. Peritoneal dialysis is not effective in removing TMP or sulfas from the circulation.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trimethoprim/sulfa and may be of significance in veterinary patients:

- **AMANTADINE:** A human patient developed toxic delirium when receiving amantadine with TMP/sulfa
- **ANTACIDS:** May decrease the bioavailability of sulfonamides if administered concurrently
- **CYCLOSPORINE:** TMP/sulfa may increase the risk of nephrotoxicity
- **DIGOXIN:** TMP/sulfa may increase digoxin levels
- **DIURETICS, THIAZIDE:** May increase risk for thrombocytopenia
- **HYPOGLYCEMIC AGENTS, ORAL:** TMP/sulfa may potentiate effects
- **METHOTREXATE:** TMP/sulfa may displace from plasma proteins and increase risk for toxic effects; it can also interfere with MTX assays (competitive protein binding technique)
- **PHENYTOIN:** TMP/sulfa may increase half-life
- **TRICYCLIC ANTIDEPRESSANTS:** TMP/sulfa may decrease efficacy
- **WARFARIN:** TMP/sulfa may prolong INR/PT

### Laboratory Considerations

- When using the Jaffe alkaline picrate reaction assay for **creatinine** determination, trimethoprim/sulfa may cause an overestimation of approximately 10%.
- Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

### Doses

**Note:** There is significant controversy regarding the frequency of dosing these drugs. See the pharmacokinetic section above for more information. Unless otherwise noted, doses are for combined amounts of trimethoprim/sulfa.

#### ■ DOGS:

For susceptible infections:

a) For UTI, pyoderma, soft tissue infections: 30 mg/kg PO q24h (not soft tissue infections) or 15 mg/kg PO q12h for 14 days.

For chronic pyoderma, acanthamebiasis: 30 mg/kg PO q12h for 21–42 days.

For systemic infections; bacteremia: 30–45 mg/kg PO q12h for 3–5 days. (Greene *et al.* 2006)

b) For bacterial UTI: 30 mg/kg q12h PO (Bartges 2007)

c) For protozoal diseases:

For toxoplasmosis: 15 mg/kg, PO q12h for 28 days.

For Neospora: 15 mg/kg, PO q12h for 4 weeks. Used concurrently with clindamycin (10 mg/kg q12h for 4 weeks) *or* pyrimethamine (1 mg/kg PO once daily for 4 weeks).

For *Hepatozoon canis*: 15 mg/kg, PO q12h for 2–4 weeks. Used concurrently with clindamycin (10 mg/kg PO q8h for 2–4 weeks) *and* pyrimethamine (0.25 mg/kg PO once daily for 2–4 weeks) (Lappin 2000b)

d) For coccidiosis: 30 mg/kg PO once daily for 10 days (Matz 1995)

e) For pneumocystosis (*Pneumocystis carinii*): 15 mg/kg PO q8h or 30 mg/kg PO q12h, both for 3 weeks. May be given with cimetidine and levamisole as potential immune stimulants. (Hawkins 2000)

f) For *Hepatozoon americanum*: TMP/sulfa (15 mg/kg PO q12h), pyrimethamine (0.25 mg/kg PO q24h), and clindamycin (10 mg/kg q8h). Once remission attained [decoquinat](#) (see monograph) can maintain. (Baneth 2007)

g) For *Hepatozoon americanum*: TMP/sulfa (15 mg/kg PO q12h for 14 days), pyrimethamine (0.25 mg/kg PO q24h for 14 days), and clindamycin (10 mg/kg q8h for 14 days). Once remission attained [decoquinat](#) (see monograph) can maintain.

For neosporosis: pyrimethamine (1 mg/kg PO daily) with TMP/sulfa (15–30 mg/kg PO twice daily). (Blagburn 2005)

## ■CATS:

For susceptible infections:

a) For UTI: 30 mg/kg PO q24h for 7–14 days.

For UTI, soft tissue infections: 15 mg/kg PO q12h for 7–14 days. (Greene *et al.* 2006)

b) 30 mg/kg q12h (if treating Nocardia, double dose) (Ford & Aronson 1985)

c) For toxoplasmosis: 15 mg/kg PO q12h for 28 days (Lappin 2000a)

d) For bacterial UTI: 30 mg/kg q12h PO (Bartges 2007)

## ■FERRETS:

For susceptible infections:

a) 30 mg/kg PO twice daily (Williams 2000)

b) For coccidiosis: 30 mg/kg PO once daily for 14 days. (Johnson 2006)

## ■RABBITS, RODENTS, SMALL MAMMALS:

a) **Rabbits:** 15–30 mg/kg, PO q12–24h; 30–48 mg/kg SC q12h. Sulfadiazine has a very short half-life (approx. 1 hour) in rabbits. (Ivey & Morrisey 2000)

b) **Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats:** 15–30 mg/kg PO q12h; or 30 mg/kg IM q12h (Adamcak & Otten 2000)

c) **Chinchillas:** 30 mg/kg PO, SC or IM q12h (Hayes 2000)

## ■CATTLE:

For susceptible infections:

a) 44 mg/kg once daily IM or IV using 48% suspension (Upson 1988)

b) 25 mg/kg, IV or IM q24h (Burrows 1980)

c) **Calves:** 48 mg/kg IV or IM q24h (Baggot 1983)

## ■HORSES:

For susceptible infections:

a) For respiratory tract infections: 15–30 mg/kg PO q12h. Give 30 minutes prior to feeding hay (grain is OK) (Foreman 1999)

b) **Foals:** 15 mg/kg IV q12h; 30 mg/kg PO q12h (Brumbaugh 1999)

c) 22 mg/kg IV q24h or 30 mg/kg, PO q24h (Upson 1988)

d) 30 mg/kg PO once daily or 21.3 mg/kg IV once daily (Package inserts; *Tribriissen*®—Coopers)

e) **Foals:** 15 mg/kg PO or IV twice daily (Furr 1999)

## ■SWINE:

For susceptible infections:

a) 48 mg/kg, IM q24h (Baggot 1983)

## ■BIRDS:

For susceptible infections:

a) Using TMP/SMX oral suspension (240 mg/5 mL): 2 mL/kg PO twice daily. Good for many gram-positive and negative enteric and respiratory infections, particularly in hand-fed babies. May cause emesis in Macaws. (McDonald 1989)

b) For respiratory and enteric infections in psittacines using the 24% injectable suspension: 0.22 mL/kg IM once to twice daily.

For coccidiosis in toucans and mynahs using TMP/SMX oral suspension (240 mg/5 mL): 2.2 mL/kg once daily for 5 days. May be added to feed.

For respiratory and enteric infections in hand-fed baby psittacines using TMP/SMX oral suspension (240 mg/5 mL): 0.22 mL/30 grams twice daily to three times daily for 5–7 days. (Clubb 1986)

c) Using oral suspension: 50–100 mg/kg (of combined product) PO q12h (Hoeffler 1995)

d) Ratites: For *Toxoplasma gondii*: 30–50 mg/kg IM twice daily (Jenson 1998)

## ■REPTILES:

For susceptible infections:

a) For most species: 30 mg/kg IM (upper part of body) once daily for 2 treatments, then every other day for 5–12 treatments. May be useful for enteric infections. (Gauvin 1993)

b) For all species: 30 mg/kg IM, first two doses 24 hours apart and then every other day (Jacobson 1999)

c) 15–25 mg/kg/day IM for 7–14 days (Lewbart 2001)

## Monitoring

■ Clinical efficacy

■ Adverse effects; with chronic therapy, periodic complete blood counts should be considered

■ In dogs, monitor tear production (one suggestion is in 5 days and every 2–3 weeks)

■ Thyroid function tests should be considered (baseline and ongoing) particularly in dogs receiving long-term treatment. Some do not feel this is necessary.

## Client Information

■ If using oral suspension, shake well before using; does not need to be refrigerated

■ Animals must be allowed free access to water and must not become dehydrated while on therapy

■ If dogs eyes are dry or become irritated contact veterinarian

## Chemistry/Synonyms

Trimethoprim occurs as odorless, bitter-tasting, white to cream-colored crystals or crystalline powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfamethoxazole occurs as a practically odorless, white to off-white, crystalline powder. Approximately 0.29 mg are soluble in 1 mL of water and 20 mg are soluble in 1 mL of alcohol.

In combination, these products may be known as: Co-trimoxazole, SMX-TMP, TMP-SMX, trimethoprim-sulfamethoxazole, sulfamethoxazole-trimethoprim, sulfadiazine-trimethoprim, trimethoprim-sulfadiazine, TMP-SDZ, SDZ-TMP, Co-trimazine or by their various trade names.

## Storage/Stability

Unless otherwise instructed by the manufacturer, trimethoprim/sulfadiazine and co-trimoxazole products should be stored at room temperature (15–30°C) in tight containers.

## Dosage Forms/Regulatory Status/Withdrawal Times

### VETERINARY-LABELED PRODUCTS:

Trimethoprim (TMP)/Sulfadiazine (SDZ) Oral Paste: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine. Available in 37.5 gram (total weight) syringes; *Tribriissen*® 400 Oral Paste (Schering-Plough); (Rx).  
FDA approved for use in horses not intended for food.

FDA-approved for use in horses not intended for food.

Trimethoprim/Sulfadiazine Sterile Injection: 48% in 100 mL vials: *Di-Biotic® 48%* (Phoenix Pharmaceutical), *Tribrissen® 48% Injection* (Schering-Plough); (Rx) FDA-approved for use in horses not intended for food.

Trimethoprim/Sulfadiazine Powder: 67 mg trimethoprim and 333 mg sulfadiazine per gram: *Tucoprим® Powder* (Pharmacia & Upjohn) in 200 grams & 400 grams bottles and 2000 grams pails, *Uniprim® Powder* (Macleod) in 37.5 grams and 1,125 grams packets, 200 grams jar, and 12 kg box; (Rx). FDA-approved for use in horses not intended for food.

In Canada, trimethoprim and sulfadoxine are available for use in cattle and swine (*Trivetrim®*—Wellcome; *Borgal®*—Hoechst). Slaughter withdrawal = 10 days; milk withdrawal = 96 hours.

## HUMAN-LABELED PRODUCTS:

Trimethoprim (alone) Tablets: 100 mg and 200 mg; *Proloprim®* (Glaxo Wellcome); *Trimpex®* (Roche); generic; (Rx)

Trimethoprim & Sulfamethoxazole (Co-Trimoxazole; TMP-SMZ) Oral Tablets: 80 mg trimethoprim & 400 mg sulfamethoxazole; Double Strength Tablets: 160 mg trimethoprim & 800 mg sulfamethoxazole; *Bactrim®* & *Bactrim® DS* (AR Scientific); *Sepra®* & *Sepra® DS* (Monarch); generic; (Rx)

Trimethoprim 8 mg/mL and Sulfamethoxazole 40 mg/mL oral suspension in 100 mL, 150 mL, 200 mL, 473 mL, and 480 mL; *Sepra®* (GlaxoWellcome); *Cotrim® Pediatric* (Lemmon), *Sulfatrim®*, (various); generic; (Rx)

Trimethoprim & Sulfamethoxazole Injection: 80 mg sulfamethoxazole, 16 mg trimethoprim per mL in 5 mL single-use vials, 10 mL, or 30 mL multiple-dose vials; generic; (Rx)

## SULFADIMETHOXINE

(sul-fa-dye-meth-o-x-eyn) Albon®

SULFONAMIDE ANTIMICROBIAL

### Prescriber Highlights

- **Sulfonamide antimicrobial agent**
- **Contraindications:** Hypersensitivity to sulfas, thiazides, or sulfonyleurea agents; severe renal or hepatic impairment; Dobermans
- **Caution:** Diminished renal or hepatic function, or urinary obstruction.
- **Adverse Effects:** Can precipitate in the urine (esp. with high dosages for prolonged periods, acidic urine or highly concentrated urine). *Dogs:* Keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal interstitial, fever, vomiting & nonseptic polyarthritis possible
- **Potentially teratogenic; weigh risk vs. benefit**

## Uses/Indications

Sulfadimethoxine injection and tablets are FDA-approved for use in dogs and cats for respiratory, genitourinary, enteric and soft tissue infections caused by susceptible organisms. Sulfadimethoxine is used in the treatment of coccidiosis in dogs although not FDA-approved for this indication.

In horses, sulfadimethoxine injection is FDA-approved for the treatment of respiratory infections caused by *Streptococcus equi*.

In cattle, the drug is FDA-approved for treating shipping fever complex, calf diphtheria, bacterial pneumonia and foot rot caused by susceptible organisms.

In poultry, sulfadimethoxine is added to drinking water to treat coccidiosis, fowl cholera, and infectious coryza.

## Pharmacology/Actions

Sulfonamides are usually bacteriostatic agents when used alone. They are thought to prevent bacterial replication by competing with para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfas.

Microorganisms that are usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *C. perfringens*, and many strains of Nocardia. Sulfas also have *in vitro* activity against some gram-negative species, including some strains of Shigella, Salmonella, *E. coli*, Klebsiella, Enterobacter, Pasturella, and Proteus. Sulfas have activity against some rickettsia and protozoa (Toxoplasma, Coccidia). Unfortunately, resistance to sulfas is a progressing phenomenon and many strains of bacteria that were once susceptible to this class of antibacterial are now resistant. The sulfas are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

## Pharmacokinetics

In dogs, cats, swine, and sheep, sulfadimethoxine is reportedly readily absorbed and well distributed. Relative volumes of distribution range from 0.17 L/kg in sheep to 0.35 L/kg in cattle and horses. The drug is highly protein bound.

In most species, sulfadimethoxine is acetylated in the liver to acetylsulfadimethoxine and excreted in the urine. In dogs, the drug is not appreciably hepatically metabolized and renal excretion is the basis for the majority of elimination of the drug. Sulfadimethoxine's long elimination half-lives are a result of its appreciable reabsorption in the renal tubules. Serum half-lives reported in various species are: swine 14 hours; sheep 15 hours; horses 11.3 hours.

## Contraindications/Precautions/Warnings

Sulfonamides are contraindicated in patients hypersensitive to them, thiazides, or sulfonyleurea agents. They are also considered contraindicated in patients with severe renal or hepatic impairment and should be used with caution in patients with diminished renal or hepatic function, or urinary obstruction.

Doberman pinschers appear to be very susceptible to sulfonamide-induced poly-systemic immune complex disease and most believe that these drugs are contraindicated in them.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

## Adverse Effects

Sulfonamides (or their metabolites) in the urine, particularly when given at high dosages for prolonged periods. Acidic urine or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH's. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but it also decreases the amount available for tubular reabsorption. Crystalluria can usually be avoided with most of the commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so

crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

Too rapid intravenous injection of the sulfas can cause muscle weakness, blindness, ataxia, and collapse.

In dogs, keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported with sulfonamides.

Oral sulfonamides can depress the normal cellulolytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

### Reproductive/Nursing Safety

Sulfas cross the placenta and may reach fetal levels of 50% or greater of those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk.

### Overdosage/Acute Toxicity

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfonamides and may be of significance in veterinary patients:

■ **ANTACIDS:** May decrease the oral bioavailability of sulfonamides if administered concurrently

### Laboratory Considerations

■ Sulfonamides may give false-positive results for **urine glucose** determinations when using the Benedict's method.

### Doses

#### ■ DOGS:

For susceptible infections:

- 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
- 100 mg/kg PO, IV or IM once daily (Upson 1988)
- 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; *Albon*®—Roche)

For coccidiosis:

- 55 mg/kg PO initially on the first day of therapy, then 27.5 mg/kg PO once daily for 9 days (Matz 1995)
- 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007)
- During the infant period (2–6 weeks): 50 mg/kg PO on the first day followed by a daily dose of 25 mg/kg PO until symptoms regress (Macintire 2004)

#### ■ CATS:

For susceptible infections:

- 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
- 100 mg/kg PO, IV or IM once daily (Upson 1988)
- 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; *Albon*®—Roche)

For coccidiosis:

- 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007)

#### ■ FERRETS:

For susceptible infections:

- 25 mg/kg PO, SC or IM once daily (Williams 2000)
- For coccidiosis: 25 mg/kg PO once daily for 14 days. (Johnson 2006)

#### ■ RABBITS, RODENTS, SMALL MAMMALS:

- Rabbits:** 10–15 mg/kg PO q12h (Ivey & Morrissey 2000)
- Rabbits:** For coccidiosis: 25 mg/kg PO once daily (Burke 1999)
- Hedgehogs:** 2–20 mg/kg/day IM, SC or PO (Smith 2000)
- Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:** As a coccidiostat: 50 mg/kg PO once, then 25 mg/kg PO once daily for 10–20 days *or* 75 mg/kg PO for 7–14 days (Adamcak & Otten 2000)

#### ■ CATTLE:

For susceptible infections:

- 110 mg/kg PO or IV once daily (Upson 1988)
- 55 mg/kg IV initially, then 27.5 mg/kg IV once daily (Baggot 1983)
- 110 mg/kg, PO q24h (Burrows 1980)
- 55 mg/kg PO or IV initially, then 27.5 mg/kg q24h (Jenkins 1986)
- 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV or PO for up to 5 days. If using sustained release boluses: 137.5 mg/kg PO every 4 days (Package insert; *Albon*®—Roche)

#### ■ HORSES:

For susceptible infections:

- 55 mg/kg, PO or IV q12h (Upson 1988)
- 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV (Package insert; *Albon*®—Roche)

#### ■ CAMELIDS (NWC):

- For coccidiosis (“regular” coccidia: *E. alpacae*, *E. lamae*, *E. punoensis*, *E. peruviana*): 15 mg/kg PO twice daily for 5 days; monitor for signs of poliоencephalomalacia. (Walker 2009)
- Treatment of Eimeria infection is generally directed at clinically affected animals using sulfadimethoxine at 110 mg/kg PO q24h (or amprolium). Treatments are effective only against the immature stages and therefore may not have a significant impact on fecal oocyst excretion initially. Given the long prepatent period, it is prudent to treat *E. macusaniensis* infections for 10–15 days. Treatment should be directly administered to the animal rather than by medicating water supplies. (McKenzie 2008)

#### ■ REPTILES:

For susceptible infections:

- For coccidia: 90 mg/kg PO on day one and then 45 mg/kg PO on 5 successive days; may also be given IM or IV. Maintain adequate hydration. (Lewbart 2001)

### Chemistry/Synonyms

A long-acting sulfonamide, sulfadimethoxine occurs as an odorless or almost odorless, creamy white powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadimethoxine may also be known as: solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, *Albon*®, *Amtech*®, *Chemiosalfa*®, *Deltin*®, *Di-Methox*®, *Risulpir*®, *Ritarsulfa*®, *SDM*®, *Sulfadren*®, *Sulfastop*®, or *Sulfasol*®, and *Sulfathox*®.

## Storage/Stability

Unless otherwise instructed by the manufacturer, store sulfadimethoxine products at room temperature and protect from light. If crystals form due to exposure to cold temperatures, either warm the vial or store at room temperature for several days to resolubilize the drug; efficacy is not impaired by this process.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Sulfadimethoxine Injection: 400 mg/mL (40%) in 100 mL vials; *Albon® Injection 40%* (Pfizer); *Di-Methox® Injection 40%* (AgriLabs), generic; (Rx) FDA-approved for use in dogs, cats, horses, swine and cattle. Not to be used in horses intended for food or calves to be processed for veal. Slaughter withdrawal (at labeled doses) = 5 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Tablets: 125 mg, 250 mg, and 500 mg; *Albon® Tablets* (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Sulfadimethoxine Oral Suspension: 50 mg/mL in 2 oz. and 16 oz. Bottles; *Albon®* (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Sulfadimethoxine Oral Boluses: 5 grams, and 15 grams; *Albon®* (Pfizer); (OTC). FDA-approved for use in cattle. Not to be used in calves to be processed for veal. No withdrawal period has been established for this in preruminating calves. Slaughter withdrawal (at labeled doses) = 7 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Boluses Sustained-Release: 12.5 g; *Albon® SR* (Pfizer); (Rx) FDA-approved for use in non-lactating cattle. Slaughter withdrawal (at labeled doses) = 21 days (cattle), a withdrawal period has not been established for pre-ruminating calves. Not for use in calves intended to be processed for veal.

Sulfadimethoxine Soluble Powder: 94.6 grams/packet (for addition to drinking water); *Albon®* (Pfizer), generic; FDA-approved for use in dairy calves, dairy heifers, beef cattle, broiler and replacement chickens only, and meat-producing turkeys. Slaughter withdrawal (at labeled doses) = 7 days (cattle); 5 days (poultry—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

Sulfadimethoxine 12.5% Concentrated Solution (for addition to drinking water): *Albon®* (Pfizer), generic; (OTC). FDA-approved for use in chickens, turkeys and cattle. Slaughter withdrawal (at labeled doses) = 7 days (for dairy calves, dairy heifers and beef cattle only. Withdrawal for pre-ruminating calves has not been established. Not to be used in calves to be processed for veal; 5 days (poultry—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

**HUMAN-LABELED PRODUCTS:** None

## SULFADIMETHOXINE/ORMETOPRIM

(or-me-toe-prim) Primor®

POTENTIATED SULFONAMIDE ANTIMICROBIAL

### Prescriber Highlights

- **Potentiated sulfa similar to trimethoprim/sulfa, but may have fewer adverse effects and is labeled for once daily dosing.**
- **Does not appear to be effective for prostate infections and is more expensive than generic trimethoprim/sulfa.**
- **The following apply to TMP/Sulfa & may apply to this agent as well:**
- **Contraindications:** Hypersensitive to sulfas, thiazides, or sulfonyleurea agents; severe renal or hepatic impairment; Dobermans
- **Caution:** Diminished renal or hepatic function, or urinary obstruction or urolithiasis
- **Adverse Effects:** *Dogs:* Keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3) acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemias, agranulocytosis, idiosyncratic hepatic necrosis in dogs. *Cats:* Anorexia, crystalluria, hematuria, leukopenias & anemias
- **Potentially teratogenic, weigh risk vs. benefit**

---

## Uses/Indications

Sulfadimethoxine/ormetoprim is FDA-approved for the treatment of skin and soft tissue infections in dogs caused by susceptible strains of *Staphylococcus aureus* and *E. coli*. Some felt that it has fewer adverse effects in dogs than trimethoprim/sulfa and can be dosed once daily. It is more expensive than trimethoprim/sulfa and does not appear to penetrate into the prostate as well.

## Pharmacology/Actions

Sulfadimethoxine/ormetoprim shares mechanisms of action and probably the bacterial spectrum of activity with trimethoprim/sulfa. Alone, sulfonamides are bacteriostatic agents, but in combination with either ormetoprim or trimethoprim, the potentiated sulfas are bactericidal. Potentiated sulfas sequentially inhibit enzymes in the folic acid pathway, thereby inhibiting bacterial thymidine synthesis. The sulfonamide blocks the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA) and ormetoprim blocks the conversion of DFA to tetrahydrofolic acid by inhibiting dihydrofolate reductase.

The potentiated sulfas have a fairly broad spectrum of activity. Gram-positive bacteria that are generally susceptible include most streptococci, many strains of staphylococcus, and Nocardia. Many gram-negative organisms of the family Enterobacteriaceae are susceptible to the potentiated sulfas, but not *Pseudomonas aeruginosa*. Some protozoa (*Pneumocystis carinii*, Coccidia and Toxoplasma) are also inhibited by the combination. Potentiated sulfas reportedly have little activity against most anaerobes, but opinions on this vary.

Resistance will develop more slowly to the combination of drugs, than to either one alone. In gram-negative organisms, resistance is usually plasmid-mediated.

## Pharmacokinetics

The pharmacokinetics of sulfadimethoxine are outlined in the previous monograph. Pharmacokinetic data for ormetoprim is not available at the time of this writing, but the manufacturer states that therapeutic levels are maintained over 24 hours at recommended doses. Unlike trimethoprim/sulfa, ormetoprim does not apparently attain clinically effective levels in the prostate for treating bacterial prostatic infections.

## Contraindications/Precautions/Warnings

The manufacturer states that ormetoprim/sulfadimethoxine should not be used in dogs showing marked liver parenchymal damage, blood dyscrasias, or in those with a history of sulfonamide sensitivity.

Doberman pinschers appear to be very susceptible to sulfonamide-induced poly-systemic immune complex disease and most believe that these drugs are contraindicated in them.

This information should not be used to guide clinical practice. © 2010 Veterinary Information Systems

This combination should be used with caution in patients with pre-existing hepatic or thyroid disease.

### Adverse Effects

This combination would be expected to exhibit an adverse reaction profile in dogs similar to that seen with trimethoprim/sulfa, including: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria, and cholestasis. Acute hypersensitivity reactions manifesting as Type I, (anaphylaxis) or Type III reaction (serum sickness) can also be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers may possibly be more susceptible to this effect than other breeds. Other hematologic effects (anemias, agranulocytosis) are possible, but fairly rare.

Long-term (8 weeks) therapy at recommended doses with ormetoprim/sulfadimethoxine (27.5 mg/kg once daily) resulted in elevated serum cholesterol, thyroid and liver weights, mild follicular thyroid hyperplasia, and enlarged basophilic cells in the pituitary. The manufacturer states that the principal treatment-related effect of extended or excessive usage is hypothyroidism.

### Reproductive/Nursing Safety

Safety of ormetoprim/sulfadimethoxine has not been established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported in some lab animals with trimethoprim/sulfa.

### Overdosage/Acute Toxicity

In experimental studies in dogs, doses greater than 80 mg/kg resulted in slight tremors and increased motor activity in some dogs. Higher doses may result in depression, anorexia, or seizures.

It is suggested that very high oral overdoses be handled by emptying the gut using standard precautions and protocols and by treating clinical signs supportively and symptomatically.

### Drug Interactions; Laboratory Considerations

■ None have been noted for this combination, but it would be expected that the potential interactions outlined for the trimethoprim/sulfa monograph would also apply to this combination; refer to that monograph for more information.

### Doses

#### ■ DOGS:

For susceptible infections:

a) Initially 55 mg/kg (combined drug) PO on the first day of therapy, then 27.5 mg/kg PO once daily for at least 2 days after remission of clinical signs. Not approved for treatment longer than 21 days. (Package insert; *Primor*®—Pfizer)

### Monitoring

- Clinical efficacy
- Adverse effects
- In dogs, monitor tear production (one suggestion is in 5 days after starting treatment and then every 2-3 weeks)

### Client Information

■ Animals must be allowed free access to water and must not become dehydrated while on therapy.

### Chemistry/Synonyms

A diaminopyrimidine structurally related to trimethoprim, ormetoprim occurs as a white, almost tasteless powder. The chemistry of sulfadimethoxine is described in the previous monograph.

Sulfadimethoxine may also be known as: sulfadimetossina, sulfadimetossipirimidina, sulphadimethoxine, *Chemiosalfa*®, *Deltin*®, *Risulpir*®, *Ritarsulfa*®, *Sulfadren*®, *Sulfastop*®, or *Sulfathox*®.

Ormetoprim may also be known as NSC-95072, ormetoprima, ormétoprime, ormetoprimum, or Ro-5-9754.

### Storage/Stability

Unless otherwise instructed by the manufacturer, store tablets in tight, light resistant containers at room temperature.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Sulfadimethoxine/Ormetoprim Tablets (scored)

120's: 100 mg Sulfadimethoxine, 20 mg Ormetoprim

240's: 200 mg Sulfadimethoxine, 40 mg Ormetoprim

600's: 500 mg Sulfadimethoxine, 100 mg Ormetoprim

1200's: 1000 mg Sulfadimethoxine, 200 mg Ormetoprim; *Primor*® (Pfizer); (Rx) FDA-approved for use in dogs.

Sulfadimethoxine/Ormetoprim medicated premix: 113.5 grams sulfadimethoxine and 68.1 grams ormetoprim per pound in 50 lb bags. FDA-approved for use in chickens [broilers, replacements (breeders and layers)], turkeys, ducks, & Chukar partridges. Slaughter withdrawal (at labeled doses) = 5 days. Do not feed to chickens over 16 weeks or age, turkeys or ducks producing eggs for food. *Rofenaïd*® 40 (Alpharma), *Romet*® 30 (Alpharma)—FDA-approved for use in salmonids (trout and salmon) and catfish. Slaughter or release as stocker fish = 42 days. (OTC)

**HUMAN-LABELED PRODUCTS:** None

---

## SULFASALAZINE

(sul-fa-sal-a-zeen) Azulfidine®

SULFONAMIDE/SALICYLATE ANTIBACTERIAL/IMMUNOSUPPRESSIVE

### Prescriber Highlights

- Sulfa-analog that has GI antibacterial & antiinflammatory activity used for inflammatory bowel disease; has also been used for vasculitis
- Contraindications: Hypersensitivity to it, sulfas or salicylates; intestinal or urinary obstructions; Dobermans
- Caution: Liver, renal or hematologic diseases; cats
- Adverse Effects: *Dogs:* Keratoconjunctivitis sicca, anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, vomiting, decreased sperm counts & an allergic dermatitis. *Cats:* Anorexia, vomiting, anemias

---

### Uses/Indications

Sulfasalazine is used for the treatment of inflammatory large bowel (colonic) disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs. It is not effective for small intestinal

mesalamine is used for the treatment of inflammatory large bowel (colonic) disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs. It is not effective for small intestinal inflammation as colonic bacteria are required to cleave the drug into mesalamine (5-ASA) and sulfapyridine.

### Pharmacology/Actions

While the exact mechanism of action for its therapeutic effects in treating colitis in small animals has not been determined, it is believed that after sulfasalazine is cleaved into sulfapyridine and 5-aminosalicylic acid (5-ASA, mesalamine) by bacteria in the gut the antibacterial (sulfapyridine) and/or antiinflammatory (mesalamine) activity alters the clinical signs/course of the disease. Levels of both drugs in the colon are higher than by giving them orally as separate agents.

### Pharmacokinetics

Only about 10–33% of an orally administered dose of sulfasalazine is absorbed. Apparently, some of this absorbed drug is then excreted unchanged in the bile. Unabsorbed and biliary excreted drug is cleaved into 5-ASA and sulfapyridine in the colon by bacterial flora. The sulfapyridine component is rapidly absorbed, but only a small percentage of the 5-ASA is absorbed.

Absorbed sulfapyridine and 5-ASA are hepatically metabolized and then renally excreted.

### Contraindications/Precautions/Warnings

Sulfasalazine is contraindicated in animals hypersensitive to it, sulfonamides or salicylates. It is also contraindicated in patients with intestinal or urinary obstructions. Doberman pinschers appear to be very susceptible to sulfonamide-induced polysystemic immune complex disease and most believe that these drugs are contraindicated in them.

It should be used with caution in animals with preexisting liver, renal or hematologic diseases. Because cats can be sensitive to salicylates (see the aspirin monograph), use caution when using this drug in this species.

### Adverse Effects

Although adverse effects do occur in dogs, with keratoconjunctivitis sicca (KCS) reported most frequently, they are considered to occur relatively uncommonly. Other potential adverse effects include anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leukopenia, vomiting, decreased sperm counts and an allergic dermatitis. Should decreased tear production be noted early, either reducing the dose or discontinuing the drug may prevent progression of KCS or increase tear production.

Cats can occasionally develop anorexia and vomiting which may be alleviated by use of the enteric-coated tablets. Anemias secondary to sulfasalazine are also potentially possible in cats.

### Reproductive/Nursing Safety

Although sulfasalazine has not been proven harmful to use during pregnancy and incidences of neonatal kernicterus in infants born to women taking sulfasalazine are low, it should only be used when clearly indicated. In laboratory animal studies (rats, rabbits), doses of six times normal (human) caused impairment of fertility in male animals; this effect is thought to be caused by the sulfapyridine component and was reversible upon discontinuation of the drug.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Sulfonamides are excreted in milk. In human newborns, they compete with bilirubin for binding sites on plasma proteins and may cause kernicterus. Use with caution in nursing patients.

### Overdosage/Acute Toxicity

Little specific information is available regarding overdoses with this agent, but because massive overdoses could cause significant salicylate and/or sulfonamide toxicity, standard protocols (empty stomach, cathartics, etc.) should be considered. Urine alkalinization and forced diuresis may also be beneficial in selected cases.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfasalazine and may be of significance in veterinary patients:

- **CHLORPROPAMIDE:** Hypoglycemic effects could be potentiated
- **DIGOXIN:** Sulfasalazine may reduce absorption
- **FEROUS SULFATE or other iron salts:** May decrease the blood levels of sulfasalazine if administered concurrently; clinical significance is unknown
- **FOLIC ACID:** Oral absorption may be inhibited
- **WARFARIN:** Potentially sulfasalazine could potentiate warfarin

### Doses

#### ■ DOGS:

For inflammatory large bowel disease:

- a) Usual initial dose: 20–40 mg/kg q8h for 3 weeks, followed by 20–40 mg/kg q12h for 3 weeks, and 10–20 mg/kg q12h for 3 weeks. (Marks 2009)
- b) 20–48.4 mg/kg (maximum total dose of one gram in refractory patients) PO q8h. May consider an initial dose of 12.5 mg/kg, q8h. Continue initial dose for a minimum of 4 weeks before modifying dosage. After signs of disease resolve, reduce dosage by 25% at 2 week intervals and eventually discontinue while maintaining dietary management. (Jergens & Willard 2000)
- c) For chronic colitis: If hypoallergenic diet does not control signs, sulfasalazine 20–50 mg/kg (up to a maximum of 1 gram) three times daily. Initial dosage usually 20–30 mg/kg three times daily. Dose may be reduced at 2–4 week intervals if stool remains normal using the following protocol: Initially same dose given twice daily, then 50% of initial dose twice daily, then 50% of that dose once daily, then discontinue. Some dogs may require chronic therapy. (Leib 2000)
- d) 10–25 mg/kg PO three times a day for 4–6 weeks. With resolution of clinical signs, reduce dose by 25 percent at 2 week intervals and eventually discontinue while maintaining dietary management. (Washabau 2005)

For adjunctive treatment of vasculitis:

- a) 20–40 mg/kg PO q8h (Hillier 2006), (Griffin 2006)
- b) 25 mg/kg PO three times a day. (Bloom 2006)

#### ■ CATS:

For inflammatory large bowel disease:

- a) 10–20 mg/kg PO once daily. Use cautiously in cats because of their sensitivity to salicylates (Jergens & Willard 2000)
- b) 10–20 mg/kg PO q24 hours (once daily) tapered to the lowest effective dose (Moore 2004), (Marks 2007)
- c) 10–20 mg/kg PO q8–12h (maximum of 10 days) (Dimski 1995)
- d) 10–20 mg/kg PO q8–24h; up to a maximum of 10 days treatment (Krecic 2002)

#### ■ FERRETS:

- a) 10–20 mg/kg PO 2–3 times a day (Williams 2000)
- b) 25 mg (total dose) PO twice daily (Weiss 2002)

### Monitoring

- Efficacy
- Adverse effects, particularly KCS; Schirmer tear tests should be performed prior to therapy (and on rechecks), especially in middle-aged to older dogs
- Occasional CBC, liver function tests are warranted with chronic therapy

### Client Information

- Clients should monitor for clinical signs of KCS (dry cornea, blepharospasm, bilateral mucopurulent discharge) and report them to the veterinarian immediately.

## Chemistry/Synonyms

Sulfasalazine is basically a molecule of sulfapyridine linked by a diazo bond to the diazonium salt of salicylic acid. It occurs as an odorless, bright yellow to brownish-yellow fine powder. Less than 0.1 mg is soluble in 1 mL of water and about 0.34 mg is soluble in 1 mL of alcohol.

Sulfasalazine may also be known as: salazosulfapyridine, salicylazosulfapyridine, sulfasalazinum, sulphasalazine, *Azulfidine*®, *Aculfin*®, *Azulfim*®, *Colo-Pleon*®, *Pleon RA*®, *Pyralin*®, *SAS*®, *Salazine*®, *Salazopirina*®, *Salazoprin*®, *Salazopyrin*®, *Salazopyrina*®, *Salazopyrine*®, *Salisulf Gastroprotecto*®, *Salopyrine*®, *Saridine*®, *Sazo*®, *Sulazine*®, or *Ulco*®.

## Storage/Stability

Sulfasalazine tablets (either plain or enteric-coated) should be stored at temperatures less than 40°C and preferably at room temperature (15–30°C, 59–86°F) in well-closed containers. The oral suspension should be stored at room temperature (15–30°C, 59–86°F); avoid freezing.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Sulfasalazine Tablets: 500 mg; *Azulfidine*® (Pfizer); generic; (Rx)

Sulfasalazine Delayed-Release Tablets: 500 mg (enteric coated); *Azulfidine*® *EN-tabs*® (Pfizer); generic; (Rx)

## TADALAFIL

(*ta-dal-a-fil*) *Cialis*®

PHOSPHODIESTERASE TYPE 5 INHIBITOR

### Prescriber Highlights

- **PDP5 inhibitor that may be useful for treating pulmonary arterial hypertension in dogs**
- **Very limited clinical experience or published data for use in dogs**
- **Appears to have a longer duration action than sildenafil**
- **Contraindicated if patients receiving organic nitrates**
- **Adverse effects not well-known for dogs; inguinal flushing, GI effects reported with sildenafil**
- **Currently, very expensive**

---

## Uses/Indications

Tadalafil is a phosphodiesterase-5 inhibitor similar to sildenafil and may be useful for treating pulmonary arterial hypertension (PAH) in dogs. A pilot study done in dogs with PAH, showed that tadalafil (1 mg/kg PO) caused modest, but significant decreases in diastolic pulmonary arterial pressure (PAP), mean PAP and tricuspid regurgitation suggesting that oral tadalafil, when added to conventional heart failure therapy, decreases PAP in dogs with PAH. Because of its longer duration of action, tadalafil has some advantages over sildenafil but it is currently very expensive.

In humans, tadalafil is approved for use in treating pulmonary artery hypertension (*Adcirca*®) and erectile dysfunction (*Cialis*®). Off-label uses include treating Raynaud's phenomenon.

## Pharmacology/Actions

Tadalafil is a selective inhibitor of cyclic guanosine monophosphate (cGMP)-specific phosphodiesterase type 5 (PDE5). PDE5 is the enzyme responsible for the degradation of cGMP and is found (in humans) in the corpus cavernosum smooth muscle, pulmonary vascular and visceral smooth muscle, skeletal muscle, platelets, kidney, lung, cerebellum, and pancreas. In patients with PAH, vascular endothelium nitric oxide release is impaired with associated reduction of cGMP. PDE5 is the primary phosphodiesterase in pulmonary vasculature and tadalafil's PDE5 inhibition increases cGMP thereby relaxing pulmonary vascular smooth muscle with resultant vasodilation.

## Pharmacokinetics

No pharmacokinetic data for tadalafil for dogs was located.

In humans, after oral administration maximum plasma concentrations occur at around 4 hours in patients with PAH. Food does not alter the rate or extent of absorption. Tadalafil is 94% bound to human plasma proteins. Tadalafil is metabolized by CYP3A4 to a catechol metabolite that then undergoes methylation and glucuronidation. These metabolites are not thought to be active. In PAH patients, mean terminal half-life is 35 hours. Excretion is primarily of the drug's metabolites via fecal routes (61%) with the majority of the remainder in the urine (approximately 36%).

## Contraindications/Precautions/Warnings

Tadalafil is contraindicated in human patients using (either regularly or intermittently) any form of organic nitrate, and in those with serious hypersensitivity to tadalafil. Dosage reductions may be required in patients with severe hepatic or renal impairment.

## Adverse Effects

An adverse effect profile for dogs at suggested doses for PAH has not been determined. Cutaneous flushing of the inguinal region has been reported with sildenafil in dogs. GI effects are possible. In a 12-month tadalafil chronic toxicity study done in dogs, no disseminated arteritis was observed as was seen in rodent studies, but 2 dogs exhibited marked decreases in neutrophils and moderate decreases in platelets with inflammatory signs when dosed at approximately 4X to 18X the equivalent human dose. These effects were reversible within 2 weeks after discontinuing the drug.

Most common adverse effects of tadalafil reported in humans with PAH, include: dyspepsia, nausea, back pain, myalgia, nasal congestion, flushing and headache. Rare, but serious adverse effects include hypersensitivity, optic neuropathy, seizures, Stevens-Johnson syndrome and exfoliative dermatitis, and deafness.

## Reproductive/Nursing Safety

Tadalafil animal reproduction studies in rats and mice demonstrated no evidence of teratogenicity, embryotoxicity, or fetotoxicity when tadalafil was given to pregnant rats or mice at exposures of up to 11X (human equivalent dose). The FDA categorizes tadalafil as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Tadalafil and/or its metabolites are secreted in the milk in lactating rats at concentrations approximately 2.4-fold found in the plasma. It is important to pose no risk to nursing offspring.

### Overdosage/Acute Toxicity

Little information is available. Single doses of up to 500 mg have been given to healthy men, and multiple daily doses of up to 100 mg have been given to men with erectile dysfunction; adverse reactions were similar to those seen at lower doses.

It is expected that overdoses in animals would mirror the drug's adverse effect profile; treat supportively. Contact an animal poison control center for guidance, if necessary.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tadalafil and may be of significance in veterinary patients:

- **ALPHA-ADRENERGIC BLOCKERS** (e.g., **phentolamine, phenothiazines, phenoxybenzamine**): May increase hypotensive effects
- **AMLODIPINE**: Potential to increase hypotensive effects
- **ANTIHYPERTENSIVE, HYPOTENSIVE DRUGS**: Potentially could increase hypotensive effects
- **AZOLE ANTIFUNGALS** (**ketoconazole, itraconazole**): May reduce tadalafil metabolism and increase AUC
- **CIMETIDINE**: May reduce tadalafil metabolism and increase AUC
- **ERYTHROMYCIN, CLARITHROMYCIN**: May reduce tadalafil metabolism and increase AUC
- **NITRATES** (e.g., **NTG, Isosorbide**): Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **NITROPRUSSIDE SODIUM**: Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **PHENOBARBITAL**: May decrease tadalafil concentrations
- **RIFAMPIN**: May decrease tadalafil concentrations

### Laboratory Considerations

- None noted

### Doses

#### ■ DOGS:

For pulmonary arterial hypertension:

- From a case report in a Yorkshire terrier: 1 mg/kg PO q48h (every other day) was added to the background treatment (furosemide, spironolactone, benazepril, dexamethasone and oxygen). Dog's condition rapidly (<24 hours) improved and 7-day follow-up showed a decrease (up to 26 mmHg) in systolic pulmonary arterial pressure and disappearance of all respiratory and cardiac signs of PAH (cyanosis, syncope and tachypnea). Authors' recommend long-term studies in more animals. (Serres *et al.* 2006)
- 1 mg/kg PO once daily. (Oyama 2009)

### Monitoring

- Clinical efficacy (improved syncope, cough, respiratory effort)
- Pulmonary artery pressure, systemic blood pressure
- Adverse effects

### Client Information

- Brief clients on the experimental nature of using this medication in small animals and the costs of therapy
- Report any adverse effects to the veterinarian

### Chemistry/Synonyms

Tadalafil has a molecular weight of 389.41. It is insoluble in water and slightly soluble in ethanol.

Tadalafil may also be known as: GF-196960, IC-351, tadalafili, tadalafilo, or tadalafilum. *Cialis*® and *Adcirca*® are trade names for tadalafil.

### Storage/Stability

Tadalafil tablets should be stored at room temperature between 59°-86°F (15° and 30°C).

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Tadalafil Oral Tablets: 2.5 mg, 5 mg, 10 mg, 20 mg: *Cialis*®, *Adcirca*® (Lilly); (Rx)

---

## TAURINE

(*tor-eeen*)

AMINO ACID NUTRITIONAL

### Prescriber Highlights

- Amino acid used primarily for the treatment of taurine deficiency cardiomyopathies in cats & dogs
  - May also be useful for many other conditions (e.g., seizures, hepatic lipidosis), but little supporting data available
  - Very low toxic potential
  - Laboratory considerations
- 

### Uses/Indications

Taurine is beneficial in preventing retinal degeneration and the prevention of taurine-deficiency dilated cardiomyopathy in cats. Although modern commercial feline diets have added taurine, some cats still develop taurine-deficiency associated dilated cardiomyopathy. It may also be of benefit in taurine ( $\pm$ carnitine) deficient cardiomyopathy in American Cocker Spaniels and certain other breeds such as, Golden Retrievers, Labrador Retrievers, Newfoundlands, Dalmations, Portuguese Water Dogs, and English Bulldogs. Preliminary studies have shown evidence that it may be useful as adjunctive treatment for cardiac disease in animals even if taurine deficiency is not present. Because of its low toxicity, some have suggested it be tried for a multitude of conditions in humans and animals; unfortunately, little scientific evidence exists for these uses.

### Pharmacology/Actions

While classically considered a “non-essential” nutrient, taurine has been found to play several “essential” roles in various mammalian species. Taurine is important for bile acid conjugation, especially in cats and dogs. *In vivo*, taurine is synthesized from methionine. Cysteinesulfinic acid decarboxylase (CSAD) and vitamin B6 are involved with this synthesis. Deficiencies of either will depress taurine synthesis. Cats are particularly susceptible to taurine deficiency as they have low CSAD activity and use taurine almost exclusively for bile acid conjugation.

Additionally taurine is important in the modulation of calcium flux, thereby reducing platelet aggregation, stabilizing neuronal membranes, and affecting cardiac function. Taurine’s effects on cardiac function include positive inotropic activity without affecting resting potential and modulating ionic currents across the cell membrane. Taurine is important for normal development of the CNS and it has a GABA-like effect that may make it useful for treating some seizure disorders.

### Pharmacokinetics

No specific information was located. Excess taurine is rapidly excreted in the kidneys, but if a deficiency exists, urinary excretion is reduced via reabsorption.

### Contraindications/Precautions/Warnings

While taurine is safe, it should not be used as a substitute for adequate diagnosis.

### Adverse Effects

Taurine appears to be very well tolerated. Minor GI distress potentially could occur after oral dosing.

### Overdosage/Acute Toxicity

No specific information was located, but toxic potential appears to be very low.

### Drug Interactions

■ None noted

### Laboratory Considerations

■ Because plasma levels may reflect the acute changes associated with dosing, whole blood levels are preferred to measure actual status of taurine in the body. Because intracellular levels of taurine are much higher than in plasma, hemolysis or collection of the buffy coat will negate the results.

### Doses

#### ■ DOGS:

- For taurine-deficiency related cardiomyopathy: In American Cocker Spaniels: Give 500 mg taurine PO q12h (with 1 gram of carnitine PO q12h). (Kittleson 2000)
- Complementary therapy for seizures: 400 mg/40 lbs of body weight PO twice daily. “May” help decrease seizure activity (Neer 2000)
- For taurine-related cardiomyopathy: 500–1500 mg (total dose) PO per day. (Reynolds 2009)
- Recommendations for taurine supplementation in dilated cardiomyopathy are: **1)** All American Cocker spaniels; **2)** Consider in animals with dilated cardiomyopathy and cysteine or urate urolithiasis (e.g., English Bulldogs and Dalmations); **3)** Consider in golden retrievers, Newfoundland dogs, Portuguese water dogs and any atypical breeds for dilated cardiomyopathy

The suggested taurine dose for dogs with dilated cardiomyopathy is 500–1000 mg PO q8–12h for dogs weighing under 25 kg and 1–2 grams PO q8–12h for dogs weighing > 25 kg. (Smith 2009)

#### ■ CATS:

- For taurine-deficiency related cardiomyopathy: 250 mg (per cat) PO q12–24h. Because taurine is safe and inexpensive, recommend using for any case of myocardial failure. (Fox 2000)
- Complementary therapy for seizures: 500 mg per cat PO twice daily. “May” help decrease seizure activity (Neer 2000)
- For adjunctive treatment of hepatic lipidosis: 250–500 mg/day is valuable. Taurine may be hepatoprotective and is required for bile conjugation. It plays a role in membrane stability and function. Cats with hepatic lipidosis waste taurine in their urine and anorexia causes a decrease in serum taurine levels. (Scherk 2007)

### Monitoring

- Clinical efficacy
- Taurine levels (if possible and affordable; whole blood levels preferable to plasma/serum levels)

### Chemistry/Synonyms

Taurine, an amino acid also known as 2-aminosulphonic acid, has a molecular wt. of 125. Solubility in 100 mL of water at 20°C is 8.8 grams.

### Storage/Stability

Unless otherwise labeled, store taurine tablets or capsules at room temperature. Protect from light and moisture.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

The following products are labeled (not FDA-approved drugs) for use in animals:

Taurine Tablets: 250 mg; *Formula V® Taurine Tablets* (PetAg); Labeled for use in cats.

Taurine Liquid: 375 mg/4 mL (one pump); *Dyna-Taurine®* (Harlmen); Labeled for use in dogs and cats.

#### HUMAN-LABELED PRODUCTS:

There are several oral dosage form products available for taurine. Technically considered a “nutrient” they are all OTC and may need to be obtained from health food stores. Most dosage forms available range from 125 mg to 500 mg.

**Telazol®—See Tiletamine/Zolazepam**

### TEPOXALIN

(te-pox-a-lin) Zubrin®

**Prescriber Highlights**

- NSAID dual inhibitor of COX & LOX indicated for the treatment of pain & inflammation associated with osteoarthritis in dogs
- Adverse effect profile still being determined, but may cause more vomiting & diarrhea than some other FDA-approved NSAIDs
- Rapidly disintegrating tablet dosage form may be useful in difficult to pill dogs

**Uses/Indications**

Tapoxalin is indicated for the treatment of pain and inflammation associated with osteoarthritis in dogs. Because of the drug's inhibitory effects on leukotrienes, there is interest in seeing if it would be beneficial in the adjunctive treatment of allergic conditions in dogs.

**Pharmacology/Actions**

Tapoxalin is a dual inhibitor of both cyclooxygenase (COX) and 5-lipoxygenase (LOX). It inhibits both COX-1 and COX-2 enzymes, but it is not clear if it is COX-2 preferential in the dog (it is not COX-2 preferential in sheep uterine cells) or if its LOX inhibition reduces the adverse effects associated with COX-1 inhibition. LOX inhibition in dogs persists for only about 6 hours after dosing. By inhibiting COX-2 enzymes, tapoxalin reduces the production of prostaglandins associated with pain, hyperpyrexia and inflammation. Its inhibition of LOX potentially reduces the production of leukotrienes, including leukotriene B<sub>4</sub>. As leukotriene B<sub>4</sub> may contribute to increased GI tract inflammation by increasing cytokine production, neutrophil longevity and release of proteinases, inhibition may reduce the GI effects routinely seen in dogs with COX-1 inhibitors. Leukotrienes may also contribute to inflammatory responses seen in osteoarthritic conditions and their inhibition could reduce clinical signs seen with the condition.

**Pharmacokinetics**

After oral administration to dogs, tapoxalin is readily absorbed and peak levels occur between 2–3 hours post-dose. The presence of food in the gut increases bioavailability. Tapoxalin is rapidly metabolized to several metabolites, including one that is active (tapoxalin pyrazole acid). Tapoxalin and tapoxalin pyrazole acid are highly bound to plasma proteins (98–99%). Elimination half-lives for tapoxalin and tapoxalin pyrazole acid are about 2 hours and 13 hours, respectively. Metabolites are eliminated in the feces; only 1% of the drug is eliminated in the urine.

In cats, tapoxalin elimination half-life is about 5 hours; the active metabolite half-life is approximately 4 hours.

**Contraindications/Precautions/Warnings**

Tapoxalin is contraindicated in dogs demonstrating prior hypersensitivity reactions to tapoxalin. It should be used with caution in patients with impaired hepatic, cardiovascular or renal function, or at risk for developing nephrotoxic effects associated with NSAIDs (*i.e.*, dehydrated or on concomitant diuretic therapy). Patients with active gastrointestinal ulcers should probably not receive this drug.

Dogs weighing less than 3 kg cannot be accurately dosed with available dosage forms. Safety in dogs less than 6 months old has not been established.

**Adverse Effects**

Adverse effects most likely seen in dogs include diarrhea, vomiting, anorexia/inappetence, enteritis, and lethargy. In one study where dogs received labeled doses for 4 weeks, 22% of dogs developed diarrhea and 20% vomited. It is unknown if giving the drug with food will decrease vomiting incidence. Other adverse effects reported (incidences <1%) include incoordination, incontinence, increased appetite, eating grass, flatulence, hair loss, and trembling. While all NSAIDs can potentially cause renal dysfunction, a study done in healthy dogs did not show that tapoxalin altered renal blood flow or renal function when used alone or with benazepril (for 7 days) or with enalapril (for 28 days) (Fusellier *et al.* 2005).

The manufacturer warns to discontinue the drug if signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus, or lethargy are observed. Safety studies in dogs less than 6 months of age have not been completed.

**Reproductive/Nursing Safety**

Safety of this drug has not been determined in pregnant, breeding, or lactating dogs; use with caution and with informed consent of client.

**Overdosage/Acute Toxicity**

Information on acute overdosage of tapoxalin was not located. Dogs receiving 300 mg/kg/day for 6 months showed decreases in total protein, albumin and calcium concentrations. At necropsy, all dogs showed gastric lesions. An acute overdose may cause significant GI distress and ulceration with GI bleeding. It is suggested to treat supportively and monitor CBC, hydration, renal function, and for evidence of GI bleeding. Contact an animal poison control center for more information.

**Drug Interactions**

A study in normal dogs showed no significant changes in renal function when **enalapril** was used with tapoxalin.

The following drug interactions have either been reported or are theoretical in humans or animals receiving tapoxalin and may be of significance in veterinary patients:

- **ASPIRIN:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS:** As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tapoxalin
- **DIGOXIN:** NSAIDs may increase serum levels
- **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans, it is unknown if fluconazole affects tapoxalin levels in dogs
- **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS (*e.g.*, furosemide, aminoglycosides, amphotericin B, etc.):** May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **WARFARIN:** The manufacturer cautions to closely monitor patients also receiving drugs that are highly bound to plasma proteins (*e.g.*, warfarin), as tapoxalin and its active metabolite are 98–99% protein bound in the dog

**Laboratory Considerations**

- No specific laboratory interactions or considerations noted

**Doses****■ DOGS:**

For pain and inflammation associated with osteoarthritis:

- On first day of treatment give 20 mg/kg PO (or 10 mg/kg PO); subsequently give 10 mg/kg PO once daily. Duration of treatment should be based on clinical response and patient tolerance to therapy. (Package insert; *Zubrin*®—Schering-Plough)

**Monitoring**

- Clinical efficacy
- Baseline and periodic CBC, chemistry panel (including bilirubin and serum creatinine)
- Signs associated with adverse effects (GI effects, appetite, vomiting, diarrhea, etc.)

## Client Information

- When dosing, the person administering the tablet should place it in dog's mouth and hold mouth closed for approximately 4 seconds to assure tablet disintegration
- Absorption may be enhanced (and vomiting reduced?) if given with food
- Owners should be instructed to discontinue the drug and contact their veterinarian if diarrhea is severe or persists, or signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus or lethargy are observed
- Dogs should have access to water; dehydration should be avoided
- The manufacturer provides a client information sheet and states to "Always provide client information sheet ..."

## Chemistry/Synonyms

A non-steroidal antiinflammatory agent (NSAID), tepoxalin occurs as a white, tasteless, crystalline material that is insoluble in water and soluble in alcohol and most organic solvents. The commercially available tablets contain a micronized form of the drug in a highly porous matrix that rapidly disintegrates in the mouth. Drug particles are released into the saliva and swallowed by the dog where it is absorbed in the intestines.

Tepoxalin may also be known as ORF-20485, RWJ-20485 and *Zubrin*®.

## Storage/Stability

Tablets should be kept in their foil blister packs until used and stored at temperatures between 2–30°C (36–86°F).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Tepoxalin Oral (rapidly-disintegrating) Tablets: 30 mg, 50 mg, 100 mg, 200 mg in foil blisters containing 10 tablets in boxes of 10 foil blisters; *Zubrin*® (Schering-Plough); (Rx). FDA-approved for use in dogs.

### HUMAN-LABELED PRODUCTS: None

## References

Foster, M.J.C. Desfosse, et al. (2005). Effect of tepoxalin on renal function in healthy dogs receiving an angiotensin-converting enzyme inhibitor. *Journal of Veterinary Pharmacology and Therapeutics* 28(6): 581–586.

---

## TERBINAFINE HCL

(*ter-bin-ah-fin*) Lamisil®

ANTIFUNGAL

### Prescriber Highlights

- **Oral & topical antifungal; used primarily for dermatophytic infections, but may be useful for other fungi (e.g., aspergillus), especially in birds**
- **Comparatively (with azole antifungals) few drug interactions**
- **Appears to be very well tolerated, but limited experience; vomiting most likely adverse effect**
- **Caution if liver or renal disease**
- **Treatment is relatively expensive, but generics are now available**

---

## Uses/Indications

Terbinafine may be useful for treating dermatophytic and other fungal infections in dogs and cats.

Terbinafine may also be useful for treating birds for systemic mycotic (e.g., aspergillosis) infections.

## Pharmacology/Actions

Terbinafine is an inhibitor of the synthesis of ergosterol, a component of fungal cell membranes. By blocking the enzyme squalene monoxygenase (squalene 2,3-epoxidase), terbinafine inhibits the conversion of squalene to sterols (especially ergosterol) and causes accumulation of squalene. Both these effects are thought to contribute to its antifungal action. Terbinafine's mechanism for inhibiting ergosterol is different from the azole antifungals.

Unlike the azole agents, terbinafine's actions are not mediated via the cytochrome P-450 enzyme system, and, therefore, do not have the concerns of drug interactions or altering testosterone or cortisol.

Terbinafine primarily has clinical activity (fungicidal) against dermatophytic organisms (*Microsporum* spp., *Trichophyton* spp., etc.). It may only be fungistatic against the yeasts (*Candida* spp.). Terbinafine has activity against *Aspergillus*, *Blastomyces*, and *Histoplasma* but is usually not used clinically for infections caused by these organisms.

## Pharmacokinetics

Little small animal specific information is available. In cats dosed at 34–46 mg/kg PO once daily for 14 days, terbinafine persisted in hair above MIC for several weeks. (Foust *et al.* 2007)

In six horses, orally administered terbinafine pharmacokinetic values have been reported. The maximum plasma concentration was 0.31 (range: 0.21-0.61) micrograms/mL and occurred at 1.7 (range: 0.75-4) hours after dosing. Mean half-life was about 8 hours, but ranged widely (range: 3.9-11.6 hours); volume of distribution (Vd/F) was about 131 L/kg (range: 50-266 L/kg); clearance was 187 mL/min/kg (range: 132–282 mL/min/kg). As intravenous terbinafine was not administered, volume of distribution, and clearance are reported per fraction of drug available (KuKanich *et al.* 2009).

In humans, terbinafine given orally is greater than 70% absorbed; after first pass, metabolism bioavailability is about 40%. Food may enhance absorption somewhat. Terbinafine is distributed to skin and into the sebum. Over 99% of drug in plasma is bound to plasma proteins. Drug in the circulation is metabolized in the liver and the effective elimination half-life is about 36 hours. The drug may persist in adipose tissue and skin for very long periods.

## Contraindications/Precautions/Warnings

Terbinafine is contraindicated in patients hypersensitive to it. The manufacturer does not recommend its use in patients with active or chronic liver disease or with significantly impaired renal function. If terbinafine is to be used in veterinary patients with markedly impaired liver or renal function, do so with extreme caution; dosage adjustments should be considered.

## Adverse Effects

Because of limited usage in veterinary patients the adverse effect profile is not well defined, but thus far, the drug appears to be well tolerated. GI effects (vomiting, inappetence, diarrhea) are possible. In case report in two cats, one cat developed lethargy (Nuttall *et al.* 2008).

Very rarely in humans, liver failure, neutropenia or serious skin reactions (e.g., TEN, Stevens-Johnson syndrome) have occurred after terbinafine use.

## Reproductive/Nursing Safety

High dose studies in pregnant rabbits and rats have not demonstrated overt fetotoxicity or teratogenicity, but definitive safety in pregnancy has not been determined. Use with caution (manufacturer recommends NOT using in pregnant women). In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

The drug enters maternal milk at levels 7 times that found in plasma; the manufacturer recommends that mothers not nurse while taking this drug. Use with caution in nursing veterinary patients.

## Overdosage/Acute Toxicity

## TERBUTALINE SULFATE

(ter-byoo-ta-teen) Brethine®

BETA-ADRENERGIC AGONIST

### Prescriber Highlights

- **Beta agonist used as a bronchodilator & sometimes to treat bradyarrhythmias or as a tocolytic**
  - **Looks promising as a test to quantitate anhidrosis in horses**
  - **Caution: Diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias)**
  - **Adverse Effects: Increased heart rate, tremors, CNS excitement (nervousness) & dizziness; after parenteral injection in horses, sweating & CNS excitation are possible**
- 

### Uses/Indications

Terbutaline is used as a bronchodilating agent in the adjunctive treatment of cardiopulmonary diseases (including tracheobronchitis, collapsing trachea, pulmonary edema, and allergic bronchitis) in small animals. It may be of some benefit in treating bradyarrhythmias in dogs and cats.

Terbutaline has been used occasionally in horses for its bronchodilating effects, but adverse effects, short duration of activity after IV administration and poor oral absorption have limited its use. It has been shown to be useful as a diagnostic agent to diagnose anhidrosis in horses after intradermal injection.

Oral and intravenous terbutaline has been used successfully in humans for the inhibition of premature labor clinical signs.

### Pharmacology/Actions

Terbutaline stimulates beta-adrenergic receptors found principally in bronchial, vascular, and uterine smooth muscles (beta<sub>2</sub>); bronchial and vascular smooth muscle relaxation occurs with resultant reduced airway resistance. At usual doses it has little effect on cardiac (beta<sub>1</sub>) receptors and usually does not cause direct cardiostimulatory effects. Occasionally, a tachycardia develops which may be a result of either direct beta stimulation or a reflex response secondary to peripheral vasodilation. Terbutaline has virtually no alpha-adrenergic activity.

### Pharmacokinetics

The pharmacokinetics of this agent have apparently not been thoroughly studied in domestic animals. In humans, only about 33–50% of an oral dose is absorbed; peak bronchial effects occur within 2–3 hours and activity persists up to 8 hours. Terbutaline is well-absorbed following SC administration with an onset of action occurring within 15 minutes, peak effects at 30–60 minutes, and duration of activity up to 4 hours.

In horses, terbutaline is very poorly absorbed after oral administration with a bioavailability <1%. When given IV, mean residence time is about 30 minutes in horses and the drug probably needs to be given as a constant rate infusion if used therapeutically.

Terbutaline is distributed into milk at levels approximately 1% of the oral dose given to the mother. Terbutaline is principally excreted unchanged in the urine (60%), but is also metabolized in the liver to an inactive sulfate conjugate.

### Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or cardiomyopathy. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

### Adverse Effects

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents, including increased heart rate, tremors, CNS excitement (nervousness) and dizziness. These effects are generally transient, mild and do not require discontinuation of therapy. After parenteral injection in horses, sweating and CNS excitation have been reported.

Transient hypokalemia has been reported in humans receiving beta-adrenergic agents. If an animal is susceptible to developing hypokalemia, it is suggested that additional serum potassium monitoring be done early in therapy.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Terbutaline is excreted in milk. In humans, nursing is not recommended with systemic terbutaline therapy.

### Overdosage/Acute Toxicity

Clinical signs of significant overdose after systemic administration may include arrhythmias (bradycardia, tachycardia, heart block, extrasystoles), hypertension, fever, vomiting, mydriasis, and CNS stimulation. If a recent oral ingestion, it should be handled like other overdoses (empty gut, give activated charcoal and a cathartic) if the animal does not have significant cardiac or CNS effects. If cardiac arrhythmias require treatment, a beta-blocking agent (*e.g.*, propranolol) can be used, but may precipitate bronchoconstriction.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving terbutaline and may be of significance in veterinary patients:

- **ANESTHETICS, INHALATION (*e.g.*, halothane, isoflurane, methoxyflurane):** Use with inhalation anesthetics may predispose the patient to ventricular arrhythmias, particularly in patients with preexisting cardiac disease—use cautiously
- **BETA-ADRENERGIC BLOCKING AGENTS (*e.g.*, propranolol):** May antagonize the actions of terbutaline
- **DIGOXIN:** Use with digitalis glycosides may increase the risk of cardiac arrhythmias
- **MONOAMINE OXIDASE INHIBITORS:** May potentiate the vascular effects of terbutaline
- **SYMPATHOMIMETICS, OTHER:** Use of terbutaline with other sympathomimetic amines may increase the risk of developing adverse cardiovascular effects
- **TRICYCLIC ANTIDEPRESSANTS:** May potentiate the vascular effects of terbutaline

### Doses

#### ■ DOGS:

- For a trial to treat intrathoracic tracheal collapse, expiratory cough or dyspnea and marked exercise intolerance: 1.25–5 mg (total dose) PO two to three times daily (Johnson, LR 2004)
- As a bronchodilator in chronic bronchitis: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h (Johnson, L 2000)
- For bradyarrhythmias: 0.2 mg/kg PO q8–12h; improvement usually partial and often temporary (Rishniw & Thomas 2000)
- For treatment of premature labor: The initial dose is 0.03 mg/kg PO or SC q8h. The drug should be discontinued 48 hours prior to the calculated delivery date to permit normal labor and delivery to occur. Exogenous progesterone can be added if myometrial contractility cannot be controlled with tocolytics. (Davidson 2008)
- For tracheal collapse: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h; 0.01 mg/kg IV, IM or SC (Ettinger & Kantrowitz 2005)

#### ■ CATS:

- For acute exacerbations of feline asthma treated at home: 0.01 mg/kg SC or IM; Beneficial response (decrease of respiratory rate or effort by 50%) occurs in 15–30 minutes. A heart rate that approaches 240 BPM indicates that the drug has been absorbed. (Padrid 2000)
- For feline asthma: 0.312–0.625 mg (total dose) per cat PO two to three times daily; may adjust dose up to 1.25 mg in larger cats if needed (Noone 1999)

c) For bradycardias: 0.625 mg PO q8-12h; improvement usually partial and often temporary (Rishniw & Thomas 2000)

d) For acute bronchoconstriction (initial crisis): 0.01 mg/kg IV, SC, IM (Cohn 2007)

#### ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

a) For use as a quantitative intradermal terbutaline sweat test (QITST) to identify anhidrosis (preliminary study): In the study a 6 cm wide strip of skin was clipped parallel with and 3 cm below the dorsal margin of the neck on the left side. Beginning at the caudal aspect of this strip, eight 0.1 mL intradermal injections of serial 10-fold dilutions of terbutaline sulfate in 0.9% saline were made through a 25 gauge needle at approximately 5 cm intervals as follows: 0 (control), 0.001, 0.01, 0.1, 1, 10, 100 and 1000 mg/L. Individual sections of absorbent pad (3 x 3 cm; Stayfree® Ultrathin regular pads) were preweighed within plastic bags. Pads were then taped over each injection site. Thirty minutes later, they were removed, replaced in plastic bags and reweighed. Sweat weights at saline control sites were, in all cases, ≤8 mg. Sweat weights increased significantly at each successive terbutaline concentration up to a mean weight of 491 mg at the 1000 mg/L dose. The lower one-sided 95% confidence limits for sweat weights were 19, 57, 96, 195 and 267 mg for terbutaline concentrations of 0.1, 1, 10, 100 and 1000 mg/L, respectively. (MacKay 2008)

b) 0.0033 mg/kg IV (Robinson 1987)

#### Monitoring

- Clinical symptom improvement; auscultation
- Cardiac rate, rhythm (if indicated)
- Serum potassium, early in therapy if animal susceptible to hypokalemia

#### Client Information

- Contact veterinarian if animal's condition deteriorates or if it becomes acutely ill

#### Chemistry/Synonyms

A synthetic sympathomimetic amine, terbutaline sulfate occurs as a slightly bitter-tasting, white to gray-white, crystalline powder that may have a faint odor of acetic acid. One gram is soluble in 1.5 mL of water or 250 mL of alcohol. The commercially available injection has its pH adjusted to 3–5 with hydrochloric acid.

Terbutaline Sulfate may also be known as: KWD-2019, terbutaline sulphate, terbutalini sulfas; many trade names are available.

#### Storage/Stability

Terbutaline tablets should be stored in tight containers at room temperature (15–30°C). Tablets have an expiration date of 3 years beyond the date of manufacture. Terbutaline injection should be stored at room temperature (15–30°C) and protected from light. The injection has an expiration date of 2 years after the date of manufacture.

Terbutaline injection is stable over a pH range of 1–7. Discolored solutions should not be used.

#### Compatibility/Compounding Considerations

Terbutaline injection is physically **compatible** with D5W and aminophylline.

#### Dosage Forms/Regulatory Status

##### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

##### HUMAN-LABELED PRODUCTS:

Terbutaline Sulfate Tablets: 2.5 mg & 5 mg; *Brethine*® (aaiPharma); generic; (Global) (Rx)

Terbutaline Injection: 1 mg/mL in 1 mL vials & 2 mL amps with 1 mL fill; *Brethine*® (aaiPharma); generic; (Rx)

## TESTOSTERONE CYPIONATE TESTOSTERONE ENANTHATE TESTOSTERONE PROPIONATE

(tes-s-tes-ter-ohn)

ANDROGENIC HORMONE

#### Prescriber Highlights

- **Principle endogenous androgen used primarily for the treatment of testosterone-responsive urinary incontinence in neutered male dogs/cats; in bovine medicine to produce an estrus-detector animal**
- **Contraindications: Known hypersensitivity to the drug; prostate carcinoma. Caution: Renal, cardiac, or hepatic dysfunction**
- **Adverse Effects: Uncommon, but perianal adenomas, perineal hernias, prostatic disorders, & behavior changes possible**
- **Testosterone products are controlled substances (C-III)**

#### Uses/Indications

The use of injectable esters of testosterone in veterinary medicine is limited primarily to its use in dogs (and perhaps cats) for the treatment of testosterone-responsive urinary incontinence in neutered males. Testosterone has been used to treat a rare form of dermatitis (exhibited by bilateral alopecia) in neutered male dogs. These drugs are also used in bovine medicine to produce an estrus-detector (teaser) animal in cull cows, heifers, and steers.

The effectiveness of testosterone to increase libido, treat hypogonadism, aspermia, and infertility in domestic animals has been disappointing.

#### Pharmacology/Actions

The principle endogenous androgenic steroid, testosterone is responsible for many secondary sex characteristic of the male as well as the maturation and growth of the male reproductive organs and increasing libido.

Testosterone has anabolic activity with resultant increased protein anabolism and decreased protein catabolism. Testosterone causes nitrogen, sodium, potassium and phosphorus retention and decreases the urinary excretion of calcium. Nitrogen balance is improved only when an adequate intake of both calories and protein occurs.

By stimulating erythropoietic stimulating factor, testosterone can stimulate the production of red blood cells. Large doses of exogenous testosterone can inhibit spermatogenesis through a negative feedback mechanism inhibiting luteinizing hormone (LH).

Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses

Testosterone may help maintain the normal uterine muscle tone and the uterine mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.

## Pharmacokinetics

Orally administered testosterone is rapidly metabolized by the GI mucosa and the liver (first-pass effect); very little reaches the systemic circulation. The esterified compounds, testosterone enanthate and cypionate are less polar than testosterone and more slowly absorbed from lipid tissue after IM injection. The duration of action of these compounds may persist for 2–4 weeks after IM injection. Testosterone propionate reportedly has a much shorter duration of action than the enanthate or cypionate esters. Because absorption is dependent upon several factors (volume injected, perfusion, etc.), duration of action may be variable.

Testosterone is highly bound to a specific testosterone-estradiol globulin (98% in humans). The quantity of this globulin determines the amount of drug that is in the free or bound form. The free form concentration determines the plasma half-life of the hormone.

Testosterone is metabolized in the liver and is, with its metabolites, excreted in the urine (~90%) and the feces (~6%). The plasma half-life of testosterone has been reported to be between 10–100 minutes in humans. The plasma half-life of testosterone cypionate has been reported to be 8 days.

## Contraindications/Precautions/Warnings

Testosterone therapy is contraindicated in patients with known hypersensitivity to the drug or prostate carcinoma. It should be used with caution in patients with renal, cardiac or hepatic dysfunction.

## Adverse Effects

Adverse effects are reportedly uncommon when injectable testosterone products are used in male dogs to treat hormone-responsive incontinence. Perianal adenomas, perineal hernias, prostatic disorders, and behavior changes (aggression) are all possible, however. Behavioral changes have been reported in cats. Polycythemia has been reported in humans receiving high dosages of testosterone. High dosages or chronic usage may result in oligospermia or infertility in intact males.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

It is not known whether androgens are excreted in milk; consider using milk replacer if using testosterone in nursing patients.

## Overdosage/Acute Toxicity

No specific information was located; refer to the Adverse Effects section for further information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving testosterone and may be of significance in veterinary patients:

- **CORTICOSTEROIDS:** Androgens may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN; ORAL ANTIDIABETIC AGENTS:** Testosterone may decrease serum glucose levels
- **PROPRANOLOL:** Testosterone cypionate may increase propranolol clearance
- **WARFARIN:** Testosterone may increase anticoagulant effects

## Laboratory Considerations

- Concentrations of protein bound iodine (PBI) can be decreased in patients receiving testosterone therapy, but the clinical significance of this is probably not important. Androgen agents can decrease amounts of thyroxine-binding globulin and decrease **total T<sub>4</sub>** concentrations and increase resin uptake of T<sub>3</sub> and T<sub>4</sub>. Free thyroid hormones are unaltered and clinically, there is no evidence of dysfunction.
- Both **creatinine** and **creatinine** excretion can be decreased by testosterone
- Testosterone can increase the urinary excretion of **17-ketosteroids**
- Androgenic/anabolic steroids may alter **blood glucose** levels
- Androgenic/anabolic steroids may suppress **clotting factors II, V, VII, and X**

## Doses

### ■ DOGS:

For testosterone-responsive urinary incontinence (may be used with phenylpropanolamine) in males:

- a) Testosterone propionate: approximately 2 mg/kg IM or SC 3 times per week. Testosterone cypionate: 200 mg IM once per month (Labato 1989; Polzin & Osborne 1985)
- b) Testosterone propionate: 2.2 mg/kg IM q2–3 days. Testosterone cypionate: 2.2 mg/kg IM once per month (Chew *et al.* 1986; Moreau & Lappin 1989)
- c) Testosterone cypionate: 2.2 mg/kg IM q4–8 weeks (Lane 2002)
- d) Testosterone propionate: 2.2 mg/kg IM or SC every 2–3 days. Testosterone cypionate: 2.2 mg/kg every 30 days or 200 mg IM every 30 days. (Bartges 2006)

For estrus control:

- a) Testosterone enanthate or cypionate 0.5 mg/kg IM once every 5 days or methyltestosterone tablets 25 mg PO twice a week; this dose is for Greyhound-sized dogs. (Purswell 1999)

To reduce mammary gland enlargement seen in pseudopregnancy:

- a) Testosterone enanthate or cypionate 0.5–1 mg/kg IM once (Purswell 1999)

### ■ CATS:

For infertility or reduced libido: Using either testosterone cypionate or propionate:

- a) 0.1–1 mg every other day or every third day for 3–5 injections IM or SC. Not indicated for testis descent. (Verstegen 2000)

For testosterone-responsive urinary incontinence (may be used with phenylpropanolamine) in males:

- a) Testosterone propionate 5–10 mg IM as needed. (Barsanti & Finco 1986; Osborne *et al.* 2000), (Bartges 2006)

### ■ CATTLE:

To produce an estrus-detector (teaser) animal (cull cows, heifers, steers):

- a) Testosterone propionate 200 mg IM on day 1 and on days 4–9. On day 10, give 1 gram IM and attach a chinball marker and put with the breeding herd. To maintain the teaser give 1 gram booster every 10–14 days.

Alternatively, initially give testosterone enanthate 0.5 gram IM and 1.5 gram SC (divided in two separate locations). After 4 days attach chinball marker and put in with breeding herd. To maintain, give 0.5–0.75 gram SC every 10–14 days. (Wolfe 1986)

## Monitoring

- Efficacy
- Adverse effects

## Chemistry/Synonyms

The esterified compounds, testosterone cypionate, enanthate, and propionate are available commercially as injectable products. Testosterone cypionate occurs as an odorless to having a faint odor, creamy white or white, crystalline powder. It is insoluble in water, soluble in vegetable oils, and freely soluble in alcohol. Testosterone cypionate has a melting range of 98°–104°C. It may also be known as testosterone cyclopentylpropionate.

Testosterone enanthate occurs as an odorless to having a faint odor, creamy white or white, crystalline powder. It is soluble in vegetable oils, insoluble in water and melts between 34–39°C.

Testosterone propionate occurs as odorless, creamy white to white, crystals or crystalline powder. It is insoluble in water, freely soluble in alcohol and soluble in vegetable oils. Testosterone propionate melts between 118–123°C.

Testosterone Cypionate may also be known as: testosterone propionate, testosterone cypionate, *Depotrone*®, *Depot-Testosterone*®, *Duratest*®, *Scheinpharm Testone-Cyp*®, *T-Cypionate*®, *Testex*®, *Testiormina*®, *Testred*®, *Virilon*®, or *depAndro*®.

Testosterone Propionate may also be known as: NSC-9166, testosterone propionas, *Malogen in Oil*®, *Sostenon*®, *Sustanon*®, *Testanon 25*®, *Testex*®, *Testoviron*®, *Testoviron Depot*®, *Testovis*®, *Tesuren*®, or *Virormone*®.

## Storage/Stability

The commercially available injectable preparations of testosterone cypionate, enanthate and propionate should be stored at room temperature; avoid freezing or exposing to temperatures greater than 40°C. If exposed to low temperature a precipitate may form, but should redissolve with shaking and rewarming. If a wet needle or syringe is used to draw up the parenteral solutions, cloudy solutions may result, but will not affect the drug's potency.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

No known testosterone products (with the exception of combinations with estradiol as growth promotant implants) FDA-approved for use in veterinary species were located. Testosterone propionate (200 mg) is available in combination with estradiol benzoate (20 mg) as a growth promotant. Trade names include *Component E-H*® (VetLife); (OTC) and *Synovex-H*® (Fort Dodge); (OTC). For use in heifers weighing 400 or more pounds.

Testosterone propionate (200 mg) with estradiol benzoate (28 mg); *Synovex-Plus*® (Fort Dodge); (OTC); for steers.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Testosterone Cypionate (in oil) Injection: 100 mg/mL & 200 mg/mL in 1 mL & 10 mL vials; *Depo-Testosterone*® (Pfizer); generic; (Rx, C-III)

Testosterone Enanthate (in oil) Injection: 200 mg/mL in 5 mL multi-dose vials; *Delatestyl*® (Indevus); generic (Paddock); (Rx, C-III)

Testosterone Pellets Implant for subcutaneous implantation: 75 mg in 1 pellet/vials; *Testopel*® (Bartor Pharmacal); (Rx, C-III)

Testosterone Transdermal System: Release Rates: 5 & 2.5 mg/24 hour, total testosterone contents: 24.3 mg & 12.2 mg (respectively); *Androderm*® (Watson Pharma); (Rx, C-III)

Testosterone Gel: 1% (50 mg testosterone) in unit-dose packets and tubes or 75 gram metered multiple dose pumps; *AndroGel*® 1% (Solvay); *Testim*® (Auxilium); (Rx, C-III)

Testosterone, Buccal System: 30 mg testosterone in blister packs; *Striant*® (Columbia); (Rx, C-III)

## TETRACYCLINE HCL

(tet-ra-sye-kleen) *Aquadrops*®, *Panmycin*®

### TETRACYCLINE ANTIBIOTIC

#### Prescriber Highlights

- **Prototype tetracycline antibiotic; many bacteria are now resistant, but still may be very useful to treat mycoplasma, rickettsia, spirochetes, & Chlamydia**
- **Dosing frequency may be an issue for small animals**
- **Extreme Caution: Pregnancy**
- **Caution: Liver or renal insufficiency**
- **Adverse Effects: GI distress, staining of developing teeth & bones, superinfections, photosensitivity; long-term use may cause uroliths. Cats: Do not tolerate very well. Horses: If stressed may break with diarrheas (oral use). Ruminants: High oral doses can cause ruminal microflora depression & ruminoreticular stasis; rapid IV of undiluted propylene glycol-based products can cause intravascular hemolysis & cardiodepressant effects; IM: local reactions, yellow staining & necrosis may be seen at the injection site**

---

## Uses/Indications

While tetracycline still is used as an antimicrobial, most small animal clinicians prefer doxycycline and large animal clinicians prefer oxytetracycline when a tetracycline is indicated to treat susceptible infections. The most common use of tetracycline HCl today is in combination with niacinamide for the treatment of certain immune-mediated skin conditions in dogs, such as pemphigus.

## Pharmacology/Actions

Tetracyclines generally act as time-dependent antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines have been deemed bacteriostatic antibiotics, but this nomenclature is more of historical importance than descriptive of their antibacterial actions. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococcus and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines include *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and tetani, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasturella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, *Enterobacter*, *Proteus* and *Pseudomonas aeruginosa* are resistant to the tetracyclines. While most strains of *Pseudomonas aeruginosa* show *in vitro* resistance to tetracyclines, those compounds attaining high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism. Hemoglobin at the site of the infection can reduce the antimicrobial activity of tetracycline.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance and a tetracycline susceptibility disk is usually used for *in vitro* testing for oxytetracycline susceptibility.

Tetracyclines have antiinflammatory and immunomodulating effects. They can suppress antibody production and chemotaxis of neutrophils; inhibit lipases, collagenases, prostaglandin synthesis, and activation of complement component 3.

## Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailabilities are approximately 60–80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration, tetracycline is erratically and poorly absorbed with serum levels usually lower than those attainable with oral therapy.

Tetracyclines as a class, are widely distributed to heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF, and therapeutic levels may not be achievable. While all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into

these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation and are distributed into milk. The volume of distribution of tetracycline is approximately 1.2–1.3 L/kg in small animals. The amount of plasma protein binding is about 20–67% for tetracycline. In cattle, the volume of distribution for oxytetracycline is between 1 and 2.5 L/kg. Milk to plasma ratios for oxytetracycline and tetracycline are 0.75 and 1.2–1.9, respectively.

Both oxytetracycline and tetracycline are eliminated unchanged primarily via glomerular filtration. Patients with impaired renal function can have prolonged elimination half-lives and accumulate the drug with repeated dosing. These drugs apparently are not metabolized, but are excreted into the GI tract via both biliary and nonbiliary routes and may become inactive after chelation with fecal materials. The elimination half-life of tetracycline is approximately 5–6 hours in dogs and cats.

### Contraindications/Precautions/Warnings

Tetracycline is contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, tetracycline must be used cautiously; lower than normal dosages are recommended with enhanced monitoring of renal and hepatic function. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs if tetracyclines are administered to these patients. Monitoring of serum levels should be considered if long-term therapy is required.

### Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause discoloration of bones and teeth to a yellow, brown, or gray color. High dosages or chronic administration may delay bone growth and healing.

Tetracyclines in high levels can exert an antianabolic effect that can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiodepressant effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well, and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs.

Horses that are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrheas after receiving tetracyclines (especially with oral administration).

Tetracycline therapy (especially long-term) may result in overgrowth of non-susceptible bacteria or fungi (superinfections).

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity, formation of anti-nuclear antibodies, or blood dyscrasias.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Tetracyclines are excreted in milk, but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals.

### Overdosage/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tetracyclines and may be of significance in veterinary patients:

■ **ATOVAQUONE:** Tetracyclines have caused decreased atovaquone levels

■ **BETA-LACTAM OR AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, have been historically thought to interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides but the actual clinical significance of this interaction is doubtful.

■ **DIGOXIN:** Tetracyclines have increased the bioavailability of digoxin in a small percentage of human patients and caused digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.

■ **DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products.

■ **METHOXYFLURANE:** Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline not recommended

■ **SUCRALFATE:** Sucralfate may impair the oral absorption of tetracycline; separate dosing by at least 2 hours to minimize this effect

■ **WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment

### Laboratory Considerations

■ Tetracyclines (not minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.

■ Tetracyclines reportedly can cause false-positive **urine glucose results** if using the cupric sulfate method of determination (Benedict's reagent, *Clinites*®), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (*Clinistix*®, *Tes-Tape*®).

### Doses

#### ■ DOGS:

For discoid lupus erythematosus:

a) For dogs weighing 10 kg or more: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing from 5–10 kg: 250 mg of each PO q8h. For dogs weighing <5 kg: 100 mg of each PO q8h. Improvement is usually noted within 6 weeks. (White 2000)

b) Dogs weighing more than 10 kg: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing less than 10 kg: 250 mg of each PO q8h. May use in combination with corticosteroids and Vitamin E. If adverse effects become a problem, reduce dose of niacinamide first. May also try this regimen for pemphigus foliaceus or pemphigus erythematous. (Campbell 1999)

c) For various immune-mediated diseases (discoid lupus erythematosus, pemphigus erythematous, pemphigus foliaceus, vasculitis, sterile pyelogramuloma, dermatomyositis and lupoid onychodystrophy: For dogs less than 10 kg: 250 mg each of niacinamide and tetracycline PO three times daily. For dogs larger than 10 kg: 500 mg each of niacinamide and tetracycline PO three times daily. May substitute doxycycline for tetracycline at 5 mg/kg PO once a day. (Tapp 2002)

For susceptible infections:

a) For UTI: 16 mg/kg PO q8h for 7–14 days;

For Rickettsiosis, Borreliosis: 22 mg/kg PO q8h for 14 days;

For systemic bacteremia, brucellosis: 22–50 mg/kg PO q8h for 28 days. (Greene *et al.* 2006)

b) For Rocky Mountain Spotted Fever: 22 mg/kg q8h for 14–21 days (Sellon & Breitschwerdt 1995)

c) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995)

d) For susceptible UTI's: 18 mg/kg PO q8h (Dowling 2009)

e) For Lyme disease: 22 mg/kg PO q8h for 14 days (Breitschwerdt 2000)

f) For small intestinal bacterial overgrowth: 5–10 mg/kg PO q8h for 28 days; has been effective for uncomplicated cases (Ludlow & Davenport 2000)

g) For Ehrlichiosis: 22 mg/kg PO q8h for 28 days. (Ford 2009)

For facial tear staining:

a) 5–10 mg/kg/day or 50 mg per dog per day. Results are variable. (Kern 1986)

For pleurodesis:

a) Using capsules or aqueous solution; mix 20 mg/kg in 4 mL per kg of saline and infuse into pleural space (Morgan 1988)

#### ■CATS:

For susceptible infections:

a) For soft tissue infections: 20 mg/kg PO q8h for 21 days;

For Hemotropic mycoplasmosis: 10–25 mg/kg PO q8–12h for 21 days;

For bacteremia, systemic infections: 7 mg/kg IV, IM q12h as long as necessary. (Greene *et al.* 2006)

b) For rickettsial diseases: 16 mg/kg, PO three times daily for 21 days (Morgan 1988)

c) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995)

d) 22–33 mg/kg PO q8h (Aronson & Aucoin 1989)

#### ■FERRETS:

For susceptible infections:

a) 25 mg/kg PO 2–3 times daily (Williams 2000)

#### ■RABBITS, RODENTS, SMALL MAMMALS:

a) **Rabbits:** 50–100 mg/kg PO q8–12h (Ivey & Morrisey 2000)

b) **Chinchillas:** 50 mg/kg PO q8–12h (Hayes 2000)

c) **Chinchillas, Guinea Pigs, Rats:** 20 mg/kg, PO q12h. **Mice:** 20 mg/kg, PO q12h or 50–60 mg/liter of drinking water **Hamsters:** 30 mg/kg, PO q6h or 400 mg/liter, drinking water. **Gerbils:** 20 mg/kg, PO or IM q24h (Adamcak & Otten 2000)

#### ■CATTLE:

For susceptible infections in calves:

a) 11 mg/kg orally (Howard 1986)

b) 11 mg/kg, PO twice daily for up to 5 days (Label directions; *Polyotic*®—American Cyanamid)

#### ■SHEEP:

For susceptible infections:

a) 11 mg/kg, PO twice daily for up to 5 days (Label directions; *Polyotic*®—American Cyanamid)

#### ■HORSES:

For susceptible infections:

a) 5–7.5 mg/kg IV q12h (Brumbaugh 1987)

#### ■SWINE:

For susceptible infections:

a) 22 mg/kg, PO for 3 to 5 days in drinking water (Label directions; *Polyotic*®—American Cyanamid)

#### ■BIRDS:

For susceptible infections:

a) For treatment of psittacosis in conjunction with *LA-200*® (see oxytetracycline doses) and/or medicated pellets and/or *Keet Life*: Using 25 mg/mL oral suspension, mix 2 teaspoonsful to 1 cup of soft food.

For mild respiratory disease (especially flock treatment): Mix 1 teaspoonful of 10 grams/6.4 oz. soluble powder per gallon of drinking water. Used as an adjunct for psittacosis with other tetracycline forms. Will not reach therapeutic levels by itself. Prepare fresh solution twice daily, as potency is rapidly lost. (McDonald 1989)

b) Mix 1 teaspoonful of 10 grams/6.4 oz. soluble powder per gallon of drinking water and administer for 5–10 days. Prepare fresh solution 2–3 times daily, as potency is rapidly lost.

For converting regimen to pelleted feeds administer oral suspension by gavage at 200–250 mg/kg once or twice daily until feeds are accepted. Is not an adequate therapy for long-term treatment of chlamydiosis (psittacosis) (Clubb 1986)

### Monitoring

- Adverse effects
- Clinical efficacy
- Long-term use or in susceptible patients: periodic renal, hepatic, hematologic evaluations

### Client Information

- Avoid giving this drug orally within 1–2 hours of feeding, giving milk or other dairy products
- If gastrointestinal upset occurs, giving with a small amount of food may help, but this may also reduce the amount of drug absorbed

### Chemistry/Synonyms

An antibiotic obtained from *Streptomyces aureofaciens* or derived semisynthetically from oxytetracycline, tetracycline HCl occurs as a moderately hygroscopic, yellow, crystalline powder. About 100 mg/mL is soluble in water and 10 mg/mL soluble in alcohol. Tetracycline base has a solubility of about 0.4 mg per mL of water and 20 mg per mL of alcohol. Commercially available tetracycline HCl for IM injection also contains magnesium chloride, procaine HCl and ascorbic acid.

Tetracycline may also be known as: tetracyclini hydrochloridum; many trade names are available.

### Storage/Stability

Unless otherwise instructed by the manufacturer, tetracycline oral tablets and capsules should be stored in tight, light resistant containers at room temperature (15–30°C). The oral suspension and powder for injection should be stored at room temperature; avoid freezing the oral suspension.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

There are a variety of Tetracycline HCl Soluble Powder (as a water additive) products that are available in various concentrations and sizes. Usual concentrations are either 25 grams/lb or 324 grams/lb and these products may be available in several sizes; may be FDA-approved for use in swine, cattle, or poultry. Withdrawal time may vary depending on age of animal and product.

An oral combination product containing tetracycline, novobiocin and prednisone (*Delta Albalplex*®) is also available; see the [novobiocin](#) monograph for more information.

#### HUMAN-LABELED PRODUCTS:

Tetracycline HCl capsules, 250 mg, 500 mg, 750 mg, 1000 mg, 1500 mg, 2000 mg, 2500 mg, 3000 mg, 3500 mg, 4000 mg, 4500 mg, 5000 mg, 5500 mg, 6000 mg, 6500 mg, 7000 mg, 7500 mg, 8000 mg, 8500 mg, 9000 mg, 9500 mg, 10000 mg, 10500 mg, 11000 mg, 11500 mg, 12000 mg, 12500 mg, 13000 mg, 13500 mg, 14000 mg, 14500 mg, 15000 mg, 15500 mg, 16000 mg, 16500 mg, 17000 mg, 17500 mg, 18000 mg, 18500 mg, 19000 mg, 19500 mg, 20000 mg, 20500 mg, 21000 mg, 21500 mg, 22000 mg, 22500 mg, 23000 mg, 23500 mg, 24000 mg, 24500 mg, 25000 mg, 25500 mg, 26000 mg, 26500 mg, 27000 mg, 27500 mg, 28000 mg, 28500 mg, 29000 mg, 29500 mg, 30000 mg, 30500 mg, 31000 mg, 31500 mg, 32000 mg, 32500 mg, 33000 mg, 33500 mg, 34000 mg, 34500 mg, 35000 mg, 35500 mg, 36000 mg, 36500 mg, 37000 mg, 37500 mg, 38000 mg, 38500 mg, 39000 mg, 39500 mg, 40000 mg, 40500 mg, 41000 mg, 41500 mg, 42000 mg, 42500 mg, 43000 mg, 43500 mg, 44000 mg, 44500 mg, 45000 mg, 45500 mg, 46000 mg, 46500 mg, 47000 mg, 47500 mg, 48000 mg, 48500 mg, 49000 mg, 49500 mg, 50000 mg, 50500 mg, 51000 mg, 51500 mg, 52000 mg, 52500 mg, 53000 mg, 53500 mg, 54000 mg, 54500 mg, 55000 mg, 55500 mg, 56000 mg, 56500 mg, 57000 mg, 57500 mg, 58000 mg, 58500 mg, 59000 mg, 59500 mg, 60000 mg, 60500 mg, 61000 mg, 61500 mg, 62000 mg, 62500 mg, 63000 mg, 63500 mg, 64000 mg, 64500 mg, 65000 mg, 65500 mg, 66000 mg, 66500 mg, 67000 mg, 67500 mg, 68000 mg, 68500 mg, 69000 mg, 69500 mg, 70000 mg, 70500 mg, 71000 mg, 71500 mg, 72000 mg, 72500 mg, 73000 mg, 73500 mg, 74000 mg, 74500 mg, 75000 mg, 75500 mg, 76000 mg, 76500 mg, 77000 mg, 77500 mg, 78000 mg, 78500 mg, 79000 mg, 79500 mg, 80000 mg, 80500 mg, 81000 mg, 81500 mg, 82000 mg, 82500 mg, 83000 mg, 83500 mg, 84000 mg, 84500 mg, 85000 mg, 85500 mg, 86000 mg, 86500 mg, 87000 mg, 87500 mg, 88000 mg, 88500 mg, 89000 mg, 89500 mg, 90000 mg, 90500 mg, 91000 mg, 91500 mg, 92000 mg, 92500 mg, 93000 mg, 93500 mg, 94000 mg, 94500 mg, 95000 mg, 95500 mg, 96000 mg, 96500 mg, 97000 mg, 97500 mg, 98000 mg, 98500 mg, 99000 mg, 99500 mg, 100000 mg, 100500 mg, 101000 mg, 101500 mg, 102000 mg, 102500 mg, 103000 mg, 103500 mg, 104000 mg, 104500 mg, 105000 mg, 105500 mg, 106000 mg, 106500 mg, 107000 mg, 107500 mg, 108000 mg, 108500 mg, 109000 mg, 109500 mg, 110000 mg, 110500 mg, 111000 mg, 111500 mg, 112000 mg, 112500 mg, 113000 mg, 113500 mg, 114000 mg, 114500 mg, 115000 mg, 115500 mg, 116000 mg, 116500 mg, 117000 mg, 117500 mg, 118000 mg, 118500 mg, 119000 mg, 119500 mg, 120000 mg, 120500 mg, 121000 mg, 121500 mg, 122000 mg, 122500 mg, 123000 mg, 123500 mg, 124000 mg, 124500 mg, 125000 mg, 125500 mg, 126000 mg, ## THIAMINE HCL

### VITAMIN B1

(*thye-a-min*)

**NUTRITIONAL; B VITAMIN**

### Prescriber Highlights

- A “B” vitamin used for treatment or prevention of thiamine deficiency. May be useful for adjunctive treatment of lead poisoning & ethylene glycol toxicity
- Adverse Effects: hypersensitivity/anaphylactic reactions (rarely); tenderness, or muscle soreness after IM injection
- Drug Interactions; lab interactions

## Uses/Indications

Thiamine is indicated in the treatment or prevention of thiamine deficiency states. Clinical signs of thiamine deficiency may be manifested as gastrointestinal (anorexia, salivation), neuromuscular/CNS signs (ataxia, seizures, loss of reflexes), or cardiac effects (brady- or tachyarrhythmias). Deficiency states may be secondary to either a lack of thiamine in the diet or the presence of thiamine destroying compounds in the diet (*e.g.*, bracken fern, raw fish, amprolium, thiaminase-producing bacteria in ruminants). Thiamine may be supplemented in camelids and other species when long-term amprolium is used.

Thiamine has also been used in the adjunctive treatment of lead poisoning and ethylene glycol toxicity (to facilitate the conversion of glyoxylate to nontoxic metabolites).

## Pharmacology/Actions

Thiamine combines with adenosine triphosphate (ATP) to form a compound (thiamine diphosphate/thiamine pyrophosphate) that is employed for carbohydrate metabolism, but does not effect blood glucose concentrations.

Absence of thiamine results in decreased lactic acid production in red blood cells and increased pyruvic acid blood concentrations. Without thiamine triphosphate, pyruvic acid is not converted into acetyl-CoA; diminished NADH results with anaerobic glycolysis producing lactic acid. Lactic acid production is further increased secondary to pyruvic acid conversion; lactic acidosis may occur.

## Pharmacokinetics

Thiamine is absorbed from the GI tract and is metabolized by the liver. Elimination is renal, the majority of the drug is eliminated as metabolites.

## Contraindications/Precautions/Warnings

Thiamine injection is contraindicated in animals hypersensitive to it or to any component of it.

## Adverse Effects

Hypersensitivity reactions have occurred after injecting this agent. Rarely, a vasovagal anaphylactic response (cardiac arrest or severe bradycardia, cardiac arrhythmias, apnea, hypotension, collapse, seizure, and protracted neuromuscular weakness), has been observed in a small number of cats when thiamine hydrochloride was administered subcutaneously. Some tenderness or muscle soreness may result after IM injection.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **A** for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) If used in doses greater than the RDA, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk, but it should not be of clinical concern.

## Overdosage/Acute Toxicity

Very large doses of thiamine in laboratory animals have been associated with neuromuscular or ganglionic blockade, but the clinical significance is unknown. Hypotension and respiratory depression may also occur with massive doses. A lethal dose of 350 mg/kg has been reported. Generally, no treatment should be required with most overdoses.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiamine and may be of significance in veterinary patients:

■ **NEUROMUSCULAR BLOCKING AGENTS:** Thiamine may enhance the activity of neuromuscular blocking agents; clinical significance is unknown

## Laboratory Considerations

■ Thiamine may cause false-positive **serum uric acid** results when using the phosphotungstate method of determination or urobilinogen urine spot tests using Ehrlich’s reagent

■ The Schack and Wexler method of determining **theophylline concentrations** may be interfered with by large doses of thiamine

## Doses

■ **DOGS:**

For thiamine deficiency:

a) 5–50 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

b) 1–2 mg IM (Greene & Braund 1989)

c) 2 mg/kg, PO once daily (Davis 1985)

d) 100–250 mg SC twice daily for several days until regression of symptoms with complete recovery (Hoskins 1988)

For adjunctive treatment for ethylene glycol toxicity:

a) 100 mg/day PO (Morgan 1988)

#### ■CATS:

For thiamine deficiency:

a) 100–250 mg parenterally twice a day (experimentally, as little as 1 mg is effective) (Armstrong & Hand 1989)

b) 10–20 mg/kg IM for several days. (Abramson 2009)

c) For adjunctive treatment of hepatic lipidosis: If neck ventroflexion is present, consider electrolyte or thiamine insufficiency; check electrolytes (potassium, phosphate, and magnesium); provide supplements as appropriate. Give 100 mg of thiamine in one liter of crystalloid fluids with additional soluble B vitamins (riboflavin, niacinamide, D-panthenol, pyridoxine, and cyanocobalamin). (Center 2005)

d) 100–250 mg SC twice daily for several days until regression of symptoms with complete recovery (Hoskins 1988)

e) 10–20 mg/kg IM or SC two to three times daily until signs abate, then 10 mg/kg PO once daily for 21 days (Morgan 1988)

#### ■CATTLE:

For thiamine deficiency:

a) For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)

b) 10–20 mg/kg IM or SC 3 times daily; if giving IV dilute in isotonic saline or isotonic dextrose. (Walz 2006)

c) 10 mg/kg up to 4 times a day; first dose may be given via slow IV and subsequent doses IM. Less severely affected animals may respond to lower or less frequent dosing. Severely affected animals may benefit from corticosteroids (dexamethasone 1–2 mg/kg) and mannitol (1 gram/kg in a 20% solution IV through a filtered IV set). (Cebra, C. 2005)

For adjunctive therapy of lead poisoning:

a) 2 mg/kg IM (at same time as CaEDTA therapy); total daily dose 8 mg/kg (Brattan & Kowalczyk 1989)

#### ■HORSES:

For thiamine deficiency:

a) 0.5–5 mg/kg IV, IM or PO (Robinson 1987)

b) 100–1000 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):

a) Foals: 1 gram in one liter of fluids IV once a day (Slovic 2003)

As part of a parenteral nutrition (PN) formula:

a) B complex vitamins (thiamine 12.5 mg/mL; niacinamide 12.5 mg/mL; pyridoxine 5 mg/mL; d-panthenol 5 mg/mL; riboflavin 2 mg/mL; cyanocobalamin 5 mg/mL) should be supplied at a rate of 1–2 mL/45 kg daily, diluted in fluids or PN. Vitamin C should be supplied at a rate of 20 mg/kg/day enterally whenever possible. (Magdesian 2010)

#### ■SWINE:

For thiamine deficiency:

a) 5–100 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

#### ■SHEEP & GOATS:

For thiamine deficiency:

a) For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)

b) Sheep: 20–200 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

#### ■CAMELIDS (NWC):

a) For prophylaxis when animals with *E. macusaniensis* treated with amprolium for >5 days (from a retrospective study): 10 mg/kg SC q24h after the 5<sup>th</sup> day of amprolium. (Cebra, C.K. *et al.* 2007)

### Monitoring

#### ■ Efficacy

### Client Information

■ Epidemiologic investigation as to the cause of thiamine deficiency (diet, plants, raw fish, etc.) should be performed with necessary changes made to prevent recurrence

### Chemistry/Synonyms

A water-soluble “B” vitamin, thiamine HCl occurs as bitter-tasting, white, small hygroscopic crystals, or crystalline powder that has a characteristic yeast-like odor. Thiamine HCl is freely soluble in water, slightly soluble in alcohol and has pK<sub>a</sub>s of 4.8 and 9.0. The commercially available injection has a pH of 2.5–4.5.

Thiamine HCl may also be known as: aneurine hydrochloride, thiamin hydrochloride, thiamine chloride, thiamini hydrochloridum, thiaminii chloridum, vitamin B-1; many trade names available.

### Storage/Stability

Thiamine HCl for injection should be protected from light and stored at temperatures less than 40°C and preferably between 15–30°C; avoid freezing.

Thiamine HCl is unstable in alkaline or neutral solutions or with oxidizing or reducing agents. It is most stable at a pH of 2.

### Compatibility/Compounding Considerations

Thiamine HCl is reportedly physically **compatible** with all commonly used intravenous replacement fluids.

Do **not** mix thiamine with alkaline drugs or alkalinizing agents (barbiturates, citrates, carbonates, acetates, copper ions) or oxidizing/reducing agents (*e.g.*, sulfites).

Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Thiamine HCl for Injection: 200 mg/mL in 100 mL and 250 mL vials & Thiamine HCl for Injection: 500 mg/mL in 100 mL vials; generic; (Rx). Labeled for use in horses, dogs and cats.

Thiamine HCl Dietary Supplement: 8,200 mg per lb.; *Horse Care Durvit B-1 Crumbles*® (Durvet); (OTC), Labeled for use in horses.

Thiamine HCl Supplement: 500 mg/oz in 1.5 lb, 4 lb and 20 lb containers; *Thia-Dex*® (Neogen), *Vitamin B-1 Powder*® (AHC); (OTC). Labeled for use in dogs & horses.

There are several B-complex vitamin preparations available that may also have thiamine included.

#### HUMAN-LABELED PRODUCTS:

Thiamine Tablets: 50 mg, 100 mg & 250 mg; generic; (OTC)

Thiamine Enteric Coated Tablets: 20 mg; *Thiamilate*® (Tyson); (OTC)

Thiamine HCl Injection: 100 mg/mL in 1 mL in 2 mL *Tubex*, 2 mL multi-dose vials; generic; (Rx)

## THIOGUANINE

(*thye-oh-gwah-nee*)

ANTINEOPLASTIC

### Prescriber Highlights

- **Oral purine analog antineoplastic that may be useful as adjunctive treatment for acute lymphocytic or granulocytic leukemia in dogs or cats**
- **Contraindications: Hypersensitivity to thioguanine**
- **Caution: Hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or history of urate urinary stones**
- **Potentially mutagenic & teratogenic; use milk replacer if nursing**
- **Adverse Effects: GI effects, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, & dermatologic reactions**
- **Cats may be more susceptible than dogs to adverse effects**
- **Low therapeutic index; monitoring mandatory**

## Uses/Indications

Thioguanine may be useful as adjunctive therapy for acute lymphocytic or granulocytic leukemia in dogs or cats.

## Pharmacology/Actions

Intracellularly, thioguanine is converted to ribonucleotides that cause the synthesis and utilization of purine nucleotides to be blocked. The drug's cytotoxic effects are believed to occur when these substituted nucleotides are inserted into RNA and DNA. Thioguanine has limited immunosuppressive activity. Extensive cross-resistance usually occurs between thioguanine and mercaptopurine.

## Pharmacokinetics

Thioguanine is administered orally, but absorption is variable. In humans, only about 30% of a dose is absorbed. Thioguanine is distributed into the DNA and RNA of bone marrow, but several doses may be necessary for this to occur. It does not apparently enter the CNS, but does cross the placenta. It is unknown whether it enters maternal milk.

Thioguanine is rapidly metabolized primarily in the liver to a methylate derivative that is less active (and toxic) than the parent compound. This and other metabolites are eliminated in the urine.

## Contraindications/Precautions/Warnings

Thioguanine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thioguanine has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

## Adverse Effects

At usual doses, GI effects (nausea, anorexia, vomiting, diarrhea) may occur in small animals. However, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, and dermatologic reactions are potentially possible. Cats may be particularly susceptible to the hematologic effects of thioguanine.

## Reproductive/Nursing Safety

Thioguanine is potentially mutagenic and teratogenic and not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although it is unknown whether thioguanine enters milk, use of milk replacer is recommended for nursing bitches or queens.

## Overdosage/Acute Toxicity

Toxicity may be acute (GI effects) or delayed (bone marrow depression, hepatotoxicity, gastroenteritis). It is suggested to use standard protocols to empty the GI tract if ingestion was recent and treat supportively.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thioguanine and may be of significance in veterinary patients:

- **HEPATOTOXIC DRUGS (e.g., halothane, ketoconazole, valproic acid, phenobarbital, primidone, etc.):** Thioguanine should be used cautiously with other drugs that can cause hepatotoxicity
- **IMMUNOSUPPRESSIVE DRUGS (e.g., azathioprine, cyclophosphamide, corticosteroids):** Use with other immunosuppressant drugs may increase the risk of infection
- **MYELOSUPPRESSIVE DRUGS (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine):** Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- **VACCINES, LIVE:** Live virus vaccines should be used with caution during therapy, if at all

## Laboratory Considerations

- Thioguanine may increase serum **uric acid** levels in some patients

## Doses

### ■ DOGS:

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] are *strongly recommended*.

a) For acute lymphocytic and granulocytic leukemia: 40 mg/m<sup>2</sup> PO once daily (q24 hours) for 4–5 days, then every 3rd day thereafter (Jacobs *et al.* 1992)

b) As part of treatment of acute myelogenous leukemias: Protocol 1: Cytarabine 100 mg/m<sup>2</sup> SC daily for 2–6 days; Thioguanine 50 mg/m<sup>2</sup> PO q24–48h. Protocol 2: Cytarabine 100 mg/m<sup>2</sup> SC daily for 2–6 days; Thioguanine 50 mg/m<sup>2</sup> PO q24–48h; Doxorubicin 10 mg/m<sup>2</sup> IV once a week (Couto 2003)

#### ■CATS:

a) For acute lymphocytic and granulocytic leukemia: 25 mg/m<sup>2</sup> PO once daily (q24 hours) for 1–5 days, then every 30 days thereafter as necessary (Jacobs *et al.* 1992)

#### Monitoring

- Hemograms (including platelets) should be monitored closely; initially every 1–2 weeks and every 1–2 months once on maintenance therapy. It is recommended by some clinicians that if the WBC count drops to between 5,000–7,000 cells/mm<sup>3</sup> the dose be reduced by 25%. If WBC count drops below 5,000 cells/mm<sup>3</sup> treatment should be discontinued until leukopenia resolves
- Liver function tests; serum amylase, if indicated
- Efficacy

#### Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality.
- Clients should contact veterinarian if the animal exhibits clinical signs of abnormal bleeding, bruising, anorexia, vomiting, jaundice, or infection.
- Although, no special precautions are necessary with handling intact tablets, it is recommended to wash hands after administering the drug.

#### Chemistry/Synonyms

A purine analog antineoplastic agent, thioguanine occurs as a pale yellow, odorless or practically odorless, crystalline powder. It is insoluble in water or alcohol. Thioguanine may also be known as: NSC-752, 6- thioguanine, TG, 6-TG, 2-Amino-6-mercaptapurine, WR-1141, *Lamvis*®, *Tabloid*®, or *Tioguanina*®.

#### Storage/Stability

Store tablets in tight containers at room temperature.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Thioguanine Tablets: 40 mg; *Tabloid*® (GlaxoSmithKline); (Rx)

### THIOPENTAL SODIUM

(*thye-oh-pen-tal*) Pentothal®

ULTRA-SHORT ACTING THIOBARBITURATE

#### Prescriber Highlights

- **Ultra-short acting thiobarbiturate used for anesthesia induction or anesthesia for very short procedures**
- **Contraindications:** Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, & conditions where hypnotic effects may be prolonged (*e.g.*, severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). Greyhounds (& other sight hounds) metabolize thiobarbiturates much more slowly than other breeds; consider using methohexital instead. **Horses:** preexisting leukopenia; thiopental alone may cause excessive ataxia & excitement
- **Avoid:** Extravasation, intra-carotid or intra-arterial injections, & use of concentrations of less than 2% in sterile water. Too rapid IV administration can cause significant vascular dilatation & hypoglycemia
- **Adverse Effects:** **Dogs:** Ventricular bigeminy **Cats:** Apnea after injection, mild arterial hypotension. **Horses:** Excitement & severe ataxia (if used alone); transient leukopenias, hyperglycemia, apnea, moderate tachycardia, mild respiratory acidosis
- **Severe CNS toxicity & tissue damage has occurred in horses receiving intra-carotid injections of thiobarbiturates**
- **C-III controlled substance**

---

#### Uses/Indications

Because of its rapid action and short duration, in young, healthy animals, thiopental is excellent induction agent (rapid IV bolus) for general anesthesia with other anesthetics or as the sole anesthetic agent for very short procedures. In sick or debilitated animals, thiopental may be used in a more cautious manner (IV, slowly to effect).

#### Pharmacology/Actions

Because of their high lipid solubility, thiobarbiturates rapidly enter the CNS and produce profound hypnosis and anesthesia. They are also known as ultrashort-acting barbiturates. See the monograph: Barbiturates, Pharmacology of, for additional information.

#### Pharmacokinetics

Following IV injection of therapeutic doses, hypnosis and anesthesia occur within one minute and usually within 15–30 seconds. The drug rapidly enters the CNS and then redistributes to muscle and adipose tissue in the body. The short duration of action (10–30 minutes) after intravenous dosing of thiopental is due less to rapid metabolism than to this redistribution out of the CNS and into muscle and fat stores. Greyhounds and other sight hounds may exhibit longer recovery times than other breeds. This may be due to these breeds low body fat levels or differences in the metabolic handling of the thiobarbiturates. Although anesthesia is short, recovery periods may require several hours.

Thiopental is metabolized by the hepatic microsomal system and several metabolites have been isolated. The elimination half-life in dogs has been reported as being approximately 7 hours and in sheep, 3–4 hours. Very little of the drug is excreted unchanged in the urine (0.3% in humans), so dosage adjustments are not necessary in patients with chronic renal failure.

## Contraindications/Precautions/Warnings

The following are considered **absolute contraindications** to the use of thiopental: absence of suitable veins for IV administration, history of hypersensitivity reactions to the barbiturates, and status asthmaticus. **Relative contraindications** include: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). These relative contraindications do not preclude the use of thiopental, but dosage adjustments must be considered and the drug must be given slowly and cautiously.

Patients with renal dysfunction or acidemia may show increased sensitivity to thiopental.

Because greyhounds (and other sight hounds) metabolize thiobarbiturates much more slowly than methohexital, many clinicians recommend using methohexital instead. In horses, thiopental should not be used if the patient has preexisting leukopenia. Some clinicians feel that thiopental should not be used alone in the horse as it may cause excessive ataxia and excitement.

Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. Extravasation and intra-arterial injections should be avoided because of the high alkalinity of the solution. Severe CNS toxicity and tissue damage has occurred in horses receiving intra-carotid injections of thiobarbiturates.

## Adverse Effects

In dogs, thiopental has an approximate arrhythmogenic incidence of 40%. Ventricular bigeminy is the most common arrhythmia seen; it is usually transient and generally responds to additional oxygen. Administration of catecholamines may augment the arrhythmogenic effects of the thiobarbiturates, while lidocaine may inhibit it. Cardiac output may also be reduced, but is probably only clinically significant in patients experiencing heart failure. Dose-related apnea and hypotension may be noted.

Cats are susceptible to developing apnea after injection and may develop a mild arterial hypotension.

Horses can exhibit clinical signs of excitement and severe ataxia during the recovery period if the drug is used alone. Horses can develop transient leukopenias and hyperglycemia after administration. A period of apnea and moderate tachycardia and a mild respiratory acidosis may also develop after dosing.

Too rapid IV administration can cause significant vascular dilatation and hypoglycemia. Repeated administration of thiopental is not advised as recovery times can become significantly prolonged. Parasympathetic side effects (e.g., salivation, bradycardia) may be managed with the use of anticholinergic agents (atropine, glycopyrrolate).

Prolonged recoveries may occur when repeated dosages of thiopental are administered.

Thiopental's high pH (10–11) can cause significant tissue irritation and necrosis if administered perivascularly; administration through an IV catheter is advised.

## Reproductive/Nursing Safety

Thiopental readily crosses the placental barrier and should be used with caution during pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Small amounts of thiopental may appear in milk following administration of large doses, but is unlikely to be of clinical significance in nursing animals.

## Overdosage/Acute Toxicity

Treatment of thiobarbiturate overdosage consists of supporting respirations (O<sub>2</sub>, mechanical ventilation) and giving cardiovascular support (do not use catecholamines, e.g., epinephrine, etc.).

## Drug Interactions

A fatal interaction has been reported in a dog receiving the proprietary product, *Diathal*® (no longer marketed; contained procaine penicillin G, dihydrostreptomycin sulfate, diphepanil methylsulfate, and chlorpheniramine) and the related compound thiamylal.

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiopental and may be of significance in veterinary patients:

- **CLONIDINE:** IV clonidine prior to induction may reduce thiopental dosage requirements by up to 37%
- **CNS DEPRESSANTS, OTHER:** May enhance respiratory and CNS depressant effects
- **DIAZOXIDE:** Potential for hypotension
- **EPINEPHRINE, NOREPINEPHRINE:** The ventricular fibrillatory effects of epinephrine and norepinephrine may be potentiated when used with thiobarbiturates and halothane
- **METOCLOPRAMIDE:** Given prior to induction may reduce thiopental dosage requirements
- **MIDAZOLAM:** May potentiate hypnotic effects
- **OPIATES:** Given prior to induction may reduce thiopental dosage requirements
- **PHENOTHIAZINES:** May potentiate thiopental effects; hypotension possible
- **PROBENECID:** May displace thiopental from plasma proteins
- **SULFONAMIDES:** Thiopental and sulfas may displace one another from plasma proteins

## Doses

**Note:** Atropine sulfate (or glycopyrrolate) is often administered prior to thiobarbiturate anesthesia to prevent parasympathetic side effects; however, some clinicians question whether routine-administration of anticholinergic agents is necessary.

Thiobarbiturates are administered strictly to effect; *doses are guidelines only.*

### ■ DOGS:

- a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; *Pentothal*®—Ceva Laboratories)
- b) 15–17 mg/kg IV for brief (7–10 minutes) anesthesia; 18–22 mg/kg IV for moderate (10–15 minutes) duration; 22–29 mg/kg IV for longer (15–25 minutes) duration (Booth 1988)
- c) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)
- d) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005)

### ■ CATS:

- a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; *Pentothal*®—Ceva Laboratories)
- b) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)
- c) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005)

### ■ RABBITS, RODENTS, SMALL MAMMALS:

- a) **Rabbits:** 15–30 mg/kg IV to effect (Ivey & Morrissey 2000)
- b) For chemical restraint: **Mice:** 50 mg/kg IP; **Rats:** 40 mg/kg IP; **Hamsters/Gerbils:** 30–40 mg/kg IP; **Guinea pig:** 15–30 mg/kg IV; **Rabbits:** 15–30 mg/kg IV (Burke 1999)
- c) For anesthesia in rabbits: 10–12 mg/kg IV to effect. (Kaiser-Klingler 2009)

### ■ CATTLE:

- a) 8.14–15.4 mg/kg IV; for unweaned calves from which food has been withheld for 6–12 hours: no more than 6.6 mg/kg IV for deep surgical anesthesia (*Pentothal*® package insert; Ceva Laboratories)
- b) For calves under 2 weeks of age: 15–22 mg/kg IV slowly until complete muscular relaxation takes place, duration of anesthesia usually lasts 10–12 minutes (Booth 1988)
- c) 5.5 mg/kg IV after sedation and administration with guaifenesin; or 8.8–11 mg/kg IV after tranquilization (Mandsager 1988)

### ■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

- a) With preanesthetic tranquilization: 6–12 mg/kg IV (an average of 8.25 mg/kg is recommended); Without preanesthetic tranquilization: 8.8–15.4 mg/kg IV (an average horse: 9.9–11 mg/kg IV) (Package insert; *Pentothal*®—Ceva Laboratories)
- b) One gram of thiopental per 90 kg body weight as a 10% solution given evenly over 20 seconds 15 minutes after premedication with either 0.22 mg/kg IV xylazine or 0.05 mg/kg IV acepromazine (Booth 1988)

c) 5.5 mg/kg IV after sedation and administration with guaifenesin; or 8.8–11 mg/kg IV after tranquilization (Mandsager 1988)

#### ■SWINE:

- a) 5.5–11 mg/kg IV (Package insert; *Pentothal*®—Ceva Laboratories)
- b) For swine weighing 5–50 kg: 10–11 mg/kg IV (Booth 1988)

#### ■SHEEP:

- a) 9.9–15 mg/kg IV depending on depth of anesthesia required (Package insert; *Pentothal*®—Ceva Laboratories)

#### ■GOATS:

- a) 20–22 mg/kg IV after atropine (0.7 mg/kg) IM (Booth 1988)

### Monitoring

- Level of hypnosis/anesthesia
- Respiratory status; cardiac status (rate/rhythm/blood pressure)

### Client Information

This drug should only be used by professionals familiar with its effects in a setting where adequate respiratory support can be performed.

### Chemistry/Synonyms

A thiobarbiturate, thiopental occurs as a bitter tasting, white to off-white, crystalline powder or a yellow-white hygroscopic powder. It is soluble in water (1 gram in 1.5 mL) and alcohol. Thiopental has a pKa of 7.6 and is a weak organic acid. Thiopental solutions are very alkaline (pH>10).

Thiopental sodium may also be known as: thiopentone sodium, sodium isopentylthiobarbituricum, penthiobarbital sodique, thiomebumalnatricum cum natrii carbonate, thiopentalum natricum, thiopentobarbitalum solubile, thiopental sodico, *Anesthal*®, *Bensulf*®, *Farmotal*®, *Hipnento*®, *Inductal*®, *Intraval*®, *Nesdona*®, *Pensodital*®, *Pentothal*®, *Sandothal*®, *Sodipental*®, *Thionembatal*®, *Thiopentax*®, *Tiobarbital*®, or *Trapanal*®.

### Storage/Stability

When stored in the dry form, thiopental sodium is stable indefinitely. Thiopental should be diluted with only sterile water for injection, sodium chloride injection, or D5W. Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. After reconstitution, solutions are stable for 3 days at room temperature and 7 days if refrigerated; however, as no preservative is present, it is recommended it be used within 24 hours after reconstitution. After 48 hours, the solution has been reported to attack the glass bottle in which it is stored. Thiopental may also adsorb to plastic IV tubing and bags. Do not administer any solution that has a visible precipitate.

### Compatibility/Compounding Considerations

**Preparation of Solution for Administration:** Use only sterile water for injection, normal saline, or D5W to dilute. A 5 gram vial diluted with 100 mL will yield a 5% solution and diluted with 200 mL will yield a 2.5% solution. Discard reconstituted solutions after 24 hours

The following agents have been reported to be physically **compatible** when mixed with thiopental: aminophylline, chloramphenicol sodium succinate, hyaluronidase, hydrocortisone sodium succinate, neostigmine methylsulfate, oxytocin, pentobarbital sodium, phenobarbital sodium, potassium chloride, propofol (1:1 mixture), scopolamine HBr, sodium iodide, and tubocurarine chloride (recommendations **conflict** with regard to tubocurarine; some clinicians recommend not mixing with thiopental).

The following agents have been reported to be physically **incompatible** when mixed with thiopental: Ringer's injection, Ringer's injection lactate, amikacin sulfate, atropine sulfate, chlorpromazine, codeine phosphate, dimenhydrinate, diphenhydramine, ephedrine sulfate, glycopyrrolate, hydromorphone, insulin (regular), levorphanol bitartrate, meperidine, metaraminol, morphine sulfate, norepinephrine bitartrate, penicillin G potassium, prochlorperazine edisylate, promazine HCl, promethazine HCl, succinylcholine chloride, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

None presently being marketed in USA.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

At the time of writing (February 2011), thiopental is not available for the US market.

Thiopental Sodium Powder for Injection: 2% (20 mg/mL) in 1 gram, 2.5 grams and 5 grams kits; 400 mg *Min-I-Mix* vials with *Min-I-Mix* injector, *Ready-to-Mix* and *Ready-to-Mix LifeShield* syringes; 2.5% (25 mg/mL) in 250 mg & 500 mg *Min-I-Mix* vials, 500 mg, 1 gram, 2.5 grams, 5 grams & 10 grams kits, 250 mg and 500 mg *Ready-to-Mix* syringes and *Ready-to-Mix LifeShield* syringes; *Pentothal*® (Abbott); generic; (Rx, C-III)

## THIOTEPA

(thye-oh-tep-ah)

ANTINEOPLASTIC

### Prescriber Highlights

- Rarely used antineoplastic for carcinomas (systemic administration), intracavitary for neoplastic effusions, & intravesical for transitional carcinomas
- Contraindications: Hypersensitivity to thiotepa; Caution: Hepatic dysfunction, bone marrow depression, infection, tumor cell infiltration of bone marrow, renal dysfunction, or history of urate urinary stones
- Adverse Effects: Leukopenia most likely adverse effect; other hematopoietic toxicity (thrombocytopenia, anemia, pancytopenia), GI toxicity possible. Intracavitary or intravesical instillation can also cause hematologic toxicity.
- Potentially teratogenic; use milk replacer if patient nursing
- Monitor diligently

## Uses/Indications

Veterinary indications for thiotepa include: systemic use for adjunctive therapy against carcinomas, and intracavitary use for neoplastic effusions. In dogs with transitional cell bladder carcinoma, intravesical instillation of thiotepa had significantly less efficacy (mean survival time = 57 days) when compared to a systemic doxorubicin/cyclophosphamide protocol (mean survival time = 259 days).

## Pharmacology/Actions

Thiotepa is an alkylating agent, thereby interfering with DNA replication and RNA transcription. It is cell cycle non-specific. Thiotepa has some immunosuppressive activity. When given via the intracavitary route, thiotepa is thought to control malignant effusions by a direct antineoplastic effect.

## Pharmacokinetics

Thiotepa is poorly absorbed from the GI tract. Systemic absorption is variable from the pleural cavity, bladder, and after IM injection. Some studies in humans have shown that absorption from bladder mucosa ranges from 10–100% of an administered dose. Distribution characteristics are not well described; it is unknown if the drug enters maternal milk. Thiotepa is extensively metabolized and then excreted in the urine.

## Contraindications/Precautions/Warnings

Thiotepa is contraindicated in patients hypersensitive to it. The drug should be used cautiously (weigh risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, tumor cell infiltration of bone marrow, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thiotepa has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

## Adverse Effects

When used systemically, leukopenia is the most likely adverse effect seen in small animals. Other hematopoietic toxicity (thrombocytopenia, anemia, pancytopenia) may be noted. Intracavitary or intravesical instillation of thiotepa may cause hematologic toxicity. GI toxicity (vomiting, diarrhea, stomatitis, intestinal ulceration) may be noted and human patients have reported dizziness and headache as well.

## Reproductive/Nursing Safety

Thiotepa is potentially mutagenic and teratogenic and is not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although it is unknown whether thiotepa enters milk, use of milk replacer is recommended for nursing bitches or queens.

## Overdosage/Acute Toxicity

There is no specific antidote for thiotepa overdose. Supportive therapy, including transfusions of appropriate blood products, may be beneficial for treatment of hematologic toxicity.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiotepa and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSIVE DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection
- **MYELOSUPPRESSIVE DRUGS** (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- **VACCINES, LIVE:** Live virus vaccines should be used with caution during therapy, if at all

## Laboratory Considerations

- Thiotepa may increase serum **uric acid** levels in some patients

## Doses

### ■ DOGS:

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] are *strongly recommended*.

a) For intracavitary use neoplastic effusions or systemically for adjunctive therapy of carcinomas: 0.2–0.5 mg/m<sup>2</sup> intracavitary; IV. (Jacobs *et al.* 1992)

## Monitoring

- Efficacy
- CBC with platelets

## Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality
- Clients should contact veterinarian should the animal exhibit clinical signs of abnormal bleeding, bruising, anorexia, vomiting, jaundice, or infection

## Chemistry/Synonyms

An ethylene derivative alkylating agent antineoplastic, thiotepa occurs as fine, white crystalline flakes. The drug has a faint odor and is freely soluble in water or alcohol.

Thiotepa may also be known as: NSC-6396, TESP, thiophosphamide, triethylenethiophosphoramide, TSPA, WR-45312, *Ledertepa*®, *Onco Tiotepa*®, *Tespamin*®, or *Thioplex*®.

## Storage/Stability

Store both the powder and the reconstituted solution refrigerated (2–8°C) and protected from light. Do not use solution that is grossly opaque (slightly opaque is OK) or if a precipitate is present. If refrigerated, reconstituted solutions are stable for up to 5 days.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Thiotepa Lyophilized Powder for Injection: 15 mg & 30 mg in vials; *Thioplex*® (Amgen); generic, (Sicor); (Rx)

## THYROTROPIN

### THYROTROPIN ALFA (rhTSH)

(three-peg, peg-pig) Thyroid Stimulating Hormone, TSH

## TIAMULIN

(*tye-am-myoo-lin*) Denagard®

DITERPINE PLEUROMUTILIN ANTIBIOTIC

### Prescriber Highlights

- Antibiotic used primarily in swine
  - Contraindications: Access to feeds containing polyether ionophores (*e.g.*, monensin, lasalocid, narasin, or salinomycin); swine over 250 pounds
  - Adverse Effects are unlikely
  - Variable withdrawal times depending on dosage
- 

### Uses/Indications

Tiamulin is FDA-approved for use in swine to treat pneumonia caused by susceptible strains of *Haemophilus pleuropneumoniae* and swine dysentery caused by *Treponema hyodysenteriae*. As a feed additive, it is used to cause increased weight gain in swine.

### Pharmacology/Actions

Tiamulin is a pleuromutilin antibiotic that is usually bacteriostatic, but can be bactericidal in very high concentrations against susceptible organisms. The drug acts by binding to the 50S ribosomal subunit, thereby inhibiting bacterial protein synthesis.

Tiamulin has good activity against many gram-positive cocci, including most Staphylococci and Streptococci (not group D streps). It also has good activity against Mycoplasma and spirochetes. With the exception of *Haemophilus* spp. and some *E. coli* and Klebsiella strains, the drug's activity is quite poor against gram-negative organisms.

### Pharmacokinetics

Tiamulin is well absorbed orally by swine. Approximately 85% of a dose is absorbed and peak levels occur between 2–4 hours after a single oral dose. Tiamulin is apparently well distributed, with highest levels found in the lungs.

Tiamulin is extensively metabolized to over 20 metabolites, some having antibacterial activity. Approximately 30% of these metabolites are excreted in the urine with the remainder excreted in the feces.

### Contraindications/Precautions/Warnings

Tiamulin should not be administered to animals having access to feeds containing polyether ionophores (*e.g.*, monensin, lasalocid, narasin, or salinomycin) as adverse reactions may occur. Not for use in swine over 250 pounds.

### Reproductive/Nursing Safety

Teratogenicity studies done in rodents demonstrated no teratogenic effects at doses up to 300 mg/kg. The manufacturer has concluded that the drug is not tumorigenic, carcinogenic, teratogenic, or mutagenic.

### Adverse Effects

Adverse effects occurring with this drug at usual doses are considered unlikely. Rarely, redness of the skin, primarily over the ham and underline, has been observed. It is recommended to discontinue the medication, provide clean drinking water, and hose down the area or move affected animals to clean pens.

### Overdosage/Acute Toxicity

Oral overdoses in pigs may cause transient salivation, vomiting, and CNS depression (calming effect). Discontinue drug and treat symptomatically and supportively if necessary.

### Drug Interactions

■ **POLYETHER IONOPHORES** (*e.g.*, monensin, lasalocid, narasin, or salinomycin): Tiamulin should not be administered to animals having access to feeds containing polyether ionophores as adverse reactions may occur

■ **LINCOSAMIDES, MACROLIDES** (*e.g.*, clindamycin, lincomycin, erythromycin, tylosin): Although not confirmed with this drug, concomitant use with other antibiotics that bind to the 50S ribosome could lead to decreased efficacy secondary to competition at the site of action

### Doses

#### ■ SWINE:

- For swine dysentery: 7.7 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; *Denagard® Liquid Concentrate*)
- For swine pneumonia: 23.1 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; *Denagard® Liquid Concentrate*)
- For use as a medicated premix: See the label for the product.

### Monitoring

■ Clinical efficacy

### Client Information

- Prepare fresh medicated water daily
- Avoid contact with skin or mucous membranes as irritation may occur

### Chemistry/Synonyms

A semisynthetic diterpene-class antibiotic derived from pleuromulin, tiamulin is available commercially for oral use as the hydrogen fumarate salt. It occurs as white to yellow, crystalline powder with a faint but characteristic odor. Approximately 60 mg of the drug are soluble in 1 mL of water.

Tiamulin may also be known as: 81723-hfu, SQ-14055, SQ-22947 (tiamulin fumarate), and *Denagard®*.

### Storage/Stability

Protect from moisture; store in a dry place. In unopened packets, the powder is stable up to 5 years. Fresh solutions should be prepared daily when using clinically.

### Dosage Forms/Regulatory Status

#### VETERINARY APPROVED PRODUCTS:

Tiamulin Medicated Premix: 10 grams/1 lb in 35 lb bags. FDA-approved for use in swine not weighing over 250 lbs. Slaughter withdrawal period at the 35 grams/ton use is 2 days and at the 200 grams/ton dose is 7 days. *Denagard® 10* (Novartis); (OTC).

Tiamulin Solution: 12.3% tiamulin hydrogen fumarate in an aqueous base in 32 oz bottles. FDA-approved for use in swine. Slaughter withdrawal: treatment at 3.5 mg/lb = 3 days, at 10.5 mg/lb = 7 days. *Denagard® Liquid Concentrate* (Boehringer Ingelheim); *TiaGard®* (Teva); (OTC)

There is also a chlortetracycline/tiamulin premix approved by the FDA.

**HUMAN APPROVED PRODUCTS:** None

---

## TICARCILLIN DISODIUM + CLAVULANATE POTASSIUM

(*tye-kar-sill-in; klav-yoo-lan-ate*) Timentin®

PARENTERAL EXTENDED SPECTRUM PENICILLIN + BETA-LACTAMASE INHIBITOR

### Prescriber Highlights

- Parenteral, extended action penicillin with a beta lactamase inhibitor; has increased spectrum of activity when compared with ticarcillin alone, but is more expensive
  - Used for serious systemic infections & as a compounded otic prep for *Pseudomonas* otitis
  - Limited experience or research in veterinary medicine, but appears quite safe
  - Patients with significantly impaired renal function or those receiving very high dosages may be more prone to develop platelet function abnormalities (bleeding) or CNS effects
- 

### Uses/Indications

Ticarcillin/clavulanate is used systemically to treat serious infections such as sepsis or nosocomial pneumonias in dogs, cats and horses. By adding clavulanate, enhanced spectrum of activity against beta-lactamase producing bacteria can be obtained. This drug combination is sometimes used to treat *Pseudomonas* otitis in dogs.

### Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The extended-spectrum penicillins, sometimes called anti-pseudomonal penicillins, include both alpha-carboxypenicillins (carbenicillin and ticarcillin) and acylaminopenicillins (piperacillin, azlocillin, and mezlocillin). These agents have similar spectrums of activity as the aminopenicillins but with additional activity against several gram-negative organisms of the family Enterobacteriaceae, including many strains of *Pseudomonas aeruginosa*. Like the aminopenicillins, these agents are susceptible to inactivation by beta-lactamases.

By adding clavulanate, ticarcillin's efficacy can be extended against beta-lactamase-producing strains of otherwise resistant *E. coli*, *Pasturella* spp., *Staphylococcus* spp., *Klebsiella*, and *Proteus*. Clavulanic acid acts by competitively and irreversibly binding to beta-lactamases, including types II, III, IV, and V, and penicillinases produced by *Staphylococcus*. Type I beta-lactamases that are often associated with *E. coli*, *Enterobacter*, and *Pseudomonas* are not generally inhibited by clavulanic acid.

Clavulanic acid has only weak antibacterial activity when used alone and at present is only available in fixed-dose combinations with either amoxicillin (oral) or ticarcillin (parenteral). Unlike sulbactam or tazobactam, clavulanic acid (clavulanate) can induce chromosomal beta-lactamases.

Synergy against *Pseudomonas aeruginosa* can occur when used with an aminoglycoside, but the drugs cannot be mixed together (see Drug Interactions).

### Pharmacokinetics

Ticarcillin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum levels. When given IM to humans, the drug is readily absorbed with peak levels occurring about 30–60 minutes after dosing. The reported bioavailability in the horse after IM administration is about 65%.

After parenteral injection, ticarcillin is distributed into pleural fluid, interstitial fluid, bile, sputum, and bone. Like other penicillins, CSF levels are low in patients with normal meninges (about 6% of serum levels), but increased (39% of serum levels) if meninges are inflamed. The volume of distribution is reportedly 0.34 L/kg in dogs and 0.22–0.25 L/kg in the horse. The drug is 45–65% bound to serum proteins (human). Ticarcillin is thought to cross the placenta and found in small quantities in milk. In cattle, mastitic milk levels of ticarcillin are approximately twice those found in normal milk, but are too low to treat most causal organisms.

Ticarcillin is eliminated primarily by the kidneys, via both tubular secretion and glomerular filtration. Concurrent probenecid administration can slow elimination and increase blood levels. In humans, about 10–15% of the drug is metabolized by hydrolysis to inactive compounds. The half-life in dogs and cats is reportedly 45–80 minutes; about 54 minutes in the horse. Clearance is 4.3 mL/kg/min in the dog and 2.8–3.2 mL/kg/min in the horse.

There is no evidence to suggest that the addition of clavulanic acid alters ticarcillin pharmacokinetics.

Clavulanic acid has an apparent volume of distribution of 0.32 L/kg in dogs and is distributed (with ticarcillin) into the lungs, pleural fluid and peritoneal fluid. Low concentrations of both drugs are found in the saliva, sputum and CSF (uninflamed meninges). Higher concentrations in the CSF are expected when meninges are inflamed, but it is questionable whether therapeutic levels are attainable. Clavulanic acid is 13% bound to proteins in dog serum.

Clavulanic acid is extensively metabolized in the dog (and rat) primarily to 1-amino-4-hydroxybutan-2-one. It is not known if this compound possesses any beta-lactamase inhibiting activity. Clavulanic acid is also excreted unchanged in the urine via glomerular filtration. In dogs, 34–52% of a dose is excreted in the urine as unchanged drug and metabolites, 25–27% in the feces, and 16–33% into respired air. The elimination half-life for clavulanic acid in dogs is faster than is ticarcillin.

### Contraindications/Precautions/Warnings

Do not use this medication in patients with documented hypersensitivity reactions to penicillins or other beta-lactams.

Dosage adjustments should be made in patients with significantly impaired renal function.

### Adverse Effects

Although clinical experience with this medication in veterinary patients is limited, it appears to be well tolerated; potentially, hypersensitivity reactions can occur. In humans, high dosages (particularly in patients with renal insufficiency) have caused platelet dysfunction and bleeding, and CNS effects (headache, giddiness, hallucinations, seizures). Intramuscular administration can cause pain, but reconstituting with 1% lidocaine (see Storage/Stability) can alleviate this effect. Local irritation to veins after IV administration is possible and best avoided by using dilute concentrations administered over not less than 30 minutes.

Antibiotic-associated diarrhea or colitis may occur.

### Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes ticarcillin/clavulanate as category B for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Although penicillins can be distributed into milk, it is unlikely that ticarcillin/clavulanate would be of significant clinical concern for nursing veterinary patients.

### Overdosage/Acute Toxicity

A single inadvertent overdose is unlikely to cause significant morbidity. In humans, very high dosages of parenteral penicillins such as ticarcillin, especially in patients with renal disease, have induced CNS effects (hallucinations, headaches, seizures) and alterations in platelet function (bleeding).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ticarcillin/clavulanate and may be of significance in veterinary patients:

■ **AMINOGLYCOSIDES** (*e.g.*, amikacin, gentamicin, tobramycin): *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. However, beta-lactam antibiotics can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.

■ **PROBENECID**: Can reduce the renal tubular secretion of ticarcillin, thereby maintaining higher systemic levels for a longer period of time; it does not affect the elimination of clavulanate

■ **WARFARIN; HEPARIN**: As ticarcillin has been implicated in rarely causing bleeding, use with caution in patients receiving anticoagulant therapy

### Laboratory Considerations

■ **Aminoglycoside serum quantitative analysis**: As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

■ **Direct antiglobulin (Coombs') tests**: False-positive results may occur

■ **Urine protein**: May produce false-positive protein results with the sulfosalicylic acid and boiling test, nitric acid test, and the acetic acid test. Strips using bromophenol blue reagent (*e.g.*, Multi-Stix®) do not appear to be affected by high levels of penicillins in the urine

### Doses

**Note**: Unless otherwise indicated, this drug combination is dosed on the basis of ticarcillin content.

#### ■ DOGS:

a) For sepsis: 40–50 mg/kg q6–8h IV (Hardie 2000)

b) 15–50 mg/kg q6–8h IV, IM or SC (Lappin 2003)

For *Pseudomonas* sepsis/bacteremia: 20–50 mg/kg IV q6–8h (Greene *et al.* 2006)

c) As an otic solution for adjunctive treatment of *Pseudomonas* otitis using the ticarcillin/clavulanic acid product—*Timentin*®: Dilute according to manufacturer's directions, then draw into 2 mL aliquots and freeze. Thaw and use each aliquot as 0.5 mL in each ear, twice daily. (White 2003)

#### ■ CATS:

a) For sepsis: 40–50 mg/kg q6–8h IV (Hardie 2000)

b) For *Pseudomonas* sepsis/bacteremia: 40 mg/kg IV q6h (Greene *et al.* 2006)

c) 50 mg/kg IV or IM 4 times daily; may need more frequent dosing or constant rate infusion for resistant *Pseudomonas* infections (Trepanier 1999)

d) 15–50 mg/kg q6–8h IV, IM or SC (Lappin 2003)

#### ■ HORSES:

For susceptible infections:

a) 50 mg/kg IV q6h (Bertone 2003)

b) Foals (neonatal septicemia): 40–60 mg/kg IV or IM q8h (Paradis 2003)

c) Foals: 50 mg/kg IV or IM q6–8h (Brumbaugh 1999)

d) For intrauterine infusion: 3–6 grams with a minimum of 200 mL of saline. Mares need to be treated frequently (every 4–6 h) in order to maintain drug concentrations above MIC. (LeBlanc 2009)

### Monitoring

■ Efficacy for the infection treated (WBC, clinical signs, etc.)

■ Serum levels and therapeutic drug monitoring are not routinely performed with this drug

### Client Information

■ Limited experience in veterinary medicine when used systemically

■ Best suited for inpatient use

### Chemistry/Synonyms

An alpha-carboxypenicillin, ticarcillin disodium occurs as a white to pale yellow, hygroscopic powder or lyophilized cake with pKas of 2.55 and 3.42. More than 600 mg is soluble in 1 mL of water. Potency of ticarcillin disodium is expressed in terms of ticarcillin and one gram of the disodium contains not less than 800 mg of ticarcillin anhydrous. One gram of the commercially available injection contains 5.2–6.5 mEq of sodium.

A beta-lactamase inhibitor, clavulanate potassium occurs as an off-white, crystalline powder that has a pKa of 2.7 (as the acid) and is very soluble in water and slightly soluble in alcohol at room temperatures. Although available commercially as the potassium salt, potency is expressed in terms of clavulanic acid.

Ticarcillin Disodium may also be known as: BRL-2288, or ticarcillinum natrium. Clavulanate potassium may also be known by the following synonyms: clavulanic acid, BRL-14151K, or kalii clavulanas. International trade names for ticarcillin/clavulanate include *Timentin*® and *Claventin*®.

### Storage/Stability

Unused vials should be stored at room temperature (below 24°C, 75°F).

A darkening of the sterile powder or solution indicates degradation and loss of potency of clavulanate.

For IM use, reconstitute vial with 2 mL of sterile water for injection, sodium chloride for injection, or 1% lidocaine (without epinephrine) per gram of ticarcillin. Each mL of the resulting solution will contain approximately 385 mg/mL (1 gram per 2.6 mL) ticarcillin. For humans, IM injections are recommended to be made into a relatively large muscle and not to administer more than one gram (2.6 mL) IM per injection site.

For IV use, initially reconstitute 3.1 gram vials with 13 mL of sodium chloride injection, dextrose 5% or LRS. Resulting solution will contain approximately 200 mg of ticarcillin per mL. If administered IV at this concentration, give as slowly as possible. Ideally, dilute further to a concentration of 10–100 mg (ticarcillin)/mL with a suitable diluent (*e.g.*, NS, LRS, D5W). Concentrations of 50 mg/mL or less will cause less vein irritation; the solution should be administered as slowly as possible (over at least 30 minutes).

When vials are reconstituted (as above) to 200 mg/mL, the resulting solution is stable for 6 hours at room temperature and 72 hours when refrigerated. Stability for solutions diluted for IV infusion (10–100 mg/mL):

Diluent	Room Temp	Refrigerated	Frozen
NS	24 hrs	7 days	30 days
D5W	24 hrs	3 days	7 days
LRS	24 hrs	7 days	30 days

*All thawed solutions should be used within 8 hours and not refrozen.*

### Compatibility/Compounding Considerations

Ticarcillin/clavulanate should **not** be mixed with aminoglycosides (*e.g.*, gentamicin, amikacin) and **may not be compatible** when infused at a Y-site with solutions containing amphotericin B cholesteryl sulfate complex, azithromycin, or vancomycin. Y-site **compatible** drugs include (partial listing): propofol, dexmetomidine, cefepime, diltiazem, doxorubicin HCl liposomes, etoposide, famotidine, fluconazole, heparin sodium, hetastarch, regular insulin, meperidine, morphine sulfate, and ondansetron.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS**: None

#### **HUMAN-LABELED PRODUCTS**:

Ticarcillin Disodium Powder for Injection (contains 4.75 mEq sodium/g) and Clavulanate Potassium (contains 0.15 mEq potassium/g): 3 grams ticarcillin and 0.1 gram clavulanic acid in 3.1 gram vials, piggyback bottles

Ticarcillin Powder for Injection (contains 18.7 mEq sodium/100 mL) and Clavulanate Potassium (contains 0.5 mEq potassium/100 mL): 3 grams ticarcillin and 0.1 gram clavulanic acid/100 mL in; *Timentin*® (GlaxoSmithKline); (Rx)

Ticarcillin (alone) has now been discontinued.

---

## TILETAMINE HCL/ZOLAZEPAM HCL

(*tye-let-a-meen* and *zoe-laze-a-pam*) Telazol®

INJECTABLE ANESTHETIC/TRANQUILIZER

### Prescriber Highlights

- **Injectable anesthetic/tranquilizer combination similar to ketamine/diazepam**
- **Contraindications: Pancreatic disease, rabbits, severe cardiac disease, use in cesarean section, or pulmonary disease**
- **Caution: Renal disease, large exotic cats, especially tigers (use avoided)**
- **Protect patient's eyes after using**
- **Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.**
- **Adverse Effects: Respiratory depression, pain after IM injection, athetoid movements, tachycardia (esp. dogs), emesis during emergence, excessive salivation & bronchial/tracheal secretions, transient apnea, vocalization, erratic &/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, & either hypertension or hypotension**
- **Monitor body temperature (may cause hypothermia)**
- **Class-III controlled substance**
- **Cost and shelf-life may be issues**

---

## Uses/Indications

*Telazol*® is indicated for restraint or anesthesia combined with muscle relaxation in cats, and for restraint and minor procedures of short duration (≈30 minutes) which require mild to moderate analgesia in dogs. Although not officially FDA-approved, it has been used also in horses and many exotic and wild species.

## Pharmacology/Actions

In cats, tiletamine decreases cardiac rate and blood pressure after IM injections. Its effect on respiratory activity is controversial, and until these effects have been clarified, respiratory function should be closely monitored. The pharmacology of this drug combination is similar to that of ketamine and diazepam; for more information, refer to their monographs.

## Pharmacokinetics

Little pharmacokinetic information is available for these agents. The onset of action may be variable and be very rapid; animals should be observed carefully after injection.

In cats, the onset of action is reported to be within 1–7 minutes after IM injection. Duration of anesthesia is dependent on dosage, but is usually about 0.33–1 hour at peak effect. This is reported to be approximately 3 times the duration of ketamine anesthesia. The duration of effect of the zolazepam component is longer than that of the tiletamine, so there is a greater degree of tranquilization than anesthesia during the recovery period. The recovery times vary in length from approximately 1–5.5 hours. Reported elimination half-life for tiletamine is 2.5 hours and 4.5 hours for zolazepam.

In dogs, the onset of action following IM injection averages 7.5 minutes. The mean duration of surgical anesthesia is about 27 minutes, with recovery times averaging approximately 4 hours. The duration of the tiletamine effect is longer than that of zolazepam, so there is a shorter duration of tranquilization than there is anesthesia. Less than 4% of the drugs are reported excreted unchanged in the urine in the dog. Reported elimination half-life for tiletamine is 2.5 hours and 1.5 hours for zolazepam.

## Contraindications/Precautions/Warnings

*Telazol*® is contraindicated in animals with pancreatic disease, or severe cardiac or pulmonary disease. Animals with renal disease may have prolonged duration of anesthetic action or recovery times.

Because *Telazol*® may cause hypothermia, susceptible animals (small body surface area, low ambient temperatures) should be monitored carefully and supplemental heat applied if needed. Like ketamine, *Telazol*® does not abolish palpebral, palpebral, pedal, laryngeal, and pharyngeal reflexes and its use (alone) may not be adequate if surgery is to be performed on these areas.

It has been reported that this drug is contraindicated in rabbits due to renal toxicity.

*Telazol*® is generally avoided for use in large, exotic cats (contraindicated in tigers) as it may cause seizures, permanent neurologic abnormalities, or death.

Cats' eyes remain open after receiving *Telazol*®, and they should be protected from injury and an ophthalmic lubricant (e.g., *Lacrilube*®) should be applied to prevent excessive drying of the cornea. Cats reportedly do not tolerate endotracheal tubes well with this agent.

Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.

## Adverse Effects

Respiratory depression is a definite possibility, especially with higher dosages of this product. Apnea may occur; observe animal carefully. Pain after IM injection (especially in cats) has been noted which may be a result of the low pH of the solution. Athetoid movements (constant succession of slow, writhing, involuntary movements of flexion, extension, pronation, etc.) may occur; do not give additional *Telazol*® in the attempt to diminish these actions. Large doses given SC or IM, versus small doses given IV, may result in longer, rougher recoveries.

In dogs, tachycardia may be a common effect and last for 30 minutes. Insufficient anesthesia after recommended doses has been reported in dogs.

*Telazol*® has been implicated in causing nephrosis in lagomorphs (rabbits/hares) and is usually not recommended for use in these species.

Other adverse effects listed by the manufacturer include: emesis during emergence, excessive salivation and bronchial/tracheal secretions (if atropine not administered beforehand), transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertonia, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, and either hypertension or hypotension.

## Reproductive/Nursing Safety

*Telazol*® crosses the placenta and may cause respiratory depression in newborns; the manufacturer lists its use in cesarean section as being contraindicated. The teratogenic potential of the drug is unknown, and it is not recommended for use during any stage of pregnancy.

## Overdosage/Acute Toxicity

The manufacturer claims a 2X margin of safety in dogs, and a 4.5X margin of safety in cats. A preliminary study in dogs (Hatch et al. 1988) suggests that doxapram at 5.5 mg/kg will enhance respirations and arousal after *Telazol*®. In massive overdoses, it is suggested that mechanically assisted ventilation be performed if necessary and other clinical signs treated symptomatically and supportively.

High doses of tiletamine have caused acute tubular necrosis in New Zealand white rabbits.

## Drug Interactions

Little specific information is available presently on drug interactions with this product.

■ **ANESTHETICS, INHALATIONAL:** Dosage may need to be reduced when used concomitantly with *Telazol*®

■ **BARBITURATES:** Dosage may need to be reduced when used concomitantly with *Telazol*®

■ **CHLORAMPHENICOL:** In dogs, chloramphenicol apparently has no effect on recovery times with *Telazol*®, but in cats, anesthesia is prolonged on average of 30 minutes by chloramphenicol.

■ **PHENOTHIAZINES:** Can cause increased respiratory and cardiac depression

For potential additional interactions from the related compounds, ketamine and midazolam:

**Ketamine:**

■ **NEUROMUSCULAR BLOCKERS (e.g., succinylcholine and tubocurarine):** May cause enhanced or prolonged respiratory depression

■ **THYROID HORMONES:** When given concomitantly with ketamine, thyroid hormones have induced hypertension and tachycardia in humans; beta-blockers (e.g., **propranolol**) may be of benefit in treating these effects

**Midazolam:**

■ **ANESTHETICS, INHALATIONAL:** Midazolam may decrease the dosages required

■ **AZOLE ANTIFUNGALS (ketoconazole, itraconazole, fluconazole):** May increase midazolam levels

■ **CALCIUM CHANNEL BLOCKERS (diltiazem, verapamil):** May increase midazolam levels

■ **CIMETIDINE:** May increase midazolam levels

■ **CNS DEPRESSANTS, OTHER:** May increase the risk of respiratory depression

■ **MACROLIDES (erythromycin, clarithromycin):** May increase midazolam levels

■ **OPIATES:** May increase the hypnotic effects of midazolam and hypotension has been reported when used with meperidine.

■ **PHENOBARBITAL:** May decrease peak levels and AUC of midazolam

■ **RIFAMPIN:** May decrease peak levels and AUC of midazolam

■ **THIOPENTAL:** Midazolam may decrease the dosages required

## Doses

### ■ DOGS:

a) For diagnostic purposes: 6.6–9.9 mg/kg IM

For minor procedures of short duration: 9.9–13.2 mg/kg IM;

If supplemental doses are necessary, give doses less than the initial dose and total dosage should not exceed 26.4 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert; *Telazol*®—Robins)

b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002)

c) For aggressive (difficult to handle) dogs that require more sedation and only if insufficient sedation from opioid, higher dose medetomidine, and midazolam: 1–2 mg/kg IM. (Moffat 2008)

### ■ CATS:

a) 9.7–11.9 mg/kg IM for procedures such as dentistry, abscess treatment, foreign body removal, etc. For procedures that require mild to moderate levels of analgesia (lacerations, castration, etc.) use 10.6–12.5 mg/kg IM.

For ovariohysterectomy and onychectomy use 14.3–15.8 mg/kg IM.

If supplemental doses are necessary, give doses less than the initial dose and the total dosage should not exceed 72 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert; *Telazol*®—Robins)

b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002)

### ■ RUMINANTS:

As an induction agent for cattle, llamas/alpacas, goats, sheep:

a) Xylazine at 0.05–0.1 mg/kg IV, IM, then *Telazol*® at 2–4 mg/kg IV (IM). Caution: xylazine can cause severe hypoxemia and pulmonary edema in sheep. (Haskell 2005)

b) **Llamas:** 4.7–6 mg/kg IM. (Wolff 2009)

### ■ RABBITS, RODENTS, SMALL MAMMALS:

For chemical restraint:

a) **Gerbils:** 20 mg/kg IP (in combination with xylazine 10 mg/kg) (Huerkamp 1995)

b) **Mice:** 80–100 mg/kg IM.

**Rats:** 20–60 mg/kg IM.

**Hamsters/Gerbils:** 20–80 mg/kg IM.

**Guinea pig:** 10–80 mg/kg IM.

**Rabbits:** Not recommended (Burke 1999)

c) **Chinchillas:** 20–40 mg/kg IM.

**Hamsters:** 50–80 mg/kg IP for immobilization/anesthesia.

**Gerbils:** 10–30 mg/kg IP.

**Mice:** 80 mg/kg IP for immobilization

**Rats:** 40 mg/kg IP for light anesthesia.

**Guinea pigs:** 40–60 mg/kg IM for immobilization (Adamcak & Otten 2000)

d) **Small rodents:** 6–10 mg/kg IM is adequate prior to inhalation anesthesia. Advantages over ketamine include better muscle relaxation, small volume of injection, rapid induction time and a wide margin of safety.

Disadvantages of this drug combination are increased respiratory secretions, variability in recovery times, and short self-life after reconstitution. (Bennett 2009)

### ■ FERRETS:

As a sedative/analgesic:

a) 22 mg/kg IM combined with glycopyrrolate (0.01 mg/kg IM). Rapid onset, but slow and rough recovery (3–4 hours) (Finkler 1999)

b) *Telazol*® alone: 22 mg/kg IM;

*Telazol*® (1.5 mg/kg) plus xylazine (1.5 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM)

*Telazol*® (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)

c) 22 mg/kg IM. (Kaiser-Klingler 2009)

#### ■HORSES: (Note: ARCI UCGFS Class 2 Drug)

a) Xylazine 1.1 mg/kg IV, 5 minutes prior to *Telazol*® at 1.65–2.2 mg/kg IV (Hubbell *et al.* 1989)

#### ■REPTILES:

- Large Snakes: 3 mg/kg IM to facilitate handling and anesthesia. Administer 30–45 minutes prior to handling. Sedation may persist for up to 48 hours. May also be used in Crocodylians at 4–8 mg/kg. (Heard 1999)
- 3–10 mg/kg IM. Lizards and snakes can generally be treated with lower end of dosage range and chelonians may require high end. If sedation is inadequate, may give incrementally up to the maximum dose. Monitor closely for apnea and ventilate if required. (Innis 2003)
- Significant interspecies and interpatient differences in effectiveness. At lower doses of 4–10 mg/kg sedation may be sufficient for some procedures (venipuncture, gastric lavage, intubation for inhalation anesthesia). At higher doses (15–40 mg/kg), recovery may be greatly prolonged. Suggest starting out at 7–15 mg/kg the first few times this is used on reptiles in your practice (and to use on your own “in house” pets first!), and then use increasing dosages as needed. (Funk 2002)
- Best used for sedation and tranquilization or to facilitate intubation, especially in large boids, crocodylians and venomous species. Author starts with a dose of 5 mg/kg IM and repeats if needed. Higher doses (6 mg/kg) are associated with very long recovery times, especially in chelonians (72 hours). (Mehler 2009)

#### ■BIRDS:

a) Ratites: 5 mg/kg IM or IV (Jenson 1998)

#### ■ZOO, EXOTIC, WILDLIFE SPECIES:

For use of *Telazol*® in zoo, exotic and wildlife medicine refer to specific references, including:

- Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.
- Handbook of Wildlife Chemical Immobilization, 3rd Ed.* Kreeger, T.J. and J.M. Arnemo. 2007.
- Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995
- Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005
- The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

#### Monitoring

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Monitor eyes to prevent drying or injury
- Body temperature

#### Client Information

Should only be administered by individuals familiar with its use.

#### Chemistry/Synonyms

Tiletamine is an injectable anesthetic agent chemically related to ketamine. Zolazepam is a diazepamine minor tranquilizer. The pH of the injectable product, after reconstitution, is 2.2–2.8.

Tiletamine HCl may also be known as: CI-634, CL-399, CN-54521-2, or *Telazol*®.

Zolazepam HCl may also be known as: CI-716.

#### Storage/Stability

After reconstitution, solutions may be stored for 4 days at room temperature and 14 days if refrigerated. Do not use solutions that contain a precipitate or are discolored..

#### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Tiletamine HCl (equivalent to 250 mg free base) and Zolazepam HCl (equivalent to 250 mg free base) as lyophilized powder/vial in 5 mL vials. When 5 mL of sterile diluent (sterile water) is added a concentration of 50 mg/mL of each drug (100 mg/mL combined) is produced; *Telazol*® (Pfizer); (Rx, C-III). FDA-approved for use in cats and dogs. *Telazol*® is a Class-III controlled substance.

#### HUMAN-LABELED PRODUCTS: None

#### TILMICOSIN

(til-mi-coe-sin) Micotil®, Pulmotil®

#### MACROLIDE ANTIBIOTIC

#### Prescriber Highlights

- Macrolide antibiotic used in cattle, sheep, & sometimes rabbits; used in swine as a medicated feed article
- Contraindications: Not to be used in automatically powered syringes or to be given IV, camelids(?)
- May be fatal in swine (when injected) & non-human primates; potentially in horses
- Adverse Effects: IM injections may cause a local tissue reaction resulting in trim loss; edema is possible at SC injection site
- Avoid contact with eyes
- In case of human injection, contact physician immediately

## Uses/Indications

Tilmicosin is indicated for the treatment of bovine or ovine respiratory diseases (BRD) caused by *Mannheimia (Pasteurella) haemolytica*.

## Pharmacology/Actions

Like other macrolides, tilmicosin has activity primarily against gram-positive bacteria, although some gram-negative bacteria are affected and the drug reportedly has some activity against mycoplasma. Preliminary studies have shown that 95% of studied isolates of *Pasteurella haemolytica* are sensitive. Bacterial isolates susceptible to tilmicosin at concentrations of 8 micrograms/mL or less are reported as susceptible to tilmicosin. The MIC90 value reported for *M. haemolytica* and *P. multocida* in cattle with BRD is 32 micrograms/mL.

## Pharmacokinetics

Tilmicosin apparently concentrates in lung tissue. At 3 days post injection, the lung:serum ratio is about 60:1. MIC95 concentrations (3.12 micrograms/mL) for *P. Haemolytica* persist for a minimum of 3 days after a single injection.

## Contraindications/Precautions/Warnings

Not to be used in automatically powered syringes or to be given intravenously as fatalities may result. Tilmicosin has been shown to be fatal in swine (when injected), non-human primates and potentially, in horses. Avoid contact with eyes.

There have been anecdotal reports of severe reactions in some camelids.

## Adverse Effects

If administered IM, a local tissue reaction may occur resulting in trim loss. Edema may be noted at the site of subcutaneous injection.

Accidental self-injection can be fatal in humans. Do not use in automatically powered syringes. Emergency treatment includes applying ice to injection site and contacting a physician immediately. Emergency medical telephone numbers are 1-800-722-0987 or 1-317-276-2000.

## Reproductive/Nursing Safety

Safe use in pregnant animals or animals to be used for breeding purposes has not been demonstrated.

## Overdosage/Acute Toxicity

The cardiovascular system is apparently the target of toxicity in animals. In cattle, doses up to 50 mg/kg IM did not cause death, but SC doses of 150 mg/kg did cause fatalities, as well as IV doses of 5 mg/kg. Doses as low as 10 mg/kg in swine caused increased respiration, emesis and seizures; 20 mg/kg IM caused deaths in most animals tested. In monkeys, 10 mg/kg administered once caused no signs of toxicity, but 20 mg/kg caused vomiting; 30 mg/kg caused death.

In cases of human injection, contact physician immediately. The manufacturer has emergency telephone numbers to assist in dealing with exposure: 1-800-722-0987 or 1-317-276-2000.

## Drug Interactions

In swine, **epinephrine** increased the mortality associated with tilmicosin. No other specific information was noted; refer to the erythromycin monograph for possible interactions.

## Doses

### ■CATTLE:

For susceptible infections (subcutaneous injection under the skin in the neck, or if not accessible, behind the shoulders and over the ribs is suggested).

- a) For treatment of pneumonic pasteurellosis: 10 mg/kg SC every 72 hours (Shewen & Bateman 1993)
- b) 10 mg/kg SC (not more than 15 mL per injection site. (Package insert; *Micotil*® 300—Elanco)

### ■SHEEP:

For susceptible infections:

- a) 10 mg/kg SC (not more than 15 mL per injection site). Subcutaneous injection under the skin in the neck, or if not accessible, behind the shoulders and over the ribs is suggested. Do not use in lambs less than 15 kg of body weight. (Package insert; *Micotil*® 300—Elanco)

### ■RABBITS, RODENTS, SMALL MAMMALS:

a) **Rabbits:** Two regimens:

- 1) 25 mg/kg SC once; repeat in 3 days if necessary.
- 2) 5 mg/kg SC on day 0, if no reaction, give 10 mg/kg SC on days 7 and 14. Can cause weakness, pallor, tachypnea and sudden death. May cause acute death if given IV. SC injections can cause local swelling and necrosis. (Ivey & Morrissey 2000)

## Monitoring

- Efficacy
- Withdrawal times

## Client Information

- If clients are administering the drug, they should be warned about the potential toxicity to humans, swine, and horses if accidentally injected
- Carefully instruct in proper injection techniques
- Avoid contact with eyes

## Chemistry/Synonyms

A semi-synthetic macrolide antibiotic, tilmicosin phosphate is commercially available in a 300 mg/mL (of tilmicosin base) injection with 25% propylene glycol.

Tilmicosin may also be known as EL-870, LY-177370, *Micotil*® or *Pulmotil*®.

## Storage/Stability

Store the injection at or below room temperature. Avoid exposure to direct sunlight.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Tilmicosin for Subcutaneous Injection: 300 mg/mL in 50 mL, 100 mL and 250 mL multi-dose vials; *Micotil*® 300 Injection (Elanco); (Rx). FDA-approved for use in cattle and sheep. Not FDA-approved for use in female dairy cattle 20 months or older. Do not use in lactating ewes if milk is to be used for human consumption. Do not use in veal calves. Slaughter withdrawal (at labeled doses) = 28 days.

Tilmicosin Feed Medication: 90.7 grams/lb. *Pulmotil*® 90 (Elanco); (OTC). FDA-approved for veterinary use in swine only. Slaughter withdrawal (at labeled doses) = 7 days.

**HUMAN-LABELED PRODUCTS:** None

## TILUDRONATE DISODIUM TILUDRONIC ACID

(til-yoo-droe-nate) Tildren®, Skelid®

BISPHOSPHONATE BONE RESORPTION INHIBITOR

### Prescriber Highlights

- Bisphosphonate bone resorption inhibitor available in some countries for the intravenous treatment of navicular disease in horses
  - Adverse effects: Signs of colic, muscle tremor (hypocalcemia), fatigue/lassitude, sweating, injection site effects, salivation, tail hypertonia
  - Must be legally imported into the USA
- 

### Uses/Indications

Tiludronate disodium (tiludronic acid) is a bisphosphonate bone resorption inhibitor that is available in some countries for the intravenous treatment of navicular disease in horses. It may be beneficial in managing lameness isolated to the navicular bone and distal tarsal osteoarthritis by decreasing bone resorption and inflammation (Kamm *et al.* 2008). Treatment earlier in the course of the disease apparently results in greater efficacy.

For humans, there is an orally administered FDA-approved product for treating Paget's disease (osteitis deformans).

### Pharmacology/Actions

Tiludronate, like other bisphosphonates, inhibit osteoclastic bone resorption by inhibiting osteoclast function after binding to bone hydroxyapatite thereby helping to regulate bone remodeling.

### Pharmacokinetics

After intravenous injection in horses the drug is rapidly distributed to bone. Binding is greater to cancellous bone than cortical bone. Plasma protein binding is reported to be approximately 85% and elimination half-life is approximately 4.5 hours. Repeated daily doses do not result in accumulation in plasma. Unbound drug is eliminated unchanged in the urine. Approximately 25–50% of a single IV dose is eliminated in the urine over 96 hours.

### Contraindications/Precautions/Warnings

The labeling for *Tildren*® states that the drug should not be used in horses with renal dysfunction or those producing milk for human consumption. Because there is an absence of data on the effects the drug may have on the skeleton of young animals, the manufacturer states to not administer to horses less than 3 years old.

Since the safety of tiludronate has not been studied in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

Use with caution in horses with hypocalcemia or cardiac dysfunction. If used in these patients, slow the rate of injection and watch these patients carefully for the first few hours post-injection.

### Adverse Effects

Acute adverse effects reported in horses include colic (reduced appetite, abdominal discomfort, pawing/scratching at ground, restlessness), muscle tremor, fatigue/lassitude and sweating. The incidences of these effects are reported at 5% or less and are postulated to be due to a mild hypoglycemic effect. The onset of colic signs appear within a few hours of treatment and generally resolve without treatment. Should they persist, conventional colic treatments are recommended. Muscle tremors may be treated with intravenous calcium if required.

Up to 9% of patients develop local reactions at the injection site (*e.g.*, phlebitis), particularly after the 4th injection.

Other adverse effects reported include salivation and tail hypertonia.

### Reproductive/Nursing Safety

Studies performed in male and female rats at dosages as high as 75 mg/kg/day demonstrated no effects on fertility.

Studies in pregnant rabbits given 2X–5X human dosages showed no skeletal abnormalities. Pregnant mice given 7X human dosages showed some adverse effects (decreased litter size, malformed paws in 6 fetuses from one litter). Rat studies have shown decreased litter sizes, but no teratogenic effects. In humans, the FDA categorizes tiludronate as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

As the safety of tiludronate has not been studied in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

### Overdosage/Acute Toxicity

Limited information is available. The manufacturer reports that doses of 3X in horses caused an increased frequency of adverse effects, particularly signs of colic and muscle tremor. Intravenous calcium administration may be considered for signs associated with hypocalcemia.

### Drug Interactions

■ **CALCIUM- or MAGNESIUM-CONTAINING INTRAVENOUS FLUIDS:** May complex with tiludronate and reduce its availability; do not mix with fluids or administer with fluids such as *Lactated Ringer's*, *Ringer's*, *Plasma-Lyte*®, *Normasol*®, etc.

### Laboratory Considerations

No specific concerns were noted.

### Doses

#### ■ HORSES:

For navicular disease:

- a) 0.1 mg/kg tiludronic acid slow IV (over 20–30 seconds per 10 mL given) once daily for 10 days. Alternate injection sites from day to day. (Label information; *Tildren*®—Ceva Sanofi)

### Monitoring

- Clinical Efficacy
- Serum Calcium
- Adverse Effects (particularly within first 4 hours after dosing)

### Client Information

- This medication should be administered by a veterinary professional
- Patient should be observed for up to 4 hours post-administration for signs of hypocalcemia (muscle tremors, etc.) or colic

### Chemistry/Synonyms

Tiludronate disodium is a bisphosphonate that occurs as a white powder having a molecular weight of 380.6. Commercially available products contain the disodium salt of tiludronic acid. 120 mg of tiludronate disodium is equivalent to 100 mg of tiludronic acid.

Tiludronate disodium or tiludronic acid may also be known as ME-3737, SR-41319, acidum tiludronicum, *Tildren*® or *Skelid*®.

### Storage/Stability

Unless otherwise indicated, store the unconstituted powder and diluent at room temperature (15–30°C) in the outer carton.

Shelf life of properly stored unconstituted product is generally 3 years. Reconstitute the powder by aseptically adding 10 mL of the provided diluent and mix gently. The resulting solution contains 5 mg/mL of tiludronic acid.

After reconstitution, use immediately. Any remaining product should be discarded.  
Do not mix or administer with intravenous fluids containing calcium or magnesium (e.g., LRS, Ringer's, etc.).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

None in the USA; it is available in France, Spain, The Netherlands, and Italy as:

Tiludronic Acid: 50 mg (as tiludronate disodium) per vial, with one 10 mL vial of sterile water for reconstitution; *Tildren*® (Sanofi/Ceva). Labeled for use in horses.

Not permitted for use in lactating animals producing milk for human consumption. Labeled meat and offal withdrawal = 0 days. Refer to individual product labels for more information.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

One source recommended for obtaining *Tildren*® via this process is: manorveterinaryexports.com

### HUMAN-LABELED PRODUCTS:

Tiludronate Disodium Oral Tablets: 240 mg (equiv. to 200 mg tiludronic acid); *Skelid*® (Sanofi-Aventis); (Rx)

**Note:** The information presented in this monograph pertains to the veterinary-labeled intravenous product only.

---

## TINIDAZOLE

(*tye-ni-dah-zole*) Tindamax®

NITROIMIDAZOLE ANTIPROTOZOAL/ANTIBIOTIC

### Prescriber Highlights

- **Drug similar to metronidazole, potentially useful for treating anaerobic infections (especially in the mouth), trichomoniasis, amebiasis and balantidiasis**
  - **Little experience in veterinary medicine**
  - **Adverse effects most likely GI-related; like metronidazole and ronidazole, tinidazole could cause neurotoxicity**
  - **Many potential drug interactions**
- 

## Uses/Indications

Little information is presently available on the use of tinidazole in dogs, cats, or horses. It potentially could be useful for treating anaerobic infections, particularly associated with dental infections in small animals. Because of its antiprotozoal effects, it has been used as an alternative for treating giardiasis in small animals, and it could have efficacy against amebiasis, trichomoniasis or balantidiasis in veterinary species, but documentation of efficacy is not available. Tinidazole has a longer duration of action in dogs and cats than does metronidazole. In a small study done in cats experimentally infected with *T. foetus*, tinidazole doses at 30 mg/kg PO once daily for 14 days, decreased fecal shedding of *T. foetus* but failed to eradicate the infection from 2 of 4 cats (Gookin *et al.* 2007).

In humans, oral tinidazole is FDA-approved for treating extraintestinal and intestinal amebiasis, (*Entamoeba histolytica*), giardiasis (*Giardia duodenalis/lambli*a), and trichomoniasis (*T. vaginalis*).

## Pharmacology/Actions

Tinidazole is a 5-nitroimidazole similar to metronidazole. It is bactericidal against susceptible bacteria. Its exact mechanism of action is not completely understood, but it is taken-up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible for the drug's antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria.

Tinidazole has activity against many obligate anaerobes and *H. pylori*. It has excellent activity against *Porphyromonas* spp. found in canine gingiva.

Tinidazole is also trichomonocidal and amebicidal. Its mechanism of action for its antiprotozoal activity is not well understood. It has therapeutic activity against *Entamoeba histolytica*, *Trichomonas*, and *Giardia*.

## Pharmacokinetics

In dogs and cats, tinidazole is practically completely absorbed after oral administration. Apparent volumes of distribution are 0.66 L/kg in dogs and 0.54 L/kg in cats. Dogs clear the drug about twice as fast as cats; elimination half-lives are about 4.4 hours in dogs, 8.4 hours in cats.

In horses, tinidazole is practically completely absorbed after oral administration. Apparent volume of distribution is 0.66 L/kg an elimination half-life of about 5.2 hours.

## Contraindications/Precautions/Warnings

Tinidazole should not be used in patients documented to be hypersensitive to it or other 5-nitroimidazoles (e.g., metronidazole).

Tinidazole is metabolized by the liver; use with caution in patients with hepatic dysfunction.

As other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats and seizures have been reported rarely with tinidazole use in humans, use with caution in animals susceptible to seizures.

The human labeling for tinidazole carries a "black box warning" stating: "Carcinogenicity has been seen in mice and rats treated chronically with another agent in the nitroimidazole class (metronidazole). Although such data have not been reported for tinidazole, avoid unnecessary use of tinidazole. Reserve its use for the conditions for which it is indicated."

## Adverse Effects

The adverse effect profiles for dogs, cats or horses are not well described since clinical use of this medication has been limited. Gastrointestinal effects including vomiting, inappetence, and diarrhea are most likely. Giving the medication with food may help alleviate these effects. Other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats; seizures have been reported rarely with tinidazole use in humans.

Tinidazole reportedly is very bitter tasting. If using compounded products, consider using capsules or having a flavored suspension prepared.

## Reproductive/Nursing Safety

In studies performed on male rats tinidazole decreased fertility and caused testicular histopathology.

Tinidazole crosses the placenta. While studies in mice and rats have not demonstrated significant fetal effects, because of its mutagenic potential, it is stated that it should not be used in women during the first trimester of pregnancy. In humans, the FDA categorizes tinidazole as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Tinidazole is distributed into maternal milk at levels approximating those found in serum. It is suggested that milk replacer be used if tinidazole is necessary for treating a nursing dam.

## Overdosage/Acute Toxicity

Very limited information is available. In studies done in rats and mice, the oral LD50 was >3.6 grams/kg for mice and >2 grams/kg for rats. Treatment of acute overdoses of tinidazole is symptomatic and supportive. Gastric lavage or induction of emesis may be helpful. Hemodialysis can remove approximately 43% of the amount in the body (human) in a 6 hour session.

## Drug Interactions

## Drug Interactions

In humans, the following drug interactions with metronidazole have been reported or are theoretical and may be of significance in veterinary patients receiving tinidazole:

- **ALCOHOL:** May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction
- **CIMETIDINE, KETOCONAZOLE:** May decrease the metabolism of tinidazole and increase the likelihood of dose-related side effects occurring
- **CYCLOSPORINE, TACROLIMUS (systemic):** Tinidazole may increase the serum levels of cyclosporine or tacrolimus
- **FLUOROURACIL (systemic):** Tinidazole may increase the serum levels of fluorouracil and increase the risk of toxicity
- **LITHIUM:** Tinidazole may increase lithium serum levels and increase the risk for lithium toxicity
- **OXYTETRACYCLINE:** Reportedly, may antagonize the therapeutic effects of metronidazole (and presumably tinidazole)
- **PHENOBARBITAL, RIFAMPIN OR PHENYTOIN:** May increase the metabolism of tinidazole thereby decreasing blood levels
- **WARFARIN:** Metronidazole (and potentially tinidazole) may prolong the prothrombin time (PT) in patients taking warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

## Laboratory Considerations

- **AST, ALT, LDH, Triglycerides, Hexokinase glucose:** Tinidazole, like metronidazole may interfere with enzymatic coupling of the assay to oxidation-reduction of nicotinamide adenine. Falsely low values, including zero, may result.

## Doses

### ■ DOGS:

- a) For stomatitis, anaerobic infections: 15–25 mg/kg PO q12h for 7 days. (Greene *et al.* 2006)
- b) For giardiasis: 44 mg/kg PO q24h for 6 days. Potentially may be useful for treating trichomoniasis, amebiasis and balantidiasis, but efficacy data lacking for animals. (Barr 2006)

### ■ CATS:

- a) For stomatitis, anaerobic infections: 15 mg/kg PO q24h for 7 days. (Greene *et al.* 2006)

### ■ HORSES:

- a) For susceptible anaerobic infections: 10–15 mg/kg PO q12h (Pvorala *et al.* 1990)

## Monitoring

- Clinical efficacy in treating the infection

## Client Information

- Give this medication with food
- Animals should not have access to alcohol when receiving this medication
- If gastrointestinal signs (vomiting, lack of appetite, diarrhea) are severe or persist, contact veterinarian
- Contact veterinarian immediately if animal shows signs of behavior changes, eyes moving back and forth (nystagmus), convulsions, or if patient has difficulty walking, climbing stairs, etc. (ataxia); these could be signs that drug toxicity is occurring

## Chemistry/Synonyms

Tinidazole occurs as an almost white or pale yellow, crystalline powder. It is practically insoluble in water, soluble in acetone, and sparingly soluble in methyl alcohol.

Tinidazole may also be known as CP-12574 or tinidazolium. International trade names include: *Estovyn-T*®, *Fastigyn*®, *Tindamax*®, *Tiniba*®, *Tiniameb*®, or *Tinidazol*®.

## Storage/Stability

Store tinidazole tablets at controlled room temperature (20–25°C) protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

As tinidazole is a nitroimidazole, its use is prohibited in animals to be used for food.

**HUMAN-LABELED PRODUCTS:**

Tinidazole Tablets (scored): 250 mg & 500 mg; *Tindamax*® (Mission Pharmacal); generic; (Rx)

---

## TIOPRONIN

(*tye-oh-proe-nin*) Thiola®, 2-MPG

ANTIUROLITHIC (CYSTINE) AGENT

### Prescriber Highlights

- **Drug for prevention (& treatment) of cystine urolithiasis**
- **Cautions:** Agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine
- **Adverse Effects:** Coombs'-positive regenerative spherocyte anemia, aggressiveness, proteinuria, thrombocytopenia, elevations in liver enzymes, dermatologic effects, & myopathy
- **Relatively expensive**

---

## Uses/Indications

Tiopronin is indicated for the prevention of cystine urolithiasis in patients where dietary therapy combined with urinary alkalization is not completely effective. It may also be useful in combination with urine alkalization and dietary (ultra-low protein diet) modification to dissolve stones.

## Pharmacology/Actions

Tiopronin is considered an antiurolithic agent. It undergoes thiol-disulfide exchange with cystine (cysteine-cysteine disulfide) to form tiopronin-cystine disulfide. This complex is more water-soluble and is readily excreted thereby preventing cystine calculi from forming.

## Pharmacokinetics

Tiopronin has a rapid onset of action and in humans, up to 48% of a dose is found in the urine within 4 hours of dosing. Tiopronin has a relatively short duration of action and its effect in humans disappears in about 10 hours. Elimination is primarily via renal routes.

## Contraindications/Precautions/Warnings

Tiopronin's risks versus its benefits should be considered before using in patients with agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine.

## Adverse Effects

There is limited information available on the adverse effect profile of tiopronin in dogs. In a retrospective study evaluating tiopronin treatment for cystinuria in about 16% of treated dogs, proteinuria, thrombocytopenia, anemia, increased liver enzymes and bile acids, lethargy, dermatologic effects (small pustules of the skin, dry crusty nose) aggressiveness, sulfur odor of the urine, or myopathy (noted as staggering and difficulty chewing) were noted (Hoppe & Denneberg 2001). Tiopronin has been associated with Coombs'-positive regenerative spherocyte anemia in dogs. Should this effect occur, the drug should be discontinued and appropriate treatment started (corticosteroids, blood component therapy) as needed.

While tiopronin is thought to have fewer adverse effects than penicillamine in humans, adverse effects that occur more frequently include dermatologic effects (ecchymosis, itching, rashes, mouth ulcers, jaundice) and GI distress; less frequently allergic reactions (specifically adenopathy), arthralgias, dyspnea, fever, hematologic abnormalities, edema, and nephrotic syndrome.

## Reproductive/Nursing Safety

There is limited information on the reproductive safety of tiopronin. Skeletal defects, cleft palates and increased resorptions were noted when rats were given 10 times the human dose of penicillamine and, therefore, may also be of concern with tiopronin. Other animal studies have suggested that tiopronin may affect fetus viability at high doses. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Because tiopronin may be excreted in milk, at present it is not recommended for use in nursing animals.

## Overdosage/Acute Toxicity

There is little information available. It is suggested to contact an animal poison control center for further information in the event of an overdose situation.

## Drug Interactions

Potentially use of tiopronin with **other drugs causing nephrotoxicity, hepatotoxicity, or bone marrow depression** could cause additive toxic effects. Clinical significance is not clear.

## Doses

### ■DOGS:

For treatment or prevention of recurrence of cystine urinary calculi:

a) Prophylactic treatment: 30 mg/kg PO q12h. Increase water intake and urine diuresis. Alkalinize urine (pH 6.5–7.0) using potassium citrate. In cases with low cystine excretion and low urolith recurrence rate, tiopronin dose may be individually decreased (<30 mg/kg) or stopped.

Dissolution of uroliths: Approximately 40 mg/kg PO q12h. Reevaluation of uroliths with ultrasound or radiography every 4<sup>th</sup> week. After urolith dissolution, give prophylactic dose of tiopronin. If urolith dissolution is not achieved after 2–3 months, surgery is recommended. Reexamination recommended 1, 3, 6, & 12 months after start of treatment and thereafter twice a year, including: physical examination, ultrasonography/radiography of the urinary tract, urinalyses (specific gravity, protein, pH, sediment, and cyanide nitroprusside reaction) using AM samples of urine, CBC (with platelets), liver enzymes (alkaline phos, ALT). Quantitative measurements of urinary cystine excretion related to the urinary creatinine excretion, AM urine samples, before start of treatment and once a year during treatment. If adverse reactions occur, stop treatment for 4 weeks. Blood and urine analysis every 1-2 weeks until remission of signs. When the adverse reactions disappear, start tiopronin again, gradually increasing the dose from 10–15 mg/kg q12h. If the adverse reactions reappear despite a lowered dose, tiopronin treatment has to be abandoned. (Hoppe & Denneberg 2001)

b) In conjunction with an alkalinizing, protein and sodium restricted diet (*e.g., u/d*®), 30–40 mg/kg PO divided into two daily doses. (Cowan 1994)

c) Treatment: 20 mg/kg PO twice daily for 1–3 months; relatively high incidence of adverse effects; Prevention: 15 mg/kg PO twice daily. (Adams & Syme 2005)

## Monitoring

■ See the recommendations for monitoring in the dose section (Hoppe and Denneberg reference)

## Client Information

■ Clients should be counseled on the importance of adequate compliance with this drug to maximize efficacy and detailed on the clinical signs to watch for regarding adverse effects.

## Chemistry/Synonyms

A sulfhydryl compound related to penicillamine, tiopronin has a molecular weight of 163.2. It occurs as a white crystalline powder that is freely soluble in water.

Tiopronin may also be known as: SF 522, N-(2-Mercaptopropionyl)-glycine (MPG), 2-MPG, thiopronine, *Acadione*®, *Captimer*®, *Epatiol*®, *Mucolysin*®, *Mucosyr*®, *Sutilan*®, *Thiola*®, *Thiosol*®, or *Tioglis*®.

## Storage/Stability

Store tablets at room temperature in tight containers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Tiopronin Tablets: 100 mg; *Thiola*® (Mission); (Rx)

## TOBRAMYCIN SULFATE

(toe-bra-mye-sin) Nebcin®, TOBI®

AMINOGLYCOSIDE ANTIBIOTIC

### Prescriber Highlights

• Parenteral aminoglycoside antibiotic that has “good” activity against a variety of bacteria, predominantly gram-negative aerobic bacilli, also in ophthalmic preps

• Because of potential adverse effects usually reserved for serious infections when given systemically, may be less nephrotoxic than gentamicin

- **Adverse Effects: Nephrotoxicity, ototoxicity, neuromuscular blockade**
- **Cats may be more sensitive to toxic effects**
- **Risk factors for nephrotoxicity: Preexisting renal disease, age (both neonatal & geriatric), fever, sepsis, & dehydration**

## Uses/Indications

While most veterinarians use gentamicin or amikacin and there are no FDA-approved veterinary tobramycin products in the U.S., tobramycin can be useful clinically to treat serious gram-negative infections in most species. It is often used in settings where gentamicin-resistant bacteria are a clinical problem. The inherent toxicity of the aminoglycosides limit their systemic use to serious infections when there is either a documented lack of susceptibility to other less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Whether tobramycin is less nephrotoxic than either gentamicin or amikacin when used clinically is controversial. Laboratory studies indicate that in a controlled setting in laboratory animals, it may indeed be so.

## Pharmacology/Actions

Tobramycin, like the other aminoglycoside antibiotics, act on susceptible bacteria presumably by irreversibly binding to the 30S ribosomal subunit thereby inhibiting protein synthesis. It is considered a bactericidal antibiotic.

Tobramycin's spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *E. coli*, Klebsiella, Proteus, *Pseudomonas*, *Salmonella*, Enterobacter, Serratia, Shigella, Mycoplasma, and Staphylococcus.

Antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment.

The aminoglycoside antibiotics are inactive against fungi, viruses and most anaerobic bacteria.

## Pharmacokinetics

Tobramycin, like the other aminoglycosides, is not appreciably absorbed after oral or intrauterine administration, but it is absorbed from topical administration (not skin or urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. Subcutaneous injection results in slightly delayed peak levels and more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

The pharmacokinetics of tobramycin in horses has been reported (Hubenov *et al.* 2007). Approximate values are (**Note:** First value is calculated value from a microbiologic assay and second from an HPLC assay): volume of distribution (steady-state): 0.24-0.55 L/kg; clearance: 101-130 mL/kg/hr; elimination half-life: 2.5-4 hours.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids, and high levels are found in sputum, bronchial secretions and bile. Aminoglycosides (other than streptomycin) are minimally protein bound (<20%) to plasma proteins. Aminoglycosides do not readily cross the blood-brain barrier nor penetrate ocular tissue. CSF levels are unpredictable and range from 0-50% those found in the serum. Therapeutic levels are found in bone, heart, gallbladder and lung tissues after parenteral dosing. Aminoglycosides tend to accumulate in certain tissues such as the inner ear and kidneys, which may help explain their toxicity. Aminoglycosides cross the placenta and fetal concentrations range from 15-50% those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

## Contraindications/Precautions/Warnings

Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections, there are no other absolute contraindications to their use; however, they should be used with extreme caution in patients with preexisting renal disease with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis, and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in "working" dogs (*e.g.*, "seeing-eye", herding, dogs for the hearing impaired, etc.).

Aminoglycosides should be used with caution in patients with neuromuscular disorders (*e.g.*, myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are generally considered contraindicated in rabbits/hares as they adversely affect the GI flora balance in these animals.

## Adverse Effects

The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity normally manifests by increases in BUN, creatinine, nonprotein nitrogen in the serum and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest with either auditory and/or vestibular clinical signs and may be irreversible. Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but either form can occur with any of the drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain or inflammation at the injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs, hematologic, and hepatic effects have been reported.

## Reproductive/Nursing Safety

Tobramycin can cross the placenta and concentrate in fetal kidneys and while rare, cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Total irreversible deafness has been reported in some human babies whose mothers received tobramycin during pregnancy. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Small amounts of aminoglycoside antibiotics are excreted in milk, but are unlikely to cause clinically significant effects in nursing offspring.

## Overdosage/Acute Toxicity

Should an inadvertent overdosage be administered, three treatments have been recommended: 1) Hemodialysis is very effective in reducing serum levels of the drug, but is not a viable option for most veterinary patients; 2) Peritoneal dialysis also will reduce serum levels, but is much less efficacious; 3) Complexation of drug with either carbenicillin or ticarcillin (12-20 grams/day in humans) is reportedly nearly as effective as hemodialysis.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tobramycin and may be of significance in veterinary patients:

■ **BETA-LACTAM ANTIBIOTICS (penicillins, cephalosporins):** May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides *in vitro* (do not mix together) and *in vivo* (patients in renal failure)

■ **CEPHALOSPORINS:** The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).

■ **DIURETICS, LOOP (e.g., furosemide, torsemide) or OSMOTIC (e.g., mannitol):** Concurrent use with loop or osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides

■ **NEPHROTOXIC DRUGS, OTHER (e.g., cisplatin, amphotericin B, polymyxin B, or vancomycin):** Potential for increased risk for nephrotoxicity

■ **NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL:** Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

## Laboratory Considerations

■ Tobramycin serum concentrations may be falsely decreased if the patient is also receiving **beta-lactam antibiotics** and the serum is stored prior analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough level.

## Doses

**Note:** There is significant inter-patient variability in aminoglycoside pharmacokinetic parameters. To insure therapeutic levels and to minimize the risks for toxicity development, consider monitoring serum levels for this drug. Like other aminoglycosides, most now recommend dosing mammals once daily; consider giving the total daily dose as a single dose (e.g., if dose listed is 2 mg/kg q8h, give 6 mg/kg once daily).

#### ■ DOGS/CATS:

For small animals, one pair of authors (Aronson and Aucoin 1989) make the following recommendations with regard to minimizing risks of toxicity, yet maximizing efficacy:

1. Dose according to animal size. The larger the animal, the smaller the dose (on a mg/kg basis).
  2. The more risk factors (age, fever, sepsis, renal disease, dehydration) the smaller the dose.
  3. In old patients or those suspected of renal disease, increase dosing interval from q8h to q16–24h.
  4. Determine serum creatinine prior to therapy and adjust by changes in level even if it remains in “normal range.”
  5. Monitor urine for changes in sediment (e.g., casts) or concentrating ability. Not very useful in patients with UTI.
  6. Therapeutic drug monitoring is recommended when possible.
- a) 2 mg/kg IV, IM, or SC q8h (avoid use or reduce dosage in patients with renal failure; recommend therapeutic drug monitoring, particularly in young animals) (Vaden & Papich 1995)
- b) For susceptible UTI: 1–2 mg/kg SC q8h (Brovida 2003)
- c) For sepsis: 2–4 mg/kg IV three times daily (q8h) (Tello 2003)
- d) Dogs:
- For soft tissue, systemic infections: 1–1.7 mg/kg IV q8h or 3–5.1 mg/kg IV q24h for less than 7 days;
  - For systemic infections: 2 mg/kg SC q8–12h or 4–6 mg/kg SC q24h for less than 7 days;
  - For persistent bacteremia: 3–5 mg/kg IV, IM, SC q8h or 9–15 mg/kg IV, IM or SC q24h for 7 days or less. (Greene *et al.* 2006)
- e) Cats:
- For soft tissue, systemic infections: 2 mg/kg IV, IM or SC q12h or 4 mg/kg IV, IM, SC q24h for 5 days or less;
  - For persistent bacteremia: 2 mg/kg IV, IM, SC q8h or 6 mg/kg IV, IM or SC q24h for 5 days or less. (Greene *et al.* 2006)

#### ■ HORSES:

For susceptible infections:

- a) Based upon a limited pharmacokinetic study (6 horses): The repeated dosing of 4 mg/kg q24h will result in the same concentration profile every day as no accumulation takes place, with the exception of a possible trapping in proximal tubule cells. These data suggest that the this dose will allow achievement of C<sub>max</sub>/MIC ratio higher than 10 for pathogen strains with a MIC of 1 microgram/mL. Further studies are required to define the real breakpoint values for C<sub>max</sub>/MIC ratio for tobramycin not only in healthy horses, but also in diseased animals. (Hubenov *et al.* 2007)

#### ■ LLAMAS:

For susceptible infections:

- a) 4 mg/kg IV q24h; 0.75 mg/kg IV q8h (Baird 2003)

#### ■ BIRDS:

For susceptible infections:

- a) 5 mg/kg IM every 12 hours (Bauck & Hoefler 1993)
- b) 2.5–5 mg/kg/day; must be given parenterally (Flammer 2003)

#### ■ REPTILES:

For susceptible infections:

- a) 2.5 mg/kg once daily IM (Gauvin 1993)

### Monitoring

- Efficacy (cultures, clinical signs associated with infection)
- Renal toxicity; baseline urinalysis, and serum creatinine/BUN. Casts in the urine are often the initial sign of impending nephrotoxicity. Frequency of monitoring during therapy is controversial, but daily urinalysis and serum creatinine may not be too frequent.
- Gross monitoring of vestibular or auditory toxicity is recommended
- Serum levels if possible

### Client Information

- With appropriate training, owners may give subcutaneous injections at home, but routine monitoring of therapy for efficacy and toxicity must still be done
- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication

### Chemistry/Synonyms

An aminoglycoside derived from *Streptomyces tenebrarius*, tobramycin occurs as a white to off-white, hygroscopic powder that is freely soluble in water and very slightly soluble in alcohol. The sulfate salt is formed during the manufacturing process. The commercial injection is a clear, colorless solution and the pH is adjusted to 6–8 with sulfuric acid and/or sodium hydroxide.

Tobramycin Sulfate may also be known as: tobramycin sulphate, *Brulamycin*®, *Gernebcin*®, *Mytobrin*®, *Nebcina*®, *Nebcine*®, *Nebicina*®, *Obracin*®, *Tobra*®, *Tobra Gobens*®, *TOBI*®, *Tobra Laf*®, *Tobra-cell*®, *Tobracil*®, *Tobradistin*®, *Tobramina*®, *Tobraneg*®, *Tobrasix*®, *Tobrex*®, *Tomycin*®, or *Trazil*®.

### Storage/Stability

Tobramycin sulfate for injection should be stored at room temperature (15–30°C); avoid freezing and temperatures above 40°C. Do not use the product if discolored.

### Compatibility/Compounding Considerations

While the manufacturers state that tobramycin should not be mixed with other drugs, it is reportedly physically **compatible** and stable in most commonly used intravenous solutions (**not** compatible with dextrose and alcohol solutions, Polysal, Polysal M, or Isolyte E, M or P) and **compatible** with the following drugs: aztreonam, bleomycin sulfate, calcium gluconate, cefoxitin sodium, ciprofloxacin lactate, clindamycin phosphate (not in syringes), floxacillin sodium, metronidazole (with or without sodium bicarbonate), ranitidine HCl, and verapamil HCl.

The following drugs or solutions are reportedly physically **incompatible** or only compatible in specific situations with tobramycin: cefamandole naftate, furosemide and heparin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

*In vitro* inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented; see the information in the Drug Interaction and Laboratory Consideration sections.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### HUMAN-LABELED PRODUCTS:

Tobramycin Sulfate Injection: 0.8 mg/mL and 1.2 mg/mL (as sulfate) in 100 mL & 50 mL (respectively) single-dose containers; Solution for Injection: 10 mg/mL in 2 mL vials and 40 mg/mL in 1.5 mL & 2 mL syringes, & 2 mL and 30 mL vials; generic; (Rx)

Tobramycin Sulfate Powder for Injection: 1.2 grams (40 mg/mL after reconstitution), preservative free in 50 mL bulk package vial; generic; (Rx)

Tobramycin solution for inhalation: 16 mg/mL in 5 mL amps; **TOBI®** (Novartis); (Rx)

Also available in ophthalmic preparations.

## TOCERANIB PHOSPHATE

(*toe-ser-a-nib*) Palladia®

TYROSINE KINASE INHIBITOR ANTINEOPLASTIC

### Prescriber Highlights

- Tyrosine kinase inhibitor FDA-approved for grades II or III canine mast cell tumors
- Most common adverse effects are: diarrhea, decreased/loss of appetite, lameness, weight loss and blood in the stool
- Adverse effects can be serious and require treatment pause or dose reduction
- Monitoring essential

---

## Uses/Indications

Toceranib is indicated for the treatment of Patnaik grade II or III, recurrent, cutaneous mast cell tumors with or without regional lymph node involvement in dogs.

Toceranib may prove useful for treating a variety of tumors in dogs, including sarcomas, carcinomas, melanomas, and myeloma. Toceranib as part of metronomic therapy (using low doses of chemotherapy and/or other anti-cancer agents to inhibit tumor angiogenesis and growth) is being investigated.

## Pharmacology/Actions

Toceranib is a small molecule tyrosine kinase inhibitor (TKIs) that selectively inhibits the tyrosine kinase activity of several split kinase receptor tyrosine kinases (RTK), including VEGFR-2 (vascular endothelial growth factor receptor-2), PDGFR-Beta (platelet-derived growth factor receptor-Beta), Kit (stem cell growth factor receptor), among others. These kinases are believed to be involved in growth, pathologic angiogenesis, and metastatic processes of certain tumors. By inhibiting TKIs, toceranib competitively inhibits ATP, preventing receptor phosphorylation and subsequent downstream signal transduction. Toceranib exerts an antiproliferative effect on endothelial cells (*in vitro*) and can induce cell cycle arrest and subsequent apoptosis in tumor cell lines expressing activating mutations in Kit. As canine mast cell tumor growth can be enhanced by activating mutations in Kit, toceranib inhibition can reduce angiogenesis and subsequent growth of these cells.

Calcitriol may enhance the antiproliferative activity of toceranib in dogs with mast cell tumors and investigations exploring this potential are ongoing (Malone *et al.* 2010).

## Pharmacokinetics

Oral bioavailability of toceranib phosphate in dogs is about 77%. The presence of food does not significantly impact absorption. Binding to canine plasma proteins is around 94% and the volume of distribution is very large (>20 L/kg). Terminal elimination half-life is about 17 hours (after IV) and 31 hours (oral). While the metabolic fate of toceranib has not been completely determined, it appears that the drug is metabolized via cytochrome P450 and/or flavin monooxygenase to an N-oxide metabolite.

## Contraindications/Precautions/Warnings

The label lists toceranib contraindications as breeding, pregnant or lactating bitches. Safe use has not been evaluated in dogs less than 24 months of age or weighing less than 5 kg. Because toceranib can cause vascular dysfunction leading to edema and thromboembolism (including pulmonary emboli), wait at least 3 days after stopping drug before performing surgery.

Use caution when handling this medication. See drug company's Client Information Sheet for more details.

When toceranib is used in the presence of systemic mast cell tumors significant mast cell degranulation with resultant adverse effects may result. The manufacturer states that attempt should be made to rule out systemic mastocytosis prior to starting toceranib.

Toceranib can cause clinical signs similar to those seen with aggressive mast cell tumors, when these occur, the drug should be stopped and the patient re-evaluated (Johannes 2010). The package insert has specific monitoring requirements with dosage adjustment or therapy pause guidelines when certain adverse effects (severe diarrhea, GI bleeding) occur or when laboratory monitoring indicates toxicity. Refer to the Monitoring section below, or the package insert for more information.

## Adverse Effects

Most common adverse effects seen with toceranib in dogs include: diarrhea, decreased/loss of appetite, lameness, weight loss and blood in the stool. Severe diarrhea or GI bleeding require immediate treatment and dictate dose interruption or dose reduction (see monitoring below). Other potential adverse effects include muscle cramping, neutropenia, hypoalbuminemia, thromboembolic disease, vasculitis, pancreatitis, nasal depigmentation, change in coat or skin color, epistaxis, seizures and pruritus.

One author (London 2010) suggests starting certain drugs 4-7 days prior to starting toceranib to reduce the likelihood of toxicity. These include antacids (famotidine, omeprazole), an antihistamine (diphenhydramine) and prednisone (to reduce tumor inflammation and possibly decrease mast cell tumor mediators' effects) and sucralfate (if dog has a positive stool hemoccult). Additionally, dogs that experience inappetence or vomiting after therapy has begun, either metoclopramide, ondansetron, or maropitant may be effective. Loperamide can be given on toceranib dosing days help prevent or lessen diarrhea. Others have found metronidazole useful. Another author states that prednisone can be continued after treatment has begun, but should only given on days when toceranib is not given and that NSAIDs and prednisone should never be used together (Garrett 2010).

## Reproductive/Nursing Safety

Toceranib is a likely teratogen and should not be used in pregnant females. It is labeled as contraindicated in breeding, pregnant, or lactating bitches.

## Overdosage/Acute Toxicity

No acute toxicity data was located, but toceranib has a narrow margin of safety. In the event of an acute overdose, consider immediate gut decontamination; contact an animal poison center for further guidance.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving toceranib and may be of significance in veterinary patients:

- **NSAIDS:** The package insert states: to use NSAIDs with caution in conjunction with toceranib due to an increased risk of gastrointestinal ulceration or perforation. However, NSAIDs (e.g., piroxicam) are often sometimes used with toceranib as part of metronomic drug protocols, they should be used with extreme caution in dogs receiving toceranib; and should never be given on the same day as GI toxicity can be exacerbated (London 2010).
- **CYP3A4 INHIBITORS** (e.g., ketoconazole, fluconazole, itraconazole, grapefruit juice, clarithromycin, verapamil): May increase toceranib concentrations. This interaction with toceranib has not been documented in dogs to date and presently is speculative. However, use caution.

## Laboratory Considerations

- None noted.

## Doses

### ■ DOGS:

For Patnaik grade II or III, recurrent, cutaneous mast cell tumors with or without regional lymph node involvement:

- Initial dose 3.25 mg/kg PO every other day (q48h). Dose reductions of 0.5 mg/kg (to a minimum dose of 2.2 mg/kg every other day and dose interruptions (cessation of treatment) for up to two weeks may be utilized, if needed, to manage adverse reactions. May be administered with or without food. Do not split tablets. The package insert has a dosage table to determine the appropriate strength and number of tablets to use for a given dog's weight. (Adapted from label information; *Palladia*®—Pfizer)
- Recent clinical experience with toceranib in dogs suggests that dosing at 2.5–2.75 mg/kg every other day is better tolerated than the higher dose, resulting in less toxicity, better owner compliance, and fewer drug holidays. Some dogs do not tolerate this dosing regimen even at the 2.5 mg/kg dose rate. The author and some other medical oncologists have found that a Monday/Wednesday/Friday schedule of dosing may be better tolerated by some dogs. This may be particularly useful when toceranib is combined with other drugs, such as cyclophosphamide or NSAIDs as part of a metronomic treatment protocol. When a dog cannot tolerate the M/W/F schedule, every third day dosing may be attempted, but this is not ideal and may result in sub-therapeutic drug exposure. (London 2010)

## Monitoring

- CBC, Hematocrit, Serum Albumin, Creatinine, Serum Phosphate. Manufacturer recommends weekly (approximately) veterinary assessment for the first 6 weeks of therapy and every 6 weeks (approximately) thereafter.
- The package insert states: Temporarily discontinue drug if anemia, azotemia, hypoalbuminemia, and hyperphosphatemia occur simultaneously. Resume treatment at a dose reduction of 0.5 mg/kg after 1 to 2 weeks when values have improved and albumin is >2.5 g/dL. Temporary treatment interruptions may be needed if any one of these occurs alone: hematocrit <26%, creatinine ≥2 mg/dL or albumin <1.5 g/dL. Then resume treatment at a dose reduction of 0.5 mg/kg once the hematocrit is >30%, the creatinine is <2.0 mg/dL, and the albumin is >2.5 g/dL. Temporarily discontinue the use of toceranib if neutrophil count is ≤1000/microL. Resume treatment after 1 to 2 weeks at a dose reduction of 0.5 mg/kg, when neutrophil count has returned to >1000/microL. Further dose reductions may be needed if severe neutropenia reoccurs.
- Other laboratory tests that have been suggested for monitoring early (first 6 weeks) include urinalysis, and full chemistry panels
- Adverse Effects (Diarrhea): If ≥4 watery stools/day or ≥ 2 days stop drug until formed stools and institute supportive care. When dosing is resumed, decrease dose by 0.5 mg/kg.
- Adverse Effects (GI-Bleeding): If fresh blood in stool or black tarry stool for > 2 days or frank hemorrhage or blood clots in stool. Stop drug and institute supportive care until resolution of all clinical signs of blood in stool, then decrease dose by 0.5 mg/kg.
- Tumor Size

## Client Information

- In the package insert, the manufacturer states to: “Always provide Client Information Sheet with prescription.” In addition, it is highly recommended to verbally reiterate some of the key points found on the client information sheet, including the sections: “How do I give *Palladia* to my dog?”; “Stop *Palladia* immediately and contact your veterinarian if you notice any of the following changes in your dog”; and “Handling Instructions”.
- May be given with or without food; do not split or crush tablets

## Chemistry/Synonyms

Toceranib phosphate is an idolinone with a molecular weight of 494.46. Toceranib may also be known as: PHA-291639, SU-11654, UNII-59L7Y0530C, toceranibum, or toceranib.

## Storage/Stability

Toceranib phosphate tablets should be stored at controlled room temperature 20–25°C (68–77° F).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Toceranib Phosphate Oral Tablets: 10 mg, 15 mg, 50 mg; *Palladia*® (Pfizer); (Rx)

### HUMAN-LABELED PRODUCTS: None

---

## TOLAZOLINE HCL

(toe-laz-oh-leen) Tolazine®

ALPHA-ADRENERGIC BLOCKER

### Prescriber Highlights

- **Alpha-adrenergic blocker used primarily as a reversal agent for xylazine**
- **Contraindications:** Horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia or shock, hypersensitivity, or with coronary artery or cerebrovascular disease
- **Adverse Effects:** *Horses:* Transient tachycardia; peripheral vasodilatation presenting as sweating & injected mucous membranes of the gingiva & conjunctiva; hyperalgesia of the lips (licking, flipping of lips); piloerection; clear lacrimal & nasal discharge; muscle fasciculations; apprehensiveness

---

## Uses/Indications

Tolazine is FDA-approved and indicated for the reversal of effects associated with xylazine in horses. It has also been used for this purpose in a variety of other species as well, but less safety and efficacy data is available. In humans, the primary uses for tolazoline are: treatment of persistent pulmonary hypertension in newborns, adjunctive treatment and diagnosis of peripheral vasospastic disorders, and as a provocative test for glaucoma after subconjunctival injection.

## Pharmacology/Actions

By directly relaxing vascular smooth muscle, tolazoline has peripheral vasodilating effects and decreases total peripheral resistance. Tolazoline also is a competitive alpha<sub>1</sub> and alpha<sub>2</sub>-adrenergic blocking agent, explaining its mechanism for reversing the effects of xylazine. Tolazoline is rapid acting (usually within 5 minutes of IV administration), but has a short duration of action and repeat doses may be required.

## Pharmacokinetics

After IV injection in horses, tolazoline is widely distributed. Animal studies have demonstrated that tolazoline is concentrated in the liver and kidneys. Half-life in horses at recommended doses is approximately 1 hour.

## Contraindications/Precautions/Warnings

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established and some believe it

should not be used in foals, as adverse reactions and fatalities have been reported.

Tolazoline should be considered contraindicated in patients known to be hypersensitive to it, or with coronary artery or cerebrovascular disease. Humans having any of the above-contraindicated conditions should use extra caution when handling the agent.

### Adverse Effects

In horses given tolazoline that may occur include: transient tachycardia; peripheral vasodilation presenting as sweating and injected mucous membranes of the gingiva and conjunctiva; hyperalgesia of the lips (licking, flipping of lips); piloerection; clear lacrimal and nasal discharge; muscle fasciculations; apprehensiveness. Adverse effects should diminish with time and generally disappear within 2 hours of dosing. The potential for adverse effects increases if tolazoline is given at higher than recommended dosages or if xylazine has not been previously administered.

### Reproductive/Nursing Safety

Safety during pregnancy, in breeding or lactating animals has not been established. It is unknown if the drug enters maternal milk.

### Overdosage/Acute Toxicity

In horses given tolazoline alone (no previous xylazine), doses of 5X recommended resulted in gastrointestinal hypermotility with resultant flatulence and defecation or attempt to defecate. Some horses exhibited mild colic and transient diarrhea. Intraventricular conduction may be slowed when horses are overdosed, with a prolongation of the QRS-complex noted. Ventricular arrhythmias may occur resulting in death with higher overdoses (5X). In humans, ephedrine (NOT epinephrine or norepinephrine) has been recommended to treat serious tolazoline-induced hypotension.

A llama that received 4.3 mg/kg IV and again 45 minutes later (approximately a 5X overdose) developed signs of anxiety, hyperesthesia, profuse salivation, GI tract hypermotility, diarrhea, convulsions, hypotension, and tachypnea. Treatment including IV diazepam, phenylephrine, IV fluids, and oxygen was successful. (Reed *et al.* 2000).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolazoline and may be of significance in veterinary patients:

■ **ALCOHOL:** Accumulation of acetaldehyde can occur if tolazoline and alcohol are given simultaneously

■ **EPINEPHRINE, NOREPINEPHRINE:** If large doses of tolazoline are given with either norepinephrine or epinephrine, a paradoxical drop in blood pressure can occur followed by a precipitous increase in blood pressure

### Doses

#### ■ DOGS/CATS:

For reversal of xylazine effects:

a) 4 mg/kg slow IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; *Tolazine*®—Lloyd Laboratories; New Zealand)

**Note:** If reversal is warranted, the high concentration (100 mg/mL) of the veterinary drug may make accurate dosing difficult; yohimbine or the human-labeled tolazoline product (25 mg/mL) may be safer alternatives than *Tolazine*® (100 mg/mL). **Note:** Tolazoline is not FDA-approved for use in dogs and cats in the USA and the US manufacturer does not recommend its use.

#### ■ HORSES:

For reversal of xylazine effects:

a) 4 mg/kg slow IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; *Tolazine*®—Lloyd Laboratories)

#### ■ LLAMAS/ALPACAS:

For reversal of xylazine effects:

a) 1–2 mg/kg IM or give 50% of initial dose slowly IV or IM and then determine if more is needed. Use with caution IV in camelids. (Wolff 2009)

b) 1–2 mg/kg IV or IM; Caution: acute death has been reported after rapid IV administration of tolazoline at high dosages. (Anderson 2005)

#### ■ BIRDS:

As a reversal agent for alpha2-adrenergic agonists (*e.g.*, xylazine, detomidine, etc.):

a) 15 mg/kg IV (Clyde & Paul-Murphy 2000)

#### ■ DEER:

**Note:** Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)

#### ■ CATTLE:

**Note:** Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)

b) The amount of reversal agent used depends on the dose and time elapsed after administering xylazine. Emergency doses of yohimbine (0.1 mg/kg IV) or tolazoline at 2 mg/kg IM can be administered, but tolazoline should not be administered IV rapidly as this can result in cardiac asystole. When dosed properly the effects of reversal should start to become evident about 10 minutes following IM administration. (Anderson & Abrahamsen 2008)

#### ■ SHEEP & GOATS:

**Note:** Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; *Tolazine*®—Lloyd Laboratories; New Zealand)

b) Small Ruminants: 1–2 mg/kg IM. Give 50% of initial dose slow IV or IM and then determine if more is needed. (Snyder 2009)

### Monitoring/Client Information

■ Reversal effects (efficacy)

■ Adverse effects (see above). Because of the risks associated with the use of xylazine and reversal by tolazoline, these drugs should be administered and monitored by veterinary professionals only.

### Chemistry/Synonyms

An alpha-adrenergic blocking agent, tolazoline HCl is structurally related to phentolamine. It occurs as a white to off-white, crystalline powder possessing a bitter taste and a slight aromatic odor. Tolazoline is freely soluble in ethanol or water. The commercially available (human) injection has pH between 3–4.

Tolazoline HCl may also be known as: benzazoline hydrochloride, tolazolium chloratum, *Prisco*®, *Priscoline*®, *Tolazine*® or *Vaso-Dilatan*®.

### Storage/Stability

Commercially available injection products should be stored between 15–30°C and protected from light.

### Compatibility/Compounding Considerations

The drug is reportedly physically **compatible** with the commonly used IV solutions.

### Dosage Forms/Regulatory Status

## ETERINARY-LABELED PRODUCTS:

Tolazoline HCl Injection: 100 mg/mL in 100 mL multi-dose vials; *Tolazine*® (Lloyd); (Rx). FDA-approved for use in horses; not to be used in food-producing animals.

**HUMAN-LABELED PRODUCTS:** None

---

## TOLFENAMIC ACID

(tole-fen-a-mik) *Tolfedine*®

NONSTEROIDAL ANTIINFLAMMATORY AGENT

### Prescriber Highlights

- NSAID approved for dogs & cats in Canada, Europe
- Available (not in USA) in both oral & injectable dosage forms
- Relatively safe for short-term use

---

## Uses/Indications

Tolfenamic acid may be useful for the treatment of acute or chronic pain and/or inflammation in dogs and acute pain/inflammation in cats. In Europe, it is also approved for use in cattle.

## Pharmacology/Actions

Tolfenamic acid exhibits pharmacologic actions similar to those of aspirin. It is a potent inhibitor of cyclooxygenase, thereby inhibiting the release of prostaglandins. It also has direct inhibition of prostaglandin receptors. Tolfenamic acid has significant anti-thromboxane activity and is not recommended for use pre-surgically because of its effects on platelet function.

## Pharmacokinetics

Tolfenamic acid is absorbed after oral administration. In dogs, peak levels occur from 2–4 hours after dosing. Enterohepatic recirculation is increased if given with food. This can increase the bioavailability, but also creates more variability in bioavailability than when given to fasted dogs. The volume of distribution in dogs is reported to be 1.2 L/kg and it has an elimination half-life of about 6.5 hours. Duration of antiinflammatory effect is 24–36 hours. Dogs with experimentally induced renal failure had significantly increased clearances of the drug presumably via increasing hepatic metabolism or enterohepatic recycling of tolfenamic acid (Lefebvre *et al.* 1997).

## Contraindications/Precautions/Warnings

Tolfenamic acid is contraindicated in animals hypersensitive to it or to other drugs in its class (*i.e.*, meclufenamic acid). Like other NSAIDs, it should not be used in animals with active GI bleeding or ulceration. Use with caution in patients with decreased renal or hepatic function.

## Adverse Effects

Tolfenamic acid is relatively safe when given as recommended in dogs and cats. Vomiting and diarrhea have been reported after oral use. Experimental studies did not demonstrate significant renal or GI toxicity until doses were more than 10 times labeled.

Because of its anti-thromboxane activity and resultant effects on platelet function, tolfenamic acid is not recommended for use pre-surgically.

## Reproductive/Nursing Safety

No specific information was located; like other NSAIDs, tolfenamic acid should be used with caution in pregnancy.

## Overdosage/Acute Toxicity

No specific information was located. It is suggested that if an acute, overdose occurs treatment follows standard overdose procedures (empty gut following oral ingestion, etc.). Supportive treatment should be instituted as necessary and IV diazepam used to help control seizures. Monitor for GI bleeding. Because tolfenamic acid may cause renal effects, monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolfenamic acid or other NSAIDs and may be of significance in veterinary patients:

- **ASPIRIN:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS:** As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tolfenamic acid
- **DIGOXIN:** NSAIDs may increase serum levels
- **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans and potentially could also affect tolfenamic acid levels in dogs
- **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS** (*e.g.*, furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea)
- **WARFARIN:** Closely monitor patients also receiving drugs that are highly bound to plasma proteins (*e.g.*, warfarin), as tolfenamic acid and its active metabolite are 98–99% protein bound in the dog

## Doses

### ■ DOGS:

a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days.

For chronic pain: 4 mg/kg, PO once daily for 3–5 consecutive days per week. The injectable is suggested for the first dose only. (Dowling 2000)

b) First dose: 4 mg/kg SC or IM; follow with tablets at 4 mg/kg PO once daily for 2–4 days. The treatment may be repeated once a week as required, or as recommended by the veterinarian, PO once daily for 3–5 days. (Label information; *Tolfedine*®—Vetoquinol Canada)

### ■ CATS:

a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days. The injectable is suggested for the first dose only. (Dowling 2000)

b) 4 mg/kg PO once daily for 3–5 days or as recommended by the veterinarian. (Label information; *Tolfedine*®—Vetoquinol Canada)

## CATTLE:

a) As registered for use in Australia: As an aid in the treatment of pneumonia and acute mastitis in cattle: Pneumonia: 2 mg/kg by IM injection high in the neck. Treatment may be repeated once only after 48 hours. Mastitis: 4 mg/kg as a single intravenous injection. DO NOT inject cattle other than into muscle tissues high on the side of the neck. Meat withdrawal = 10 days (IM), 4 days (IV); Milk withdrawal = 12 hours (1 milking). (Label Information; *Tolfejec*®—Troy Labs, Australia)

## ■SWINE:

a) As registered for use in Australia: As an aid in the treatment of metritis-mastitis-agalactia in pigs: 2 mg/kg IM once. Meat withdrawal = 6 days. (Label Information; *Tolfejec*®—Troy Labs, Australia)

## Monitoring

- Clinical efficacy
- Adverse effects

## Client Information

- The weekly dosing regimen (3–5 consecutive days per week for dogs) is important to follow to minimize risks of adverse effects
- Report any changes in appetite, water consumption, or GI distress to veterinarian

## Chemistry/Synonyms

A non-steroidal antiinflammatory agent in the anthranilic acid (fenamate) category, tolfenamic acid is related chemically to meclofenamic acid.

Tolfenamic Acid may also be known as: acidum tolfenamicum, *Bifenac*®, *Clotam*®, *Clotan*®, *Fenamic*®, *Flocur*®, *Gantil*®, *Migea*®, *Polmonin*®, *Purfalox*®, *Rociclyn*®, *Tolfamic*®, *Tolfedine*®, *Tolfejec*® or *Turbaund*®.

## Storage/Stability

Unless otherwise labeled, store tolfenamic acid tablets and solution at room temperature.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA.

In Canada, New Zealand, Australia and Europe: Tolfenamic Acid Tablets: 6 mg, 30 mg, 60 mg and Tolfenamic Acid Injection 40 mg/mL are available. Common trade name is *Tolfedine*® (Vetoquinol).

**HUMAN-LABELED PRODUCTS:** None in the USA

## TOLTRAZURIL

(*tole-traz-yoo-riil*) Baycox®

ANTIPROTOZOAL/ANTICOCCIDIAL

### Prescriber Highlights

- Antiprotozoal labeled for treating coccidia in poultry (in Europe)
  - May be considered as an alternative for treating coccidiosis in dogs & cats, oocyst shedding stage of toxoplasmosis in cats, etc.
  - Not commercially available in the USA, must be legally imported
  - Adverse effect profile not well described
- 

## Uses/Indications

Toltrazuril is an antiprotozoal agent that may be considered as an alternative treatment for coccidiosis in dogs and cats, Isospora or Hepatozoon infections, or for treating the oocyst shedding stage of toxoplasmosis in cats. It has also been used as a treatment for overwhelming parasitic loads in lizards (Bearded Dragons).

Toltrazuril has activity against parasites of the genus *Hepatozoon*, but other drugs (*e.g.*, imidocarb, primaquine, doxycycline) are generally used. Toltrazuril can induce initial excellent clinical responses in dogs with American canine hepatozoonosis (ACH), but cannot completely eliminate the parasites, and remission is transient in most dogs.

While toltrazuril has been used to treat equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*, use of FDA-approved products now available (*e.g.*, ponazuril, pyrimethamine/sulfadiazine) is preferred. Toltrazuril has been used in some countries to treat *Isospora suis* in piglets.

## Pharmacology/Actions

Toltrazuril is the parent compound to ponazuril (toltrazuril sulfone). Its mechanism of action is not well understood, but it appears to inhibit protozoal enzyme systems.

Toltrazuril has activity against *Hepatozoon*, *Isospora*, *Sarcocystis*, *Toxoplasma*, and all intracellular stages of coccidia.

## Pharmacokinetics

Little information is available. Toltrazuril is about 50% absorbed after oral consumption in poultry. Highest concentrations are found in the liver; it is rapidly metabolized into the sulfone derivative (ponazuril).

## Contraindications/Precautions/Warnings

Toltrazuril should not be used in patients who have had prior hypersensitivity reactions to it or other triazinone (triazine) antiprotozoals (*e.g.*, ponazuril, diclazuril).

The principle metabolite of toltrazuril reportedly persists in the environment and can contaminate groundwater, however there appears to be little risk for significant environmental contamination when toltrazuril is used in dogs, cats, horses, or other companion animals (pet birds, reptiles).

## Adverse Effects

Toltrazuril appears to be well tolerated in birds. An adverse effect profile in mammals is not well described. Potentially, GI signs could occur. Some horses receiving the related drug ponazuril, developed blisters on their nose and mouth, and some, a rash or hives during field trials.

## Reproductive/Nursing Safety

No reproductive or nursing safety information was located; weigh potential risks versus benefits of use during pregnancy or lactation.

## Overdosage/Acute Toxicity

Very limited information is available. Doses of up to 10X in horses were tolerated without significant adverse effects. 5X overdoses in poultry have been tolerated without clinical signs noted. Decreased water intake has been seen if overdoses are greater than 5X.

children such as overdoses are greater than 5%.

## Drug Interactions

- None reported

## Laboratory Considerations

- No issues were noted.

## Doses

### ■ DOGS:

- For coccidiosis (Cystoisosporosis): 10–20 mg/kg PO one time to all puppies at 3–4 weeks of age will help prevent problems associated with intestinal coccidiosis (Dauguschies *et al.* 2000)
- For coccidiosis: 15 mg/kg PO once daily for 3–6 days (Dubey, J. & Greene 2006)
- For *Isospora* spp. infections: 10–30 mg/kg PO once daily for 1–3 days. (Dubey, J.P. *et al.* 2009)
- For coccidiosis: 20 mg/kg PO once daily for 3 days. (Marks 2007)

### ■ CATS:

- For enteroepithelial cycle of toxoplasmosis (oocyst shedding): 5–10 mg/kg PO once daily for 2 days (Dubey, J. & Lappin 2006)
- For coccidiosis: 30 mg/kg PO once daily for 2–3 days (Greene *et al.* 2006)
- For coccidiosis: 20 mg/kg PO once daily for 3 days. (Marks 2007)

### ■ SHEEP:

- For ovine coccidiosis (*Eimeria ovinoidalis*): Controlled study comparing efficacy against diclazuril: 20 mg/kg PO once. (Mundt *et al.* 2009)

### ■ BIRDS:

- For coccidiosis in raptors: 7 mg/kg PO once daily for 2–3 days (Jones 2004)

### ■ REPTILES:

- For parasitism in Bearded Dragons: 5–15 mg/kg PO once daily for 3 days (Kramer 2006)

## Monitoring

- Clinical efficacy

## Client Information

- Avoid direct contact with this medication; the manufacturer recommends wearing synthetic rubber gloves when handling the 2.5% solution. Wash exposed skin after use.

## Chemistry/Synonyms

Related to other antiprotozoals such as ponazuril, toltrazuril is a triazinone (triazine) antiprotozoal (anticoccidial) agent. The commercially available (in Europe) 2.5% oral solution is an alkaline, clear, colorless to yellow brown solution that also contains triethanolamine 30 mg/mL and polyethylene glycol 80.7 mg/mL. Toltrazuril has a molecular weight of 425.4

Toltrazuril may also be known as Bay-Vi-9142, toltrazurilo, toltrazurilum and *Baycox*®.

## Storage/Stability

The 2.5% solution should be stored at temperatures at 25°C or below.

Dilutions in drinking water more concentrated than 1:1000 (1 mL of the 2.5% solution to 1 liter of water) may precipitate. After dilution, the resulting solution is stable for 24 hours. It is recommended that medicated drinking water not consumed after 24 hours be discarded.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA

In some European countries: Toltrazuril 2.5% (25 mg/mL) for dilution in drinking water in 1 liter bottles; *Baycox*® 2.5% Solution (Bayer); (Rx). FDA-approved for treatment of coccidiosis in poultry. In the UK, slaughter withdrawal is 18 days for poultry. Not for use in birds producing eggs for human consumption.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

**HUMAN-LABELED PRODUCTS:** None

---

## TOPIRAMATE

(*toe-pie-rah-mate*) Topamax®

ANTICONVULSANT

Prescriber Highlights

- Antiseizure medication that may be useful for seizure disorders in dogs, particularly partial seizure activity; may be of benefit in treating cats, but little information available
- Very short half-life in dogs (2–4 hours), but therapeutic activity may persist secondary to high affinity for receptors in brain
- Adverse effect profile may include GI distress, inappetence, & irritability in dogs; in cats, sedation & inappetence have been noted
- Expense may be an issue; generics now available

## Uses/Indications

Topiramate may be useful for treating seizures in dogs, particularly partial seizure activity. It may also be of benefit in treating cats, but little information is available.

## Pharmacology/Actions

While the exact mechanism for its antiseizure action is not known, topiramate possesses three properties that probably play a role in its activity: Topiramate blocks in a time-dependent manner action potentials elicited repetitively by a sustained depolarization of neurons; it increases the frequency that GABA activates GABAA receptors; and it antagonizes the kainite/AMPA receptors without affecting the NMDA receptor subtype. Topiramate's actions are concentration-dependent; effects can first be seen at 1 microMole and maximize at 200 microMoles. Topiramate is a weak inhibitor of carbonic anhydrase isoenzymes CA-II and CA-IV, but it is believed that this effect does not contribute significantly to its antiepileptic actions.

## Pharmacokinetics

In dogs, topiramate is rapidly absorbed after oral administration, but absolute bioavailability varies between 30–60%. Half-life ranges from 2–4 hours after multiple doses (Streeter *et al.* 1995). Comparatively, the half-life in humans is about 21 hours in adults, but shorter in children. In humans, the drug is not extensively metabolized and about 70% is excreted unchanged in the urine.

## Contraindications/Precautions/Warnings

Topiramate is contraindicated in patients hypersensitive to it. It should be used with caution (in humans) with impaired hepatic or renal function.

## Adverse Effects

Because this drug rarely has been used in veterinary patients, an accurate adverse effect profile is not known. In dogs, most prevalent adverse effects reported include GI distress, inappetence, and irritability. In cats, sedation and inappetence have been noted.

In humans, the most likely adverse effects include somnolence, dizziness, nervousness, confusion, and ataxia. Very rarely, acute myopia with secondary angle closure glaucoma has been reported. Incidence of kidney stones is about 2–4 times higher in patients taking topiramate than in the general population. Topiramate can cause a hyperchloremic metabolic acidosis and reduce citrate excretion in the urine thus increasing urine pH leading to calcium phosphate renal calculi.

## Reproductive/Nursing Safety

In humans, the FDA categorizes topiramate as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Teratogenic effects were noted in mice and rats given topiramate at dosages equivalent to those used in humans.

Topiramate enters maternal milk; use with caution in nursing patients.

## Overdosage/Acute Toxicity

Overdoses in humans have cause convulsions, drowsiness/lethargy, slurred speech, blurred and double vision, impaired mentation/ stupor, ataxia, metabolic acidosis, hypotension, agitation, and abdominal pain.

There were 140 exposures to topiramate reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 129 were dogs with 16 showing clinical signs and 11 were cats with 5 showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia and lethargy.

Treatment consists of gut emptying protocols if the ingestion was recent, and supportive therapy. Hemodialysis is effective in enhancing the elimination of topiramate from the body.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving topiramate and may be of significance in veterinary patients:

■ **AMITRIPTYLINE:** Topiramate may increase levels

■ **CARBONIC ANHYDRASE INHIBITORS (acetazolamide, dichlorphenamide, etc.):** Used concomitantly with topiramate, may increase the risk of renal stone formation

■ **CNS DEPRESSANT DRUGS, OTHER:** Other CNS depressant drugs may exacerbate the adverse effects of topiramate

■ **LAMOTRIGINE:** May increase topiramate levels

■ **PHENYTOIN:** May decrease topiramate levels; phenytoin levels may increase

■ **VALPROIC ACID:** May decrease topiramate and VPA levels

## Laboratory Considerations

■ No specific laboratory interactions or considerations were noted. Plasma concentrations of topiramate are usually not monitored in human patients, but therapeutic levels are thought to range from 2–25 mg/L.

## Doses

### ■ DOGS:

a) As an alternative second line anticonvulsant: 5–10 mg/kg PO q12h (Shell 2003)

b) As an alternative treatment for refractory generalized and focal seizures: 5–10 mg/kg PO twice daily (Smith 2002)

c) Initial dose of 2–10 mg/kg PO q12h. (Podell 2006)

d) 5–10 mg/kg PO twice daily; start at the lower dosage to reduce adverse effects. (Kortz 2005)

e) For refractory epilepsy: Presently, the author is using this drug at 2.5–5 mg/kg PO three times daily, but at this stage there is not enough data to know how effective this treatment will be. (Platt 2008)

### ■ CATS:

a) 12.5–25 mg PO (total dose) q8–12h. In author's experience, topiramate has been most useful to treat automatisms (especially running fits) and focal seizure activity. Gradual adaptation in dosing is recommended.

Inappetence is a major adverse effect with higher doses. (Podell 2006; Podell 2008)

## Monitoring

■ Efficacy

■ Adverse effects

## Client Information

■ Clients must understand that the clinical use of this agent is relatively "investigational" in veterinary patients, that it must be dosed often in dogs, and the potential costs

■ Caution clients not to stop therapy abruptly or "rebound" seizures may occur

■ Have clients maintain a seizure diary to help determine efficacy

## Chemistry/Synonyms

A sulfamate-substituted derivative of D-fructose antiepileptic, topiramate occurs as a white crystalline powder with a bitter taste. Its solubility in water is 9.8 mg/mL; it is freely soluble in alcohol.

Topiramate may also be known as: McN-4853, RWJ-17021, *Epitomax*®, *Topamac*®, *Topamax*®, or *Topimax*®.

## Storage/Stability

Topiramate tablets should be stored in tight containers at room temperature (15–30°C; 59–86°F); protect from moisture. Topiramate sprinkle capsules should be stored in tight containers at temperatures below 25°C (76°F); protect from moisture.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Topiramate Tablets: 25 mg, 50 mg & 100 mg; Sprinkle Capsules: 15 mg & 25 mg; *Topamax*® (Janssen); *Topiragen*® (Unsher-Smith); generic: (Rx)

## Laboratory Considerations

Torsemide can affect **serum electrolytes, glucose, uric acid,** and **BUN** concentrations.

## Doses

### ■ DOGS/CATS:

- For adjunctive treatment of refractory congestive heart failure: Injectable furosemide can restore a diuresis in some animals, and torsemide (*now only available PO in the USA*) can also be tried at approximately 0.2–0.3 mg/kg q12-24 hours when other diuretics have become ineffective. (Rush 2008)
- 0.2 mg/kg PO once a day to three times a day. (Atkins 2008)

## Monitoring

- Serum electrolytes, BUN, creatinine, glucose (if diabetic)
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated

## Client Information

- Contact veterinarian if clinical signs of water or electrolyte imbalance occur. Signs such as excessive thirst, lethargy, restlessness, increased urination, GI distress or rapid heart rate may indicate electrolyte or water balance problems.

## Chemistry/Synonyms

Torsemide is a pyridyl sulfonylurea loop diuretic that occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol. The injection (no longer marketed in USA) has a pH >8.3.

Torsemide may also be known as torasemide, AC-3525, AC 4464, BM-02.015, JDL-464, and *Demadex*®. International trade names include *Torem*® and *Unat*®.

## Storage/Stability

Torsemide tablets should be stored below 40°C; preferably between 15–30°C (59–86°F).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance.

**HUMAN-LABELED PRODUCTS:**

Torsemide Oral Tablets: 5 mg, 10 mg, 20 mg, & 100 mg; *Demadex*® (Meda); generic; (Rx)

---

## TRAMADOL HCL

(*tram-ah-doll*) Ultram®

OPIATE-LIKE (*MU*-RECEPTOR) AGONIST

### Prescriber Highlights

- Synthetic *mu*-receptor opiate-like agonist that also inhibits reuptake of serotonin & norepinephrine
- May be useful as an analgesic or antitussive. May take up to two weeks for full analgesic activity in chronic pain states.
- Not a controlled drug in USA, but has some potential for human abuse
- Appears well tolerated in dogs; sedation most likely adverse effect
- Avoid use with SSRIs (*e.g.*, fluoxetine) or MAOIs (*e.g.*, selegiline)
- Relatively inexpensive

---

## Uses/Indications

Tramadol may be a useful alternative or adjunct for the treatment of post-operative or chronic pain or cough in dogs and potentially, other species. When used in combination with NSAIDs, or other analgesic drugs (*e.g.*, amantadine, gabapentin, alpha-2 agonists) it may be particularly useful for chronic pain conditions. Epidurally administered tramadol may also be useful as an analgesic in horses, but no appropriate commercial dosage forms are presently available in the USA.

## Pharmacology/Actions

Tramadol is a centrally acting opiate-like agonist that has primarily *mu*-receptor activity, but also inhibits reuptake of serotonin and norepinephrine. These pharmacologic actions all contribute to its analgesic properties. At least one metabolite (O-desmethyltramadol; ODT; M1) has activity. When compared to tramadol in lab animal studies, M1 is 6 times more potent an analgesic and has 20 times more potency in binding to *mu*-receptors. Naloxone only partially antagonizes the analgesic effects of tramadol.

## Pharmacokinetics

In dogs after oral administration of immediate-release tablets, bioavailability is about 65%, but there is significant interpatient variability. Rectal bioavailability is only about 10%. Volume of distribution is approximately 3.8 L/kg. Total body clearance and half-life are about 55 mL/kg/min and 1.7 hours, respectively. Tramadol is extensively metabolized via several metabolic pathways. At least one metabolite (M1) has agonist activity, but is a minor metabolite in dogs; M1 has a half-life of about 2 hours after oral tramadol administration in dogs.

One study in 8 cats using the immediate release oral tablet, showed high interpatient variability in absorption (with two cats there was not enough data to analyze). The elimination half-life for the parent compound was about 2.5 hours; for the M1 metabolite, 4.5 hours. Neurologic effects (mydriasis, dysphoria) were seen in 25% of cats (2 of 4 females) in the study group and the drug was observed to be unpalatable to cats (Papich & Bledsoe 2007). Another study in 6 cats demonstrated approximate values of: oral bioavailability—60%, volume of distribution (steady-state)—2 L/kg, clearance—12 mL/min/kg, and terminal half-life—191 minutes. Terminal half-life for ODT after oral administration was about 290 minutes (Pypendop & Ilkiw 2007).

In neonatal and weaned foals, tramadol has different pharmacokinetics. After oral administration, higher bioavailability (53% vs. 20%), shorter time to peak concentration (1 hr. vs. 1.25 hr.), and peak levels occurred with

neonatal (2 week old) versus weaned foals (4 months old). Elimination half-life did not significantly differ (approx. 2 hours). The active metabolite (M1; ODT) remained above the reported therapeutic concentration for humans for 3 hours in neonatal foals and 8 hours in weaned foals (Stewart *et al.* 2006). In adult horses, tramadol has relatively poor oral absorption (approx. 14%) and an elimination half-life has been reported to be approximately 2–10 hours, depending on the study. The active metabolite, (m1; ODT) is reported as 4 hours (Cox *et al.* 2010).

### Contraindications/Precautions/Warnings

Tramadol is contraindicated in patients hypersensitive to it or other opioids. The combination product containing acetaminophen is contraindicated in cats.

Use with caution in conjunction with other drugs that can cause CNS or respiratory depression. Because tramadol has caused seizures in humans, it should be used with caution in animals with preexisting seizure disorders or receiving other drugs that may reduce the seizure threshold. Like other opiate-like compounds, tramadol should be used with caution in geriatric or severely debilitated animals. Patients with impaired renal or hepatic function may need dosage adjustments.

While the risk of physical dependence occurring is less than that of several other opiates, it has been reported in humans. The drug should be withdrawn gradually in animals that have received it chronically. While not a controlled substance in the USA, humans can potentially abuse tramadol and significant diversion of the drug reportedly occurs. Veterinarians should be alert to “clients” seeking tramadol for their animals.

Extended-release tablets (generally not currently recommended or used in veterinary patients) must not be broken, crushed or chewed or toxicity could occur.

### Adverse Effects

Tramadol appears to be well tolerated in dogs. Potentially, it could cause a variety of adverse effects associated with its pharmacologic actions, including: CNS effects (excessive sedation, agitation, anxiety, tremor, dizziness), or GI (inappetence, vomiting, constipation to diarrhea).

Very limited information is available on the adverse effects in cats. Dysphoria, mydriasis, and dose avoidance (unpalatability) have been reported.

Approximately 10% of humans receiving the drug develop pruritus. Injectable tramadol may cause respiratory and cardiac depression.

### Reproductive/Nursing Safety

In humans, the FDA categorizes tramadol as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) At dosages 3–15 times usual, tramadol was embryotoxic and fetotoxic in laboratory animals. Tramadol and its active metabolite enter maternal milk in very low levels, but the drug’s safety in neonates has not been established.

### Overdosage/Acute Toxicity

Acute oral overdoses may cause either CNS depressive signs or serotonin syndrome. Lethargy, mydriasis, ataxia and vomiting are most common, but stimulatory signs (tachycardia, tremors, vocalization) may also be seen.

There were 308 exposures to tramadol reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 246 were dogs with 46 showing clinical signs, 60 were cats with 33 showing clinical signs, 1 case involved a bird that showed clinical signs and the remaining 1 case involved a lagomorph that showed no clinic signs. Common findings in dogs recorded in decreasing frequency included sedate, ataxia, agitation, somnolence, and seizures. Common findings in cats recorded in decreasing frequency included mydriasis, hypersalivation, tachycardia, agitation, lethargy, and ataxia.

Treatment is primarily supportive (maintaining respiration, treating seizures with benzodiazepines or barbiturates, etc.). Naloxone may NOT be useful in tramadol overdoses as it may only partially reverse some of the effects of the drug and may, in fact, increase the risk of seizures. Naloxone did not decrease the drug’s lethality in tramadol overdoses given to mice. Cyproheptadine and phenothiazines can be used to treat the stimulatory signs.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tramadol and may be of significance in veterinary patients:

- **DIGOXIN:** In humans, tramadol has been rarely linked to digoxin toxicity
- **MAO INHIBITORS (including amitraz and possibly, selegiline):** Potential for serotonin syndrome; use together should be avoided
- **ONDANSETRON:** In humans, use together may reduce the effectiveness of both drugs
- **QUINIDINE:** May increase tramadol concentrations and decrease M1 (active metabolite) concentrations
- **SAME:** Theoretically, concurrent use of SAME with tramadol could cause additive serotonergic effects
- **SEVOFLURANE:** Pretreatment with tramadol reduced MAC values by approximately 30% in dogs (Seddighi *et al.* 2009), and 40% in cats (Dirikolu *et al.* 2009).
- **SSRI ANTIDEPRESSANTS (fluoxetine, sertraline, paroxetine, etc.):** Can inhibit the metabolism of tramadol to its active metabolites thereby decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures).
- **TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.):** Increased risk for seizures; amitriptyline may inhibit tramadol metabolism
- **WARFARIN:** In humans, increased PT and INR in patients taking tramadol has been reported (relatively rare)

### Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

### Doses

- **DOGS:**
  - a) Current dosing recommendations for dogs are 5 mg/kg PO q6-8h and up to 10 mg/kg PO q6-8h in non-responsive dogs. The efficacy of these dosages has not been evaluated. It is important to remember that maximum analgesic effects may not occur immediately and may be delayed up to 14 days for chronic pain conditions such as cancer and degenerative joint disease. (KuKanich 2010)
  - b) As an analgesic: Recent investigations and clinical use suggest a starting dose of 2–5 mg/kg four times daily. (Hellyer 2006)
  - c) For chronic pain: 2–5 mg/kg PO 2-3 times a day is reasonable for mild pain, although both dose and dosing interval may need to be adjusted for more severe pain. The pharmacokinetics in the dog are somewhat erratic, so the drug is best used as multimodal therapy with NSAIDs or other analgesic drugs. (Grubb 2010)
- **CATS:**
  - a) Based upon the pharmacokinetics of tramadol and O-desmethyltramadol (ODT) in cats, a dose of 2 mg/kg twice daily is a reasonable starting dose. (Boothe 2010)
  - b) Current dosing recommendations for cats is 1–2 mg/kg PO q12h. The efficacy of these dosages has not been evaluated. It is important to remember that maximum analgesic effects may not occur immediately and may be delayed up to 14 days for chronic pain conditions such as cancer and degenerative joint disease. (KuKanich 2010)
  - c) For chronic pain: 1–4 mg/kg PO 2–3 times a day is reasonable for mild pain, although both dose and dosing interval may need to be adjusted for more severe pain. (Grubb 2010)
- **HORSES:**
  - a) In a study of 10 horses with chronic laminitis pain: tramadol at 5 mg/kg PO twice daily for seven days, alone or with ketamine at 0.6 mg/kg/hr IV during six hours each day for the first 3 days of treatment, pain relief was enhanced. (Guedes *et al.* 2009)

### ZOO, EXOTIC, WILDLIFE SPECIES:

For use of tramadol in zoo, exotic and wildlife medicine refer to specific references, including:

- a) *Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005
- b) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

### Monitoring

- Clinical efficacy
- Adverse effects

### Client Information

- May be given with or without food

■ Keep out of reach of children

■ May cause changes in alertness or behavior

■ Clients should understand that the clinical experience with this drug in animals is limited and to report adverse effects to the veterinarian

## Chemistry/Synonyms

A *mu*-receptor opiate agonist, tramadol HCl occurs as a white crystalline powder that is freely soluble in water or alcohol, and very slightly soluble in acetone. Tramadol is not derived from opium nor is it a semi-synthetic opioid, but is entirely synthetically produced.

Tramadol HCl may also be known as: CG-315; CG-315E; tramadoli hydrochloridum; U-26225A; many trade names are available.

## Storage/Stability

Unless otherwise labeled, tramadol tablets should be stored at room temperature 25°C (77°F); excursions permitted to 15–30°C (59–86°F). Dispense in tight, light-resistant containers.

## Compatibility/Compounding Considerations

Tramadol HCl injection 50 mg/mL (not available commercially in the USA) is reportedly **not compatible** when mixed in the same syringe with injectable diazepam, diclofenac sodium, indomethacin, midazolam, piroxicam, phenylbutazone, or lysine aspirin.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Tramadol HCl Oral Tablets (film-coated) 50 mg; *Ultram*® (Janssen); generic; (Rx)

Tramadol HCl Extended-Release Tablets: 100 mg, 200 mg & 300 mg; *Ultram ER*® (Ortho-McNeil); *Ryzolt*® (Purdue Pharma); generic; (Rx). **Note:** Dogs apparently do not absorb this product as well as humans, and potentially could “overdose” if the tablet is chewed.

Tramadol HCl Oral Disintegrating Tablets: 50 mg in UD 30s; *Rybix ODT*® (Victory Pharma); (Rx)

Tramadol is also available in a fixed dose combination of tramadol HCl 37.5 mg and acetaminophen 325 mg tablets. USA trade name is *Ultracet*® (Ortho-McNeil); (Rx). **Warning:** Be certain this combination product is not dispensed for cats.

In several countries (but not the USA), tramadol injection is available commercially.

---

## TRAZODONE HCL

(*traz-oh-done*) Desyrel®

SEROTONIN 2A ANTAGONIST/REUPTAKE INHIBITOR

### Prescriber Highlights

- Antidepressant that may be useful for adjunctive treatment of behavioral disorders (esp. anxiety- or phobia-related) in dogs
- Little research or clinical experience available regarding veterinary use
- Relatively inexpensive

---

## Uses/Indications

Trazodone may be useful in treating behavioral disorders in small animals, particularly as an adjunctive treatment in those patients that do not adequately respond to conventional therapies.

In a retrospective study of 56 dogs (Gruen & Sherman 2008), evaluating trazodone as an adjunctive treatment for anxiety disorders in dogs, it was found to be well tolerated over a wide dose range and enhanced behavioral calming. The authors concluded that further controlled studies are needed to more fully evaluate the pharmacokinetics, safety profile, and efficacy of this drug in dogs.

In humans, trazodone is used for treating depression, aggressive behavior, alcohol or cocaine withdrawal, migraine prevention, and insomnia. It has fewer anticholinergic effects than the tricyclic antidepressants and is among the antidepressants with the lowest seizure risk.

## Pharmacology/Actions

Trazodone is classified as a serotonin 2A antagonist/reuptake inhibitor (SARI) that primarily potentiates serotonin activity in the CNS. In laboratory animals, trazodone selectively inhibits serotonin uptake by brain synaptosomes and potentiates the behavioral changes induced by the serotonin precursor, 5-hydroxytryptophan. In dogs, trazodone exerts qualitatively different and less pronounced cardiac conduction effects than do the tricyclic antidepressants. Trazodone can antagonize alpha-1 adrenergic receptors and reduce blood pressure. As trazodone can antagonize 5-HT2 receptors and cause their down-regulation, it can augment the efficacy of SSRIs (Virga 2010).

## Pharmacokinetics

No information was located regarding the pharmacokinetics of trazodone in dogs. In humans, oral bioavailability of trazodone (immediate-release tablets) is about 65%; presence of food increases absorption (AUC is increased), but decreases C<sub>max</sub> (peak plasma level) and delays T<sub>max</sub> (time of peak level). It is approximately 90–95% bound to plasma proteins. Volume of distribution ranges from 0.47–0.84 L/kg. Metabolism is extensive and occurs primarily in the liver. An active metabolite, m-chlorophenylpiperazine (mCCP) is formed via oxidative cleavage by CYP3A4 that is further metabolized to inactive compounds via CYP2D6. Excretion is mostly (70–75%) via renal mechanisms with only a very small amount (0.13%) excreted unchanged in the urine. About 21% of a dose is excreted in the feces. Elimination half-life of the parent compound is around 7 hours (immediate-release tablets) and 10 hours (sustained-release tablets).

## Contraindications/Precautions/Warnings

Trazodone is contraindicated in patients hypersensitive to it or those receiving MAO inhibitors (including amitraz and possibly, selegiline). It should be used with caution in patients with severe cardiac disease or hepatic or renal impairment.

## Adverse Effects

The adverse effect profile for trazodone in dogs is not well documented. Potential adverse effects include sedation, lethargy, ataxia, cardiac conduction disturbances, increased anxiety, and aggression. In a retrospective study

In 56 dogs (Gruen & Sherman 2008), trazodone adverse effects were in general mild, and only 3 dogs had to have the drug discontinued. Approximately 80% of the dogs in the study had no reported adverse effects. Adverse effects that were reported included: vomiting/gagging (2), behavioral changes (within hours of a dose) be such as getting onto counters (1), or into trash (1), increased excitement (2), sedation (2), increased appetite (2) and colitis (1). Should trazodone be used more extensively in dogs, a more defined adverse effect profile may be discerned.

Trazodone alone is unlikely to cause serotonin syndrome at clinically used dosages, but when used with other serotonergic drugs, it is possible. The most common clinical signs seen with serotonin syndrome in dogs include (in descending order): vomiting, diarrhea, seizures, hyperthermia, hyperesthesia, depression, mydriasis, vocalization, death, blindness, hypersalivation, dyspnea, ataxia/paresis, disorientation, hyperreflexia, and coma (Wismer 2006).

In humans, the most common adverse effects include blurred vision; confusion, dizziness, dry mouth, orthostatic hypotension, sweating, lethargy or somnolence. QT prolongation can occur, but is much less common in humans with trazodone than with the tricyclic antidepressants. Priapism has been reported rarely in men taking trazodone.

### Reproductive/Nursing Safety

Trazodone appears to be relatively safe to use during pregnancy. At very high dosages (15–50X) in rats and rabbits, some increase in fetal death/resorption rates and congenital abnormalities were noted. For humans, the FDA categorizes trazodone as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Tramadol is excreted into milk at very low levels and clinical effects in offspring seem unlikely. However, weigh the potential risks of using this medication versus the benefits in pregnant or nursing animals.

### Overdosage/Acute Toxicity

No specific information was located regarding trazodone overdoses in veterinary patients. In humans, incidence of serious toxicity from trazodone overdose (alone) was low compared with tricyclic antidepressant overdoses. However, in the event of substantial overdose of trazodone, it is recommended to contact an animal poison control center for further guidance.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trazodone and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS:** Trazodone may increase reductions in blood pressure and cause hypotension
- **ASPIRIN:** Increase risk for GI bleeding; monitor
- **AZOLE ANTIFUNGALS (e.g., ketoconazole, fluconazole):** May increase trazodone blood levels
- **CNS DEPRESSANTS:** Use with trazodone may cause additive CNS depressant effects
- **DIGOXIN:** Trazodone may increase digoxin levels
- **MACROLIDE ANTIBIOTCS (e.g., erythromycin, clarithromycin):** May increase trazodone blood levels
- **METOCLOPRAMIDE:** Increased risk for serotonin syndrome
- **NSAIDS:** Increased risk for GI bleeding; monitor
- **PHENOTHIAZINES:** May increase trazodone blood levels; cause additive CNS effects
- **SSRI ANTIDEPRESSANTS (e.g., fluoxetine):** Increased risk for serotonin syndrome. Trazodone is commonly used together with SSRI's, but be alert for signs associated with serotonin syndrome (see adverse effects above).

### Laboratory Considerations

- None noted

### Doses

#### ■ DOGS:

As an adjunctive treatment of anxiety-related disorders:

- a) From a retrospective study of 56 dogs. To allow dogs to become tolerant to the drug and avoid potential gastrointestinal adverse effects, trazodone was begun at an initial dose that was half of the target dose and administered for 3 days. Then the target dose was established as the lowest effective dose needed for behavioral calming. Additional dose increments were made empirically over time.

Weight (kg)	Initial Dosage (total; NOT mg/kg) Range	Target Dosage (total; NOT mg/kg) Range
<10 kg	≤ 25 mg q8-24h	≤ 50 mg q8-24h
≥10-20 kg	50 mg q12-24h	100 mg q8-24h
≥20-40 kg	100 mg q12-24h	200 mg q8-24h
>40 kg	100 mg q12-24h	200–300 mg q8-24h

In the study, the following minimum, maximum and mean daily dosages and dosing frequencies were used:

Daily medication only: 1.9 mg/kg/day–16.2 mg/kg/day (mean = 7.3 mg/kg/day)

As needed only: 2.2 mg/kg/day– 14 mg/kg/day (mean 7.7 mg/kg/day)

Daily medication and as needed: 1.7 mg/kg/day–19.5 mg/kg/day (mean 7.25 mg/kg/day) (Gruen & Sherman 2008)

- b) 1 mg/kg PO q12h for 7 days, then up to 3 mg/kg PO q12h. (Frank 2010)
- c) 1–4.8 mg/kg PO twice daily; (titrate to effect in 1 mg increments every 7 days). (Virga 2010)
- d) In addition to the daily serotonin enhancing medication, trazodone can be used as an adjunctive drug to increase clinical control of anxiety related conditions. It is given about an hour prior to the onset of anxiety and with a typical starting dose between 2–5 mg/kg and adjusting upwards as necessary to get control (maximum dose 14 mg/kg/day). (Neilson 2010)

### Monitoring

- Clinical efficacy and adverse effects

### Client Information

- Preferably give with food
- Clients should understand that trazodone has not been used extensively in dogs and to report any unforeseen adverse effects to the veterinarian

### Chemistry/Synonyms

Trazodone is a triazolopyridine antidepressant agent. It occurs as a white to off-white crystalline powder and is sparingly soluble in water, alcohol, or chloroform.

Trazodone may also be known as AF-1161, trazodona, trazodon, or “sleepy.” A common trade name is *Desyrel*®.

### Storage/Stability

Store between 20-25°C (68-77°F); excursions are permitted to 15-30°C (59-86°F). Keep in an airtight container and protect from light.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Trazodone Oral Tablets: 50 mg, 100 mg, 150 mg, & 300 mg; generic; (Rx)

## TRIAMCINOLONE ACETONIDE

(trye-am-sin-oh-lone) Vetalog®

### GLUCOCORTICOID

#### Prescriber Highlights

- **Oral, parenteral, topical & inhaled glucocorticoid that is 4–10X (some say up to 40X) more potent than hydrocortisone; no appreciable mineralocorticoid activity**
- **Contraindications (relatively): Systemic fungal infections, manufacturer lists: “in viral infections, ... animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, & Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, & active tuberculosis necessitates carefully controlled use.”**
- **If using systemically for therapy, goal is to use as much as is required & as little as possible for as short an amount of time as possible**
- **Primary adverse effects are “Cushingoid” in nature with sustained use**
- **Many potential drug & lab interactions**

---

## Uses/Indications

The systemic veterinary labeled product (*Vetalog® Injection*) is labeled as “indicated for the treatment of inflammation and related disorders in dogs, cats, and horses. It is also indicated for use in dogs and cats for the management and treatment of acute arthritis, allergic and dermatologic disorders.”

In horses, intra-articular (IA) injection of triamcinolone acetonide (TA), particularly in high motion joints is often recommended as studies have demonstrated that IA injection can improve clinical lameness and reduce articular protein, inflammatory cell infiltration, intimal hyperplasia and subintimal fibrosis, and synovial levels of hyaluronan and glycosaminoglycan can be increased. Combining TA with a local anesthetic (*e.g.*, mepivacaine) has been shown not to alter the potency or duration of action of TA and may be useful to both confirm the joint causing lameness and to reduce synovitis (Kay *et al.* 2008). There is some evidence supporting the IA use of TA with hyaluronic acid. In clinically normal horses, IA triamcinolone acetonide diffused directly from the distal interphalangeal joint with or without hyaluronic acid and, after additional studies, may prove to be useful in treating navicular syndrome (Boyce *et al.* 2010).

Intralesional injection of triamcinolone into esophageal strictures has been done in dogs and cats prior to dilation (Richter 2009).

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (*e.g.*, adrenal insufficiency), rheumatic diseases (*e.g.*, rheumatoid arthritis), collagen diseases (*e.g.*, systemic lupus), allergic states, respiratory diseases (*e.g.*, asthma), dermatologic diseases (*e.g.*, pemphigus, allergic dermatoses), hematologic disorders (*e.g.*, thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (*e.g.*, ulcerative colitis exacerbations), and renal diseases (*e.g.*, nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

## Pharmacology/Actions

Triamcinolone acetonide is considered an intermediate acting (metabolic activity of 24-48 hours when given orally) glucocorticoid that is approximately 4-10 times more potent than hydrocortisone. When injected IM, duration of activity may persist for 4-6 (and sometimes up to 8) weeks.

Glucocorticoids have effects on virtually every cell type and system in mammals. For more information, refer to the Glucocorticoid Agents, General Information monograph.

## Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia or hypersensitive to a particular compound. Sustained-release injectable glucocorticoids use is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (*e.g.*, surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy.

## Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP) and polyuria (PU), may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially, more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

## Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas and mammary development.

Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

## Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamcinolone and may be of significance in veterinary patients:

■**AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia

■**ANALGESICS, OPIATE and/or ANESTHETICS, LOCAL (epidural injections):** Combination with glucocorticoids in epidurals has caused serious CNS injuries and death; do not use more volume than very small intrathecal test doses of these agents with glucocorticoids

■**ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration

■**ASPIRIN:** Glucocorticoids may reduce salicylate blood levels

■**BARBITURATES:** May increase the metabolism of glucocorticoids and decrease blood levels

■**CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required

■**CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear

■**DIURETICS, POTASSIUM-DEPLETING (e.g., spironolactone, triamterene):** Administered concomitantly with glucocorticoids may cause hypokalemia

■**ERYTHROMYCIN, CLARITHROMYCIN:** May increase TMC levels

■**ESTROGENS:** The effects of TMC, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens

■**INSULIN:** Insulin requirements may increase in patients receiving glucocorticoids

■**ISONIAZID:** TMC may decrease isoniazid levels

■**KETOCONAZOLE and other AZOLE ANTIFUNGALS:** May decrease the metabolism of glucocorticoids and increase TMC blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis

■**MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency

■**NSAIDS:** Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration

■**PHENOBARBITAL:** May increase the metabolism of glucocorticoids and decrease TMC blood levels

■**RIFAMPIN:** May increase the metabolism of glucocorticoids and decrease TMC blood levels

■**VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoid

■**WARFARIN:** TMC may affect INR's; monitor

### Laboratory Considerations

■ Glucocorticoids may increase **serum cholesterol**

■ Glucocorticoids may increase **serum and urine glucose** levels

■ Glucocorticoids may decrease **serum potassium**

■ Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T<sub>3</sub> & T<sub>4</sub>** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of **I131** by the thyroid may be decreased by glucocorticoids.

■ Reactions to **skin tests** may be suppressed by glucocorticoids

■ False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids

■ Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation

■ Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

### Doses

#### ■**DOGS:**

For glucocorticoid effects:

a) 2 mg PO once daily for 7 days; 0.11–0.22 mg/kg IM or SC (Kirk 1989)

b) For antiinflammatory effects: 0.05 mg/kg PO two to three times daily (Williamson 2003)

c) For tablets: 0.11 mg/kg PO initially once a day, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dose gradually to 0.028–0.055 mg/kg/day. (Package insert; *Vetalog® Tablets*—Solvay)

d) For injectable product: 0.11–0.22 mg/kg for inflammatory or allergic disorders, and 0.22 mg/kg for dermatological disorders. Effects generally persist for 7–15 days; if symptoms recur, may repeat or institute oral therapy.

For intralesional injection: Usual dose is 1.2–1.8 mg; inject around lesion at 0.5–2.5 cm intervals. Do not exceed 0.6 mg at any one site or 6 mg total dose. May repeat as necessary. (Package insert; *Vetalog® Injection*—Solvay)

e) To prevent re-stricture after esophageal dilation: Using an endoscopically directed needle, inject 0.5–1 mL of *Vetalog®* (2 mg/mL) submucosally at time of dilation procedure. Infiltration is done circumferentially at four points around the site. (Marks 2004)

#### ■**CATS:**

a) 0.25–0.5 mg PO once daily for 7 days (Kirk 1989)

b) For pododermatitis, feline plasmacytic pharyngitis: 2–4 mg (total dose) PO once a day or every other day 0.4–0.6 mg/kg PO once daily, then taper. For pemphigus complex: 0.4–0.8 mg/kg/day PO (Williamson 2003)

c) For tablets: 0.11 mg/kg PO initially once a day, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dose gradually to 0.028–0.055 mg/kg/day (Booth 1988), (Package insert; *Vetalog® Tablets*—Solvay)

d) For injectable product: 0.11–0.22 mg/kg for inflammatory or allergic disorders, and 0.22 mg/kg for dermatological disorders. Effects generally persist for 7–15 days; if symptoms recur, may repeat or institute oral therapy.

For intralesional injection: Usual dose is 1.2–1.8 mg; inject around lesion at 0.5–2.5 cm intervals. Do not exceed 0.6 mg at any one site or 6 mg total dose. May repeat as necessary. (Package insert; *Vetalog® Injection*—Solvay)

e) To prevent re-stricture after esophageal dilation: Using an endoscopically directed needle, inject 0.5–1 mL of *Vetalog®* (2 mg/mL) submucosally at time of dilation procedure. Infiltration is done circumferentially at four points around the site. (Marks 2004)

f) For adjunctive treatment of miliary dermatitis: 0.2–0.6 mg/kg PO once daily for 10–14 days, then tapered. (Beale 2008)

#### ■**CATTLE:**

For glucocorticoid effects:

a) 0.02–0.04 mg/kg IM; 6–18 mg intra-articularly. (Howard 1986)

#### ■**HORSES: (Note: ARCI UCGFS Class 4 Drug)**

For glucocorticoid effects:

a) 0.011–0.022 mg/kg PO twice daily;

0.011–0.022 mg/kg IM or SC;

0.014–0.022 mg/kg IM or SC,  
6–18 mg intra-articularly or intrasynovially, may repeat after 3–4 days (Package inserts; *Vetalog® Powder and Injection*—Solvay)

b) For intra-articular injection: 12 mg IA on days 0, 13, 27 (McClure 2002)

## Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

## Chemistry/Synonyms

Triamcinolone acetonide, a synthetic glucocorticoid, occurs as slightly odorous, white to cream-colored, crystalline powder with a melting point between 290–294°C. It is practically insoluble in water, very soluble in dehydrated alcohol and slightly soluble in alcohol. The commercially available sterile suspensions have a pH range of 5–7.5.

Triamcinolone acetonide may also be known as: triamcinoloni acetonidum; many trade names are available.

## Storage/Stability

Triamcinolone acetonide products should be stored at room temperature (15–30°C); the injection should be protected from light.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Triamcinolone Acetonide Tablets: 0.5 mg, 1.5 mg; *Vetalog®* (BIVI), generic; (Rx). FDA-approved for use in dogs and cats.

Triamcinolone acetonide Suspension for Injection: 2 mg/mL; 6 mg/mL; *Vetalog® Parenteral* (BIVI); (Rx). FDA-approved for use in dogs, cats, and horses not intended for food.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Triamcinolone Acetonide Injection: 10 mg/mL suspension & 40 mg/mL suspension in 1 mL, 5 mL and 10 mL vials; *Kenalog-10 & -40* (Bristol-Myers Squibb); (Rx)

Triamcinolone Hexacetonide Injection: 5 mg/mL & 20 mg/mL suspension in 1 mL & 5 mL vials; *Aristospan Intralesional® & Intra-articular®* (Sandoz); (Rx)

Many topical preparations are available, alone and in combination with other agents. Oral mucosal paste & Inhaled products are also FDA-approved. All are Rx.

## TRIAMTERENE

(trye-am-the-reen) Dyrenium®

POTASSIUM-SPARING DIURETIC

### Prescriber Highlights

- **Potassium-sparing diuretic that may be considered as an alternative to spironolactone for treating CHF in dogs; limited clinical experience with this drug in dogs/cats**
- **Contraindications: Anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation**
- **Hyperkalemia possible; must monitor serum K+**

---

## Uses/Indications

Triamterene is a potassium-sparing diuretic that potentially could be used as an alternative to spironolactone for the adjunctive treatment of congestive heart failure in dogs, however, there is little experience associated with its use in dogs or cats.

## Pharmacology/Actions

By exerting a direct effect on the distal renal tubule, triamterene inhibits the reabsorption of sodium in exchange for hydrogen and potassium ions. Unlike spironolactone, it does not competitively inhibit aldosterone. Triamterene increases excretion of sodium, calcium, magnesium and bicarbonate; urinary pH may be slightly increased. Serum concentrations of potassium and chloride may be increased. When used alone, triamterene has little effect on blood pressure. Triamterene can reduce GFR slightly, probably by affecting renal blood flow. This effect is reversible when the medication is discontinued.

## Pharmacokinetics

Pharmacokinetic data for dogs or cats was not located. In humans, triamterene is rapidly absorbed after oral administration and oral bioavailability is about 85%. Onset of diuresis occurs in 2–4 hours and diminishes after about 8 hours. Triamterene is metabolized in the liver to 6-p-hydroxytriamterene and its sulfate conjugate. These metabolites are eliminated in the bile/feces and urine; elimination half-life is about 2 hours.

## Contraindications/Precautions/Warnings

Triamterene is contraindicated for human patients (and presumably dogs and cats) with anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, history of triamterene-induced hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation.

## Adverse Effects

Because triamterene has been infrequently used in veterinary medicine, an accurate adverse effect profile for small animals is not known, however, hyperkalemia is a definite possibility and monitoring of electrolytes and renal function are necessary. In humans, hyperkalemia rarely occurs in patients with normal urine output and potassium intake.

Less common adverse effects reported in humans include headache/dizziness, GI effects, hyponatremia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking

Other common adverse effects reported in humans include headache, dizziness, GI effects, hypokalemia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking triamterene. Other rare adverse effects include triamterene-nephrolithiasis, agranulocytosis, thrombocytopenia, or megaloblastosis.

### Reproductive/Nursing Safety

Studies to determine triamterene's effects on fertility have not been performed.

Studies in pregnant rats given triamterene at 6–20X (human dose) did not show adverse effects to the fetuses. Triamterene crosses the placental barrier. For humans, triamterene is either in FDA category **B** or category **C**, depending on the reference. Category **C** for use during pregnancy states: *Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.* If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Triamterene is distributed into milk. Although unlikely to pose much risk to nursing animals, safety during nursing cannot be assured.

### Overdosage/Acute Toxicity

The oral LD50 for triamterene in mice is 380 mg/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. GI effects or hypotension are also possible. Consider gut emptying protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation, with fluid, electrolyte (especially serum potassium) and acid-base monitoring. Supportive treatment should be initiated if required.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamterene and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **enalapril**, **benazepril**): Increased risks for hyperkalemia
- **ANTIDIABETIC AGENTS** (**insulin**, **oral hypoglycemic agents**): Triamterene may increase blood glucose
- **ANTIHYPERTENSIVE AGENTS**: Possible potentiation of hypotensive effects
- **DIURETICS, POTASSIUM-SPARING** (**spironolactone**, **amiloride**): Increase risk of hyperkalemia; use of these drugs with triamterene in humans is contraindicated
- **LITHIUM**: Triamterene may reduce lithium clearance
- **NSAIDS**: Triamterene with NSAIDs (esp. **indomethacin**) may increase the risks of nephrotoxicity
- **POTASSIUM SUPPLEMENTS or HIGH POTASSIUM FOODS**: Increased risk for hyperkalemia

### Laboratory Considerations

- **Quinidine**: Triamterene may interfere with fluorescent assay of quinidine

### Doses

- **DOGS**:
  - a) For adjunctive treatment of recurrent heart failure associated with chronic mitral valve insufficiency: 1–2 mg/kg PO q12h. Documentation of use is limited; spironolactone is drug of choice. (Haggstrom *et al.* 2005)
  - b) As a diuretic for adjunctive treatment of CHF: 2–(4) mg/kg/day PO (Ware 2003)

### Monitoring

- Serum electrolytes (especially potassium), BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Signs of edema; patient weight, if indicated

### Client Information

- Give this medication with food to help prevent stomach upset
- Urine may develop a bluish hue, this is normal
- Because this medication has not been used very much in dogs or cats; report any unusual effects to the veterinarian

### Chemistry/Synonyms

Triamterene is structurally related to folic acid and occurs as a yellow, odorless, crystalline powder. It is practically insoluble in water and very slightly soluble in alcohol. At 50°C, it is slightly soluble in water. In acidified solutions, triamterene gives off a blue fluorescence.

Triamterene may also be known as NSC-77625, KF-8542, FI-6143, triamteren, trimaterenum, triamtereen, or *Dyrenium*®. International trade names include *Dytac*®, *Dyazide*®, *Maxzide-25*® and *Triteren*®. There are many international trade names for combination products with hydrochlorothiazide.

### Storage/Stability

Triamterene capsules should be stored between 15–30°C (59–86°F) in tight, light-resistant containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

**HUMAN-LABELED PRODUCTS:**

Triamterene Capsules: 50 mg & 100 mg; *Dyrenium*® (SmithKline Beecham); (Rx)

In humans, triamterene is often prescribed as a fixed-dose combination with hydrochlorothiazide. Products include:

Triamterene 37.5 mg/Hydrochlorothiazide 25 mg Tablets and Capsules; generic, *Dyazide*®, *Maxzide-25MG*®; generic; (Rx)

Triamterene 50 mg/Hydrochlorothiazide 25 mg Capsules; generic; (Rx)

Triamterene 75 mg/Hydrochlorothiazide 50 mg Tablets; *Maxzide*®; generic; (Rx)

**TRIENTINE HCL**

(trye-en-teen) Syprine®

CHELATING AGENT

Prescriber Highlights

- Oral copper chelating agent for copper hepatopathy
  - Probably fewer adverse effects than penicillamine, but acute renal failure possible
  - Very limited experience with this drug
  - More expensive than penicillamine; may need to be compounded into smaller dosages
  - Give on an empty stomach
- 

### Uses/Indications

Trientine may be useful for the treatment of copper-associated hepatopathy in dogs, particularly when dogs cannot tolerate the adverse effects (*e.g.*, vomiting) associated with penicillamine.

### Pharmacology/Actions

Trientine is an effective chelator of copper and increases its elimination via urinary excretion. It apparently has a greater affinity for copper in plasma than penicillamine, but penicillamine has a greater affinity for tissue copper.

### Pharmacokinetics

No data was located.

### Contraindications/Precautions/Warnings

Trientine is contraindicated in patients hypersensitive to it. It is not indicated for cystinuria, rheumatoid arthritis, or biliary cirrhosis.

### Adverse Effects

Albeit with limited veterinary experience, trientine has had relatively minimal adverse effects in dogs treated for copper hepatotoxicity, but acute renal failure has been reported. Human patients have developed iron deficiency anemia after taking trientine long-term. There is a chance for topical dermatitis developing if trientine gets on skin; wash off immediately. The drug should be given in a capsule (may need to be compounded) and not sprinkled on food.

### Reproductive/Nursing Safety

Trientine is a potential teratogen. It was teratogenic in rats given doses similar to those for humans and should only be used in pregnancy when the benefits to the mother outweigh the risks to offspring. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in breast milk. Exercise caution when administering to nursing patients.

### Overdosage/Acute Toxicity

Little information is available; a case of a human ingesting 30 grams of trientine without significant morbidity has been reported.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trientine and may be of significance in veterinary patients:

- **IRON:** Iron and trientine inhibit the absorption of one another; if iron therapy is needed, give doses at least 2 hours apart from one another
- **ZINC:** Because trientine may also chelate zinc or other minerals, separate doses as above

### Doses

#### ■ DOGS:

As a chelator for copper hepatotoxicity:

- 10–15 mg/kg PO twice daily; 1–2 hours before a meal (Twedt 1999)
- 10–15 mg/kg PO q12h; give one hour before meals (Johnson 2000)
- 15–30 mg/kg PO twice daily (q12h). Give prior to meals (Richter 2002)

### Monitoring

- Periodic quantitative hepatic copper levels

### Client Information

- While it is preferable to give on an empty stomach, if the drug causes vomiting or lack of appetite give with a small amount of food

### Chemistry/Synonyms

An oral copper chelator, trientine HCl occurs as a white to pale yellow crystalline powder. It is hygroscopic and freely soluble in water.

Trientine HCl may also be known as: MK-0681, 2,2,2-tetramine, trien hydrochloride, triethylenetetramine dihydrochloride, trientine hydrochloride or *Syprine*®.

### Storage/Stability

Store trientine capsules in the refrigerator (2–8°C) in tightly closed containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Trientine HCl Oral Capsules: 250 mg; *Syprine*® (Aton); (Rx)

### TRILOSTANE

(*trye-low-stane*) Vetoryl®

ADRENAL STEROID SYNTHESIS INHIBITOR

## Prescriber Highlights

- **Competitive inhibitor of 3-beta hydroxysteroid dehydrogenase thereby reducing synthesis of cortisol, aldosterone, & adrenal androgens**
  - **May be useful in dogs for treatment of pituitary-dependent hyperadrenocorticism, adrenal dependent hyperadrenocorticism, Alopecia X in Pomeranians & Alaskan malamutes; in cats for treatment of feline pituitary dependent hyperadrenocorticism, & in horses for equine hyperadrenocorticism (HAC)**
  - **Potential adverse effects in dogs include lethargy, inappetence, vomiting, electrolyte abnormalities, & diarrhea**
  - **Rare case reports of hypoadrenocorticism & death**
  - **Expense of treatment may be an issue**
- 

## Uses/Indications

Trilostane may be useful for treating pituitary-dependent hyperadrenocorticism or adrenal dependent hyperadrenocorticism in dogs, feline pituitary-dependent hyperadrenocorticism, and equine hyperadrenocorticism (HAC). It may also be useful in treating Pomeranians with Alopecia X and Alaskan malamutes with adult-onset alopecia.

## Pharmacology/Actions

Trilostane is a competitive inhibitor of 3-beta hydroxysteroid dehydrogenase thereby reducing synthesis of cortisol, aldosterone, and adrenal androgens. Inhibition is reversible and apparently dose dependent.

## Pharmacokinetics

In dogs, orally administered trilostane is rapidly, but erratically absorbed with peak levels occurring between 1.5–2 hours post dose. It is unknown whether the presence of food in the gut significantly alters absorption characteristics. After 18 hours, the drug reportedly returns to baseline levels. Effects on cortisol production apparently last for no more than 20 hours, and more likely wane within 10 hours of dosing. Trilostane is metabolized in the liver to several metabolites including ketotrilostane, which is active.

## Contraindications/Precautions/Warnings

Trilostane is contraindicated in animals hypersensitive to it. It should be used with caution in patients with renal or hepatic impairment. Do not use in pregnant dogs.

When used for controlling clinical signs of Cushing's in dogs with adrenal tumors, trilostane will not shrink the tumor and adrenal glands may actually increase in size during treatment.

## Adverse Effects

Trilostane appears to be relatively well tolerated in dogs, but up to 63% of treated dogs can develop lethargy, mild electrolyte abnormalities (hyponatremia, hyperkalemia), vomiting, diarrhea and inappetence are commonly noted during the first few days of therapy secondary to steroid withdrawal. These effects are usually relatively mild and self-limiting. Withholding the drug for a few days and then giving it every other day for a week may alleviate lethargy and vomiting. Although adrenal suppression caused by trilostane is reversible in most cases, rarely adrenal necrosis and death have occurred in dogs.

In one study of trilostane given to 20 horses with equine Cushing's (McGowan & Neiger 2003), no adverse effects were noted.

## Reproductive/Nursing Safety

Because trilostane can significantly reduce the synthesis of progesterone *in vivo*, it should not be used in pregnancy. Trilostane reportedly (not confirmed) is classified by the FDA as a category X drug (*Contraindicated in pregnancy*).

Information on trilostane levels in maternal milk were not located; use with caution in lactating animals.

## Overdosage/Acute Toxicity

Specific information on trilostane acute toxicity was not located. One source states that trilostane overdoses would be unlikely to threaten life and no clinical signs would be expected. However, blood pressure, hydration status, and electrolyte balance should be monitored. If the animal is stressed, consider giving exogenous corticosteroids short-term. Because the drug's effects are relatively short lived, monitoring of patients without complications should only be required for a few days post ingestion.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trilostane and may be of significance in veterinary patients:

- **ACE INHIBITORS** (*e.g.*, **benazepril**, **enalapril**): Could increase risk for hyperkalemia
- **AMINOGLUTETHIMIDE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **KETOCONAZOLE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **MITOTANE**: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- **POTASSIUM-SPARING DIURETICS** (*e.g.*, **spironolactone**): Could increase risk for hyperkalemia
- **POTASSIUM-SUPPLEMENTS; HIGH POTASSIUM FOODS**: Could increase risk for hyperkalemia

## Laboratory Considerations

- No specific laboratory interactions or considerations were located.

## Doses

### ■ DOGS:

For treatment of canine hyperadrenocorticism (HAC):

- a) The starting dose for the treatment of hyperadrenocorticism in dogs is 2.2–6.7 mg/kg PO once a day with food based on body weight and capsule size. The package insert has a dosing table (Table 1) to help determine the appropriate size and number of capsules to administer.

After approximately 10-14 days at this dose, re-examine the dog and conduct a 4–6 hour post-dosing ACTH stimulation test. If physical examination is acceptable adjust dose according to Table 2 (found in the package insert). Individual dose adjustments and close monitoring are essential. Re-examine and conduct an ACTH stimulation test 10-14 days after every dose alteration. Care must be taken during dose increases to monitor the dog's clinical signs and serum electrolyte concentrations. Once daily administration is recommended. However, if clinical signs are not controlled for the full day, twice daily dosing may be needed. To switch from a once daily dose to a twice daily dose, increase the total daily dose by 1/2 to 1/2 and divide the total amount into two doses given 12 hours apart. (Label Information; *Vetoryl*®—Dechra)

- b) For treatment of canine hyperadrenocorticism (HAC) whether due to adrenal tumor or PDH: Initial therapy at 2–10 mg/kg PO once daily. Adjust dosage per monitoring parameters below. Doses of up to 50 mg/kg/day divided twice daily have been given without untoward side effects. Give with food. Some dogs require twice daily administration.

ACTH stimulation test done at 10–14 days, 30 days and 90 days after starting therapy. ACTH stimulation tests should be performed 4–6 hours post-trilostane dose. Interpret ACTH test in light of physical exam. If ACTH Stim results are <20 nMol/L (0.72 micrograms/dL), then the drug is discontinued for 48–72 hours and then re-started at a lower dosage. If ACTH Stim results are >200 nMol/L (7.2 micrograms/dL), then the dose is increased. If the ACTH Stim results are between these two values and the dog is clinically well-controlled, then no change. If between these two results and the patient appears not to be clinically well-controlled, then the drug may need to be given twice daily. Once the dog is stable, repeat ACTH Stim test every 3–6 months. (Neiger 2004)

- c) Author's (Feldman) experience is that trilostane is not more effective or safer than mitotane and that trilostane is less predictable (under dose, over dose, resolution of signs, or the need for dosing more than once per day) than mitotane.

If using trilostane current recommendation is: Initiate at 1 mg/kg PO once daily and continue for about one week until a veterinary recheck can occur. Have owners collect a small urine sample from their dog

before leaving home the morning of the scheduled recheck prior to trilostane administration. Trilostane should then be given by veterinarian 2-3 hours later. The goal of therapy is an owner who is completely pleased with the response. The urine should be checked, at a minimum, for specific gravity, glucose and urine cortisol:creatinine ratio (UCCR). An ACTH stimulation test should be started at the time that the dog is seen (about 2-3 hours after trilostane dose). The UCCR result should be within the reference interval and the post-ACTH serum cortisol concentration should be between 1.5 and 5.5 micrograms/dL. If the serum cortisol concentration is within that goal and the UCCR is abnormal, the medication should be given twice daily. If the serum cortisol concentration is too high, the trilostane dose should be increased and if the serum cortisol concentration is too low, the dose should be decreased. This approach should be utilized at each recheck until the dog is doing well. (Feldman 2007)

For treatment of Alopecia X:

- In Alaskan Malamutes: 3–3.6 mg/kg PO twice a day for 4–6 months. Three dogs treated; no adverse effects reported. (Leone *et al.* 2005)
- In Miniature poodles and Pomeranians: Average dose was 10.85 mg/kg per day given either once a day or divided twice a day for 4–8 weeks. (Cerundolo *et al.* 2004)

#### ■CATS:

- For treatment of feline hyperadrenocorticism: 7 mg/kg/day divided and given twice daily. Doses of up to 60 mg per cat per day have been used in a small number of cats with PDH. (Greco 2007)
- Treatment with trilostane may improve clinical signs, but cats typically remain diabetic. Effective doses range from 15 mg (total dose) PO once daily to 60 mg (total dose) PO q12h. ACTH stimulation tests should be used to titrate the dose, similar to the protocol for dogs. (Scott-Moncrieff 2010)

#### ■HORSES:

- For treatment of equine Cushing’s syndrome: 0.4–1 mg/kg (total dose 120–240 mg) PO once daily. (McGowan & Neiger 2003)

### Monitoring

- Clinical effects
- Adverse effects
- Serum electrolytes
- Urinalysis including specific gravity, glucose and urine cortisol:creatinine ratio (UCCR)
- ACTH stimulation tests (see doses for recommendations). For long-term monitoring, the manufacturer recommends: Once an optimum dose has been reached, re-examine the dog at 30 days, 90 days and every 3 months thereafter. At a minimum, this monitoring should include a thorough history and physical examination, ACTH stimulation test (conducted 4-6 hours after trilostane administration), and serum biochemical tests (with particular attention to electrolytes, renal and hepatic function). A post-ACTH stimulation test resulting in a cortisol of <1.45 micrograms/dL (<40 nMol/L), with or without electrolyte abnormalities, may precede the development of clinical signs of hypoadrenocorticism. Good control is indicated by favorable clinical signs as well as post-ACTH serum cortisol of 1.45-9.1 micrograms/dL (40-250 nMol/L). If the ACTH stimulation test is <1.45 micrograms/dL (<40 nMol/L) and/or if electrolyte imbalances characteristic of hypoadrenocorticism (hyperkalemia and hyponatremia) are found, trilostane should be temporarily discontinued until recurrence of clinical signs consistent with hyperadrenocorticism and test results return to normal (1.45-9.1 micrograms/dL or 40-250 nMol/L). Trilostane may then be re-introduced at a lower dose.

### Client Information

- Keep out of reach of children and pets
- Trilostane capsules do not require any special safety handling precautions. The manufacturer states: Wash hands after use. Do not empty capsule contents and do not attempt to divide the capsules. Do not handle the capsules if pregnant or if trying to conceive. Clients should report any adverse effects to the veterinarian
- Give the drug with food, unless otherwise directed by veterinarian
- Clients should understand that trilostane is a treatment for the condition and not a cure

### Chemistry/Synonyms

A synthetic steroid analog, trilostane has a molecular weight of 329.4 and its chemical name is 4-alpha, 5-alpha-Epoxy-17-beta-hydroxy-3-oxoandrosterone-2-alpha-carbonitrile. It reportedly is relatively insoluble in water. Trilostane may also be known as: WIN 24540, *Vetoryl*®, *Desopan*®, *Modrastane*® or *Modrenal*®.

### Storage/Stability

Commercially available trilostane capsules should be stored at room temperature in tight, light-resistant containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA.

Trilostane Oral Capsules: 10 mg, 30 mg, & 60 mg packaged in aluminum foil blister cards of 10 capsules; *Vetoryl*® (Dechra); (Rx).

**HUMAN-LABELED PRODUCTS:**

*Modrastane*® is reportedly still an FDA-approved human drug, but was withdrawn from the market in the USA in 1994.

### TRIMEPRAZINE TARTRATE WITH PREDNISOLONE

(trye-mep-ra-zeen) Temaril-P®

PHENOTHIAZINE ANTIHISTAMINE & CORTICOSTEROID

#### Prescriber Highlights

- **Combination phenothiazine antihistamine & corticosteroid used for pruritus & potentially as an antitussive**
  - **Relatively Contraindicated:** Systemic fungal infections, hypovolemia, or shock & in patients with tetanus or strychnine intoxication. **Caution:** Hepatic dysfunction, cardiac disease, active bacterial or viral infections, peptic ulcer, acute psychoses, corneal ulcer, Cushingoid syndrome, diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, general debilitation, very young animals
  - **Primary adverse effects:** Sedation, may cause significant hypotension, cardiac rate abnormalities, hypo- or hyper- thermia, “Cushingoid” effects with sustained use
  - **Many potential drug & lab interactions**
- 

### Uses/Indications

Trimeprazine with prednisolone is used for the treatment of pruritic conditions, especially if induced by allergic conditions. Many dermatologists believe, and there is reasonable evidence to support, that when prednisolone

combined with trimeprazine (*Temaril-P®*), less prednisolone is required to control pruritus. The manufacturer suggests the drug is for use in dogs with pruritic conditions or as an antitussive.

## Pharmacology/Actions

Trimeprazine has antihistaminic, sedative, antitussive, and antipruritic qualities. The veterinary FDA-approved product also has prednisolone in its formulation that provides additional antiinflammatory effects.

## Pharmacokinetics

The pharmacokinetics of trimeprazine have apparently not been studied.

## Contraindications/Precautions/Warnings

The contraindications and precautions of this product follow those of the other phenothiazines and antihistaminic agents. For more information, it is suggested to review the acepromazine and chlorpheniramine monographs.

## Adverse Effects

For trimeprazine, possible adverse reactions include: sedation, depression, hypotension and extrapyramidal reactions (rigidity, tremors, weakness, restlessness, etc.).

Additional adverse effects, if using the product containing steroids include: elevated liver enzymes, weight loss, polyuria/polydipsia, vomiting, and diarrhea. If used chronically, therapy must be withdrawn gradually and Cushing's syndrome may develop.

The manufacturer of the veterinary combination product (*Temaril®-P*) includes the following adverse effects in its package insert: sodium retention and potassium loss, negative nitrogen balance, suppressed adrenocortical function, delayed wound healing, osteoporosis, possible increased susceptibility to and/or exacerbation of bacterial infections, sedation, protruding nictitating membrane, blood dyscrasias. In addition, intensification and prolongation of the action of sedatives, analgesics or anesthetics can be noted and potentiation of organophosphate toxicity and of procaine HCl activity.

## Reproductive/Nursing Safety

The manufacturer of the veterinary combination product (*Temaril®-P*) warns that corticosteroids can induce the first stages of parturition if administered during the last trimester of pregnancy.

## Overdosage/Acute Toxicity

Acute overdosage should be handled as per the acepromazine monograph found at the beginning of the book.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine (a related phenothiazine antihistamine) or prednisolone and may be of significance in veterinary patients:

- **ACE INHIBITORS:** Phenothiazines may increase effects
- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTIDIARRHEAL MIXTURES (e.g., Kaolin/pectin, bismuth subsalicylate mixtures):** May cause reduced GI absorption of oral phenothiazines
- **ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels
- **CISAPRIDE:** Increased risk for cardiac arrhythmias when used with phenothiazines
- **CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.):** May cause additive CNS depression if used with phenothiazines
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
- **DIGOXIN:** Secondary to hypokalemia, increased risk for arrhythmias
- **DIURETICS, POTASSIUM-DEPLETING (furosemide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May increase metabolism
- **ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE:** May decrease metabolism
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of other ulcerogenic drugs with glucocorticoids may increase risk
- **PAROXETINE:** May increase phenothiazine plasma levels
- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids
- **PHENYTOIN:** May increase the metabolism of glucocorticoids
- **RIFAMPIN:** May increase the metabolism of glucocorticoids
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

## Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease serum **potassium**.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T<sub>3</sub>** & **T<sub>4</sub>** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of <sup>131</sup>I by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids or trimeprazine.
- False-negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

## Doses

### ■ DOGS:

- a) For antipruritic and antitussive therapy: Weight up to 10 lb = ½ tab PO twice daily; 11–20 lb = 1 tablet twice daily; 21–40 lb = 2 tablets twice daily; over 40 lb = 3 tablets twice daily. After 4 days reduce dose to ½ of initial dose or to an amount just sufficient to maintain remission of symptoms; adjust as necessary. (Package Insert; *Temaril®-P*—Pfizer)
- b) For treatment of pruritus: 1 tablet per 10 kg of body weight once daily for 3–5 days, then every other day. Giving with an EFA (essential fatty acid) may reduce the dose and frequency, if not the need for, glucocorticoids. (White 2003)
- c) For atopic dermatitis: 1 tablet of *Temaril®-P* per 5 kg body weight q12h for one week, then once daily for one week, then q48h (every other day). (Hillier 2006)

## Monitoring

- Efficacy
- Degree of sedation, and anticholinergic effects

- Adverse effects associated with corticosteroids

## Client Information

- Follow veterinarians dosage recommendations carefully
- Dog's appetite and water consumption may increase
- If side effects are worrisome, contact veterinarian

## Chemistry/Synonyms

A phenothiazine antihistamine related to promethazine, trimeprazine tartrate occurs as an odorless, white, to off-white crystalline powder with a melting range of 160–164°C. Approximately 0.5 gm is soluble in 1 mL water, and 0.05 gram is soluble in 1 mL of alcohol.

Trimeprazine Tartrate may also be known as: trimeprazine tartrate, alimemazine tartrate, *Chemists Own Peetalix*®, *Nedeltran*®, *Panectyl*®, *Repelitin*®, *Temaril*®, *Theralen*®, *Theralene*®, *Theralene*®, *Vallergan*®, or *Variargil*®.

## Storage/Stability

Store trimeprazine products at room temperature (15–30°C); protect tablets from light.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

No single agent trimeprazine products are FDA-approved for veterinary medicine.

Trimeprazine Tartrate 5 mg; Prednisolone 2 mg Tablets; *Temaril-P*® Tablets (Pfizer); (Rx). FDA-approved for use in dogs. Trade name in Canada is *Vanectyl-P*®.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS: None

## TRIPLENNAMINE HCL

(tri-pel-ehn-a-meen) Re-Covr®

ANTIHISTAMINE

### Prescriber Highlights

- **Injectable antihistamine**
  - **Contraindications: Do not give IV to horses**
  - **Adverse Effects: CNS stimulation (if given IV to horses), sedation, depression, ataxia, GI effects (oral use)**
- 

## Uses/Indications

Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects. Tripeleppamine has been used as a CNS stimulant in “Downer cows” when administered slow IV.

## Pharmacology/Actions

Antihistamines (H1-receptor antagonists) competitively inhibit histamine at H1 receptor sites. They do not inactivate or prevent the release of histamine, but can prevent histamine's action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). Tripeleppamine is considered to have moderate sedative activity and minimal anticholinergic activity when compared to other antihistamines.

## Pharmacokinetics

The pharmacokinetics of tripeleppamine have apparently not been thoroughly studied in domestic animals or humans. One study performed in horses and camels (Wasfi *et al.* 2000), showed that after IV administration similar pharmacokinetic profiles were obtained for both species. Terminal elimination half-lives were around 2+ hours; volumes of distribution steady-state approximately 1.5–3 L/kg; protein binding was 80% and total body clearance approximately 1 L/hour/kg.

## Contraindications/Precautions/Warnings

Do not administer Tripeleppamine IV in horses (see Adverse Effects).

## Adverse Effects

CNS stimulation (hyperexcitability, nervousness, and muscle tremors) lasting up to 20 minutes, has been noted in horses after receiving tripeleppamine intravenously. Other effects seen (in all species) include CNS depression, incoordination, and GI disturbances.

## Overdosage/Acute Toxicity

Overdosage of tripeleppamine reportedly can cause CNS excitation, seizures and ataxia. Treat symptomatically and supportively if clinical signs are severe. Phenytoin (IV) is recommended in the treatment of seizures caused by antihistamine overdose in humans; barbiturates and diazepam are generally avoided.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tripeleppamine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER:** Increased sedation can occur if chlorpheniramine is combined with other CNS depressant drugs
- **HEPARIN, WARFARIN:** Antihistamines may partially counteract the anti-coagulation effects of heparin or warfarin.

## Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to **antigen skin testing**. In humans, it is suggested that antihistamines be discontinued at least 4 days prior to testing.

## Doses

It is recommended to warm the solution to near body temperature before injecting; give IM injections into large muscle areas. **Note:** Oral dosage forms may no longer be obtainable.

## ■DOGS:

- a) 1mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)

## ■CATS:

- a) 1 mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)

## ■CATTLE:

- a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IV (for more immediate effect) or IM q6–12h as needed (Package Insert; *Re-Covr*®—Solvay)
- b) As adjunctive treatment in “Downer Cow Syndrome” as a CNS stimulant: 0.5 mg/kg slow IV in conjunction with parenteral mineral treatment (Caple 1986)
- c) 1 mg/kg IV or IM (Howard 1986)

## ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

- a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IM q6–12h as needed (Package Insert; *Re-Covr*®—Solvay)
- b) 1 mg/kg IM (Robinson 1987)

## ■SWINE:

- a) 1 mg/kg IV or IM (Howard 1986)

## Monitoring

- Clinical efficacy
- Adverse effects

## Chemistry/Synonyms

An ethylenediamine-derivative antihistamine, tripeleonnamine HCl occurs as a white, crystalline powder that will slowly darken upon exposure to light. It has a melting range of 188–192°C and pKas of 3.9 and 9.0. One gram is soluble in 1 mL of water or 6 mL of alcohol.

Tripeleonnamine HCl may also be known as: tripeleonnaminium chloride, *Azaron*®, *Etono*®, *Fenistil*®, *PBZ*®, *Pelamine*®, *Pyribenzamine*®, *Re-Covr*® or *Vaginex*®.

## Storage/Stability

Store the injection at room temperature and protect from light; avoid freezing or excessive heat.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Tripeleonnamine HCl for Injection: 20 mg/mL in 20 mL, 100 mL, and 250 mL vials; *Re-Covr*® (Fort Dodge) Note: This product is still listed as FDA-approved, but may not be available commercially; generic (various manufacturers and trade names); (Rx). Tripeleonnamine HCl injection is FDA-approved for use in cattle and horses. Treated cattle must not be slaughtered for food purposes for 4 days following the last treatment. Milk must not be used for food for 24 hours (2 milkings) after treatment. No specific tolerance for residues has been published.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS: None

## TRYPAN BLUE

(*trip-ann bloo*)

ANTI-BABESIAL AGENT; OPHTHO SURGERY DYE

### Prescriber Highlights

- Uncommonly used alternative treatment for babesia (*B. canis*) in dogs that can rapidly alleviate clinical signs, but does not eliminate parasite
  - Must follow-up treatment with other antibabesial drugs (*e.g.*, diminazene, imidocarb)
  - Must be given IV
  - Will stain all body tissues and secretions for several weeks
  - Likely teratogen when used systemically
- 

## Uses/Indications

Trypan blue was among the first agents used to treat Babesia. It may be useful as an adjunctive treatment for dogs with mild, to moderate signs of infection with babesiosis (*B. canis*). Some have recommended its use in dogs with severe infections as it does not possess imidocarb’s anticholinergic effects or the CNS toxic effects of some of the other diamidine drugs (*e.g.*, diminazene, pentamidine). Trypan blue suppresses parasitemia and can alleviate clinical signs, but it does not eliminate the infection and results can be variable. Other treatments (*e.g.*, imidocarb, diminazene) must be used within a month of trypan blue to be curative (Greene & Ewing 2006; Taboada & Lobetti 2006). In a study comparing the effects of trypan blue and diminazene on hematocrit and parasitemia in dogs with clinically mild to moderate, uncomplicated babesiosis, there were no significant differences between diminazene and trypan blue on hematocrit or parasite clearance (Jacobson *et al.* 1996).

Trypan blue is also used as a dye in eye surgery to stain the anterior capsule of the lens and the epiretinal membranes.

## Pharmacology/Actions

Trypan blue blocks the C3b receptor on both the erythrocyte membrane and the Babesia organism and likely prevents the parasite from entering the erythrocyte.

## Pharmacokinetics

No information was located.

## Contraindications/Precautions/Warnings

As trypan blue is a known teratogen it should be used during pregnancy in dogs only when the benefits to the dam outweigh the potential effects on puppies.

## Pharmacology/Actions

While tulathromycin is a macrolide antibiotic such as erythromycin or azithromycin, it is structurally unique in that it has three amine groups (tribasic), while erythromycin and azithromycin have one (monobasic) and two (dibasic) groups, respectively. The tribasic group of compounds are called triamilide macrolides.

It is believed that tulathromycin's tribasic structure allows it to better penetrate gram-negative pathogenic bacteria and its low affinity for bacterial efflux pumps may allow the drug to remain and accumulate within the bacteria.

The mechanism of action of tulathromycin is similar to other macrolides in that it inhibits protein synthesis by penetrating the cell wall and binding to the 50S ribosomal subunits in susceptible bacteria. It is considered a bacteriostatic antibiotic, but it possesses some bactericidal activity as well, particularly for *Mannheimia haemolytica* and *Pasteurella multocida*.

Tulathromycin's efficacy is probably enhanced by its ability to accumulate and be released by host phagocytic cells. Neither time-dependent nor concentration-dependent models may accurately predict or describe the drug's efficacy. Some modern macrolides (*e.g.*, azithromycin) efficacy may be more predictive by assessing the total drug exposure to the pathogen; the AUC:MIC ratio may be helpful.

Bacterial isolates susceptible to tulathromycin at concentrations of 16 micrograms/mL or less are reported as susceptible to tulathromycin. The MIC<sub>90</sub> values reported for *M. haemolytica* and *P. multocida* in cattle with BRD are 2 micrograms/mL and 1 microgram/mL, respectively. To date, resistance development to tulathromycin has not been a major problem.

## Pharmacokinetics

In feeder calves given 2.5 mg/kg SC (in the neck), tulathromycin is rapidly and nearly completely absorbed (bioavailability >90%). Peak plasma concentrations generally occur within 15 minutes after dosing. Volume of distribution is very large (approximately 11 L/kg) and total systemic clearance is approximately 170 mL/hr/kg. This extensive volume of distribution is largely responsible for the long elimination half-life of this compound. In plasma, elimination half life is approximately 2.75 days, but in lung tissue it is about 8.75 days. Tulathromycin is eliminated from the body primarily unchanged via biliary excretion.

Following intramuscular administration to feeder pigs at a dosage of 2.5 mg/kg, tulathromycin is readily and rapidly absorbed (bioavailability 88%) with peak levels occurring in about 15 minutes. Tulathromycin rapidly distributes into body tissues, and the volume of distribution is 13–15 L/kg. Plasma half-life is approximately 60–90 hours, but lung tissue half life is about 5.9 days. Tulathromycin is eliminated from the body primarily unchanged via the feces and urine.

## Contraindications/Precautions/Warnings

Tulathromycin is contraindicated in animals with a prior hypersensitivity reaction to the drug.

Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in pre-ruminating calves. Do not use in calves to be processed for veal.

Swine intended for human consumption must not be slaughtered within 5 days from the last treatment.

## Adverse Effects

At labeled doses, adverse effects appear to be minimal in cattle and swine. Transient hypersalivation has been reported and one feeder calf in field studies developed transient dyspnea. Injection site reactions are most commonly reported and there have been some reports to the FDA's Adverse Drug Reporting database of anorexia in cattle.

Hypersensitivity reactions are possible, but no reports were located.

Subcutaneous or intramuscular injection can cause a transient local tissue reaction that may result in trim loss at slaughter.

## Reproductive/Nursing Safety

Reproductive safety is not known, the product is labeled: "The effects of *Draxxin*® on bovine (and porcine) reproductive performance, pregnancy and lactation have not been determined.

## Overdosage/Acute Toxicity

In cattle (feeder calves), single subcutaneous doses of up to 25 mg/kg caused transient indications of pain at the injection, including head shaking and pawing at the ground. Injection site swelling, discoloration of the subcutaneous tissues at the injection site and corresponding histopathologic changes were seen in animals in all dosage groups.

In swine, single IM doses of up to 25 mg/kg caused transient indications of pain at the injection site, restlessness, and excessive vocalization. Tremors occurred briefly in one animal receiving 7.5 mg/kg BW.

No systemic treatment for single overdoses should be necessary, localized treatment at the injection site (*e.g.*, ice pack) to reduce swelling and pain as well as FDA-approved analgesic medications can be considered.

## Drug Interactions

■ No drug interactions are noted in the manufacturer's label and none could be found in other references for tulathromycin.

## Laboratory Considerations

■ No concerns were noted

## Doses

### ■ CATTLE:

For labeled indications:

a) Inject subcutaneously as a single dose in the neck at a dosage of 2.5 mg/kg (1.1 mL/100 lb) body weight (BW). Do not inject more than 10 mL per injection site. (Label directions; *Draxxin*®—Pfizer)

### ■ SWINE:

For labeled indications:

a) Inject intramuscularly as a single dose in the neck at a dosage of 2.5 mg/kg (0.25 mL/22 lb) BW. Do not inject more than 2.5 mL per injection site. (Label directions; *Draxxin*®—Pfizer)

### ■ HORSES:

a) For foals with *R. equi*: Anecdotally, 2.5 mg/kg IM every 5–7 days has been used successfully in milder clinical cases. (Divers 2009)

## Monitoring

■ Clinical efficacy

## Client Information

■ Follow dosing guidelines exactly; adhere to withdrawal times

■ Not for female dairy cattle (20 months or older) or veal calves

■ Cattle are dosed subcutaneously in the neck, not more than 10 mL per injection site

■ Swine are dosed intramuscularly in the neck, not more than 2.5 mL per injection site

## Chemistry/Synonyms

Tulathromycin is a semi-synthetic macrolide antibiotic of the subclass triamilide. It occurs as white to off-white-crystalline powder that is readily soluble in water at pH<8. At a pH of 7.4 (physiological pH), tulathromycin (a weak base) is approximately 50 times more soluble in hydrophilic than hydrophobic media.

The commercially available injection contains 100 mg/mL of tulathromycin in an equilibrated mixture of the two isomeric forms of tulathromycin in a 9:1 ratio. The injectable vehicle consists of 50% propylene glycol, monothioglycerol (5 mg/mL); citric and hydrochloric acids are added to adjust pH. It has a relatively low viscosity.

Tulathromycin may also be known as tulathromycine, tulathromycinum, CP-472295 (component A), CP-547272 (component B), or *Draxxin*®.

## Storage/Stability

Tulathromycin injection should be stored at, or below 25°C (77°F). The product is stable at room temperature for up to 36 months.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Tulathromycin Injection 100 mg/mL in 50, 100, 250, & 500 mL vials: *Draxxin*® (Pfizer); FDA-approved for use in cattle and swine. Cattle intended for human consumption must not be slaughtered within 18 days from the

chloramphenicol injection 100 mg/mL in 50, 100, 250, & 500 mL vials. **Draxsin® (Tylan®)**, FDA approved for use in cattle and swine. Cattle intended for human consumption must not be slaughtered within 10 days from the last treatment. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in pre-ruminating calves. Do not use in calves to be processed for veal.

Swine intended for human consumption must not be slaughtered within 5 days from the last treatment.

**HUMAN-LABELED PRODUCTS:** None

## TYLOSIN

(*tye-loe-sin*) Tylan®

MACROLIDE ANTIBIOTIC

[Prescriber Highlights](#)

- **Macrolide antibiotic related to erythromycin, used primarily in cattle & swine; sometimes used orally in cats/dogs for chronic colitis; has been used anecdotally in cats as an immunomodulating agent for treating FIP**
- **Contraindications: hypersensitivity to it or other macrolide antibiotics; probably contraindicated in horses**
- **Adverse Effects: Pain & local reactions after IM injection, GI upset (anorexia, & diarrhea). May cause severe diarrheas if administered PO to ruminants or by any route to horses. Swine: edema of rectal mucosa & mild anal protrusion with pruritus, erythema, & diarrhea**

---

## Uses/Indications

Although the injectable form of tylosin is FDA-approved for use in dogs and cats, it is rarely used parenterally in those species. Oral tylosin is sometimes recommended for the treatment of chronic colitis in small animals (see Doses). A double-blinded prospective study, comparing tylosin to placebo in dogs with a history of chronic diarrhea that was thought to be responsive to tylosin in the past, showed that 85% dogs receiving tylosin had perceived normal fecal consistency versus 29% of those receiving placebo (Kilpienn *et al.* 2009). Tylosin has been used anecdotally in cats as an immunomodulating agent for treating FIP. In dogs, tylosin has been used orally to treat tear staining (epiphora).

Tylosin is also used clinically in cattle and swine for infections caused by susceptible organisms.

## Pharmacology/Actions

Tylosin is thought to have the same mechanism of action as erythromycin (binds to 50S ribosome and inhibits protein synthesis) and exhibits a similar spectrum of activity. It is a bacteriostatic antibiotic. Tylosin may also have immunomodulatory effects on cell-mediated immunity. In dogs, tylosin increases concentrations of enterococci (*Enterococcus faecalis*) in the jejunum. Enterococci are thought to have probiotic effects.

For more specific information on organisms where tylosin is usually active, refer to the erythromycin monograph; cross-resistance with erythromycin occurs.

## Pharmacokinetics

Tylosin tartrate is well absorbed from the GI tract, primarily from the intestine. The phosphate salt is less well absorbed after oral administration. Tylosin base injected SC or IM is reportedly rapidly absorbed.

Like erythromycin, tylosin is well distributed in the body after systemic absorption, with the exception of penetration into the CSF. The volume of distribution of tylosin is reportedly 1.7 L/kg in small animals and 1–2.3 L/kg in cattle. In lactating dairy cattle, the milk to plasma ratio is reported to be between 1–5.4.

Tylosin is eliminated in the urine and bile apparently as unchanged drug. The elimination half-life of tylosin is reportedly 54 minutes in small animals, 139 minutes in newborn calves, and 64 minutes in calves 2 months of age or older.

## Contraindications/Precautions/Warnings

Tylosin is contraindicated in patients hypersensitive to it or other macrolide antibiotics (*e.g.*, erythromycin). Most clinicians feel that tylosin is contraindicated in horses, as severe and sometimes fatal diarrheas may result from its use in that species.

## Adverse Effects

Most likely adverse effects with tylosin are pain and local reactions at intramuscular injection sites, and mild GI upset (anorexia and diarrhea). Tylosin may induce severe diarrheas if administered orally to ruminants or by any route to horses. In swine, adverse effects reported include edema of rectal mucosa and mild anal protrusion with pruritus, erythema, and diarrhea.

## Reproductive/Nursing Safety

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

## Overdosage/Acute Toxicity

Tylosin is relatively safe in most overdose situations. The LD50 in pigs is greater than 5 grams/kg orally, and approximately 1 gram/kg IM. Dogs are reported to tolerate oral doses of 800 mg/kg. Long-term (2 year) oral administration of up to 400 mg/kg produced no organ toxicity in dogs. Shock and death have been reported in baby pigs overdosed with tylosin, however.

## Drug Interactions

Drug interactions with tylosin have not been well documented. It has been suggested that tylosin may increase **digoxin** blood levels with resultant toxicity. It is suggested to refer to the erythromycin monograph for more information on potential interactions.

## Laboratory Considerations

- Macrolide antibiotics may cause falsely elevated values of **AST** (SGOT), and **ALT** (SGPT) when using colorimetric assays.
- Fluorometric determinations of **urinary catecholamines** can be altered by concomitant macrolide administration.

## Doses

### ■ DOGS:

When using *Tylan® Soluble* (100 grams per bottle) powder: Using volumetric containers to measure powders is not necessarily accurate, but 1 level teaspoonful (5 mL) of powder contains approximately 2.5–2.7 grams of tylosin; ¼th of a teaspoonful contains approximately 325 mg tylosin.

a) For small intestinal bacterial overgrowth: 10–20 mg/kg PO q12h; recommended for chronic cases, may require therapy for as long as 6 weeks. (Ludlow & Davenport 2000)

b) For adjunctive treatment of IBD: 10 mg/kg PO three times daily. Therapeutic trial for 21 days to evaluate efficacy. (Simpson 2003)

c) For clostridial colitis: 10–40 mg/kg PO twice daily. Practically (using the wettable powder): 1/16<sup>th</sup> of teaspoon 2–3 times daily for dogs (<7kg); ¼th of a teaspoon 2–3 times a day for medium dogs (7–15 kg); and ½ teaspoon 2–3 times a day for larger dogs (>15 kg). Mix with food to hide unpleasant taste or put into capsules. Animals with chronic clostridial colitis can often be controlled with one treatment every 2–3 days. (Willard 2006)

d) For IBD and antibiotic responsive diarrhea: 20–40 mg/kg PO q12h (Marks 2007)

e) 25 mg/kg PO once daily (in the study dogs were treated for 7 days, but the authors state that in dogs with tylosin-responsive diarrhea the stool remains normal as long as treatment continues, but diarrhea reappears within weeks after discontinuation). (Kilpien *et al.* 2009)

#### ■CATS:

When using *Tylan® Soluble* (100 grams per bottle) powder: Using volumetric containers to measure powders is not necessarily accurate, but 1 level teaspoonful (5 mL) of powder contains approximately 2.5–2.7 grams of tylosin; 1/8th of a teaspoonful contains approximately 325 mg tylosin.

- For adjunctive treatment of IBD: 10 mg/kg PO three times daily. Therapeutic trial for 21 days to evaluate efficacy. (Simpson 2003)
- For treatment of IBD or diarrheas caused by *C. perfringens*: 20–40 mg/kg PO twice daily (Marks 2002)
- For IBD: 40 mg/kg PO q12h (Zoran 2007)
- For clostridial colitis: 10–40 mg/kg PO twice daily. Practically (using the wettable powder): 1/16<sup>th</sup> of teaspoon 2–3 times daily. Mix with food to hide unpleasant taste or put into capsules. Animals with chronic clostridial colitis can often be controlled with one treatment every 2–3 days. (Willard 2006)

#### ■FERRETS:

For susceptible infections:

- 10 mg/kg PO once to twice daily (Williams 2000)

#### ■RABBITS, RODENTS, SMALL MAMMALS:

- Rabbits:** 10 mg/kg PO, SC, IM q12–24h (Ivey & Morrissey 2000)
- Gerbils, Hamsters, Rats:** 10 mg/kg SC q24h (Adamcak & Otten 2000)

#### ■CATTLE:

For susceptible infections:

- 17.6 mg/kg IM once daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 5 days. Do not inject more than 10 mL per site. Use the 50 mg/mL formulation in calves weighing less than 200 pounds. (Package insert; *Tylosin® Injection*—TechAmerica)
- For bronchopneumonia and fibrinous pneumonia in cattle associated with penicillin G-refractory *C. pyogenes* infections or other bacteria sensitive to tylosin and resistant to sulfas, penicillin G and tetracyclines: using Tylosin 200 mg/mL: 44 mg/kg IM q24h. Recommend a 21-day slaughter withdrawal at this dosage. (Hjerpe 1986)
- 5–10 mg/kg IM or slow IV once daily; not to exceed 5 days (Huber 1988)
- Tylosin base injectable: 10 mg/kg IM initially, then 6 mg/kg IM q8h (q8–12h in calves) (Baggot 1983)

#### ■SWINE:

For susceptible infections:

- 8.8 mg/kg IM twice daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 3 days. Do not inject more than 5 mL per site. (Package insert; *Tylosin® Injection*—TechAmerica)
- 5–10 mg/kg until 24 hours after remission of disease signs; not to exceed 3 days therapy (Huber 1988)
- Tylosin base injectable: 12.5 mg/kg IM q12h (Baggot 1983)

#### ■SHEEP & GOATS:

For susceptible infections:

- 10 mg/kg, treatment not to exceed 5 days (Huber 1988)

#### ■BIRDS:

For susceptible infections:

- For initial therapy in caged birds for upper respiratory infections (especially if mycoplasma suspected).  
Using 200 mg/mL injectable: 40 mg/kg IM. Used in combination with aminoglycosides. (McDonald 1989)
- For initial therapy of upper respiratory infections and air sacculitis. Using 50 mg/mL or 200 mg/mL injectable: 10–40 mg/kg IM twice daily or three times daily (Clubb 1986)
- 30 mg/kg IM q12h (Hoeffler 1995)

#### ■REPTILES:

For susceptible infections:

- For tortoises: 5 mg/kg IM once daily for at least 10 days. Used primarily for chronic respiratory infections or when Mycoplasma is suspected (Gauvin 1993)
- All species: 5 mg/kg IM once daily (Jacobson 1999)

### Monitoring

- Clinical efficacy
- Adverse effects

### Client Information

- Follow veterinarians dosage recommendations carefully
- Tylosin powder in food can be very unpalatable. Placing the proper dose in a gelatin capsule and dosing may be preferable to mixing in food. Another suggestion for dogs or cats that absolutely won't eat food that has tylosin in it is to: Melt approximately 1/4 teaspoon of butter and place in one of the compartments in a mini-ice tray. Add the proper dose of tylosin powder, mix well and freeze. (**Note:** Stability information for this procedure has not been performed).
- When administered orally to small animals, tylosin is usually very well tolerated, but contact veterinarian if adverse effects are seen.

### Chemistry/Synonyms

A macrolide antibiotic related structurally to erythromycin, tylosin is produced from *Streptomyces fradiae*. It occurs as an almost white to buff-colored powder with a pKa of 7.1. It is slightly soluble in water and soluble in alcohol. Tylosin is considered highly lipid soluble. The tartrate salt is soluble in water. The injectable form of the drug (as the base) is in a 50% propylene glycol solution.

Tylosin may also be known as Desmycosin, tilosina, tylozin, tylosiini, tylosinum, tylozyna or *Tylan®*.

### Storage/Stability

Unless otherwise instructed by the manufacturer, injectable tylosin should be stored in well-closed containers at room temperature. Tylosin, like erythromycin, is unstable in acidic (pH <4) media. It is not recommended to mix the parenteral injection with other drugs.

### Compatibility/Compounding Considerations

Because converting volume measurements into weights is not very accurate for powders, it is recommended to actually weigh powders when using them for pharmaceutical purposes. However, if this is not possible, one (1) level teaspoon (5 mL) of commercially-available tylosin tartrate (*Tylan® Soluble*) contains approximately 2.5–2.7 grams of tylosin; 1/8th of a teaspoonful contains approximately 325 mg tylosin.

Tylan tartrate powder added to food can be very unpalatable for dogs or cats. Placing the proper dose in a gelatin capsule and dosing may be preferable to mixing in food. Another suggestion for dogs or cats that absolutely won't eat food that has tylosin in it is to: Melt approximately 1/4 teaspoon of butter and place in one of the compartments in a mini-ice tray. Add the proper dose of tylosin powder, mix well and freeze. (**Note:** Stability information for this procedure has not been performed).

### Dosage Forms/Regulatory Status

## VETERINARY-LABELED PRODUCTS:

**Note:** The product *Tylan® Plus Vitamins* was used extensively orally in companion animals, but has been withdrawn from the market. *Tylan® Soluble* may be substituted, but is significantly more concentrated than *Tylan® Plus Vitamins* and dosage sizes (teaspoons are not equivalent) will be different.

Tylosin Injection: 50 mg/mL, 200 mg/mL; *Tylan®* (Elanco); generic; (OTC). FDA-approved for use in nonlactating dairy cattle, beef cattle, swine, dogs, and cats. Slaughter withdrawal (at labeled doses): cattle = 21 days; swine = 14 days. **Note:** Although this author (Plumb) was unable to locate parenteral products FDA-approved for use in lactating dairy animals, one source (Huber 1988a) states that tylosin has a 72 hour milk withdrawal for dairy cattle, and 48 hour milk withdrawal in dairy goats and sheep. Contact FARAD for more information before using in lactating dairy animals.

Tylosin Tartrate Powder: (approximately 2.5–2.7 grams/level teaspoonsful) in 100 gram bottles; *Tylan® Soluble* (Elanco); (OTC). FDA-approved for use in turkeys (not layers), chickens (not layers) and swine. Slaughter withdrawal swine = 2 days; chickens = 1 day; turkeys = 5 days.

There are many FDA-approved tylosin products for addition to feed or water for use in beef cattle, swine, and poultry. Many of these products have other active ingredients included in their formulations.

**HUMAN-LABELED PRODUCTS:** None.

## URSODIOL

(*ur-soe-dye-ole*) Actigall®, Ursodeoxycholic acid

### BILE ACID

### Prescriber Highlights

- **Bile acid that may be useful for adjunctive treatment of hepatobiliary disease in dogs/cats. May also be used for cholesterol containing gallstones**
- **Contraindications: Rabbits & other hindgut fermenters. Caution: Complications associated with gallstones (e.g., biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis)**
- **Adverse Effects: Appears to be well tolerated in dogs/cats**

---

## Uses/Indications

In small animals, ursodiol may be useful as adjunctive therapy for the medical management of cholesterol-containing gallstones and/or in patients with chronic liver disease, particularly where cholestasis (bile toxicity) plays an important role. Ursodiol's benefit in treating canine or feline hepatobiliary disease is unknown at the time of writing (studies are ongoing), but it may be of help in slowing the progression of inflammatory hepatic disorders, particularly autoimmune hepatitis and acute hepatotoxicity.

## Pharmacology/Actions

After oral administration, ursodiol suppresses hepatic synthesis and secretion of cholesterol. Ursodiol also decreases intestinal absorption of cholesterol. By reducing cholesterol saturation in the bile, it is thought that ursodiol allows solubilization of cholesterol-containing gallstones. Ursodiol also increases bile flow and in patients with chronic liver disease, it apparently reduces the hepatocyte toxic effects of bile salts by decreasing their detergent action, and may protect hepatic cells from toxic bile acids (e.g., lithocholate, deoxycholate, and chenodeoxycholate).

## Pharmacokinetics

Ursodiol is well absorbed from the small intestine after oral administration. In humans, up to 90% of dose is absorbed. After absorption, it enters the portal circulation. In the liver, it is extracted and combined (conjugated) with either taurine or glycine and secreted into the bile. Only very small quantities enter the systemic circulation and very little is detected in the urine. After each entero-hepatic cycle, some quantity of conjugated and free drug undergoes bacterial degradation; eventually most of the drug is eliminated in the feces after being oxidized or reduced to less soluble compounds. Ursodiol detected in the systemic circulation is highly bound to plasma proteins.

## Contraindications/Precautions/Warnings

Ursodiol is contraindicated in rabbits and other hindgut fermenters as it is converted into lithocholic acid (toxic). Patients sensitive to other bile acid products may also be sensitive to ursodiol. The benefits of using ursodiol should be weighed against its risks in patients with complications associated with gallstones (e.g., biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis). While ursodiol may be useful in treating patients with chronic liver disease, some patients may experience further impairment of bile acid metabolism.

## Adverse Effects

While ursodiol use in animals has been limited, it appears to be well tolerated in dogs and cats. Although hepatotoxicity has not been associated with ursodiol therapy, some human patients have an inability to sulfate lithocholic acid (a naturally occurring bile acid and also a metabolite of ursodiol). Lithocholic acid is a known hepatotoxin; veterinary significance is unclear. Diarrhea and other GI effects have rarely been noted in humans taking ursodiol. Ursodiol will not dissolve calcified radiopaque stones or radiolucent bile pigment stones.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether ursodiol is excreted in breast milk.

## Overdosage/Acute Toxicity

Overdosage of ursodiol would most likely cause diarrhea. Treatment, if required, could include supportive therapy; oral administration of an aluminum-containing antacid (e.g., aluminum hydroxide suspension); gastric emptying (if large overdose) with concurrent administration of activated charcoal or cholestyramine suspension.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ursodiol and may be of significance in veterinary patients:

■ **ALUMINUM-CONTAINING ANTACIDS:** May bind to ursodiol, thereby reducing its efficacy

■ **CHOLESTYRAMINE RESIN:** May bind to ursodiol, thereby reducing its efficacy

■ **TAURINE:** Although not documented, concern has been raised that chronic administration of ursodiol in cats may lead to taurine deficiency.

## Laboratory Considerations

■ As ursodiol is detected by many **serum bile acid** tests, bile acids may remain falsely elevated. One study in normal dogs did not show any effects. However if possible, stop ursodiol for 2-3 days before running test.

## Doses

### ■ DOGS:

For adjunctive treatment of chronic hepatitis:

- 5–15 mg/kg PO divided q12h, with immunosuppressive therapy. (**Note:** Use of this drug at this dose is preliminary, but promising) (Johnson & Sherding 1994)
- 10–15 mg/kg PO once daily. Little work has yet been done in dogs and cats, but at 10 mg/kg it is safe and potentially beneficial in cases of cholestatic liver disease, cholangitis/cholangiohepatitis, chronic hepatitis, and copper-associated hepatopathy. (Webb & Twedt 2008)
- For use in chronic active hepatitis, fibrosis and cirrhosis. May use as primary or adjunctive therapy. Dose: 11–15.4 mg/kg PO either once daily or divided twice daily (Tams 2000)

### ■ CATS:

For adjunctive treatment of chronic hepatitis:

- 10–15 mg/kg PO once daily. Little work has yet been done in dogs and cats, but at 10 mg/kg it is safe and potentially beneficial in cases of cholestatic liver disease, cholangitis/cholangiohepatitis, chronic hepatitis, and copper-associated hepatopathy. (Webb & Twedt 2008)
- For use in chronic active hepatitis, fibrosis, and cirrhosis. May use as primary or adjunctive therapy. Dose: 11–15.4 mg/kg PO either once daily or divided twice daily. Cats usually get 1/6th of a capsule mixed with a small amount of food. Cats may still eat their food even if drug is sprinkled on top. (Tams 2000)
- 10 mg/kg/day PO (Zoran 2006)

### ■ BIRDS:

For adjunctive treatment of liver disease:

- 10–15 mg/kg PO once daily. (Oglesbee 2009)

## Monitoring

- Efficacy (ultrasonography for gallstones; improved liver function tests for chronic hepatic disease)
- Monitoring of SGPT/SGOT (AST/ALT) on a routine basis (in humans these tests are recommended to be performed at the initiation of therapy and at 1 and 3 months after starting therapy; then every 6 months).

## Client Information

■ Because ursodiol dissolves more rapidly in the presence of bile or pancreatic juice, it should be given with food.

## Chemistry/Synonyms

A naturally occurring bile acid, ursodiol, also known as ursodeoxycholic acid has a molecular weight of 392.6.

Ursodiol may also be known as: acidum ursodeoxycholicum, UDCA, ursodesoxycholic acid; many trade names are available, including *Actigall*®.

## Storage/Stability

Unless otherwise specified by the manufacturer, ursodiol capsules should be stored at room temperature (15–30°C) in tight containers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Ursodiol Oral Capsules: 300 mg; *Actigall*® & generic (Watson); (Rx)

Ursodiol Oral Tablets: 250 mg & 500 mg; *URSO*® 250 & *-Forte* (Axcan Scandipharm); generic; (Rx)

---

## VALPROIC ACID

### VALPROATE SODIUM

### DIVALPROEX SODIUM

(*val-proe-ik*; *val-proe-ayte*; *die-val-proe-ex*)

Depakene®, Depakote®, Depacon®

### Prescriber Highlights

- **2nd to 4th line anticonvulsant that may be useful as adjunctive treatment in some dogs; most do not recommend its use in veterinary patients**
- **Contraindications: Significant hepatic disease or dysfunction, previous hypersensitivity**
- **Caution: Thrombocytopenia or altered platelet aggregation function**
- **Adverse Effects: GI effects (may be diminished by giving with food) most likely; hepatotoxicity, CNS (sedation, ataxia, behavioral changes, etc.), dermatologic reactions, (alopecia, rash, etc.), hematologic reactions, (thrombocytopenia, reduced platelet aggregation, leukopenias, anemias, etc.), pancreatitis, & edema are possible**
- **May be teratogenic**

---

## Uses/Indications

Because of its cost, apparent unfavorable pharmacokinetic profile, and potential hepatotoxicity, valproic acid must be considered at best, a third or fourth line drug in the treatment of seizures in the dog. Some clinicians feel it is of benefit when added to phenobarbital in patients not adequately controlled with that drug alone. Additionally, it is less protein bound in dogs than in humans, so the human serum therapeutic range of the drug (40–100 micrograms/mL) may be too high in dogs. The drug (free form) actually may concentrate in the CSF, and anticonvulsant effects may persist even after valproate levels are non-detectable in CSF, lending to the idea that serum levels do not accurately reflect clinical efficacy. Clearly, additional studies are needed to determine the clinical role, if any, for this drug.

## Pharmacokinetics

## Pharmacology/Actions

The mechanism of the anticonvulsant activity of valproic acid is not understood. Animal studies have demonstrated that valproic acid inhibits GABA transferase and succinic aldehyde dehydrogenase causing increased CNS levels of GABA. Additionally, one study has demonstrated that valproic acid inhibits neuronal activity by increasing potassium conductance.

## Pharmacokinetics

Sodium valproate is rapidly converted to valproic acid in the acidic environment of the stomach where it is rapidly absorbed from the GI tract. The bioavailability reported in dogs following oral administration is approximately 80%; peak levels occur in approximately 1-hour. Food may delay absorption, but does not alter the extent of it. Divalproex in its enteric-coated form has an approximately 1-hour delay in its oral absorption. Patients' who exhibit GI (nausea, vomiting) adverse effects may benefit from this dosage form.

Valproic acid is rapidly distributed throughout the extracellular water spaces and plasma. It is approximately 80–95% plasma protein bound in humans, and 78–80% plasma protein bound in dogs. CSF levels are approximately 10% those found in plasma. Milk levels are 1–10% those found in plasma; it readily crosses the placenta.

Valproic acid is metabolized in the liver and is conjugated with glucuronide. These metabolic conjugates are excreted in the urine; only very small amounts of unchanged drug are excreted in the urine. The elimination half-life in humans ranges from 5–20 hours; in dogs from 1.5–2.8 hours.

## Contraindications/Precautions/Warnings

Valproic acid is contraindicated in patients with significant hepatic disease or dysfunction, or exhibiting previous hypersensitivity to the drug. It should be used with caution in patients with thrombocytopenia or altered platelet aggregation function.

## Adverse Effects

Because of the limited experience with this agent, the following adverse effects may not be complete nor valid for dogs: Gastrointestinal effects consisting of nausea, vomiting, anorexia, and diarrhea are the most common adverse effects seen in people and also apparently, in dogs. GI effects may be diminished by administration with food. Hepatotoxicity is the most serious potential adverse (human) reaction reported and must be considered for canine patients also. Dose related increases in liver enzymes may be seen and, rarely, hepatic failure and death may occur. In humans, incidences of hepatotoxicity are greater in very young (<2 yr. old) patients, those on other anticonvulsants, or with multiple congenital abnormalities.

Other potential adverse effects include: CNS (sedation, ataxia, behavioral changes, etc.), dermatologic (alopecia, rash, etc.), hematologic (thrombocytopenia, reduced platelet aggregation, leukopenias, anemias, etc.), pancreatitis, and edema.

## Reproductive/Nursing Safety

A 1–2% incidence of neural tube defects in children born of mothers taking valproic acid during the first trimester of pregnancy has been reported. Use in pregnant dogs only when the benefits outweigh the risks of therapy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Concentrations of valproic acid in maternal milk are 1–10% of serum concentrations. It is unknown if this would have any detrimental effect on nursing offspring.

## Overdosage/Acute Toxicity

There were 14 exposures to valproic acid/valproate reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 11 were dogs with 1 showing clinical signs and the remaining 3 reported cases were cats that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included sedation.

Severe overdoses can cause profound CNS depression, asterixis, motor restlessness, hallucinations, and death. One human patient recovered after a serum level of 2000 micrograms/mL (20 times over therapeutic) was measured. Treatment consists of supportive measures and maintenance of adequate urine output is considered mandatory. Because the drug is rapidly absorbed, emesis or gastric lavage may be of limited value. Because of its delayed absorptive characteristics, the divalproex form may be removed by lavage or emesis if ingestion occurred recently. Naloxone is reported to be of benefit in reversing some of the CNS effects of valproic acid, but may also reverse the anticonvulsant properties of the drug.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving valproic acid and may be of significance in veterinary patients:

- **ANTICOAGULANTS:** Valproic acid may have effects on platelet aggregation; use with caution with other drugs that affect coagulation status
- **ASPIRIN:** Salicylates may displace valproic acid from plasma protein sites, thus increasing valproic acid levels
- **CLONAZEPAM:** The sedative effects of clonazepam may be enhanced by valproic acid and the anticonvulsant efficacy of both may be diminished
- **CNS DEPRESSANTS, OTHER:** VPA may enhance the CNS depressant effects of other CNS active drugs.
- **PHENOBARBITAL, PRIMIDONE:** Valproic acid may increase serum levels of phenobarbital and primidone

## Laboratory Considerations

- A keto-metabolite of valproic acid is excreted into the urine and may yield false positive **urine ketone** tests.
- Altered **thyroid function tests** have been reported in humans with unknown clinical significance.

## Doses

**Note:** Because of its very short half-life in dogs, most neurologists do not recommend using VPA in dogs.

- **DOGS:**
  - a) Add on therapy with phenobarbital or bromide: 60 mg/kg PO q8h (Thomas 2000)

## Monitoring

- Anticonvulsant efficacy
- If used chronically, routine CBC's and liver enzymes at least every 6 months

## Client Information

- Compliance with therapy must be stressed to clients for successful epilepsy treatment. Encourage administering daily doses at same time each day, preferably with food.
- Veterinarian should be contacted if animal develops significant adverse reactions (including clinical signs of anemia and/or liver disease) or if seizure control is unacceptable.

## Chemistry/Synonyms

Structurally unrelated to other anticonvulsant agents; valproic acid, valproate sodium, divalproex sodium are derivatives of carboxylic acid. Valproic acid occurs as a colorless to pale yellow clear liquid. It is slightly viscous; has a characteristic odor, a pKa of 4.8, is slightly soluble in water and freely soluble in alcohol. It is also known as Dipropylacetic acid, DPA, 2-propylpentanoic acid, and 2-propylvaleric acid.

Valproate sodium occurs as a white, crystalline, saline tasting, very hygroscopic powder. It is very soluble in water or alcohol. The commercially available oral solution has a pH of 7–8.

Divalproex sodium is a stable compound in a 1:1 molar ratio of valproic acid and valproate sodium. It occurs as a white powder with a characteristic odor. It is insoluble in water and very soluble in alcohol.

Valproate sodium may also be known as: Abbott-44090, natrii valproas; many trade names are available.

Valproic acid may also be known as: Abbott-44089, acidum valproicum; many trade names are available.

## Storage/Stability

Valproic acid capsules should be stored at room temperature (15–30°C) and in tight containers; avoid freezing. Valproate sodium oral solution should be stored at room temperature and in tight containers; avoid freezing. Divalproex sodium enteric-coated tablets should be stored at room temperature in tight, light resistant containers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

## UNLabeled Products:

Valproic Acid Oral Capsules: 250 mg; *Depakene*® (Abbott); generic; (Rx)

Valproate Sodium Syrup: 250 mg/5 mL in 473 mL; *Depakene*® (Abbott); generic; (Rx)

Divalproex Sodium Delayed/Extended Release Tablets/Capsules: 125 mg, 250 mg, 500 mg; *Depakote*® & *Depakote ER*® (Abbott); *Stavzor*® (Noven); generic; (Rx)

Divalproex Sodium Oral Capsules (Sprinkle): 125 mg; *Depakote*® (Abbott); generic; (Rx)

Valproate Sodium Injection Concentrate: 100 mg/mL in 5 mL single-dose vials (may be preservative free); *Depacon*® (Abbott); generic; (Rx)

## VANADIUM

### VANADYL SULFATE

(van-ay-eh-dee-um; van-ah-dil)

Vanadyl Fuel®

TRACE METAL

### Prescriber Highlights

- Trace metal “nutraceutical” that may be useful as an adjunctive treatment for diabetes mellitus in cats
- Efficacy questionable, but probably safe

## Uses/Indications

Vanadium supplementation may be useful in the adjunctive treatment of diabetes mellitus, particularly in cats. There is controversy whether or not this treatment is beneficial.

## Pharmacology/Actions

In humans with non-insulin dependent diabetes mellitus (NIDDM), vanadium can reduce fasting blood glucose and glycosylated hemoglobin levels, reduces hepatic glucose release, and increases peripheral glucose disposal and uptake into skeletal muscle mediated by insulin. Vanadium does not influence blood glucose levels in normal patients. While the exact mechanism of action of vanadium is unknown, it apparently inhibits protein tyrosine phosphatase (PTP). PTP is important in signal transduction and allows vanadium to act via both insulin-dependent and insulin-independent pathways.

## Pharmacokinetics

Little information on the pharmacokinetics of vanadium was located. Only about 5% is absorbed from foodstuffs. *In vivo* it is converted to the vanadyl cation and forms complexes with ferritin and transferrin. Highest vanadium concentrations are found in the liver, bone and kidney. Vanadium is eliminated via renal routes. Effects on glucose in NIDDM humans may persist for weeks after discontinuation of therapy.

## Contraindications/Precautions/Warnings

Vanadium supplements could potentially exacerbate renal insufficiency; use with caution in these patients.

## Adverse Effects

Gastrointestinal effects have been reported in some cats receiving vanadium supplements; anorexia and vomiting is most commonly reported. It has been reported that cats initially unable to tolerate vanadium, can have therapy re-instituted without ill effect. Vanadium in high dosages may have renal toxic effects.

## Reproductive/Nursing Safety

It is unknown if supplemental vanadium is safe in pregnancy.

Vanadium is unlikely to have negative effects in nursing kittens.

## Overdosage/Acute Toxicity

Vanadyl sulfate may be mildly toxic. The oral LD50 in rats is 450 mg/kg. Consider gut removal protocols if an acute overdose occurs. Contact an animal poison control center for further guidance. Chronic overdoses may cause kidney damage.

## Drug Interactions

■ No specific interactions of note were located. When used with other agents for diabetes management, effects may be additive.

## Laboratory Considerations

■ No specific laboratory interactions or considerations were noted

## Doses

**Note:** Because vanadium is given as a salt, do not confuse dosages for vanadium with vanadyl sulfate. Vanadyl sulfate reportedly contains 31% elemental vanadium, but labeled amounts of vanadium vary considerably.

### ■CATS:

- Using *Super Vanadyl Fuel*® (Twin Labs; also contains chromium): ½ capsule PO once daily with food. (Dowling 2000)
- For adjunctive use in treating feline type 2 diabetes: Vanadium (**Note:** salt not specified, assume elemental vanadium) 0.2 mg/kg PO once daily in food or water. (Greco 2002)
- For diabetes mellitus: Vanadyl sulfate 1 mg/kg PO once daily or vanadium 0.2 mg/kg PO once daily. (Wynn 2002)
- For early NIDDM using *Vanadyl Fuel*® (Twin Labs; also contains chromium): One capsule PO once daily (q24h) (Melendez & Lorenz 2002)

## Monitoring

■ As there is no reliable way to measure vanadium in the body, a clinical trial is the only way to determine whether vanadium is effective in helping to control blood glucose. Standard methods for monitoring efficacy of diabetes treatment should be followed (*e.g.*, fasting blood glucose, appetite, attitude, body condition, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels).

## Client Information

- Clients should give the medication only as prescribed and not change brands without their veterinarian's guidance
- Give with food

## Chemistry/Synonyms

A trace element, vanadium (V, atomic number 23) is usually given in the form of the inorganic salt, vanadyl sulfate. Vanadyl sulfate occurs as blue crystals and is very soluble in water. Vanadyl sulfate reportedly contains

A trace element, vanadium (V, atomic number 23) is usually given in the form of the inorganic salt, vanadyl sulfate. Vanadyl sulfate occurs as blue crystals and is very soluble in water. Vanadyl sulfate reportedly contains 31% elemental vanadium.

Vanadyl sulfate may also be known as: vanadium (IV) sulfate oxide; vanadium oxysulfate, oxo[sulfato(2--O)]-vanadium, oxysulfato vanadium (IV); vanadyl (IV) sulfate, or vanadyl (IV)-sulfate hydrate.

### Storage/Stability

While vanadyl sulfate is stable under ordinary conditions, refer to the label for each product used.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

No oral products are FDA-approved as pharmaceuticals.

Oral vanadyl sulfate products are considered nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by regulatory bodies.

Supplements are available from a wide variety of sources. Common products include 7.5 mg, and 10 mg tablets or 15 mg capsules. One proprietary product that has been used in cats is *Super Vanadyl Fuel*® (Twin Labs).

This is a combination product that contains per capsule (among many other ingredients): 150 micrograms chromium (from chromium nicotinate and picolinate) and 1.25 mg of elemental vanadium (from BMOV [bi(maltolato) oxovanadium] and vanadyl sulfate). Bioequivalence between products cannot be assumed.

## VANCOMYCIN HCL

(van-koe-mye-sin) Vancocin®

GLYCOPEPTIDE ANTIBIOTIC

### Prescriber Highlights

- **Glycopeptide antibiotic reserved for IV use for multi-drug resistant Staph or Enterococcus infections; can also be used PO to treat *Clostridium difficile* diarrhea**
- **Oral vancomycin is not absorbed systemically and is only useful for treating GI *C. difficile* overgrowth**
- **When used systemically, must be given IV; severe pain & tissue injury occurs with SC or IM injection**
- **May be synergistic with aminoglycoside therapy, but increased risk of nephrotoxicity, ototoxicity & neutropenia also possible**
- **If decreased renal dysfunction, adjust dosage**

---

### Uses/Indications

Vancomycin should only be used to treat infections that are documented resistant to other antibiotics and susceptible to vancomycin, usually methicillin-resistant *Staphylococcus* spp. (MRSA) or multidrug-resistant *Enterococcus* spp. It potentially is useful for oral treatment of pseudomembranous colitis caused by *Clostridia difficile*.

### Pharmacology/Actions

Vancomycin inhibits cell-wall synthesis and bacterial cell-membrane permeability. It also affects bacterial RNA synthesis. It is only effective against gram-positive bacteria, including many strains of streptococci, staphylococci, and enterococci. Vancomycin is generally a bactericidal antibiotic, but is bacteriostatic against enterococci. Vancomycin also has activity against *Clostridium difficile*, *Listeria monocytogenes*, *Corynebacterium*, and *Actinomyces* spp.. Vancomycin and aminoglycosides can have synergistic action against susceptible bacteria. Pus and cellular debris may bind to vancomycin and reduce its efficacy.

Resistance to vancomycin by certain strains of enterococci and staphylococci is an increasing concern in human medicine and potentially, for veterinary patients.

### Pharmacokinetics

When given orally, vancomycin is not appreciably absorbed. After intravenous administration, vancomycin is widely distributed. Therapeutic levels can be found in pleural, ascitic, pericardial, and synovial fluids. At usual serum levels, it does not readily distribute into the CSF.

The elimination half-life of vancomycin in patients with normal renal function is approximately 4-6 hours. Prolonged dosing can allow the drug to accumulate. The drug is eliminated primarily via glomerular filtration; small amounts are excreted into the bile.

### Contraindications/Precautions/Warnings

Vancomycin is an important antibiotic for treating multi-drug resistant infections in humans. It should not be used in veterinary patients when other antibiotics can be used to successfully treat the infection; some believe that the drug should never be used in veterinary patients.

Patients with decreased renal function that require vancomycin should have dosages reduced or dosing interval increased. Serum levels should be monitored.

### Adverse Effects

When given parenterally, nephrotoxicity and ototoxicity are the most serious potential adverse effects of vancomycin. Unlike aminoglycosides, these effects are believed to be uncommon. In humans, dermatologic reactions and hypersensitivity can occur; it is unknown if these effects are issues for veterinary patients. Reversible neutropenia has been reported in humans, particularly when dosage is high and prolonged.

Do not administer IV rapidly or as a bolus; thrombophlebitis, severe hypotension or cardiac arrest (rare) have been reported. Vancomycin must be given over at least 30 minutes as a dilute solution.

Do not give IM, SC, or IP. Severe tissue damage and pain may occur.

Oral therapy may cause GI effects (nausea, inappetence).

### Reproductive/Nursing Safety

When used orally, vancomycin is relatively safe to use during pregnancy (FDA category **B**). When used IV, it is not known whether vancomycin can cause fetal harm. A limited study performed in humans did not detect fetal harm, but the numbers studied were small. In humans, the FDA categorizes IV vancomycin as a category **C** drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Because in veterinary patients, vancomycin should only be used for serious infections, the potential benefits of therapy will probably outweigh the risks in most circumstances.

Vancomycin is excreted into milk. Because the drug is not appreciably absorbed, it is unlikely to pose significant harm to nursing animals, although diarrhea could occur.

### Overdosage/Acute Toxicity

Patients with colitis associated with *Clostridia difficile* taking an oral overdose, could potentially absorb enough drug to cause adverse effects. The IV LD50 for vancomycin in mice and rats is 400 mg/kg and 319 mg/kg, respectively. Intravenous overdoses of vancomycin may cause an increased risk of adverse effects, particularly ototoxicity and nephrotoxicity. Supportive care is advised. Hemodialysis does not appear to remove the drug in significant amounts.

### Drug Interactions

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vancomycin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Vancomycin may increase the risk of aminoglycoside-related ototoxicity or nephrotoxicity. Because this combination of drugs may be medically required (there is evidence of synergy against staphylococci and enterococci), only enhanced monitoring is suggested.
- **ANESTHETIC AGENTS:** In children, vancomycin used with anesthetic agents has caused erythema and a histamine-like flushing
- **NEPHROTOXIC DRUGS, OTHER (e.g., amphotericin B, cisplatin):** Use with caution with other nephrotoxic drugs

## Laboratory Considerations

- No specific concerns were noted

## Doses

To prepare parenteral solution using vancomycin 500 mg or 1 gram powder for injection: Reconstitute the 500 mg for injection vial by adding 10 mL of sterile water for injection. Add 20 mL to the 1 gram vial. Before administering to patient, further dilute reconstituted solutions with (at least 100 mL for 500 mg; 200 mL for 1 gram vial) a compatible diluent (e.g., D5W, lactated Ringer's, 0.9% NaCl).

### ■ DOGS:

For susceptible infections:

**Note:** *Oral vancomycin is not appreciably absorbed and is only effective for susceptible enteric infections.*

- a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
- b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003)
- c) For oral use to treat *C. difficile* enterocolitis: 10–20 mg/kg PO q6h for 5–7 days;  
For IV use to treat skin, urinary, soft tissue infections: 10–20 mg/kg IV q12h for 7–10 days;  
For IV use to treat systemic infections, bacteremia: 15 mg/kg IV q6h for 10 days. (Greene *et al.* 2006)

### ■ CATS:

For susceptible infections:

- a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
- b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003)

## Monitoring

When used parenterally:

- Renal function, baseline and periodic
- Vancomycin levels, maintain trough level above 5 micrograms/mL (some say troughs between 10–15 micrograms/mL)
- Periodic CBC if therapy is prolonged

## Client Information

- Parenteral vancomycin is used in an inpatient setting
- Oral vancomycin may be used for outpatient therapy; clients should be counseled to give as prescribed
- May give oral dosage forms with a small amount of food

## Chemistry/Synonyms

A glycopeptide antibiotic, vancomycin HCl occurs as an odorless, tan to brown free-flowing powder. It is freely soluble in water. A 5% aqueous solution has a pH of 2.5–4.5.

Vancomycin may also be known as: vanco, vancomycini, or *Vancocin*®; there are many registered international trade names available.

## Storage/Stability

Vancomycin should be stored at room temperature in tight containers that are protected from light. Once reconstituted (see directions in package insert or in the Doses section), the injectable or oral solutions are stable for 14 days if refrigerated. If diluted further with D5W or sodium chloride 0.9% for parenteral administration, solutions are stable for 24 hours at room temperature and 2 months if refrigerated.

## Compatibility/Compounding Considerations

Vancomycin is **compatible** with D5W, 0.9% NaCl, and lactated Ringer's injection.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Vancomycin HCl Oral Capsules: 125 mg & 250 mg; *Vancocin*® (ViroPharma); (Rx)

Vancomycin HCl Powder for Injection Solution: 500 mg, 750 mg, 1 gram, 5 grams, & 10 grams (some preservative free) in single-dose vials, 100 mL pharmacy bulk packagers and premixed 100 mL & 200 mL *Galaxy* containers; generic; (Rx)

## VASOPRESSIN

(vay-soe-press-in) Pitressin®

HORMONE

### Prescriber Highlights

- **Hormone used primarily as a diagnostic agent & sometimes for treatment of diabetes insipidus; it may be useful for the adjunctive treatment of shock syndromes and cardio-pulmonary cerebral resuscitation (CPCR)**
- **Contraindications:** Chronic nephritis until nitrogen retention is resolved to reasonable levels, or patients hypersensitive to it; **Caution:** Vascular disease, seizure disorders, heart failure, or asthma
- **Adverse Effects:** Local irritation at the injection site (including sterile abscesses), skin reactions, abdominal pain, hematuria, &, rarely, a hypersensitivity (urticarial) reaction
- **Overdosage can lead to water intoxication**

## Uses/Indications

Vasopressin is used in veterinary medicine as a diagnostic agent and in the treatment of diabetes insipidus in small animals. In recent years, there has been significant interest in using vasopressin for treating shock syndromes and for cardiopulmonary cerebral (CPCR) in humans and animals. In ventricular asystole or pulseless electrical activity, vasopressin has some advantages over epinephrine. Vasopressin can act as a vasoconstricting agent even when acidosis is present and may cause less vasoconstriction of coronary and renal vasculature, thereby increasing myocardial perfusion and does not have the arrhythmogenic or chronotropic effects that are associated with epinephrine. Ongoing research is being conducted.

In human medicine, vasopressin has been used to treat acute GI hemorrhage and to stimulate GI peristalsis. Vasopressin CRI is also being used for treatment of hypotensive septic patients unresponsive to conventional vasopressor. Prior to radiographic procedures, it has been used to disperse interfering gas shadows or help concentrate contrast media.

## Pharmacology

Vasopressin or antidiuretic hormone (ADH) acts through at least 5 different receptors (three subtypes, V1, V2, V3, the oxytocin receptor, and the purinergic P2 receptor). It promotes the renal reabsorption of solute-free water in the distal convoluted tubules and collecting duct. ADH increases cyclic adenosine monophosphate (cAMP) at the tubule which increases water permeability at the luminal surface resulting in increased urine osmolality and decreased urine flow. Without vasopressin, urine flow can be increased up to 90% greater than normal.

At doses above those necessary for antidiuretic activity, vasopressin can cause smooth muscle contraction. Capillaries and small arterioles are most affected, with resultant decreased blood flow to several systems. Hepatic flow may actually be increased, however.

Vasopressin can cause contraction of smooth muscle of the bladder and gall bladder and increase intestinal peristalsis, particularly of the colon. Vasopressin may decrease gastric secretions and increase GI sphincter pressure; gastric acid concentration remains unchanged.

Vasopressin possesses minimal oxytocic effects, but at large doses may stimulate uterine contraction. Vasopressin also causes the release of corticotropin, growth hormone, and follicle-stimulating hormone (FSH).

## Pharmacokinetics

Vasopressin is destroyed in the GI prior to being absorbed and therefore must be administered either intranasally or parenterally. After IM or SC administration in dogs, aqueous vasopressin has antidiuretic activity for 2–8 hours.

Vasopressin is distributed throughout the extracellular fluid. The hormone apparently is not bound to plasma proteins.

Vasopressin is rapidly destroyed in the liver and kidneys. The plasma half-life has been reported to be only 10–20 minutes in humans.

## Contraindications/Precautions/Warnings

In humans, vasopressin is contraindicated in patients hypersensitive to it or with chronic nephritis until nitrogen retention is resolved to reasonable levels.

Because of its effects on other systems, particularly at high doses, vasopressin should be used with caution in patients with vascular disease, seizure disorders, heart failure, or asthma.

## Adverse Effects

Adverse effects that can be seen include local irritation at the injection site (including sterile abscesses), skin reactions, platelet aggregation, bilirubinemia, abdominal pain, hematuria, and, rarely, a hypersensitivity (urticarial) reaction. Overdosage can lead to water intoxication (see below).

## Reproductive/Nursing Safety

Although the drug has minimal effects on uterine contractions at usual doses, it should be used with caution in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Early clinical signs of overdose-induced water intoxication can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures, and eventually death. Treatment for mild intoxication is stopping vasopressin therapy and restricting water access until resolved. Severe intoxication may require the use of osmotic diuretics (mannitol, urea, or dextrose) with or without furosemide.

## Drug Interactions

The following drugs may **inhibit** the antidiuretic activity of vasopressin:

- ALCOHOL
- DEMECLOXYCLINE
- EPINEPHRINE (large doses)
- HEPARIN
- NOREPINEPHRINE (large doses)

The following drugs may **potentiate** the antidiuretic effects of vasopressin:

- ANTIDEPRESSANTS, TRICYCLIC
- CARBAMAZEPINE
- CHLORPROPAMIDE
- CLOFIBRATE
- FLUDROCORTISONE
- PHENFORMIN
- UREA

## Doses

### ■DOGS:

As a diagnostic agent after the water deprivation test (WDT); monitor carefully. The WDT is considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin. Refer to a current small animal internal medicine text for further information.

a) Exogenous vasopressin test: After WDT, empty bladder and start IV catheter and slowly reintroduce water. Give aqueous vasopressin in D5W IV at a dose of 2.5 mU/kg over one hour. To make one liter of a 5 mU/mL solution add 5 Units of vasopressin to one liter of D5W. Empty bladder and collect urine at 30 minutes, 60 minutes, and 90 minutes. If urine specific gravity >1.1015 = ADH-responsive DI; if <1.1015 = either nephrogenic DI or medullary washout effect. (Nichols & Miller 1989)

For adjunctive treatment of shock/CPCR:

a) In patients with vasodilatory shock that is unresponsive to fluid resuscitation and catecholamine (dobutamine, dopamine, and norepinephrine) administration: 0.01–0.04 Units/minute IV (*Note: This dose is not dependent upon patient weight*). DO NOT exceed 0.04 Units/minute. Risk of myocardial ischemia. DO NOT use in patients with cardiogenic shock.

For CPCR with pulseless electrical activity or ventricular asystole, vasopressin may be beneficial for myocardial and cerebral blood flow: 0.2–0.8 Units/kg, IV once. (**Note: This reference has a stepwise guidance flowchart for treating vasodilatory shock and CPCR with pulseless electrical activity or ventricular asystole that veterinary practices are encouraged to have on hand—Plumb**) (Scroggin & Quandt 2009)

For treatment of central diabetes insipidus: [**Note: Because vasopressin tannate in oil is no longer commercially available; most clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.**]

### ■CATS:

As a diagnostic agent after the water deprivation test (WDT): The WDT is generally considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin.

central or hepatogenic in origin.

a) Immediately after the end-point of the WDT, give aqueous vasopressin 0.5 U/kg IM; continue to withhold food and water. At 30, 60, and 120 minutes after vasopressin, empty bladder and determine specific gravity (osmolality). Upon completion, the cat is gradually allowed access to water. Inability to concentrate urine during the water deprivation test followed by a rise in urine specific gravity above 1.025 after vasopressin is indicative of central DI. (Peterson & Randolph 1989)

For adjunctive treatment of shock/CPCR:

a) In patients with vasodilatory shock that is unresponsive to fluid resuscitation and catecholamine (dobutamine, dopamine, and norepinephrine) administration: 0.01–0.04 Units/minute IV.

For CPCR with pulseless electrical activity or ventricular asystole, vasopressin may be beneficial for myocardial and cerebral blood flow: 0.2–0.8 Units/kg, IV once. (**Note:** *This reference has a stepwise guidance flowchart for treating vasodilatory shock and CPCR with pulseless electrical activity or ventricular asystole that veterinary practices are encouraged to have on hand—Plumb*) (Scroggin & Quandt 2009)

For treatment of central diabetes insipidus: [**Note:** Because vasopressin tannate in oil is no longer commercially available; most clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.]

## Monitoring

- Urine output/frequency
- Water consumption
- Urine specific gravity &/or osmolality

## Chemistry/Synonyms

A hypothalamic hormone stored in the posterior pituitary, vasopressin is a 9-amino acid polypeptide with a disulfide bond. In most mammals (including dogs and humans), the natural hormone is arginine vasopressin, while in swine the arginine is replaced with lysine. Lysine vasopressin has only about ½ the antidiuretic activity of arginine vasopressin. The commercially available vasopressin products may be a combination of arginine or lysine vasopressin derived from natural sources or synthetically prepared. The products are standardized by their pressor activity in rats [USP posterior Pituitary (pressor) Units]; their antidiuretic activity can be variable. Commercially available vasopressin has little, if any, oxytocic activity at usual doses.

Vasopressin injection occurs as a clear, colorless or practically colorless liquid with a faint, characteristic odor. Vasopressin is soluble in water.

Vasopressin may also be known as: ADH, antidiuretic hormone, 8-arginine vasopressin, beta-hypophamine, *Neo-Lidocaton*®, *Pitressin*® or *Pressyn*®.

## Storage/Stability

Vasopressin (aqueous) injection should be stored at room temperature; avoid freezing.

## Compatibility/Compounding Considerations

If the aqueous injection is to be administered as an intravenous or intra-arterial infusion, it may be diluted in either D5W or normal saline. For infusion use in humans, it is usually diluted to a concentration of 0.1–1 Unit/mL.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Vasopressin Injection: 20 pressor Units/mL in 0.5 mL, 1 mL & 10 mL vials; *Pitressin*® *Synthetic* (JHP Pharm); generic; (Rx)

Vasopressin Tannate Sterile Suspension in oil is no longer commercially available.

## VECURONIUM BROMIDE

(vek-yew-roe-nee-um) Norcuron®

NONDEPOLARIZING NEUROMUSCULAR BLOCKER

### Prescriber Highlights

- **Nondepolarizing neuromuscular blocking agent**
  - **Caution: Severe renal dysfunction, hepatic, or biliary disease; extreme caution: myasthenia gravis**
  - **Adverse Effects: None, other than pharmacologic actions**
  - **No analgesia or anesthetic effects**
- 

## Uses/Indications

Vecuronium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation. It causes very minimal cardiac effects and generally does not cause the release of histamine. Vecuronium has been used topically to cause mydriasis in birds.

## Pharmacology/Actions

Vecuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor endplate, thereby inhibiting the effects of acetylcholine. The potency of vecuronium when compared to pancuronium (on a weight basis) has been described as being equipotent to up to 3 times as potent.

## Pharmacokinetics

The onset of neuromuscular blockade after IV injection is dependent upon the dose administered. In dogs administered 0.1 mg/kg IV, full neuromuscular block occurs within 2 minutes and the duration of action at this dose is approximately 25 minutes (also receiving halothane anesthesia). Vecuronium has a shorter duration of action than pancuronium (approx. ½–½ as long), but is very similar to that of atracurium.

A study done in rats showed that vecuronium was absorbed after intratracheal administration with an onset of action that was slower than intravenous administration, but faster than intramuscular. Intratracheal administration resulted in a longer duration of action than intravenous dosing (Sunaga *et al.* 2006).

Vecuronium is partially metabolized; it and its metabolites are excreted into the bile and urine. Prolonged recovery times may result in patients with significant renal or hepatic disease.

## Contraindications/Precautions/Warnings

Vecuronium is contraindicated in patients hypersensitive to it. It should be used with caution in patients with severe renal dysfunction. Lower doses may be necessary in patients with hepatic or biliary disease. Vecuronium has no analgesic or sedative/anesthetic actions. In patients with myasthenia gravis, neuromuscular blocking agents should be used with extreme caution, if at all. One case of successful use in a dog with myasthenia gravis has been reported.

## Adverse Effects

In human studies and one limited dog study, adverse effects other than what would be seen pharmacologically (skeletal muscle weakness to profound, prolonged musculoskeletal paralysis) have not been reported.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

No cases of vecuronium overdosage have yet been reported (human or veterinary). Should an inadvertent overdose occur, treat conservatively (mechanical ventilation, O<sub>2</sub>, fluids, etc.). Reversal of blockade might be accomplished by administering an anticholinesterase agent (edrophonium, physostigmine, or neostigmine) with an anticholinergic (atropine or glycopyrrolate). A suggested dose for neostigmine is 0.06 mg/kg IV after atropine 0.02 mg/kg IV.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vecuronium and may be of significance in veterinary patients:

■ **NON-DEPOLARIZING MUSCLE RELAXANT DRUGS, OTHER:** May have a synergistic effect if used with vecuronium

■ **SUCCINYLCHOLINE:** May speed the onset of action and enhance the neuromuscular blocking actions of vecuronium; do not give vecuronium until succinylcholine effects have subsided  
The following agents may enhance or prolong the neuromuscular blocking activity of vecuronium:

■ **AMINOGLYCOSIDES**

■ **ANESTHETICS (HALOTHANE, ISOFLURANE, SEVOFLURANE)**

■ **CLINDAMYCIN, LINCOMYCIN**

■ **DANTROLENE**

■ **MAGNESIUM SALTS**

■ **PIPERACILLIN, MEZLOCILLIN**

■ **QUINIDINE**

■ **TETRACYCLINES**

■ **VERAPAMIL**

## Doses

### ■ DOGS:

a) 0.1 mg/kg IV initially (after meperidine and/or acepromazine pre-op 30 minutes before); may give subsequent incremental doses of 0.04 mg/kg IV. Duration of action after initial dose averages 25 minutes. (Jones & Seymour 1985)

b) 10–20 micrograms/kg IV (Morgan 2003)

c) If using CRI propofol-fentanyl anesthesia: CRI maintenance infusion rate of vecuronium at 0.2 mg/kg/hr;

    If using CRI fentanyl-isoflurane or fentanyl-sevoflurane anesthesia: CRI maintenance infusion rate of vecuronium at 0.1 mg/kg/hr. (Nagahama *et al.* 2006)

### ■ CATS:

a) 20–40 micrograms/kg (0.02–0.04 mg/kg) IV (Morgan 2003)

## Monitoring

■ Level of neuromuscular relaxation

## Client Information

■ This drug should only be used by professionals familiar with its use

## Chemistry/Synonyms

Structurally similar to pancuronium, vecuronium bromide is a synthetic, nondepolarizing neuromuscular blocking agent. It contains the steroid (androstane) nucleus, but is devoid of steroid activity. It occurs as white to off-white, or slightly pink crystals or crystalline powder. In aqueous solution, it has a pKa of 8.97, and the commercial injection has a pH of 4 after reconstitution. 9 mg are soluble in 1 mL of water; 23 mg are soluble in 1 mL of alcohol.

Vecuronium Bromide may also be known as: Org-NC-45, *Curlem*®, *Norcuron*®, *Rivecrum*®, *Vecural*®, or *Vecuron*®.

## Storage/Stability

The commercially available powder for injection should be stored at room temperature and protected from light. After reconstitution with sterile water for injection, vecuronium bromide is stable for 24 hours at either 2–8°C or at room temperature (less than 30°C) if stored in the original container. As it contains no preservative, unused portions should be discarded after reconstitution. The drug is stable for 48 hours at room temperature or refrigerated when stored in plastic or glass syringes, but the manufacturer recommends that it be used within 24 hours.

## Compatibility/Compounding Considerations

Vecuronium bromide has been shown to be physically **compatible** with D5W, normal saline, D5 in normal saline, and lactated Ringer's.

It should **not** be mixed with alkaline solutions (*e.g.*, thiobarbiturates).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Vecuronium Bromide Powder for Injection: 10 mg & 20 mg; in 10 mL & 20 mL vials, with and without diluent; *Norcuron*® (Organon); generic; (Rx)

## VERAPAMIL HCL

(*ver-ap-a-mill*) Calan®, Isoptin®, Verelan®

**CALCIUM-CHANNEL BLOCKER**

### Prescriber Highlights

- **Calcium channel blocking agent used for supraventricular tachycardias in dogs & cats**
  - **Contraindications:** Cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia), hypotension, sick sinus syndrome, 2nd or 3rd degree AV block, digoxin intoxication, or hypersensitive to verapamil. IV is contraindicated within a few hours of IV beta-adrenergic blockers.
  - **Caution:** Heart failure, hypertrophic cardiomyopathy, & hepatic or renal impairment. Use very cautiously in patients with atrial fibrillation & Wolff-Parkinson-White (WPW) syndrome.
  - **Adverse Effects:** Hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache, or fatigue
  - **Drug Interactions**
- 

### Uses/Indications

Veterinary experience with this agent is somewhat limited, but in dogs and cats verapamil may be useful for supraventricular tachycardias and, possibly, treatment of atrial flutter or fibrillation. Verapamil is being studied as an adjunctive treatment for pharmaco-resistant epilepsy.

### Pharmacology/Actions

A slow-channel calcium blocking agent, verapamil is classified as a class IV antiarrhythmic drug. Verapamil exerts its actions by blocking the transmembrane influx of extracellular calcium ions across membranes of vascular smooth muscle cells and myocardial cells. The result of this blocking is to inhibit the contractile mechanisms of vascular and cardiac smooth muscle. Verapamil has inhibitory effects on the cardiac conduction system and these effects produce its antiarrhythmic properties. Electrophysiologic effects include increased effective refractory period of the AV node, decreased automaticity and substantially decreased AV node conduction. On ECG, heart rate and RR intervals can be increased or decreased; PR and A-H intervals are increased. Verapamil has negative effects on myocardial contractility and decreases peripheral vascular resistance.

Verapamil is an inhibitor of P-glycoprotein which is the mechanism proposed for its potential to treat pharmaco-resistant epilepsy.

### Pharmacokinetics

In humans, about 90% of a dose of verapamil is rapidly absorbed after oral administration, but because of a high first-pass effect, only about 20–30% is available to the systemic circulation. Patients with significant hepatic dysfunction may have considerably higher percentages of the drug systemically bioavailable. Food will decrease the rate and extent of absorption of the sustained-release tablets, but less so with the conventional tablets.

Verapamil's volume of distribution is between 4.5–7 L/kg in humans and has been reported to be approximately 4.5 L/kg in dogs. In humans, approximately 90% of the drug in the serum is bound to plasma proteins. Verapamil crosses the placenta and milk levels may approach those in the plasma.

Verapamil is metabolized in the liver to at least 12 separate metabolites, with norverapamil being the most predominant. The majority of the amounts of these metabolites are excreted into the urine. Only 3–4% is excreted unchanged in the urine. In humans, the half-life of the drug is 2–8 hours after a single IV dose, but it can increase after 1–2 days of oral therapy (presumably due to a saturable process of the hepatic enzymes). Serum half-lives of 0.8 hours and 2.5 hours have been reported in the dog.

### Contraindications/Precautions/Warnings

Verapamil is contraindicated in patients with cardiogenic shock or severe CHF (unless secondary to a supraventricular tachycardia amenable to verapamil therapy), hypotension (<90 mmHg systolic), sick sinus syndrome, 2nd or 3rd degree AV block, digoxin intoxication, or hypersensitive to verapamil.

IV verapamil is contraindicated within a few hours of IV beta-adrenergic blocking agents (*e.g.*, propranolol) as they both can depress myocardial contractility and AV node conduction. Use of this combination in patients with wide complex ventricular tachycardia (QRS >0.11 seconds) can cause rapid hemodynamic deterioration and ventricular fibrillation.

Verapamil should be used with caution in patients with heart failure, hypertrophic cardiomyopathy, and hepatic or renal impairment. Toxicity may be potentiated in patients with hepatic dysfunction. It should be used very cautiously in patients with atrial fibrillation and Wolff-Parkinson-White (WPW) syndrome as fatal arrhythmias may result.

Because verapamil may increase blood glucose in dogs, it should be used with caution in diabetic animals.

Verapamil is potentially a neurotoxic substrate of P-glycoprotein; use with caution in those herding breeds (*e.g.*, Collies) that may have the gene mutation that causes a nonfunctional protein.

### Adverse Effects

The following adverse reactions may occur: hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache or fatigue.

### Reproductive/Nursing Safety

Oral verapamil in rats with doses 1.5–6 times the human dose was embryocidal and retarded fetal growth and development, probably due to reduced weight gains in dams. Verapamil crosses the placenta and can be detected in umbilical vein blood at delivery. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Verapamil is excreted in milk. Consider discontinuing nursing if the dam requires verapamil therapy.

### Overdosage/Acute Toxicity

Clinical signs of overdosage may include bradycardia, hypotension, hyperglycemia, junctional rhythms, and 2nd or 3rd degree AV block.

If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered. Treatment is generally supportive in nature; vigorously monitor cardiac and respiratory function. Intravenous calcium salts (1 mL of 10% solution per 10 kgs of body weight) have been suggested to treat the negative inotropic clinical signs, but may not adequately treat clinical signs of heart block. Use of fluids and pressor agents (*e.g.*, dopamine, norepinephrine, etc.) may be utilized to treat hypotensive clinical signs. The AV block and/or bradycardia can be treated with isoproterenol, norepinephrine, atropine, or cardiac pacing. Patients that develop a rapid ventricular rate after verapamil due to antegrade conduction in flutter/fibrillation with WPW syndrome, have been treated with D.C. cardioversion, lidocaine, or procainamide.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving verapamil and may be of significance in veterinary patients:

- **ACE INHIBITORS:** May cause additive hypotensive effects
- **ALPHA-ADRENERGIC BLOCKERS (*e.g.*, prazosin):** May cause additive hypotensive effects
- **BETA-ADRENERGIC BLOCKERS (*e.g.*, propranolol):** May cause additive negative cardiac inotrope and chronotrope effects
- **DOXORUBICIN:** Verapamil may increase concentrations
- **COPP CHEMOTHERAPY (cyclophosphamide, vincristine, procarbazine, prednisone):** May decrease oral absorption of verapamil
- **CYCLOSPORINE:** Verapamil may increase levels
- **DANTROLENE:** Cardiovascular collapse reported in animals when used with verapamil
- **DIGOXIN:** Verapamil may increase the blood levels of digoxin; monitoring of digoxin levels recommended
- **DISOPYRAMIDE:** May cause additive effects; impair left ventricular function; use together within 24–48 hours not recommended
- **DIURETICS:** May cause additive hypotensive effects
- **ERYTHROMYCIN, CLARITHROMYCIN:** May increase verapamil levels
- **FLECAINIDE:** Possible additive effects; use is together with verapamil is to be avoided in humans
- **NEUROMUSCULAR BLOCKERS:** Neuromuscular blocking effects of nondepolarizing muscle relaxants may be enhanced by verapamil
- **PHENOBARBITAL:** May reduce verapamil levels
- **QUINIDINE:** Additive alpha-adrenergic blocking activity; increased hypotensive effect; verapamil can block quinidine's AV conductive effects and increase quinidine levels
- **RIFAMPIN:** May reduce verapamil levels
- **THEOPHYLLINE:** Verapamil may increase serum levels of theophylline and lead to toxicity

■ **VINCRISTINE:** Calcium channel blockers increase intracellular vincristine by inhibiting the drug's outflow from the cell

## Laboratory Considerations

■ Verapamil may elevate blood glucose in dogs and confuse **blood glucose** determinations

## Doses

### ■ DOGS:

- Initial dose of 0.05 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–2 mg/kg PO q8h (Ware 2000)
- For treatment of hypertension: 1–5 mg/kg PO q8h (Brovida 2002)
- For emergency treatment for hemodynamically unstable and sustained (continuous) supraventricular tachycardia: As an alternative to diltiazem, verapamil can be given IV in a series of 0.05 mg/kg boluses IV (slowly) up to a total dose of 0.15 mg/kg. (Smith 2009)
- 1–5 mg/kg PO three times daily; 0.05–0.25 mg/kg IV slowly (Kramer 2003)
- For the acute termination of supraventricular tachycardia: Initial dose of 0.05 mg/kg should be administered over 1–2 minutes while ECG is monitored; if not effective, may repeat in 5–10 minutes. If arrhythmia still not terminated, may give one last dose of 0.05 mg/kg (total = 0.15 mg/kg). Effect may persist for 30 minutes or less. For longer control, may give as a CRI at 2–10 micrograms/kg/minute. (Kittleson 2006)

### ■ CATS:

- Initial dose of 0.025 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–1 mg/kg PO q8h (Ware 2000)

### ■ HORSES: (NOTE: ARCI UCGFS CLASS 4 DRUG)

- To control ventricular rate in atrial fibrillation: 0.025–0.05 mg/kg IV q 30 minutes; give less than 0.2 mg/kg total dose (Reimer 2002)

### ■ SMALL MAMMALS:

- Hamsters:** 0.25–0.5 mg (total dose per hamster) SC;  
**Rabbits:** 8–16 mg/kg PO + 0.5–2 mg/kg SC once daily (q24h). (Heatley 2009)

## Monitoring

- ECG
- Clinical signs of toxicity (see Adverse Effects);
- Blood pressure, during acute IV therapy
- Serum concentration, if efficacy or toxicity warrant (100–300 ng/mL is considered therapeutic)

## Client Information

- To be effective, the animal must receive all doses as prescribed
- If animal becomes lethargic or becomes exercise intolerant, begins wheezing, has shortness of breath or cough, or develops a change in behavior or attitude, notify veterinarian.

## Chemistry/Synonyms

A calcium channel blocking agent, verapamil HCl occurs as a bitter-tasting, nearly white, crystalline powder. It is soluble in water and the injectable product has a pH of 4–6.5. Verapamil HCl tablets should be stored at room temperature (15–30°C); the injectable product should be stored at room temperature (15–30°C) and protected from light and freezing. Verapamil may also be known as: CP-16533-1, D-365, iproveratril hydrochloride, verapamili hydrochloridum; many trade names are available.

## Compatibility/Compounding Considerations

Verapamil HCl for injection is physically **compatible** when mixed with all commonly used intravenous solutions. However, a crystalline precipitate may form if verapamil is added to an infusion line with 0.45% sodium chloride with sodium bicarbonate running. Verapamil is reported to be physically **compatible** with the following drugs: amikacin sulfate, aminophylline, ampicillin sodium, ascorbic acid, atropine sulfate, bretylium tosylate, calcium chloride/gluconate, cefazolin sodium, cefotaxime sodium, ceftiofur sodium, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dexamethasone sodium phosphate, diazepam, digoxin, dobutamine HCl (slight discoloration due to dobutamine oxidation), dopamine HCl, epinephrine HCl, furosemide, gentamicin sulfate, heparin sodium, hydrocortisone sodium phosphate, hydromorphone HCl, insulin, isoproterenol, lidocaine HCl, magnesium sulfate, mannitol, meperidine HCl, metamizolol bitartrate, methylprednisolone sodium succinate, metoclopramide HCl, morphine sulfate, multivitamin infusion, nitroglycerin, norepinephrine bitartrate, oxytocin, pancuronium Br, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, phenolamine mesylate, phenytoin sodium, potassium chloride/phosphate, procainamide HCl, propranolol HCl, protamine sulfate, quinidine gluconate, sodium bicarbonate, sodium nitroprusside, tobramycin sulfate, vasopressin, and vitamin B complex with C.

The following drugs have been reported to be physically **incompatible** with verapamil: albumin injection, amphotericin B, hydralazine HCl, and trimethoprim/sulfamethoxazole. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Verapamil HCl Tablets: 40 mg, 80 mg & 120 mg; *Calan*® (Pfizer); generic; (Rx)

Verapamil HCl Sustained/Extended-Release Tablets/Capsules: 100 mg, 120 mg, 180 mg, 200 mg, 240 mg, 300 mg & 360 mg; *Calan*® SR & *Covera-HS*® (Pfizer); *Isoptin*® SR (FSC Laboratories); *Verelan*® & *Verelan*® PM (Schwarz Pharma); generic; (Rx)

Verapamil HCl for Injection: 2.5 mg/mL in 2 mL & 4 mL vials, amps and syringes, 2 mL fill in single-use 2 mL *Carpject* & *Carpject Interlink* syringes; generic; (Rx)

## VINBLASTINE SULFATE

(*vin-blas-teen*) **Velban**®

ANTINEOPLASTIC

### Prescriber Highlights

- A Vinca alkaloid antineoplastic used for a variety of tumors in dogs (& sometimes cats)
- **Contraindications:** Preexisting leukopenia or granulocytopenia (unless a result of the disease being treated) or active bacterial infection; reduce dose if hepatic disease

- **Adverse Effects: Gastroenterocolitis (nausea/vomiting), myelosuppression (more so than with vincristine); may also cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw & muscle pain, & loss of deep tendon reflexes**
  - **Cats can develop neurotoxicity causing constipation or paralytic ileus & aggravating anorexia; can also develop reversible axon swelling & paranodal demyelination**
  - **Potentially teratogenic**
  - **Avoid extravasation; wear gloves & protective clothing when preparing or administering**
  - **Drug Interactions**
- 

### Uses/Indications

Vinblastine may be employed in the treatment of lymphomas, carcinomas, mastocytomas, and splenic tumors in small animals. It is more effective than vincristine in the treatment of canine mast cell tumors.

### Pharmacology/Actions

Vinblastine apparently binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation.

### Pharmacokinetics

Vinblastine is administered IV. After injection, it is rapidly distributed to tissues. In humans, approximately 75% is bound to tissue proteins and the drug does not appreciably enter the CNS.

Vinblastine is extensively metabolized by the liver and is primarily excreted in the bile/feces; lesser amounts are eliminated in the urine.

### Contraindications/Precautions/Warnings

Vinblastine is contraindicated in patients with preexisting leukopenia or granulocytopenia (unless a result of the disease being treated), or active bacterial infection.

Doses of vinblastine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dL.

Because vinblastine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies) that may have the gene mutation (MDR1; *ABCB1*) that causes a nonfunctional protein. Bone marrow suppression (decreased blood cell counts, particularly neutrophils) and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the *ABCB1* mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25-30% and carefully monitoring these patients (WSU-VetClinPharmLab 2009).

As vinblastine may be a skin irritant, gloves and protective clothing should be worn when preparing or administering the medication. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

### Adverse Effects

Vinblastine can cause gastroenterocolitis (nausea/vomiting), which generally lasts less than 24-hours. It can be myelosuppressive at usual dosages (nadir at 4–9 days after treatment; recovery at 7–14 days). Vinblastine is considered more myelosuppressive than is vincristine.

Vinblastine may not possess the degree of peripheral neurotoxic effects seen with vincristine, but at high doses, these effects may be seen. Additionally, vinblastine may cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw and muscle pain, and loss of deep tendon reflexes.

Cats can develop neurotoxicity that can be associated with constipation or paralytic ileus thereby aggravating anorexia. They may develop reversible axon swelling and paranodal demyelination.

Extravasation of vinblastine may cause significant tissue irritation and cellulitis. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw the drug from the vial. Should clinical signs of extravasation be noted, discontinue infusion immediately at that site and apply moderate heat to the area to help disperse the drug. Injections of hyaluronidase have also been suggested to help diffuse the drug.

### Reproductive/Nursing Safety

Little is known about the effects of vinblastine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known whether vinblastine is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if dams are being given this drug.

### Overdosage/Acute Toxicity

In dogs, the lethal dose for vinblastine has been reported as 0.2 mg/kg. Effects of an overdosage of vinblastine are exacerbations of the adverse effects outlined above. Additionally, neurotoxic effects similar to those associated with vincristine may also be noted.

A case report of a cat receiving a 4X IV overdose has been published (Grant *et al.* 2010). The following were noted with this patient after the overdose: Within hours the cat developed depression and was unable to jump; days 1-11 anorexia; days 2-6 neutropenia with a fever on day 4; days 2-10 thrombocytopenia and anemia; days 4-10 vomiting and diarrhea, and on days 3-10 syndrome of inappropriate ADH (SIADH). Aggressive therapeutic interventions supporting the patient resulted in a positive outcome.

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants, and prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vinblastine and may be of significance in veterinary patients:

■ **OTOTOXIC DRUGS (e.g., cisplatin, carboplatin):** May cause additive risk for ototoxicity

Caution is advised if using other drugs that can inhibit **p-glycoprotein** particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”), unless tested “normal”. Drugs and drug classes involved include:

■ **AMIODARONE**

■ **AZOLE ANTIFUNGALS (e.g., ketoconazole)**

■ **CARVEDILOL**

■ **CYCLOSPORINE**

■ **DILTIAZEM**

■ **ERYTHROMYCIN; CLARITHROMYCIN**

■ **QUINIDINE**

■ **SPIRONOLACTONE**

■ **TAMOXIFEN**

■ **VERAPAMIL**

### Laboratory Considerations

■ Vinblastine may significantly increase both blood and urine concentrations of **uric acid**

### Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages

should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] are strongly recommended.

#### ■ DOGS/CATS:

The following are doses are general guidelines (see above). Depending on the protocol and the disease treated, vinblastine doses are usually 2–2.2 mg/m<sup>2</sup> IV every 1-2 weeks often in combination with other chemo drugs (e.g., in dogs, cyclophosphamide and prednisolone). There is one protocol for dogs (Woods 2010), where it is given on four subsequent days every 3 weeks.

#### Monitoring

- Efficacy
- Toxicity (complete blood counts with platelets; liver function tests prior to therapy and repeated as necessary; serum uric acid)

#### Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Contact the veterinarian if the patient exhibits any symptoms of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising

#### Chemistry/Synonyms

Commonly referred to as a Vinca alkaloid, vinblastine sulfate is isolated from the plant *Cantharanthus roseus* (*Vinca rosea* Linn) and occurs as a white or slightly yellow, hygroscopic, amorphous or crystalline powder that is freely soluble in water. The commercially available injection has a pH of 3–5.5.

Vinblastine may also be known as: 29060-LE, NSC-49842, sulfato de vimblastina, vinblastini sulfas, vincal leukoblastine sulphate, VBL, *Alkaban*®, *Blastovin*®, *Cellblastin*®, *Cytoblastin*®, *Ifabla*®, *Lemblastine*®, *Periblastine*®, *Serovin*®, *Solblastin*®, *Velban*®, *Velbe*®, *Velsar*®, or *Xintoprost*®.

#### Storage/Stability

The sterile powder for injection, solution for injection and reconstituted powder for injection should all be protected from light. The powder for injection and injection should be stored in the refrigerator (2–8°C). The intact powder for injection is stable at room temperature for at least one month. After reconstituting with bacteriostatic saline, the powder for injection is stable for 30 days if refrigerated.

#### Compatibility/Compounding Considerations

Vinblastine sulfate is reportedly physically **compatible** with the following intravenous solutions and drugs: D5W and bleomycin sulfate. In syringes or at Y-sites with: bleomycin sulfate, cisplatin, cyclophosphamide, droperidol, fluorouracil, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vincristine sulfate.

Vinblastine sulfate **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: doxorubicin HCl and heparin sodium (in syringes).

Vinblastine sulfate is reportedly physically **incompatible** with furosemide.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### **HUMAN-LABELED PRODUCTS:**

Vinblastine Sulfate Injection: 1 mg/mL in 10 mL & 25 mL vials; generic; (Rx)

Vinblastine Powder for Injection: 10 mg in vials; *Velban*® (Lilly); generic; (Rx)

## VINCRIStINE SULFATE

(vin-*kris*-teen) Oncovin®

ANTINEOPLASTIC

### Prescriber Highlights

- A Vinca alkaloid antineoplastic used for a variety of tumors in dogs & cats (primarily lymphoid & hematopoietic neoplasms); also used for the treatment of immune-mediated thrombocytopenia
- **Caution:** Hepatic disease, leukopenia, infection, or preexisting neuromuscular disease; reduce dose if hepatic disease
- **Adverse Effects:** Much less myelosuppressive than vinblastine, but may cause more peripheral neurotoxic effects; neuropathic clinical signs can include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation; *Cats* can develop neurotoxicity causing constipation or paralytic ileus & aggravating anorexia; can also develop reversible axon swelling & paranodal demyelination
- Potentially teratogenic
- Avoid extravasation; wear gloves & protective clothing when preparing or administering
- **Drug Interactions**

---

#### Uses/Indications

Vincristine is used as an antineoplastic primarily in combination drug protocols in dogs and cats in the treatment of lymphoid and hematopoietic neoplasms. In dogs, it may be used alone in the therapy of transmissible venereal neoplasms.

Because vincristine can induce thrombocytosis (at low doses) and has some immunosuppressant activity, it may also be employed in the treatment of immune-mediated thrombocytopenia, but efficacy is questionable.

#### Pharmacology/Actions

Vincristine apparently binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle and urea formation. Tumor resistance to one Vinca alkaloid does not imply resistance to another.

Vincristine can induce thrombocytosis (mechanism unknown) and has some immunosuppressant activity.

#### Pharmacokinetics

Vincristine is administered IV as it is unpredictably absorbed from the GI tract. After injection it is rapidly distributed to tissues. Vincristine is bound to tissue proteins and the drug does not appreciably enter the CNS.

Vincristine is extensively metabolized, presumably by the liver and primarily excreted in the bile/feces; lesser amounts are eliminated in the urine. The elimination half-life in dogs is reportedly biphasic with an alpha half-life of 13 minutes and a beta half-life of 75 minutes.

### Contraindications/Precautions/Warnings

Vincristine should be used with caution in patients with hepatic disease, leukopenia, infection, or preexisting neuromuscular disease.

Doses of vincristine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dL.

Because vincristine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (*e.g.*, Collies) that may have the gene mutation that causes a nonfunctional protein. Bone marrow suppression (decreased blood cell counts, particularly neutrophils) and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the *ABCB1* mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25-30% and carefully monitoring these patients (WSU-VetClinPharmLab 2009).

As vincristine may be a skin irritant, gloves and protective clothing should be worn when preparing or administering the medication. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

### Adverse Effects

Although structurally related to and having a similar mechanism of action as vinblastine, vincristine has a different adverse reaction profile. Vincristine is much less myelosuppressive (mild leukopenia) at usual doses than is vinblastine, but may cause more peripheral neurotoxic effects. Neuropathic clinical signs may include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation. In humans, vincristine commonly causes mild sensory impairment and peripheral paresthesias. These may also occur in animals, but are not usually noted due to difficulty in detection. Cats, however, can develop neurotoxicity that can be associated with constipation or paralytic ileus thereby aggravating anorexia. They can develop reversible axon swelling and paranodal demyelination.

Additionally, in small animals, vincristine may cause impaired platelet aggregation, increased liver enzymes, inappropriate ADH secretion, jaw pain, alopecia, stomatitis, or seizures.

A case report of cat developing pulmonary edema attributed to vincristine administration has been published (Polton & Elwood 2008).

Extravasation injuries associated with perivascular injection of vincristine can range from irritation to necrosis and tissue sloughing. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw it from the vial. Recommendations of therapy for extravasation include discontinuing the infusion immediately at that site and applying moderate heat to the area to help disperse the drug. Injections of hyaluronidase have been suggested to help diffuse the drug. Others have suggested applying ice to the area to limit the drug's diffusion and minimize the area affected. Topical dimethyl sulfoxide (DMSO) has also been recommended by some to treat the area involved.

### Reproductive/Nursing Safety

Little is known about the effects of vincristine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males. In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

It is not known whether this drug is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if dams are being given this drug.

### Overdosage/Acute Toxicity

In dogs, it is reported that the maximally tolerated dose of vincristine is 0.06 mg/kg every 7 days for 6 weeks. Animals receiving this dose showed signs of slight anemia, leukopenia, increased liver enzymes, and neuronal shrinkage in the peripheral and central nervous systems.

In cats, the lethal dose of vincristine is reportedly 0.1 mg/kg. Cats receiving toxic doses showed clinical signs of weight loss, seizures, leukopenia, and general debilitation. A case report of cat receiving a 10X overdose (5 mg/m<sup>2</sup>) has been published (Hughes *et al.* 2009). Despite intensive treatment including using calcium folinate, the cat died 72 hours after the overdose.

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants, and prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality. There have been some reports of leucovorin calcium being used to treat vincristine overdoses in humans, but efficacy of this treatment has not yet been confirmed.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vincristine and may be of significance in veterinary patients:

■ **ASPARAGINASE:** Additive neurotoxicity may occur; is apparently less common when asparaginase is administered after vincristine

■ **MITOMYCIN:** In humans who have previously or simultaneously received mitomycin-C with Vinca alkaloids, severe bronchospasm has occurred

Caution is advised if using other drugs that can inhibit **p-glycoprotein** particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. "white feet"), unless tested "normal". Drugs and drug classes involved include:

■ **AMIODARONE**

■ **AZOLE ANTIFUNGALS** (*e.g.*, ketoconazole)

■ **CARVEDILOL**

■ **CYCLOSPORINE**

■ **DILTIAZEM**

■ **ERYTHROMYCIN; CLARITHROMYCIN**

■ **QUINIDINE**

■ **SPIRONOLACTONE**

■ **TAMOXIFEN**

■ **VERAPAMIL**

### Laboratory Considerations

■ Vincristine may significantly increase both blood and urine concentrations of **uric acid**

### Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] are *strongly recommended*.

#### ■ DOGS:

For neoplastic diseases (usually used in combination protocols with other drugs; consultation with a veterinary oncologist is encouraged before use; see above): Vincristine is usually dosed in dogs at 0.5–0.75 mg/m<sup>2</sup> (*NOT* mg/kg) IV and administered every 1–2 weeks. When used for transmissible venereal tumor, vincristine is used as sole therapy usually at 0.5 mg/m<sup>2</sup> (maximum dose 1 mg) IV once weekly for 4-6 weeks of therapy.

For adjunctive treatment of immune-mediated thrombocytopenia:

a) 0.5 mg/m<sup>2</sup> IV if platelet count <10-20,000 cells/mcL or bleeding; consider bone marrow aspiration to document presence of megakaryocytes. (Saxon 2008)

b) If refractory to prednisone (3–5 days), give vincristine at 0.5–0.7 mg/m<sup>2</sup> IV bolus or as an infusion over 4–6 hours. (Trepanier 1999)

c) 0.02 mg/kg IV once; generally single use (Cohn 2004)

#### ■ CATS:

For neoplastic diseases; (consultation with a veterinary oncologist is encouraged before use; see above): Vincristine is usually dosed in cats at 0.5–0.75 mg/m<sup>2</sup> (*NOT* mg/kg) IV and administered every 1-3 weeks.

#### ■ HORSES:

For neoplastic diseases; consultation with a veterinary oncologist is encouraged before use.

a) Usual doses used in horses are: 0.5 mg/m<sup>2</sup> (usually 2.5–3 mg total dose per horse) IV weekly. For generalized lymphoma the CAP protocol was used at the time of publication by one of the authors: cytarabine (cytosine arabinoside) at an average dose of 1–1.2 grams (total dose), SC or IM once every 1–2 weeks; cyclophosphamide at a dose of 1 gram (total dose) IV every 2 weeks (alternating with cytarabine); and prednisolone at a dose of 1 mg/kg PO every other day. Vincristine at 2.5 mg (total dose) IV is added on the weeks when the cytarabine is administered if there is no response. These are starting doses; the total doses can be increased by 20–30% without expecting complications. With remission, the starting doses are maintained for 2–3 months and then the horse is switched onto a maintenance protocol. The first cycle of maintenance therapy increases the treatment interval for each drug by one week (except prednisolone which is kept at the same frequency but with a reducing dose). If horse is still in remission after 2–3 months of the first cycle, the second cycle is begun by adding a further week to the treatment intervals of each drug. (Mair & Couto 2006)

## Monitoring

- Efficacy (tumor burden reduction or platelet count)
- Toxicity (peripheral neuropathic clinical signs; complete blood counts with platelets; liver function tests prior to therapy and repeated as necessary; serum uric acid)

## Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Clients should contact the veterinarian if the patient exhibits any signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising, severe constipation, or severe peripheral neuropathic signs
- Avoid contact with treated patient's urine, saliva or feces after treatment. Vincristine or metabolites have been detected in dogs' urine up to 7 days after treatment.

## Chemistry/Synonyms

Commonly referred to as a Vinca alkaloid, vincristine sulfate is isolated from the plant *Cantharanthus roseus* (*Vinca rosea* Linn) and occurs as a white or slightly yellow, hygroscopic, amorphous or crystalline powder that is freely soluble in water and slightly soluble in alcohol. The commercially available injection has a pH of 3–5.5. Vincristine sulfate has pKas of 5 and 7.4

Vincristine Sulfate may also be known as: leurocristine sulfate, VCR, LCR compound 37231, leurocristine sulphate, NSC-67574, 22-oxovincal leukoblastine sulphate, sulfato de vincristina, vincristini sulfas and *Oncovin*®; many other trade names are available.

## Storage/Stability

Vincristine sulfate injection should be protected from light and stored in the refrigerator (2–8°C).

## Compatibility/Compounding Considerations

Vincristine sulfate is reportedly physically **compatible** with the following intravenous solutions and drugs: D5W, bleomycin sulfate, cytarabine, fluorouracil, and methotrexate sodium. In syringes or at Y-sites with: bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin HCl, droperidol, fluorouracil, heparin sodium, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vinblastine sulfate.

Vincristine sulfate is reportedly physically **incompatible** with furosemide. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Vincristine Sulfate Injection: 1 mg/mL in 1 mL, 2 mL & 5 mL vials and flip-top vials; *Vincasar*® PFS (Sicor); generic; (Rx)

## VITAMIN E/SELENIUM

### VITAMIN E

(*se-lee-nee-um*)

NUTRITIONAL; FAT SOLUBLE VITAMIN

### Prescriber Highlights

- **Lipid-soluble vitamin (E) with or without selenium used alone for discoid lupus erythematosus, canine demodicosis, acanthosis nigricans, hepatic fibrosis, or adjunctive therapy of exocrine pancreatic deficiency or hepatopathy in dogs & cats; used in combination for selenium-tocopherol deficiency (white muscle disease)**
- **Contraindications: Vitamin E/selenium products should only be used in the species for which they are FDA-approved**
- **Selenium overdoses can be extremely toxic**
- **Adverse Effects: Anaphylactoid reactions; IM injections may cause transient muscle soreness. Selenium ODs can cause depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, & a "garlic" odor on the breath**

## Uses/Indications

Depending on the actual product and species, vitamin E/selenium is indicated for the treatment or prophylaxis of selenium-tocopherol deficiency (STD) syndromes in ewes and lambs (white muscle disease), sows, weanling and baby pigs (hepatic necrosis, mulberry heart disease, white muscle disease), calves and breeding cows (white muscle disease), and horses (myositis associated with STD).

Vitamin E may be useful as adjunctive treatment of discoid lupus erythematosus, canine demodicosis, and acanthosis nigricans in dogs. It may also be of benefit in the adjunctive treatment of hepatic fibrosis or adjunctive therapy of copper-associated hepatopathy in dogs. There is some evidence that vitamin E and silymarin have synergistic effects on hepatocytes. Some dogs and cats with dilated cardiomyopathy have low vitamin E levels, but it is unknown if vitamin E supplementation has any clinical effect.

## Pharmacology/Actions

Both vitamin E and selenium are involved with cellular metabolism of sulfur. Vitamin E has antioxidant properties and, with selenium, protects against red blood cell hemolysis and prevents the action of peroxidase on unsaturated bonds in cell membranes.

## Pharmacokinetics

After absorption, vitamin E is transported in the circulatory system via lipoproteins. It is distributed to all tissues and adipose tissue. Vitamin E is only marginally transported across the placenta. Vitamin E is metabolized in the liver and excreted primarily into the bile. Absorption of vitamin E may be impaired in patients with severe cholestatic liver disease or in animals with fat malabsorption syndromes.

Pharmacokinetic parameters for selenium were not located.

### Contraindications/Precautions/Warnings

Vitamin E/selenium products should only be used in the species for which they are FDA-approved. Because selenium can be extremely toxic, the promiscuous use of these products cannot be condoned.

Give slowly when administering intravenously to horses.

### Adverse Effects

Anaphylactoid reactions have been reported. Intramuscular injections may be associated with transient muscle soreness. Other adverse effects are generally associated with overdoses of selenium (see below).

### Overdosage/Acute Toxicity

Selenium is quite toxic in overdose quantities, but has a fairly wide safety margin. Cattle have tolerated chronic doses of 0.6 mg/kg/day with no adverse effects (approximate therapeutic dose is 0.06 mg/kg). Clinical signs of selenium toxicity include depression, ataxia, dyspnea, blindness, diarrhea, muscle weakness, and a “garlic” odor on the breath. Horses suffering from selenium toxicity may become blind, paralyzed, slough their hooves, and lose hair from the tail and mane. Dogs may exhibit clinical signs of anorexia, vomiting, and diarrhea at high dosages.

Large overdoses of vitamin E can cause coagulopathies.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving vitamin E/selenium and may be of significance in veterinary patients:

■ **IRON:** Large doses of vitamin E may delay the hematologic response to iron therapy in patients with iron deficiency anemia.

■ **MINERAL OIL:** May reduce the absorption of orally administered vitamin E

■ **VITAMIN A:** Absorption, utilization and storage may be enhanced by vitamin E

■ **WARFARIN:** Vitamin E may increase the effects of warfarin

### Doses (Vitamin E alone):

For doses of vitamin E/selenium products see the Dosage Form section

#### ■ DOGS:

For adjunctive treatment of discoid lupus erythematosus, canine demodicosis or acanthosis nigricans:

a) 200–400 Units PO three times daily; variable efficacy, but relatively innocuous at these dosages (White 2000)

For adjunctive treatment of cholestatic hepatopathies; necro-inflammatory hepatopathies:

a) 10–15 Units/kg per day PO as alpha-tocopherol acetate. (Webster & Cooper 2009)

For adjunctive treatment of copper-associated hepatopathy:

a) 400–600 Units PO per day (Johnson, S. 2000)

For treatment of tocopherol deficiency associated with exocrine pancreatic disease:

a) 100–400 Units PO once daily for one month then every 1–2 weeks as needed (Williams 2000)

#### ■ CATS:

For treatment of tocopherol deficiency associated with exocrine pancreatic disease:

a) 30 Units PO once daily for one month then every 1–2 weeks as needed (Williams 2000)

For adjunctive treatment of hepatic lipidosis:

a) 10 Units/kg once PO once daily. (Scherk & Center 2005)

#### ■ HORSES:

For adjunctive treatment of ionophore (monensin) toxicity:

a) 4–12 Units/kg PO once daily (Mogg 1999)

For adjunctive therapy for EPM:

a) 8000–9000 Units PO per day (Dowling 1999)

For adjunctive therapy for metabolic syndrome:

a) 10,000 Units PO once daily (Johnson, P. 2003)

For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):

a) Foals: 4,000 Units PO once daily; Mares: 10,000 Units PO once daily (Slovits 2003)

### Monitoring

■ Clinical efficacy

■ Blood selenium levels (when using the combination product). Normal values for selenium have been reported as: >1.14 micromol/L in calves, >0.63 micromol/L in cattle, >1.26 micromol/L in sheep, and >0.6 micromol/L in pigs. Values indicating deficiency are: <0.40 micromol/L in cattle, <0.60 micromol/L in sheep, and <0.20 micromol/L in pigs. Intermediate values may result in suboptimal production

■ Optionally, glutathione peroxidase activity may be monitored

### Chemistry/Synonyms

Vitamin E is a lipid soluble vitamin that can be found in either liquid or solid forms. The liquid forms occur as clear, yellow to brownish red, viscous oils that are insoluble in water, soluble in alcohol and miscible with vegetable oils. Solid forms occur as white to tan-white granular powders that disperse in water to form cloudy suspensions. Vitamin E may also be known as alpha tocopherol.

Selenium in commercially available veterinary injections is found as sodium selenite. Each mg of sodium selenite contains approximately 460 micrograms (46%) of selenium.

### Storage/Stability

Vitamin E/Selenium for injection should be stored at temperatures less than 25°C (77°F).

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

*Vitamin E (Alone) Injection*

Vitamin E Injection: 300 mg/mL in 250 mL vials; *Emulsivit® E-300* (Vedco); *Vital E®-300* (Schering-Plough); (OTC or Rx)

*Vitamin E/Selenium Oral*

*Equ-SeE®* (Vet-A-Mix) (one teaspoonful contains 1 mg selenium and 220 Units vitamin E) and *Equ-Se5E®* (one teaspoonful contains 1 mg selenium and approximately 1100 Units vitamin E); (Vet-a-Mix); (OTC) FDA-approved for oral use in horses.

Other top dress equine products containing Vitamin E and Selenium include: Vitamin E and Selenium Powder (Farnam, Horse Health), *Vitamin E and Selenium Crumbles®* (Horse Health)

## Vitamin E/Selenium Injection

**Mu-Se®** (Schering); (Rx): Each mL contains: selenium 5 mg (as sodium selenite); Vitamin E 68 Units; 100 mL vial for injection. FDA-approved for use in non-lactating dairy cattle and beef cattle. Slaughter withdrawal (at labeled doses) = 30 days. Dose: For weanling calves: 1 mL per 200 lbs. body weight IM or SC. For breeding beef cows: 1 mL per 200 lbs. body weight during middle third of pregnancy and 30 days before calving IM or SC.

**Bo-Se®** (Schering); (Rx): Each mL contains selenium 1 mg (as sodium selenite) and Vitamin E 68 Units; 100 mL vial for injection. FDA-approved for use in calves, swine and sheep. Slaughter withdrawal (at labeled doses) = 30 days (calves); 14 days (lambs, ewes, sows, and pigs). Dose: Calves: 2.5–3.75 mL/100 lbs body weight (depending on severity of condition and geographical area) IM or SC. Lambs (2 weeks of age or older): 1 mL per 40 lbs. body weight IM or SC (1 mL minimum). Ewes: 2.5 mL/100 lbs. body weight IM or SC. Sows and weanling pigs: 1mL/40 lbs. body weight IM or SC (1 mL minimum). Do not use on newborn pigs.

**L-Se®** (Schering); (Rx): Each mL contains: selenium 0.25 mg (as sodium selenite) and Vitamin E 68 Units in 30 mL vials. FDA-approved for use in lambs and baby pigs. Slaughter withdrawal (at labeled doses) = 14 days. Dose: Lambs: 1 mL SC or IM in newborns and 4 mL SC or IM in lambs 2 weeks of age or older; Baby Pigs: 1 mL SC or IM.

**E-Se®** (Schering); (Rx): Each mL contains selenium 2.5 mg (as sodium selenite) and Vitamin E 68 Units in 100 mL vials. FDA-approved for use in horses. Dose: Equine: 1 mL/100 lbs. body weight slow IV or deep IM (in 2 or more sites; gluteal or cervical muscles). May be repeated at 5–10 day intervals.

**Seletoc®** (Schering); (Rx): Each mL contains selenium 1 mg (as sodium selenite) and Vitamin E 68 Units in 10 mL vials. FDA-approved for use in dogs. Dose: Dogs: Initially, 1 mL per 20 pounds of body weight (minimum 0.25 mL; maximum 5 mL) SC, or IM in divided doses in 2 or more sites. Repeat dose at 3 day intervals until satisfactory results then switch to maintenance dose. If no response in 14 days reevaluate. Maintenance dose: 1 mL per 40 lbs body weight (minimum 0.25 mL) repeat at 3–7 day intervals (or longer) to maintain.

## HUMAN-LABELED PRODUCTS:

Vitamin E Tablets: 100 Units, 200 Units, 400 Units, 500 Units & 800 Units; generic (various); OTC)

Vitamin E Capsules: 100 Units, 200 Units, 400 Units & 1000 Units; *Mixed E 400 Softgels®* & *d'ALPHA E 1000 Softgels®* (Naturally); *Vita-Plus E®* (Scot-Tussin); generic; (OTC)

Vitamin E Drops: 15 Units/0.3 mL in 12 mL & 30 mL; *Aquasol E®* (Mayne Pharma); *Aquavit-E®* (Cypress); (OTC)

Vitamin E Liquid: 15 Units/30 mL in 30 mL, 60 mL & 120 mL; 798 Units/30 mL in 473 mL; Vitamin E (Freeda); *Nutr-E-Sol®* (Advanced Nutritional Technology); (OTC)

Topicals are available. There are no FDA-approved vitamin E/selenium products, but there are many products that contain either vitamin E (alone, or in combination with other vitamins ± minerals) or selenium (as an injection alone or in combination with other trace elements) available.

## VORICONAZOLE

(vor-ih-koh-nah-zohl) Vfend®

SECOND GENERATION TRIAZOLE ANTIFUNGAL

### Prescriber Highlights

- **Broad-spectrum oral/parenteral triazole antifungal**
- **Very little clinical experience thus far in veterinary medicine; extremely expensive**
- **Cats appear to be susceptible to adverse effects. Until further pharmacokinetic and safety studies can be done, it should only be used in cats as a last resort.**
- **Like other compounds in this class, there are many potential drug interactions**

## Uses/Indications

Voriconazole may be a useful treatment for a variety of fungal infections in veterinary patients, particularly against *Blastomyces*, *Cryptococcus*, and *Aspergillus*. It has high oral bioavailability in a variety of species and can cross into the CNS. Currently available human dosage forms are extremely expensive, however, and little clinical experience has occurred using voriconazole in veterinary patients. There is considerable interest in using voriconazole for treating aspergillosis in pet birds as their relative small size may allow the drug to be affordable; additional research must be performed before dosing regimens are available.

## Pharmacology/Actions

Voriconazole a synthetic derivative of fluconazole, has broad-spectrum antifungal activity against a variety of organisms, including *Candida*, *Aspergillus*, *Trichosporon*, *Histoplasma*, *Cryptococcus*, *Blastomyces*, and *Fusarium* species. Like the other azole/triazole antifungals it inhibits cytochrome P-450-dependent 14-alpha-sterol demethylase that is required for ergosterol biosynthesis in fungal cell walls. Unlike fluconazole, voriconazole also inhibits 24-methylene dehydrolanosterol demethylation in molds such as *Aspergillus* giving it more activity against these fungi.

## Pharmacokinetics

In dogs, voriconazole is rapidly and essentially completely absorbed after oral administration. Peak levels occur about 3 hours after oral dosing. Voriconazole is only moderately (51%) bound to canine plasma proteins and volume of distribution is about 1.3 L/kg. It is metabolized in the liver to a variety of metabolites with the N-oxide metabolite being the primary circulating metabolite. This metabolite has only weak (<100X as active as the parent) antifungal activity. The elimination pharmacokinetics of voriconazole in dogs is very complex. Both dose-dependent non-linear elimination and auto-induced metabolism after multiple dosages are seen complicating any dosage regimen scenarios; dosages may need to be increased over time. Auto-induction of metabolism apparently does not occur in humans, rabbits or guinea pigs.

In horses, voriconazole is well absorbed after oral administration with peak levels occurring at approximately 1-3 hours post-dose. Voriconazole has low protein binding (31%); volume of distribution is about 1.35-1.6 L/kg. The drug is distributed into the CSF, tears and synovial fluid. Elimination half-life is quite long—approximately 13 hours after oral dosing. It is not known if voriconazole self-induces hepatic metabolism after multiple doses in the horse.

After single oral doses to alpacas, voriconazole had a low bioavailability (approx. 24%), but IV doses of 4 mg/kg yielded plasma levels above 0.1 micrograms/mL for at least 24 hours. Elimination half-life is about 8 hours (Chan *et al.* 2009).

In Hispaniolan Amazon parrots, oral voriconazole had a short half-life (about one hour). The authors concluded that the drug could be safely administered to this species at a dose of 18 mg/kg PO q8h for 11 days, but that further studies were necessary to determine safety and efficacy of long-term treatment (Guzman *et al.* 2010).

## Contraindications/Precautions/Warnings

Voriconazole is contraindicated in patients hypersensitive to it other azole antifungals. It should be given with caution to patients with hepatic dysfunction, or proarrhythmic conditions.

The intravenous product contains 3200 mg of sulfobutyl ether beta-cyclodextrin sodium (SBECD) per vial. This compound can accumulate in patients with decreased renal function.

## Adverse Effects

Accurate adverse effect profiles are unknown for veterinary species. Liver enlargement and up to a 2–3 fold increase in cytochrome P450 hepatic microsomal enzyme concentrations were noted in dogs orally dosed for 30 days. This may significantly impact the metabolism of other drugs that are hepatically metabolized (See Drug Interactions).

Two cats initially treated with 10 mg/kg PO once daily developed significant adverse reactions including azotemia, inappetence, lethargy, and weight loss. One developed a presumed cutaneous drug reaction which

Two cats initially treated with 10 mg/kg PO once daily developed significant adverse reactions, including ataxia, inappetence, lethargy, and weight loss. One developed a presumed cutaneous drug reaction which resolved when voriconazole was discontinued and the other cat developed ataxia and hind limb paresis (Smith & Hoffman 2010). In another published case report (Quimby *et al.* 2010), three cats receiving voriconazole at doses from 10–13 mg/kg PO once daily developed neurologic signs that included: ataxia in all subjects; 2 of the 3 cats developed paraplegia of hind limbs, 2 of the 3 cats had visual signs (mydriasis, decreased or absent pupillary light responses, and reduced menace response). One cat developed an arrhythmia and in one cat, hypokalemia was noted.

In humans, commonly encountered adverse effects include visual disturbances (blurring, spots, wavy lines) usually within 30 minutes of dosing or if higher drug concentrations are attained, and rashes (usually mild to moderate in severity). Less frequent adverse effects include gastrointestinal effects (nausea, vomiting, diarrhea), hepatotoxicity (jaundice, abnormal liver function tests), hypertension/hypotension, tachycardia, peripheral edema, hypokalemia, and hypomagnesemia. Rarely, eye hemorrhage, anemia, leukopenia, thrombocytopenia, pancytopenia, QT prolongation, torsade de pointes, and nephrotoxicity have been reported.

### Reproductive/Nursing Safety

Voriconazole was teratogenic in rats at low dosages (10 mg/kg) and embryotoxic in rabbits at higher dosages (100 mg/kg). In humans, the FDA categorizes voriconazole as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) Weigh the risks of treatment versus the benefits when considering use in pregnant patients.

It is unknown if voriconazole enters milk.

### Overdosage/Acute Toxicity

The minimum lethal dose in rats and mice was 300 mg/kg (4–7X maintenance dose). Toxic effects included increased salivation, mydriasis, ataxia, depression, dyspnea, and seizures. Accidental single overdoses of up to 5X in human pediatric patients caused only brief photophobia. No antidote is known for voriconazole overdoses. Gut emptying should be considered for very large oral overdoses, followed by close observation and supportive treatment if required.

### Drug Interactions

There are many potential drug interactions involving voriconazole. The following partial listing includes reported or theoretical interactions in humans receiving voriconazole that may also be of significance in veterinary patients. Because, in dogs, voriconazole induces hepatic microsomal enzymes (in humans it does not) additional interactions and further clarification may be reported as clinical use increases in veterinary patients.

- **ANTIDIABETIC AGENTS (sulfonylureas):** Voriconazole may increase serum concentrations of these drugs and increase risk for hypoglycemia
- **BARBITURATES (phenobarbital):** Decreased voriconazole concentrations; use together contraindicated
- **BENZODIAZEPINES:** Voriconazole may increase benzodiazepine concentrations
- **CALCIUM-CHANNEL BLOCKERS (amlodipine, diltiazem, verapamil):** Voriconazole may increase serum concentrations, dosage adjustment may be required
- **CARBAMAZEPINE:** Decreased voriconazole concentrations; use together contraindicated
- **CISAPRIDE:** Potential for serious cardiac arrhythmias; use is contraindicated
- **CORTICOSTEROIDS (prednisolone):** Potentially increased AUC for prednisolone
- **IMMUNOSUPPRESSIVE AGENTS (systemic: cyclosporine, tacrolimus):** Increased cyclosporine and tacrolimus concentrations; decrease cyclosporine dosage by 50% when starting voriconazole; decrease tacrolimus dosage by 33% when starting voriconazole
- **METHADONE:** Voriconazole may increase plasma concentrations of R-methadone; monitor for methadone toxicity and adjust dosage if necessary
- **PHENYTOIN:** Can decrease voriconazole concentrations and voriconazole can increase phenytoin concentrations; monitoring and dosage adjustment may be required
- **PIMOZIDE:** Potential for serious cardiac arrhythmias; use is contraindicated
- **PROTON-PUMP INHIBITORS (omeprazole):** Voriconazole may increase omeprazole (and potentially other PPI's) concentrations
- **QUINIDINE:** Potential for serious cardiac arrhythmias; use is contraindicated
- **RIFAMPIN, RIFABUTIN:** Decreased voriconazole concentrations; use together contraindicated
- **VINCA ALKALOIDS (vincristine, vinblastine):** Possible increased Vinca alkaloid concentrations; monitor for toxicity
- **WARFARIN:** Voriconazole may potentiate warfarin's effects

### Laboratory Considerations

- No specific concerns were noted; see Monitoring for additional information.

### Doses

- **DOGS:**
  - a) For coccidioidomycosis: 4 mg/kg PO q12h. (Graupmann-Kuzma *et al.* 2008)
- **CATS:**
  - a) From a published case report in 3 cats: Two of the cats were treated with oral voriconazole for orbital aspergillosis initially at 10 mg/kg PO once daily. Both responded to treatment, but significant systemic reactions were noted. Authors concluded that based on their experience, voriconazole should be used with caution as adverse side effects may be common. (Smith & Hoffman 2010)
- **HORSES:**
  - a) Based upon pharmacokinetic studies, doses of 3 mg/kg PO q24h should be sufficient to treat aspergillosis, but higher doses (4–5 mg/kg) are probably necessary to treat infections with *Fusarium* spp. However, clinical experience is lacking, and the drug is currently too expensive for practical use. (Davis 2008)
- **BIRDS:**
  - a) Based upon this pharmacokinetic study in Hispaniolan Amazon parrots the authors concluded that the drug could be safely administered to this species at a dose of 18 mg/kg PO q8h for 11 days, but that further studies were necessary to determine safety and efficacy of long-term treatment (Guzman *et al.* 2010).
  - b) For avian aspergillosis: 12.5 mg/kg PO twice daily for 60-90 days or by nebulization as a 1 mg/mL solution for 60 minutes once daily. (Black 2008)

### Monitoring

- Efficacy
- Liver function tests, serum electrolytes

### Client Information

- Inform clients of the investigational nature of using this drug in veterinary species and the associated expense
- Give at least one hour before or one hour after feeding
- Because experience with this medication has been limited, report any possible adverse effects to the veterinarian immediately, including itching/rash, yellowing of whites of the eyes, reduced appetite, difficulty walking, vision problems, etc.

### Chemistry/Synonyms

A triazole antifungal, voriconazole occurs as a white to light colored powder with a molecular weight of 349.3. Aqueous solubility is 0.7 mg/mL.

Voriconazole may also be known as UK-109496, voriconazol, voraconazolium, or *Vfend*®.

### Storage/Stability

Voriconazole tablets should be stored at 15–30°C.

The unconstituted powder for oral suspension should be stored in the refrigerator (2–8°C); it has a shelf-life of approximately 18 months. Once reconstituted, it should be stored in tightly closed containers at room temperature (15–30°C); do not refrigerate or freeze. After reconstitution, the suspension is stable for 14 days. The suspension should be shaken well for 10 seconds prior to each administered dose.

The powder for injection should be stored at room temperature (15–30°C). After reconstitution with 19 mL of sterile water for injection, the powder reconstituted using immediately; however, chemical and physical stability remain for up to 24 hours if stored in the refrigerator (2–8°C). Discard solution if it is not clear or particles are visible.

### Compatibility/Compounding Considerations

The injectable solution must be further diluted to a concentration of 5mg/mL or less for administration over 1–2 hours. Suitable diluents for IV infusion include (partial list): NS, LRS, D5LRS, and D5W. Voriconazole is **not compatible** with simultaneous infusion with blood products.

Voriconazole tablets can be crushed and made into a 2.5 mg/mL oral suspension by mixing a crushed tablet with 25:75 *v/v* water:*OraPlus*® (Paddock Labs). This suspension will pass through a 10-French feeding needle. To prepare, mix a crushed 200-mg tablet with 20 mL water and then add 60 mL *OraPlus*®. The suspension should be thoroughly vortex-mixed or shaken until no particles are visible (usually takes 2-3 minutes) and then for ~30-60 seconds before each use. The suspension is stable under refrigeration for 14 days. (Guzman *et al.* 2010), (Flammer 2008)

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Voriconazole Tablets: 50 mg & 200 mg; *Vfend*® (Roerig); (Rx)

Voriconazole Powder for Oral Suspension: 45 grams (40 mg/mL after reconstitution); in 100 mL bottles; *Vfend*® (Roerig); (Rx)

Voriconazole Powder for Injection, Lyophilized: 200 mg in single-use vials; *Vfend I.V.*® (Roerig); (Rx). Also contains 3200 mg of sulfobutyl ether beta-cyclodextrin sodium (SBECD) per vial (See Warnings) to solubilize the drug for IV administration.

## WARFARIN SODIUM

(*war-far-in*) Coumadin®

ANTICOAGULANT

### Prescriber Highlights

- Coumarin derivative anticoagulant used primarily for long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in cats, dogs, or horses
- **Contraindications:** Preexistent hemorrhage, pregnancy, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, surgery of large, open surfaces, active bleeding from the GI, respiratory, or GU tract; aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, & visceral carcinomas
- **Adverse Effects:** Dose-related hemorrhage
- **Teratogenic; contraindicated in pregnancy**
- **Must actively monitor coagulation status**
- **Many potentially significant drug interactions**

---

### Uses/Indications

In veterinary medicine, warfarin is used primarily for the oral, long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in cats, dogs, or horses. Use of warfarin in veterinary species is somewhat controversial and due to unproven benefit in reducing mortality, increased expense associated with monitoring, and potential for serious effects (bleeding), many do not recommend its use.

### Pharmacology/Actions

Warfarin acts indirectly as an anticoagulant (it has no direct anticoagulant effect) by interfering with the action of vitamin K1 in the synthesis of the coagulation factors II, VII, IX, and X. Sufficient amounts of vitamin K1 can override this effect. Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. The S enantiomer is a significantly more potent vitamin K antagonist than the R enantiomer in species studied.

### Pharmacokinetics

Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. Warfarin is rapidly and completely absorbed in humans after oral administration. In cats, warfarin is also rapidly absorbed after oral administration. After absorption, warfarin is highly bound to plasma proteins in humans, with approximately 99% of the drug bound. In cats, more than 96% of the drug is protein bound. It is reported that there are wide species variations with regard to protein binding; horses have a higher free (unbound) fraction of the drug than do rats, sheep or swine. Only free (unbound) warfarin is active. While other coumarin and indanedione anticoagulants are distributed in milk, warfarin does not enter milk in humans.

Warfarin is principally metabolized in the liver to inactive metabolites that are excreted in urine and bile (and then reabsorbed and excreted in the urine). The plasma half-life of warfarin may be several hours to several days, depending on the patient (and species?). In cats, the terminal half-life of the S enantiomer is approximately 23–28 hours and the R enantiomer approximately 11–18 hours.

### Contraindications/Precautions/Warnings

Warfarin is contraindicated in patients with preexistent hemorrhagic tendencies or diseases, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, or surgery of large, open surfaces. It should not be used in patients with active bleeding from the GI, respiratory, or GU tract. Other contraindications include: aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, pregnancy, and visceral carcinomas.

### Adverse Effects

The principal adverse effect of warfarin use is dose-related hemorrhage, which may manifest with clinical signs of anemia, thrombocytopenia, weakness, hematomas and ecchymoses, epistaxis, hematemesis, hematuria, melena, hematochezia, hemathrosis, hemothorax, intracranial and/or pericardial hemorrhage, and death.

### Reproductive/Nursing Safety

Warfarin is embryotoxic, can cause congenital malformations and considered contraindicated during pregnancy. If anticoagulant therapy is required during pregnancy, most clinicians recommend using low-dose heparin. In humans, the FDA categorizes this drug as category *X* for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Based on very limited published data, warfarin has not been detected in the breast milk of humans treated, but there are reports of some breast-fed infants whose mothers were treated having prolonged prothrombin times. Use with caution in nursing patients.

## Overdosage/Acute Toxicity

Acute overdoses of warfarin may result in life-threatening hemorrhage. In dogs and cats, single doses of 5–50 mg/kg have been associated with toxicity. It must be remembered that a lag time of 2–5 days may occur before signs of toxicity occur, and animals must be monitored and treated accordingly.

Cumulative toxic doses of warfarin have been reported as 1–5 mg/kg for 5–15 days in dogs and 1 mg/kg for 7 days in cats.

If overdosage is detected early, prevent absorption from the gut using standard protocols. If clinical signs are noted, they should be treated with blood products and vitamin K1 (phytonadione). Refer to the phytonadione monograph for more information.

## Drug Interactions

Drug interactions with warfarin are perhaps the most important in human medicine. The following drug interactions have either been reported or are theoretical in humans or animals receiving warfarin and may be of significance in veterinary patients:

A multitude of drugs have been documented or theorized to interact with warfarin. The following drugs or drug classes may **increase the anticoagulant response** of warfarin (not necessarily complete):

- ACETAMINOPHEN
- ALLOPURINOL
- AMIODARONE
- ANABOLIC STEROIDS
- AZITHROMYCIN
- CHLORAMPHENICOL
- CIMETIDINE
- CISAPRIDE
- CO-TRIMOXAZOLE (trimethoprim/sulfa)
- DANAZOL
- DIAZOXIDE
- ERYTHROMYCIN
- ETHACRYNIC ACID
- FLUOROQUINOLONES
- FLUOXETINE
- HEPARIN
- METRONIDAZOLE
- NSAIDS
- PENTOXIFYLLINE
- PROPYLTHIOURACIL
- QUINIDINE
- SALICYLATES
- SERTRALINE
- SULFONAMIDES
- THYROID MEDICATIONS
- ZAFIRLUKAST

The following drugs or drug classes may **decrease the anticoagulant response** of warfarin (not necessarily complete):

- BARBITURATES (phenobarbital, etc.)
- CORTICOSTEROIDS
- ESTROGENS
- GRISEOFULVIN
- MERCAPTOPYRINE
- RIFAMPIN
- SPIRONOLACTONE
- SUCRALFATE
- VITAMIN K

Should concurrent use of any of the above drugs with warfarin be necessary, enhanced monitoring is required. Refer to other references on drug interactions for more specific information.

## Laboratory Considerations

- Warfarin may cause falsely decreased **theophylline** values if using the Schack and Waxler ultraviolet method of assay

## Doses

### ■ DOGS:

For adjunctive therapy of thromboemboli:

- a) For adjunctive maintenance therapy for venous thrombosis with or without pulmonary thromboembolism (PTE): warfarin may be considered at a dose of 0.22 mg/kg PO q12h initially and then adjusted to achieve a PT prolongation of 1.25 to 1.5 times the pretreatment value. (Lunsford & Mackin 2007)
- b) 0.22 mg/kg PO q12h; target dosage to prolong PT by 1.25–1.5 times the pretreatment value. (Brooks 2000)
- c) For prophylactic use in patients with glomerular disease and severe proteinuria: Initially, 0.22 mg/kg, PO once daily. Monitor PT and adjust dose so that PT is maintained at 1.5 times normal. (Grauer & DiBartola 2000)

### ■ CATS:

For adjunctive therapy of thromboembolism:

- a) For adjunctive maintenance therapy for venous thrombosis with or without pulmonary thromboembolism (PTE): warfarin may be considered at a dose of 0.5 mg (total dose per cat) PO once daily and then adjusted to achieve a PT prolongation of 1.25 to 1.5 times the pretreatment value.

For maintenance therapy for feline arterial thromboembolism: Aspirin (ultra-low dose 5 mg) is often preferred over warfarin as it is difficult to dose accurately (active enantiomers not evenly distributed in tablets and they must be finely crushed and carefully compounded for precise dosing), and frequent and costly monitoring is required. Pharmacokinetic and pharmacodynamic studies in cats have demonstrated that a warfarin dose of 0.06 to 0.09 mg/kg/day is appropriate. Heparinization is recommended during the first 5 to 7 days that warfarin is administered. (Lunsford & Mackin 2007)

- b) For long-term thromboprophylaxis: Initially warfarin at 0.06–0.09 mg/kg per day PO. Due to unequal drug distribution, tablets should be crushed and mixed well. PT, adjusted to international normalized ratio

(INR) is used to monitor therapy. Cats overlap therapy with heparin at least 4–5 days. Reevaluate anticoagulation status with any change in concurrent drug therapy. (Smith 2004)

c) Initially, 0.25–0.5 mg (total dose) per cat PO once daily. Adjust dosage to prolong PT to twice normal value, or INR to be between 2–3. Overlap therapy with heparin. (Fox 2007)

d) For cardiogenic arterial thromboembolism: 0.25–0.5 mg total dose per cat PO q24h (once daily). If using 1 mg tablets = ¼–½ tab. Heparin (150–250 Units/kg SC q8h should be administered concurrently during the first 4–6 days of warfarin therapy. Cats on warfarin should generally be kept indoors to prevent traumatic events, but these can occur indoors as well. Monitoring is done by evaluating prothrombin time (PT) or INR. Baseline values should be obtained prior to initiating therapy and repeated daily during the first week of therapy then twice weekly for 2–4 weeks. If stable, the PT is repeated weekly for 1–2 months followed by once every 1–3 months. The target range is 1.3–1.6 times baseline value. If using INR, target INR range is typically 2.0–3.0 and monitoring times are the same as for PT. (Hogan 2007)

#### ■HORSES: (Note: ARCI UCGFS Class 5 Drug)

As an anticoagulant:

a) For adjunctive treatment of laminitis: 0.0198 mg/kg PO once daily; monitor OSPT (one-step prothrombin time) until prolonged 2–4 seconds beyond baseline (Brumbaugh *et al.* 1999)

b) Initially, 0.018 mg/kg PO once daily and increase dose by 20% every day until baseline PT is doubled. Final dose rates may be from 0.012 mg/kg to 0.57 mg/kg daily. (Vrins *et al.* 1983)

#### Monitoring

**Note:** The frequency of monitoring is controversial, and is dependent on several factors including dose, patient's condition, concomitant problems, etc. See the Dosage section above for more information.

■ While Prothrombin Times (PT) or International Normalized Ratio (INR; not validated for veterinary patients) are most commonly used to monitor warfarin, PIVKA (proteins induced by vitamin K antagonists) has been suggested as being more sensitive. PT's are usually recommended to be 1.5–2X normal and INR's to be between 2–3.

■ Platelet counts and hematocrit (PCV) should be done periodically

■ Occult blood in stool and urine; other observations for bleeding

■ Clinical efficacy

#### Client Information

■ Clients must be counseled on both the importance of administering the drug as directed

■ Immediately report any signs or symptoms of bleeding

#### Chemistry/Synonyms

A coumarin derivative, warfarin sodium occurs as a slightly bitter tasting, white, amorphous or crystalline powder. It is very soluble in water and freely soluble in alcohol. The commercially available products contain a racemic mixture of the two optical isomers.

Warfarin Sodium may also be known as: sodium warfarin, warfarinum natrium, *Coumadin*®, *Jantoven*®, or *Panwarfin*®; there are many other trade names internationally.

#### Storage/Stability

Warfarin sodium tablets should be stored in tight, light-resistant containers at temperatures less than 40°C, preferably at room temperature. Warfarin sodium powder for injection should be protected from light and used immediately after reconstituting.

#### Compatibility/Compounding Considerations

A method of suspending warfarin tablets in an oral suspension has been described (Enos 1989). To make 30 mL of a 0.25 mg/mL suspension: Crush three 2.5 mg tablets with a mortar and pestle. Add 10 mL glycerin to form a paste; then 10 mL of water; add sufficient amount of dark corn syrup (*Karo*®) to obtain a final volume of 30 mL. Warm gently; shake well and use within 30 days.

#### Dosage Forms/Regulatory Status

##### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

##### HUMAN-LABELED PRODUCTS:

Warfarin Sodium Oral Tablets (scored): 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg & 10 mg; *Coumadin*® (Bristol-Myers Squibb), *Jantoven*® (Upsher-Smith), generic; (Rx)

Warfarin Sodium Powder for Injection, lyophilized: 5.4 mg (2 mg/mL when reconstituted) preservative-free in 5 mg vials; *Coumadin*® (Bristol-Myers Squibb); (Rx)

#### XYLAZINE HCL

(zyl-a-zeen) Rompun®

ALPHA2-ADRENERGIC AGONIST

#### Prescriber Highlights

- **Alpha<sub>2</sub>-adrenergic agonist used for its sedative & analgesic in a variety of species; sometimes used as an emetic in cats**
- **Contraindications:** Animals receiving epinephrine or having active ventricular arrhythmias. Extreme caution: preexisting cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Should generally not be used in the last trimester of pregnancy, particularly in cattle. Do not give to ruminants that are debilitated, dehydrated, or with urinary tract obstruction. Horses may kick after a stimulatory event (usually auditory); use caution. Avoid intra-arterial injection; may cause severe seizures & collapse. Caution in patients treated for intestinal impactions. Use cautiously in horses during the vasoconstrictive development phase of laminitis.
- **Adverse Effects: Cats:** emesis, muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, & increased urination.
- **Adverse Effects: Dogs:** Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, emesis, bloat from aerophagia which may require decompression.
- **Adverse Effects: Horses:** Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, sweating, increased intracranial pressure, or decreased mucociliary clearance.
- **Adverse Effects: Cattle:** Salivation, ruminal atony, bloating, regurgitation, hypothermia, diarrhea, bradycardia, premature parturition, & ataxia.
- Yohimbine, atipamezole, & tolazoline may be used alone or in combination to reverse effects or speed recovery times

- **Dosages between species can be very different; be certain of product concentration when drawing up into syringe, especially if treating ruminants**
- **Drug Interactions**

## Uses/Indications

Xylazine is FDA-approved for use in dogs, cats, horses, deer, and elk. It is indicated in dogs, cats, and horses to produce a state of sedation with a shorter period of analgesia, and as a preanesthetic before local or general anesthesia.

Xylazine use in small animals is somewhat controversial and because it can cause arrhythmias, reduce cardiac output, and increase risk for general anesthesia-related death, it is usually reserved for “healthy animals.” Because of the emetic action of xylazine in cats, it is occasionally used to induce vomiting after ingesting toxins.

## Pharmacology/Actions

A potent alpha<sub>2</sub>-adrenergic agonist, xylazine is classified as a sedative/analgesic with muscle relaxant properties. Although xylazine possesses several of the same pharmacologic actions as morphine, it does not cause CNS excitation in cats, horses or cattle, but causes sedation and CNS depression. In horses, the visceral analgesia produced has been demonstrated to be superior to that produced by meperidine, butorphanol or pentazocine.

Xylazine can also have alpha<sub>1</sub>-agonist activity and is less selective for alpha<sub>2</sub>-receptors than detomidine, dexmedetomidine or romifidine.

Xylazine causes skeletal muscle relaxation through central mediated pathways. Emesis is often seen in cats, and occasionally in dogs receiving xylazine. While thought to be centrally mediated, neither dopaminergic blockers (e.g., phenothiazines) nor alpha-blockers (yohimbine, tolazoline) block the emetic effect. Xylazine does not cause emesis in horses, cattle, sheep or goats. Xylazine depresses thermoregulatory mechanisms and either hypothermia or hyperthermia is a possibility depending on ambient air temperatures.

Effects on the cardiovascular system include an initial increase in total peripheral resistance with increased blood pressure followed by a longer period of lowered blood pressures (below baseline). A bradycardic effect can be seen with some animals developing a second-degree heart block or other arrhythmias. An overall decrease in cardiac output of up to 30% may be seen. Xylazine has been demonstrated to enhance the arrhythmogenic effects of epinephrine in dogs with or without concurrent halothane.

Xylazine’s effects on respiratory function are usually clinically insignificant, but at high dosages it can cause respiratory depression with decreased tidal volumes and respiratory rates, and an overall decreased minute volume. Brachycephalic dogs and horses with upper airway disease may develop dyspnea.

Xylazine can increase blood glucose secondary to decreased serum levels of insulin; in non-diabetic animals, there appears to be little clinical significance associated with this effect.

In horses, sedatory signs include a lowering of the head with relaxed facial muscles and drooping of the lower lip. The retractor muscle is relaxed in male horses, but unlike acepromazine, no reports of permanent penile paralysis have been reported. Although, the animal may appear to be thoroughly sedated, auditory stimuli may provoke arousal with kicking and avoidance responses.

With regard to the sensitivity of species to xylazine, definite differences are seen. Ruminants are extremely sensitive to xylazine when compared with horses, dogs, or cats. Ruminants generally require approximately 1/10th the dosage that is required for horses to exhibit the same effect. In cattle (and occasionally cats and horses), polyuria is seen following xylazine administration, probably because of decreased production of vasopressin (anti-diuretic hormone, ADH). Bradycardia and hypersalivation are also seen in cattle and diminished by pretreating with atropine. Because swine require 20–30 times the ruminant dose, it is not routinely used.

## Pharmacokinetics

Absorption is rapid following IM injection, but bioavailabilities are incomplete and variable. Bioavailabilities of 40–48% in horses, 17–73% in sheep, and 52–90% in dogs have been reported after IM administration.

In horses, the onset of action following IV dosage occurs within 1–2 minutes with a maximum effect 3–10 minutes after injection. The duration of effect is dose dependent but may last for approximately 1.5 hours. The serum half-life after a single dose of xylazine is approximately 50 minutes in the horse; recovery times generally take from 2–3 hours.

In dogs and cats, the onset of action following an IM or SC dose is approximately 10–15 minutes, and 3–5 minutes following an IV dose. The analgesic effects may persist for only 15–30 minutes, but the sedative actions may last for 1–2 hours depending on the dose given. The serum half-life of xylazine in dogs has been reported as averaging 30 minutes. Complete recovery after dosing may take 2–4 hours in dogs and cats.

Xylazine is not detected in milk of lactating dairy cattle at 5 and 21 hours post-dose, but the FDA has not approved its use in dairy cattle and no meat or milk withdrawal times have been specified.

## Contraindications/Precautions/Warnings

Xylazine is contraindicated in animals receiving epinephrine or having active ventricular arrhythmias. It should be used with extreme caution in animals with preexisting cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Because it may induce premature parturition, it should generally not be used in the last trimester of pregnancy, particularly in cattle.

Be certain of product concentration when drawing up into syringe, especially if treating ruminants. Do not give to ruminants that are dehydrated, debilitated, or with urinary tract obstruction. It is not FDA-approved for any species to be consumed for food purposes.

Horses have been known to kick after a stimulatory event (usually auditory); use caution. The addition of opioids (e.g., butorphanol) may help temper this effect, but may cause increased risks for hypotension or ileus development. Avoid intra-arterial injection; may cause severe seizures and collapse. The manufacturers warn against using xylazine in conjunction with other tranquilizers. Because this drug may inhibit gastrointestinal motility, use with caution in patients treated for intestinal impactions. Use cautiously in horses during the vasoconstrictive development phase of laminitis as xylazine has been shown to reduce digital flow of blood for about 8 hours after administration.

## Adverse Effects

Emesis is generally seen within 3–5 minutes after xylazine administration in cats and occasionally in dogs. To prevent aspiration, do not induce further anesthesia until this time has lapsed. Other adverse effects listed in the package insert (*Gemini*®, Butler) for dogs and cats include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and increased urination in cats.

Xylazine can reduce tear production in cats and cause diuresis in dogs.

Dogs may develop bloat from aerophagia that may require decompression. Because of gaseous distention of the stomach, xylazine’s use before radiography can make test interpretation difficult.

Adverse effects listed in the package insert (*AnaSed*®, Lloyd) for horses include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and sweating (rarely profuse). Additionally, horses receiving xylazine may develop transient hypertension, or decreased mucociliary clearance rates.

Adverse reactions reported in cattle include: salivation, ruminal atony, bloating and regurgitation, hypothermia, diarrhea, and bradycardia. Hypersalivation and bradycardia may be alleviated by pretreating with atropine.

Large animals may become ataxic following dosing and caution should be observed.

## Reproductive/Nursing Safety

Limited information was located on the safety of xylazine in pregnancy; apparently, there are no reports of teratogenicity in animals. Xylazine may induce premature parturition in cattle.

Xylazine does not appear to be excreted in detectable quantities in cows’ milk.

## Overdosage/Acute Toxicity

In the event of an accidental overdosage, cardiac arrhythmias, hypotension, and profound CNS and respiratory depression may occur. Seizures have also been reported after overdoses. There has been much interest in using alpha-blocking agents as antidotes or reversal agents to xylazine. Yohimbine, atipamezole, and tolazoline have been suggested for use alone and in combination to reverse the effects of xylazine or speed recovery times. Separate monographs for yohimbine and atipamezole are available with suggested doses, etc.

To treat the respiratory depressant effects of xylazine toxicity, mechanical respiratory support with respiratory stimulants (e.g., doxapram) have been recommended for use.

## Drug Interactions

The manufacturers warn against using xylazine in conjunction with **other tranquilizers**.

■ **ACEPROMAZINE:** The combination use of acepromazine with xylazine is generally considered safe, but there is potential for additive hypotensive effects and this combination should be used cautiously in animals susceptible to hemodynamic complications.

■ **CHLORAMPHENICOL:** Prolonged sedation and gastrointestinal stasis possible (Davis 2007)

■ **CNS DEPRESSANT AGENTS, OTHER (barbiturates, narcotics, anesthetics, phenothiazines, etc.):** May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.

■ **EPINEPHRINE:** The use of epinephrine with or without the concurrent use of halothane with xylazine may induce the development of ventricular arrhythmias.

■ **RESERPINE:** A case of a horse developing colic-like clinical signs after reserpine and xylazine has been reported. Until more is known about this potential interaction, use of these two agents together should be avoided.

## Doses

■ **DOGS:**

a) 1.1 mg/kg IV, 1.1–2.2 mg/kg IM or SC (Package Insert; *Rompun*®—Miles) **Note:** Many believe the labeled dosage is too high.

b) As a preanesthetic: Dosage range for xylazine 0.2–1 mg/kg IV, IM or SC is very broad, and dosages on the label are relatively high. Xylazine has depressant, sedative, analgesic, and muscle relaxing effects. It is very effective for restraint and analgesia, but does not produce immobilization and sedated animals can respond to noxious stimuli and noise. Xylazine is associated with significant cardiac rhythm disturbances when dosed according to the recommendations on the label, especially in dogs. In low doses, the benefits of xylazine can be realized while eliminating some of its detrimental side effects. (Hartsfield 2007)

c) Alpha-2 agonists can be used in low doses with opioids to provide dependable and profound restraint in healthy animals. Healthy animals can be given xylazine at a dose of 0.05–0.2 mg/kg (route not listed). (Dyson 2008)

d) For epidural injection: 0.02–0.25 mg/kg; dilute with sufficient quantity of sterile saline to a volume of 0.26 mL/kg. Onset of action 20–30 minutes; 2–5 hour duration.

Xylazine 0.02 mg/kg with morphine 0.1 mg/kg; dilute with sufficient quantity of sterile saline to a volume of 0.26 mL/kg. Onset of action 30–60 minutes; 10–20 hour duration.

As an analgesic: 0.1–1 mg/kg IV, IM or SC. For post-operative anxiety: 0.1–0.5 mg/kg IV, IM or SC (Carroll 1999)

#### ■CATS:

a) 1.1 mg/kg IV, 1.1–2.2 mg/kg IM or SC (Package Insert; *Rompun*®—Miles) **Note:** Many believe the labeled dosage is too high.

b) As a preanesthetic: Dosage range for xylazine 0.2–1 mg/kg IV, IM or SC is very broad, and dosages on the label are relatively high. Xylazine has depressant, sedative, analgesic, and muscle relaxing effects. It is very effective for restraint and analgesia, but does not produce immobilization and sedated animals can respond to noxious stimuli and noise. Xylazine is associated with significant cardiac rhythm disturbances when dosed according to the recommendations on the label, especially in dogs. In low doses, the benefits of xylazine can be realized while eliminating some of its detrimental side effects. (Hartsfield 2007)

b) As an emetic: 0.44 mg/kg IM (Morgan 1988; Riviere 1985)

c) As an analgesic: 0.1–1 mg/kg IV, IM or SC. For post-operative anxiety: 0.1–0.5 mg/kg IV, IM or SC (Carroll 1999)

#### ■RABBITS, RODENTS, SMALL MAMMALS:

a) **Rabbits:** For minimally invasive procedures lasting less than 30–45 minutes: 5 mg/kg once SC or IM in combination with ketamine (35 mg/kg). **Mice/Rats:** General anesthesia 13 mg/kg once IP in combination with ketamine (87 mg/kg). **Hamsters/Guinea pigs:** General anesthesia 8–10 mg/kg once IP in combination with ketamine (200 mg/kg for hamsters and 60 mg/kg for Guinea pigs) (Huerkamp 1995)

b) **Rabbits: 1)** Ketamine 35 mg/kg + xylazine 5 mg/kg IM; surgical anesthesia for 20-30 min, good relaxation, sleep time is 60–120 min, some effects reversible with atipamezole. **2)** Ketamine 25 mg/kg + xylazine 5 mg/kg + butorphanol 0.1 mg/kg IM; surgical anesthesia for 60-90 min, good relaxation, sleep time is 120–180 min. **3)** Ketamine 25 mg/kg + xylazine 5 mg/kg + acepromazine 1 mg/kg IM; surgical anesthesia for 45-75 min, good relaxation, sleep time is 100-150 min. **Gerbils:** Ketamine 50 mg/kg + xylazine 2 mg/kg IP; **Guinea Pigs:** Ketamine 40 mg/kg + xylazine 5 mg/kg IP; **Hamsters:** Ketamine 200 mg/kg + xylazine 10 mg/kg IP; **Mice:** Ketamine 80 mg/kg + xylazine 10 mg/kg IP; **Rats:** Ketamine 75 mg/kg + xylazine 10 mg/kg IP; Atipamezole 1 mg/kg SC, IM, IO or IV can be used to reverse xylazine. (Flecknell 2008)

c) **Rodents:** Xylazine (5 mg/kg) + ketamine (50 mg/kg) + atropine (0.05 mg/kg) IP. (Bennett 2009)

#### ■FERRETS:

a) As a sedative/analgesic: Xylazine: 0.5–2 mg/kg IM or SC. Usually combined with atropine (0.05 mg/kg) or glycopyrrolate (0.01 mg/kg IM) or Butorphanol/Xylazine: Butorphanol 0.2 mg/kg plus Xylazine (2 mg/kg) IM (Finkler 1999)

b) Xylazine (2 mg/kg) plus butorphanol (0.2 mg/kg) IM;

Telazol (1.5 mg/kg) plus xylazine (1.5 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM)

Telazol (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)

#### ■BIRDS:

a) As a sedative/analgesic: 1–4 mg/kg IM, provides sedation for ketamine anesthesia. Has been used at dosages of up to 10 mg/kg in small psittacines (Clyde & Paul-Murphy 2000)

b) In combination with ketamine: Ketamine 10–30 mg/kg IM; Xylazine 2–6 mg/kg IM; birds less than 250 grams require a higher dosage (per kg) than birds weighing greater than 250 g. Xylazine is not recommended for use in debilitated birds because of its cardiodepressant effects. (Wheler 1993)

#### ■CATTLE:

**Caution:** Cattle are extremely sensitive to xylazine's effects; be certain of dose and dosage form. Pretreatment with atropine can decrease bradycardia and hypersalivation.

a) For analgesia and restraint for standing procedures in cattle: A protocol for use of IM butorphanol/xylazine/ketamine (BXK) has been reported (Miesner 2009). It consists of butorphanol (0.01–0.025 mg/kg) + xylazine (0.02–0.05 mg/kg) + ketamine (0.04–0.1 mg/kg). For a 450 kg animal, 5 mg butorphanol, 10 mg xylazine, and 20 mg ketamine would constitute the low end of the dosing range. Up to an hour of cooperation was accomplished using this protocol, but more fractious patients may require increased doses. Suggested to give no more than 10 mg butorphanol or 20 mg of xylazine for the initial dose to an animal greater than 450 kg. (Coetzee 2010)

b) 0.1–0.3 mg/kg IM; 0.05–0.15 mg/kg IV; 0.05–0.07 mg/kg epidurally. When used IV/IM, analgesia can be very short-lived (½ hour). (Walz 2006)

#### ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

a) 1.1 mg/kg IV; 2.2 mg/kg IM. Allow animal to rest quietly until full effect is reached. (Package Insert; *Rompun*®—Bayer)

b) Sedative/analgesic for colic: 0.2–0.5 mg/kg IV (will provide analgesia for 20–30 minutes); or 0.6–1 mg/kg IM (effects for 1–2 hours). Evaluate heart rate prior to therapy. (Moore 1999)

c) For sedation analgesia: 0.2–1.1 mg/kg IV, or IM; higher doses IM are required to achieve same effect as IV.

As a caudal epidural for analgesia:

Alone in first coccygeal space: 0.03–0.35 mg/kg; perineal sweating common; 3–5 hour duration of effect.

In combination in first coccygeal space: xylazine 0.17 mg/kg with lidocaine (0.22 mg/kg); can cause ataxia or recumbency, perineal sweating; duration of effect 5-6 hours.

For lumbosacral analgesia (via catheter): 0.2 mg/kg (Sellon 2007)

d) As a short-acting, potent analgesic for mild, to moderate colic that will control pain but allow an estimate of the severity of the colic episode: 0.3–0.5 mg/kg IV; may be combined with butorphanol (0.01 mg/kg) and dosed at 0.3 mg/kg IV.

If the signs of colic are so violent as to prevent safe IV administration, an increased dose of xylazine (1.1 mg/kg) or detomidine (0.02 mg/kg) may be administered IM. The general rule is to double the IV dose. Expect a longer duration of effect with the IM route. (Blikslager 2008)

e) For field anesthesia: Sedate with xylazine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures). If adequate sedation does not occur, either: **1)** Redose xylazine: up to half the original dose, **2)** Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes. **3)** Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes. **4)** Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)

f) As part of a balanced anesthesia protocol: 0.5–1 mg/kg IV given over ½–1 minute. (MAC sparing effect approximately 20-34%). (Driessen 2008)

#### ■SHEEP & GOATS:

**Note:** Use xylazine with extreme caution in these species. Use only the 20 mg/mL solution.

a) 0.01 mg/kg IV for light standing sedation to 0.2 mg/kg IM for recumbency of an hour's duration. Goats are bit more sensitive than sheep. When beginning to use these drugs, it is advisable to start with a conservative dose until one develops a feel for level of sedation provided. A reversal agent should always be on hand; reversal of sedative effects also reverses analgesic effects. (Snyder 2009)

#### ■CAMELIDS:

**Note:** Use xylazine with extreme caution in these species. Use only the 20 mg/mL solution.

a) For procedural pain (e.g., castrations) when recumbency (up to 30 minutes) is desired: Alpacas: butorphanol 0.046 mg/kg; xylazine 0.46 mg/kg; ketamine 4.6 mg/kg. Llamas: butorphanol 0.037 mg/kg; xylazine 0.37 mg/kg; ketamine 3.7 mg/kg. All drugs are combined in one syringe and given IM. May administer 50% of original dose of ketamine and xylazine during anesthesia to prolong effect up to 15 minutes.

If doing mass castrations on 3 or more animals, can make up bottle of the "cocktail." Add 10 mg (1 mL) of butorphanol and 100 mg (1 mL) xylazine to a 1 gram (10 mL vial) of ketamine. This mixture is dosed at 1 mL/40 lbs. (18 kg) for alpacas, and 1 mL/50 lbs. (22 kg) for llamas. Handle quietly and allow plenty of time before starting procedure. Expect 20 minutes of surgical time; patient should stand 45 minutes to

**ZOO, EXOTIC, WILDLIFE SPECIES:**

For use of xylazine in zoo, exotic and wildlife medicine refer to specific references, including:

- Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.
  - Handbook of Wildlife Chemical Immobilization, 3rd Ed.* Kreeger, T.J. and J.M. Arnemo. 2007.
  - Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995
  - Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005
- e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

**Monitoring**

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Hydration status if polyuria present

**Client Information**

- Xylazine should only be used by individuals familiar with its use

**Chemistry/Synonyms**

Xylazine HCl is an alpha<sub>2</sub>-adrenergic agonist structurally related to clonidine. The pH of the commercially prepared injections is approximately 5.5. Dosages and bottle concentrations are expressed in terms of the base.

Xylazine HCl may also be known as Bay-Va-1470, *Rompun*®, *AnaSed*®, *Sedazine*®, *X-Ject*®, or *Xyla-Ject*®.

**Storage/Stability**

Do not store above 30°C (86°F).

**Compatibility/Compounding Considerations**

Xylazine is reportedly physically **compatible** in the same syringe with several compounds, including: acepromazine, buprenorphine, butorphanol, chloral hydrate, and meperidine.

A study (Taylor *et al.* 2009) evaluating the stability, sterility, pH, particulate formation and efficacy in laboratory rodents of compounded ketamine, acepromazine and xylazine (“KAX”) supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored at room temperature in the dark.

**Dosage Forms/Regulatory Status****VETERINARY-LABELED PRODUCTS:**

Xylazine Injection: 20 mg/mL in 20 mL vials or 100 mg/mL in 50 mL vials: *Rompun*® (Bayer), *AnaSed*®, *Cervizine*® (300 mg/mL; for deer and elk) (Lloyd); *Sedazine*® (BIVI); *Chanazine*® (Teva); generic; (Rx); FDA-approved for use (depending on strength and product) in dogs, cats, horses, deer, and elk.

While xylazine is not FDA-approved for use in cattle in the USA, at labeled doses in Canada it reportedly has been assigned withdrawal times of 3 days for meat and 48 hours for milk. FARAD has reportedly suggested a withdrawal of 7 days for meat and 72 hours for milk for extra-label use.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**YOHIMBINE HCL**

(yo-*him*-been) Yohine®, Antagonil®

**ALPHA2-ADRENERGIC ANTAGONIST****Prescriber Highlights**

- **Alpha<sub>2</sub>-adrenergic antagonist used to reverse xylazine, other alpha<sub>2</sub> agonists & potentially amitraz; may be used prophylactically before amitraz dips**
- **Caution: Renal disease, seizure disorders**
- **Adverse Effects: Transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, & hyperemic mucous membranes; more likely in small animals and horses**
- **Drug interactions**

**Uses/Indications**

Yohimbine is indicated to reverse the effects of xylazine in dogs, but it is being used clinically for other alpha<sub>2</sub> agonists and in several other species as well.

Yohimbine may be efficacious in reversing some of the toxic effects associated with other agents (*e.g.*, amitraz) and can be used prophylactically before amitraz dips.

**Pharmacology/Actions**

Yohimbine is an alpha<sub>2</sub>-adrenergic antagonist that can antagonize the effects of xylazine. Alone, yohimbine increases heart rate, blood pressure, causes CNS stimulation and antidiuresis, and has hyperinsulinemic effects.

By blocking alpha<sub>2</sub>-receptors, yohimbine causes sympathetic outflow (norepinephrine) to be enhanced. Peripheral alpha<sub>2</sub>-receptors are also found in the cardiovascular system, genitourinary system, GI tract, platelets, and adipose tissue.

### Pharmacokinetics

The pharmacokinetics of this drug have been reported in steers, dogs, and horses (Jernigan et al. 1988). The apparent volume of distribution (steady-state) is approximately 5 L/kg in steers, 2–5 L/kg in horses, and 4.5 L/kg in dogs. The total body clearance is approximately 70 mL/min/kg in steers, 35 mL/min/kg in horses, and 30 mL/min/kg in dogs. The half-life of the drug is approximately 0.5–1 hours in steers, 0.5–1.5 hours in horses, and 1.5–2 hours in dogs.

Yohimbine is believed to penetrate the CNS quite readily and, when used to reverse the effects of xylazine, onset of action generally occurs within 3 minutes. The metabolic fate of the drug is not known.

### Contraindications/Precautions/Warnings

Yohimbine is contraindicated in patients hypersensitive to it. In humans, yohimbine is contraindicated in patients with renal disease.

Yohimbine should be used cautiously in patients with seizure disorders. When used to reverse the effects of xylazine, normal pain perception may result.

### Adverse Effects

Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animals and horses.

### Reproductive/Nursing Safety

Safe use of yohimbine in pregnant animals has not been established. No information on safety during lactation was located.

### Overdosage/Acute Toxicity

Dogs receiving 0.55 mg/kg (5 times recommended dose) exhibited clinical signs of transient seizures and muscle tremors.

There were 5 exposures to yohimbine reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, all 5 were dogs with 2 showing clinical signs. Reported findings in dogs included diarrhea, disorientation, hyperactivity, panting, tachycardia, and hypersalivation.

For more information on clinical effects and treatment for yohimbine toxicity see: (Volmer et al. 1994)

### Drug Interactions

Little information is available, use with caution with **other alpha<sub>2</sub>-adrenergic antagonists** or **other drugs that can cause CNS stimulation**.

The following drug interaction has been reported in humans receiving yohimbine and may be of significance in veterinary patients:

■ **TRICYCLIC ANTIDEPRESSANTS:** In humans, yohimbine is not recommended for use with antidepressants or other mood-altering agents; hypertension has been reported with tricyclics

### Doses

#### ■ DOGS:

For alpha<sub>2</sub> agonist reversal:

a) For xylazine: 0.11 mg/kg IV slowly (Package insert; *Yobine*®—Lloyd)

b) For xylazine: 0.1 mg/kg IV (Gross & Tranquilli 1989)

c) For medetomidine: 0.11 mg/kg IV. (Park et al. 2009)

For reversal or prevention of amitraz effects:

a) To reverse centrally mediated bradycardia and hypotension associated with amitraz ingestion: 0.1 mg/kg IV; repeat as necessary (Manning 2000)

b) In cases of toxicity or to prevent a dog from having an acute episode of toxicity associated with demodicosis treatment: Yohimbine at 0.11 mg/kg IV or 0.25 mg/kg IM with atipamezole (50 micrograms/kg IM). (Torres 2007)

c) For treatment or prevention of side effects associated with amitraz dips: 0.1 mg/kg IV; may give prior to, or after bathing to prevent effects. (Hillier 2006)

As an antiemetic:

a) 0.25–0.5 mg/kg SC or IM q12h. (Washabau & Elie 1995), (Encarnacion et al. 2009), (Neiger 2007)

#### ■ RABBITS, RODENTS, SMALL MAMMALS:

To reverse the effects of xylazine and to partially antagonize the effects of ketamine and acepromazine:

a) **Rabbits:** 0.2 mg/kg IV as needed

b) **Mice/Rats:** 0.2 mg/kg IP as needed (Huerkamp 1995)

#### ■ BIRDS:

As a reversal agent for alpha<sub>2</sub>-adrenergic agonists (e.g., xylazine):

a) 0.1 mg/kg IV (Clyde & Paul-Murphy 2000)

#### ■ CATTLE:

For xylazine reversal:

a) 0.125 mg/kg IV (Gross & Tranquilli 1989)

b) Yohimbine (or tolazoline) may be used to reverse the effects of xylazine to facilitate a quicker recovery at the end of a procedure and minimize the risks of gastrointestinal complications. IM administration of the reversal agent is preferred in all but emergency situations as it decreases the risk of CNS excitement or cardiovascular complications. The amount of reversal agent used depends on the dose and time elapsed after administering xylazine. Reversal of xylazine should not be attempted until sufficient time has elapsed to allow any ketamine or *Telazol*® used to resolve (30–45 min. post IM and 15–30 min. post-IV administration) to reduce the chances of a rough recovery. When dosed properly the effects of reversal should start to become evident about 10 minutes following IM administration. Emergency doses of yohimbine at 0.1 mg/kg can be administered IV, but the shorter duration of action when given IV can result in the return of the effects of IM administered xylazine. (Anderson & Abrahamsen 2008)

#### ■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

For xylazine reversal:

a) 0.075 mg/kg IV (Gross & Tranquilli 1989)

#### ■ LLAMAS:

For xylazine reversal:

a) 0.25 mg/kg IV or IM (Fowler 1989)

#### ■ ZOO, EXOTIC, WILDLIFE SPECIES:

For use of yohimbine in zoo, exotic and wildlife medicine refer to specific references, including:

a) *Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.

b) *Handbook of Wildlife Chemical Immobilization, 3rd Ed.* Kreeger, T.J. and J.M. Arnemo. 2007.

c) *Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995

d) *Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

## Monitoring

- CNS status (arousal level, etc.)
- Cardiac rate; rhythm (if indicated), blood pressure (if indicated and practical)
- Respiratory rate

## Client Information

- This agent should be used with direct professional supervision only

## Chemistry/Synonyms

A Rauwolfia or indolealkylamine alkaloid, yohimbine HCl has a molecular weight of 390.9. It is chemically related to reserpine.

Yohimbine may also be known as: aphrodine hydrochloride, chlorhydrate de quebrachine, corynine hydrochloride, *Aphrodyne*®, *Dayto Himbin*®, *Pluriviron mono*®, *Prowess Plain*®, *Urobine*®, *Virigen*®, *Yobine*®, *Yocor*®, *Yocoral*®, *Yohimex*®, *Yohydrol*, *Yomax*®, or *Zumba*®.

## Storage/Stability

Yohimbine injection should be stored at room temperature (15–30°C) and protected from light and heat.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Yohimbine Sterile Solution for Injection: 2 mg/mL in 20 mL vials; *Yobine*® (Lloyd); (Rx). FDA-approved for use in dogs.

### HUMAN-LABELED PRODUCTS:

Oral 5.4 mg tablets are available, but would unlikely to be of veterinary benefit.

---

## ZAFIRLUKAST

(zaf-fur-luh-kast) Accolate®

LEUKOTRIENE-RECEPTOR ANTAGONIST

### Prescriber Highlights

- **Leukotriene-receptor antagonist; potentially useful for canine atopic dermatitis, feline asthma, or inflammatory bowel disease, but efficacy has either been disappointing or not well studied in veterinary patients**
- **Not for treatment of acute bronchospasm**
- **Well tolerated**
- **Dose on an empty stomach**

---

## Uses/Indications

While zafirlukast potentially could be useful for treating a variety of conditions (*e.g.*, feline asthma, atopic dermatitis, inflammatory bowel disease) where leukotrienes are thought to contribute to morbidity, to date, efficacy has been shown to be disappointing, limited, or not fully studied. A study using zafirlukast to evaluate effects on pruritus (owner subjective evaluation) in dogs with atopic dermatitis, showed that only 11% of treated dogs had at least 50% reductions in pruritus (Senter *et al.* 2002).

## Pharmacology/Actions

Zafirlukast selectively and competitively inhibits leukotriene receptors, specifically receptors for leukotriene D<sub>4</sub> and E<sub>4</sub> (LTD<sub>4</sub> and LTE<sub>4</sub>). Additionally, it competes for receptors with some components of slow-reacting substance of anaphylaxis (SRS-A). These substances have all been implicated in the inflammatory and bronchoconstrictive aspects of bronchial asthma.

## Pharmacokinetics

No specific veterinary data was located. In humans, zafirlukast is rapidly absorbed after oral administration. Food may impair the absorption of the drug, therefore, give on an empty stomach. Peak plasma levels occur about 3 hours after dosing. Zafirlukast is highly bound to plasma proteins (>99%). The drug is extensively metabolized; less than 10% of a dose is excreted in the urine, the rest in the feces. Half lives in humans average about 10 hours.

## Contraindications/Precautions/Warnings

Zafirlukast is contraindicated in patients hypersensitive to it.

Zafirlukast is not indicated for, and is ineffective for treating bronchospasm associated with acute asthma attacks.

Patients with significantly decreased hepatic function may have reduced clearances (and increased plasma levels) of zafirlukast.

## Adverse Effects

Veterinary experience is very limited, but some dogs reportedly have vomited after oral dosing. In humans, the adverse effect profile seems to be minimal; headache was noted most often, but incidence is not much different than placebo.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Zafirlukast is excreted in milk, but it is probably safe to administer to nursing veterinary patients.

## Overdosage/Acute Toxicity

in dogs, doses up to 500 mg/kg were tolerated without mortality.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zafirlukast and may be of significance in veterinary patients:

- **ASPIRIN:** May significantly increase zafirlukast plasma levels
- **ERYTHROMYCIN:** May decrease the bioavailability of zafirlukast
- **THEOPHYLLINE:** May decrease plasma levels of zafirlukast
- **WARFARIN:** Zafirlukast may significantly increase the prothrombin time of patients taking warfarin.

## Laboratory Considerations

- None were noted

## Doses

### ■ DOGS:

For adjunctive treatment of atopic dermatitis:

a) 20 mg (total dose) PO twice daily; only moderate success (Foil 2003)

b) In the study dogs received: 5 mg PO q12h, if the dog weighed less than 11.4 kg (25 lb); 10 mg PO q12h, if 11.4–22.3 kg (25–49 lb); 20 mg PO q12h, if 22.7–34.1 kg (50–75 lb); and 30 mg PO q12h, if greater than 34.1 kg (75 lb). Given on an empty stomach, 1 hour before, or 2 hours after meals. (Senter *et al.* 2002)

### ■ CATS:

For adjunctive treatment of feline bronchial “asthma.”

a) 1–2 mg/kg PO once to twice daily (Noone 1999)

b) 0.5–1 mg/kg q12–24h. (Scherk 2010)

c) 5 mg (total dose) per cat PO q12h. (Lappin 2008)

For adjunctive treatment of mild inflammatory bowel disease:

a) 0.15–0.2 mg/kg PO once daily. Author has used a combination of zafirlukast (3 months), famotidine (4 weeks), and sucralfate (2 weeks) (along with a low-allergen diet) to successfully treat a case. (Boothe 2009)

## Monitoring

- Clinical efficacy

## Client Information

- Preferably give on an empty stomach.
- Give this medication even if animal appears well; do not use to treat acute asthma clinical signs.
- Because experience in veterinary medicine is limited, report any untoward effects to the veterinarian.

## Chemistry/Synonyms

A leukotriene-receptor antagonist, zafirlukast occurs as a white to pale yellow, fine amorphous powder. It is practically insoluble in water.

Zafirlukast may also be known as: ICI-204219, *Accolate*®, *Accoleit*®, *Aeronix*®, *Azimax*®, *Olmoran*®, *Resma*®, *Vanticon*®, *Zafarisma*®, *Zafirst*®, or *Zuvair*®.

## Storage/Stability

Zafirlukast tablets should be stored at room temperature and protected from light and moisture. The manufacturer states that the tablets should be dispensed only in the original, unopened container.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Zafirlukast Tablets (film-coated): 10 mg & 20 mg; *Accolate*® (AstraZeneca); (Rx)

---

## ZIDOVUDINE (AZT)

(*zid-o-vee-den*) **Retrovir**®

**ANTIRETROVIRAL**

### Prescriber Highlights

- Antiretroviral agent that may be useful for adjunctive treatment of FeLV or FIV in cats
  - Use with caution if renal, hepatic, or bone marrow dysfunction present
  - Anemia (non-regenerative) most common adverse effect in cats
- 

## Uses/Indications

In veterinary medicine, zidovudine may be useful for treating feline immunodeficiency virus (FIV) or feline leukemia virus (FeLV). While zidovudine can reduce the viral load in infected cats and improve clinical signs, it may not alter the natural course of the disease to a great extent.

## Pharmacology/Actions

Zidovudine is considered an antiretroviral agent. While its exact mechanism of action is not fully understood, zidovudine is converted *in vivo* to an active metabolite (triphosphate) that interferes with viral RNA-directed DNA polymerase (reverse transcriptase). This causes a virustatic effect in retroviruses.

Zidovudine has some activity against gram-negative bacteria and can be cytotoxic as well.

### Pharmacokinetics

Zidovudine is well absorbed after oral administration. In cats, oral bioavailability is approximately 95%. When administered with food, peak levels may be decreased, but total area under the curve may not be affected; peak levels occur about one hour post-dosing in cats. The drug is widely distributed, including into the CSF. It is only marginally bound to plasma proteins. Zidovudine is rapidly metabolized and excreted in the urine. Half-life in cats is about 1.5 hours.

### Contraindications/Precautions/Warnings

Zidovudine is considered contraindicated in patients who have developed life threatening hypersensitivity reactions to it in the past.

Use zidovudine with caution in patients with bone marrow, renal or hepatic dysfunction. The European Advisory Board on Cat Diseases (ABCD) guidelines on prevention and management of feline immunodeficiency state that: Cats with bone marrow suppression should not be treated (with zidovudine; see monitoring guidelines, below). Dosage adjustment may be necessary in cats with renal or hepatic dysfunction.

### Adverse Effects

In cats, reductions in RBC's, PCV and hemoglobin are the most common adverse effects reported. Anemia may be non-regenerative and is most commonly seen with the higher end of the dosage range (10–15 mg/kg). Diarrhea and weakness have also been reported. While there are many adverse effects reported in humans, granulocytopenia and GI effects appear to be the most likely to occur.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Zidovudine is excreted in milk. Clinical significance is not clear for nursing offspring.

### Overdosage/Acute Toxicity

Human adults and children have survived oral overdoses of up to 50 grams without permanent sequelae. Vomiting and transient hematologic effects are the most consistent adverse effects reported with overdoses.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zidovudine and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (ketoconazole, etc.):** May increase zidovudine levels
- **ATOVAQUONE:** May increase zidovudine levels
- **DOXORUBICIN:** May antagonize each other's effects; avoid use together
- **INTERFERON ALFA:** Increased risk for hematologic and hepato-toxicity
- **PROBENECID:** May increase zidovudine levels
- **MYELO-/CYTOTOXIC DRUGS (e.g., chloramphenicol, doxorubicin, flucytosine, vincristine, vinblastine):** Administered with zidovudine may increase the risk of hematologic toxicity
- **RIFAMPIN:** May decrease blood levels (AUC) of zidovudine

### Laboratory Considerations

- None were noted.

### Doses

#### ■ CATS:

For adjunctive therapy of FeLV and FIV:

- 5–10 mg/kg q12h PO or SC. The higher dose should be used carefully as side effects can develop. For SC injection, the lyophilized product should be diluted in isotonic sodium chloride solution to prevent local irritation. For PO dosing, syrup or gelatin capsules (dosage/weight calculated individually for each cat) can be given. See the ABCB monitoring guidelines below. (Hosie *et al.* 2009)
- 5–10 mg PO or SC q12h. The higher dose should be carefully used in FeLV-infected cats because side effects, particularly non-regenerative anemia, can develop. (Levy *et al.* 2008)
- For FELV: 5 mg/kg PO or SC q12h. If giving SC dilute in sterile normal saline to prevent local irritation. Check CBC weekly the first month as anemia (non-regenerative) can be seen. If values are stable; may monitor monthly. Some cats develop mild decreases in hematocrit that resolves even if treatment is continued. (Hartmann 2007)
- For FIV encephalopathy: 20 mg/kg PO q12h (Taylor 2003)

### Monitoring

- The European Advisory Board on Cat Diseases (ABCD) guidelines on prevention and management of feline immunodeficiency (Hosie *et al.* 2009) recommends: During treatment, a CBC should be performed weekly for the first month, because non-regenerative anemia is common, especially at higher doses. If the values are stable, monthly checks are sufficient. If hematocrit drops below 20%, treatment should be discontinued, and anemia then usually resolves within a few days.
- CD4/CD8 rates, if possible
- Clinical efficacy

### Client Information

- Must be considered "experimental" therapy for cats
- Must be administered as prescribed for efficacy
- Regular blood tests required

### Chemistry/Synonyms

A thymidine analog, zidovudine is synthetically produced and occurs as a white to beige-colored, odorless, crystalline solid. Approximately 20 mg are soluble in one mL of water.

Zidovudine may also be known as: ZDV, azidodeoxythymidine, 3'-azido-2',3'-dideoxythymidine, azidothymidine, AZT, BW-A509U, BW-509U, compound-S, zidovudinum or *Retrovir*®; many other trade names are available.

### Storage/Stability

Zidovudine oral tablets or capsules should be stored at room temperature. Protect from heat, light and moisture. The oral solution should be stored at room temperature. Zidovudine injection (for IV infusion) should be stored at room temperature and protected from light.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Zidovudine Oral Tablets: 300 mg; *Retrovir*® (GlaxoSmithKline); generic; (Rx)

Zidovudine Oral Capsules: 100 mg; *Retrovir*® (GlaxoSmithKline); generic; (Rx)

Zidovudine Oral Syrup: 50 mg/5 mL in 240 mL; *Retrovir*® (GlaxoSmithKline); generic; (Rx)

## ZINC ACETATE

## ZINC SULFATE

## ZINC GLUCONATE

(zinc)

NUTRITIONAL; TRACE ELEMENT

### Prescriber Highlights

- **Metal nutritional agent that may be used for zinc deficiency, to reduce copper toxicity in susceptible dog breeds (Bedlington Terriers, West Highland White Terriers) with hepatic copper toxicosis, & treat hepatic fibrosis in dogs. Has astringent & antiseptic activity topically.**
- **Contraindications: None; consider obtaining zinc & copper levels before treating.**
- **Adverse Effects: Large doses may cause GI disturbances or hematologic abnormalities (usually hemolysis), particularly if a coexistent copper deficiency exists**
- **Zinc overdoses (e.g., U.S. pennies) can be serious**

---

## Uses/Indications

Zinc sulfate is used systemically as a nutritional supplement in a variety of species. Oral zinc acetate has been shown to reduce copper toxicity in susceptible dog breeds (Bedlington Terriers, West Highland White Terriers) with hepatic copper toxicosis. Zinc therapy may also be of benefit in the treatment of hepatic fibrosis in the dog. Zinc sulfate is used topically as an astringent and as a weak antiseptic both for dermatologic and ophthalmic conditions.

For more information, the reader is encouraged to refer to a thorough review of zinc physiology, pathophysiology, toxicity and deficiency in veterinary patients (Cummings & Kovacic 2009).

## Pharmacology/Actions

Zinc is a necessary nutritional supplement; it is required by over 200 metalloenzymes for proper function. Enzyme systems that require zinc include alkaline phosphatase, alcohol dehydrogenase, carbonic anhydrase, and RNA polymerase. Zinc is also necessary to maintain structural integrity of cell membranes and nucleic acids. Zinc dependent physiological processes include sexual maturation and reproduction, cell growth and division, vision, night vision, wound healing, immune response, and taste acuity.

When administered orally, large doses of zinc can inhibit the absorption of copper.

## Pharmacokinetics

About 20–30% of dietary zinc is absorbed, principally from the duodenum and ileum. Bioavailability is dependent upon the food in which it is present. Phytates can chelate zinc and form insoluble complexes in an alkaline pH. Zinc is stored mostly in red and white blood cells, but is also found in the muscle, skin, bone, retina, pancreas, liver, kidney, and prostate. Elimination is primarily via the feces, but some is also excreted by the kidneys and in sweat. Zinc found in feces may be reabsorbed in the colon.

## Contraindications/Precautions/Warnings

Zinc supplementation should be carefully considered before administering to patients with copper deficiency.

When dosing, do not confuse the concentrations of zinc salts with elemental zinc.

## Adverse Effects

Large doses may cause GI disturbances. Hematologic abnormalities (usually hemolysis) may occur with large doses or serum levels greater than 1000 micrograms/dL (1 mg/dL), particularly if a coexistent copper deficiency exists. Zinc acetate or methionine may be less irritating to the stomach. Mixing the contents of the capsule with a small amount of tuna or hamburger may minimize vomiting.

## Reproductive/Nursing Safety

Although zinc deficiency during pregnancy has been associated with adverse perinatal outcomes, other studies report no such occurrences. In humans, since zinc deficiency is very rare, the routine use of zinc supplementation during pregnancy is not recommended. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Signs associated with overdoses of zinc in mammals include hemolytic anemia, hypotension, jaundice, vomiting, and pulmonary edema. Suggestions for treatment of overdoses of oral zinc include removing the source, dilution with milk or water, and chelation therapy using edetate calcium disodium (Calcium EDTA). Refer to that monograph for possible doses and usage information.

Zinc intoxication in birds is relatively common, but clinical signs of intoxication in birds are varied and nonspecific. They include lethargy, anorexia, regurgitation, polyuria, polydipsia, hematuria, hematochezia, pallor, dark or bright green diarrhea, foul-smelling feces, paresis, seizures, and sudden death (Puschner & Poppenga 2009). Treatment involves removing the source of zinc, chelation therapy (edetate calcium disodium or succimer), and supportive care.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zinc and may be of significance in veterinary patients:

- **COPPER:** Large doses of zinc can inhibit copper absorption in the intestine; if this interaction is not desired, separate copper and zinc supplements by at least two hours
- **FLUOROQUINOLONES (e.g., enrofloxacin, ciprofloxacin):** Zinc salts may reduce the oral absorption of some fluoroquinolones
- **PENICILLAMINE:** May potentially inhibit zinc absorption; clinical significance is not clear
- **TETRACYCLINES:** Zinc salts may chelate oral tetracycline and reduce its absorption; separate doses by at least two hours
- **URSODIOL:** May potentially inhibit zinc absorption; clinical significance is not clear

## Doses

### ■ DOGS:

For adjunctive treatment and prophylaxis of hepatic copper toxicosis:

- Initially, give a loading dose of 100 mg *elemental* zinc (zinc acetate used in this study) twice daily (separate doses by at least 8 hours) for about 3 months; then reduce dose to 50 mg (elemental zinc) twice daily. If animal vomits, give doses with a small piece of meat. Do not give within one hour of a meal. Monitoring of zinc levels every 2–3 months initially is recommended. Target zinc levels are 200–500 micrograms/dL. Do not allow levels to increase higher than 1000 micrograms/dL. May require 3–6 months of therapy before significant efficacy is noted. (Brewer *et al.* 1992)

- Antiseizure medication that may be useful as an “add-on” drug for refractory epilepsy. May be considered for initial treatment as monotherapy in dogs.
- Half-life of 15 hours makes twice daily dosing possible in dogs; 33 hour half-life in cats may allow once daily dosing.
- Adverse effect profile not fully elucidated for dogs; sedation, ataxia, & inappetence have been reported
- Known teratogen in dogs
- Contraindicated in patients hypersensitive to sulfonamides
- Generics now available

### Uses/Indications

Zonisamide may be useful as an “add-on” drug for refractory epilepsy in dogs. It has been suggested that it could be useful as monotherapy as the initial drug choice for dogs, particularly when the client wishes to avoid adverse effects associated with phenobarbital or bromides (Thomas 2010).

### Pharmacology/Actions

The exact mechanism of action for zonisamide is not known. It may produce its antiseizure activity by blocking sodium channels and reducing transient inward currents, thereby stabilizing neuronal membranes and suppressing neuronal hypersynchronization. It does not appear to potentiate GABA. Zonisamide has weak carbonic anhydrase inhibitory activity.

### Pharmacokinetics

In dogs, zonisamide is well absorbed (bioavailability about 70%) after oral administration and has low protein binding. Zonisamide has been demonstrated to be absorbed rectally in dogs. The elimination half-life in dogs is about 15 hours. Most of the drug is excreted via the kidneys into the urine, but about 20% is metabolized, primarily in the liver. Unlike in humans, zonisamide exhibits linear pharmacokinetics (dose to plasma trough concentrations) in dogs (at doses between 5–30 mg/kg PO twice daily) (Fukunaga *et al.* 2010).

Zonisamide has a long half-life in cats of approximately 33 hours (Hasegawa *et al.* 2008).

### Contraindications/Precautions/Warnings

Zonisamide is contraindicated in patients hypersensitive to it or to any of the sulfonamide drugs.

### Adverse Effects

Because there has been limited use of this drug in veterinary patients the adverse effect profile is not fully known. Adverse effects that have been reported in dogs include sedation (usually transient), ataxia, and inappetence. Because it is a sulfonamide, there is concern (yet no reports as of writing) that zonisamide may cause KCS or other sulfonamide-related adverse effects in dogs or cats.

In a combined pharmacokinetic and toxicity study in cats, half of cats receiving 20 mg/kg per day developed adverse effects that included inappetence, diarrhea, vomiting, ataxia and somnolence (Hasegawa *et al.* 2008). Tolerance to therapy is possible.

In humans, the most common adverse effects associated with zonisamide include anorexia, nausea, dizziness, somnolence, agitation and headache. Rarely, serious dermatologic reactions (Stevens-Johnson syndrome, TEN), blood dyscrasias, oligohidrosis, and hyperthermia have been reported in humans.

### Reproductive/Nursing Safety

When zonisamide was administered to pregnant dogs at 10 or 30 mg/kg/day (approximate therapeutic dosages in dogs), ventricular septal defects, cardiomegaly and various valvular and arterial anomalies were seen at the higher dose. A plasma level of 25 micrograms/mL was the threshold level for malformation. If this drug is to be used in pregnant dogs, the owner must accept the significant risks associated with its use.

It is not known if zonisamide enters maternal milk; use with caution in nursing animals.

### Overdosage/Acute Toxicity

The LD50 of zonisamide in dogs is reportedly 1 gram/kg. In human overdoses, effects reported include coma, bradycardia, hypotension, and respiratory depression. Treatment recommendations include GI evacuation, if ingestion was recent, and supportive therapy. Because of the drug’s long half-life, support may be required for several days.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zonisamide and may be of significance in veterinary patients:

■ **PHENOBARBITAL:** In dogs, phenobarbital may increase the clearance of zonisamide as repeated phenobarbital dosing decreased the bioavailability, peak concentrations, half-life, and area under the curve of zonisamide, but it did not affect the time to peak level or the volume of distribution of zonisamide. This effect persisted up to 10 weeks after phenobarbital discontinuation (Orito *et al.* 2008). See the dose section for suggestions on altering zonisamide doses for dogs on phenobarbital.

### Laboratory Considerations

- No specific laboratory interactions or considerations were noted
- While plasma concentrations of zonisamide are not routinely monitored in human patients, in dogs, the therapeutic range has been suggested to be from 10–40 micrograms/mL

### Doses

- **DOGS:**
  - a) 5–10 mg/kg PO q12h. The high end of the dose range is needed when used in combination with phenobarbital, probably as a result of phenobarbital-induced microsomal enzyme induction. (Munana 2010)
  - b) As monotherapy: Initially at 5 mg/kg PO twice daily (q12h). When used in combination with phenobarbital: 10 mg/kg PO q12h. (Thomas 2010), (Martin-Jimenez 2010)
  - c) As initial monotherapy: 3–5 mg/kg PO q12h. As an add-on agent: 10 mg/kg PO q12h. (Mariani 2010)
  - d) Initial dose: 5–10 mg/kg PO q12h; gradual adaptation in dosing is recommended. Reduce phenobarbital doses by 25% at the time of starting zonisamide. (Podell 2006)

- **CATS:**

- a) There are anecdotal reports of the use of zonisamide in cats, with oral doses of 5 mg/kg every 12-24 hours most commonly utilized. (Munana 2010)
- b) Because of its long half-life, doses of 5–10 mg/kg PO once daily are likely to be appropriate in cats, although additional studies are needed to determine this. The authors report using the drug in 2 cats that were refractory to phenobarbital therapy; one developed anorexia and the drug had to be discontinued, but the other responded well. (Bailey & Dewey 2009)
- c) 10–20 mg/kg PO once daily. (Martin-Jimenez 2010)

### Monitoring

- Efficacy
- Monitoring zonisamide blood levels may be useful in veterinary patients, but this has not been confirmed nor have veterinary therapeutic blood concentrations been identified. Therapeutic levels for humans are thought to be: 10–40 micrograms/mL.
- Adverse effects

### Client Information

Caution clients abruptly or "rebound" seizures occur

Have clients maintain a seizure diary to help determine efficacy

### Chemistry/Synonyms

A sulfonamide unrelated to other antiseizure drugs, zonisamide occurs as a white powder with a pKa of 10.2. It is moderately soluble in water (0.8 mg/mL).

Zonisamide may also be known as: AD-810, CI-912, PD-110843, *Excegran*®, or *Zonegran*®.

### Storage/Stability

Zonisamide capsules should be stored at 25°C (76°F); excursions permitted to 15–30°C (59–86°F). Store in a dry place and protected from light.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Zonisamide Capsules: 25 mg, 50 mg & 100 mg; *Zonegran*® (Eisai); generic; (Rx)

### Appendix

#### Ophthalmic Products, Topical

The following section lists the majority of veterinary-labeled ophthalmic topical products and some of the more commonly used human-labeled products in veterinary medicine; written by Gigi Davidson, DICVP with input from Michael Davidson, DVM, DACVO. Drugs are listed by therapeutic class.

For additional information, an excellent review on veterinary ophthalmic pharmacology and therapeutics can be found in both of the following textbooks: Slatter's Fundamentals of Veterinary Ophthalmology, 4th Edition. David Maggs, Paul Miller, Ron Ofri, Editors, Elsevier, 2007, 496 pages, and Veterinary Ophthalmology, 4th Edition; Kirk N Gelatt, Editor; Lippincott Williams & Wilkins, Media, Pennsylvania, 2007. 1568 pp.

#### Routes of Administration For Ophthalmic Drugs

The route of administration selected to deliver therapy for an ocular condition is critical to successful therapy. The following table lists advantages and disadvantages of each route of administration for ocular medications.

Route	Tissues Reached	Dosage Form	Advantages	Disadvantages	Comments
<b>Typical</b>	Conjunctiva; Cornea; Anterior uvea; Lids	<b>Solutions</b> <b>Suspensions</b>	Easier administration for small animals; minimal interference with vision; lower incidence of contact dermatitis; less toxic to interior of eye if penetrating wound	More difficult to administer to horses; less contact time with eye; requires more frequent application than ointment; diluted by tearing; generally more expensive than ointment; more systemic absorption	Doses > 1 drop rarely indicated in small animals (maximum tear capacity is 10–20 µl, volume of a drop is 25–50 µl); allow 5 minutes between drops; instill in order of least viscous to most in order of aqueous prior to oil base
		<b>Ointments</b>	Longer contact time; less frequent administration; protect cornea from drying; not diluted by tearing; generally less expensive than solutions/suspensions	Contribute to volume of ocular discharge; temporary blurring of vision; more difficult for client administration; more contact dermatitis; should not be applied to penetrating corneal wounds as oils will cause a granulomatous uveitis; difficult to determine exact dose; metal tubes often fatigue and split before all medication is used	Owners should be counseled to avoid contact of application tube with eye; observe patient for short while after application due to temporary blurred vision
<b>Subconjunctival injection</b>	Cornea; Anterior uvea	<b>Sterile solutions and suspensions</b>	Longer duration of action; higher anterior chamber concentrations than topical	Limited number of injections can be performed; may create scar tissue; cannot be removed once applied; temporary pain; drug vehicle residues	Indicated for poorly compliant owners, uncooperative patients; indicated for drugs with poor corneal penetration
<b>Retrolidial injection</b>	Posterior segment; Optic nerve	<b>Sterile solutions and suspensions</b>			Primarily used for local anesthetic prior to enucleation of the eye
<b>Intracameral injection</b>	Anterior chamber; Posterior segment	<b>Sterile solutions and suspensions</b>	Allows very high drug concentrations for intraocular infections	Risk of hemorrhage, retinal detachment, cataract formation, and retinal degeneration	Rarely used except for severe intraocular infections or for administration of DNA to dissolve fibrin clots in the anterior chamber
<b>Systemic Drugs</b>	Lids; Posterior segment; Optic nerve; Anterior uvea (occasionally)	<b>Oral</b> <b>Intramuscular</b> <b>Subcutaneous</b> <b>Intravenous</b>	Allows drug penetration to areas where topical therapy will not reach	Systemic toxicity; Does not reach cornea; expense directly proportional to body weight in most cases	See monographs for use of systemic agents.

### Diagnostic Agents

**Note:** A logical sequence of diagnostic tests must be used to perform ocular examination based on the special needs of each diagnostic agent and test. For example, evaluation of the tear film is performed with the Schirmer Tear Test and must be done before the eye is manipulated or any drug agents are instilled in order to provide a true picture of tear production. Likewise, cultures of the external ocular structures must be done prior to extensive cleaning or administration of any drugs that may alter bacterial culture. The use of mydriatics is essential to examination of the interior elements of the eye, but must not be given prior to measuring intraocular pressure as these agents will likely affect aqueous humor outflow. Intraocular pressure determination requires topical anesthetic, but must quickly be recorded prior to excessive manipulation of the eye or before the patient becomes anxious and uncooperative.

### FLUORESCEIN SODIUM

(*fluore-e-seen*)

#### Indications/Pharmacology

Fluorescein sodium is a yellow water-soluble dye that fluoresces under a Wood's Lamp, but is plainly visible after binding to corneal stroma through an ophthalmic examination light source. It is used most commonly to delineate full thickness loss of corneal epithelium indicating the presence of a corneal ulceration. In this instance, it will stain the corneal stroma. The epithelium is not stained because its outer lipid cell membrane repels the stain. Descemet's membrane will not stain with fluorescein stain and this is used to indicate descemetocele formation, an ocular emergency.

Fluorescein stain is applied to the precorneal tear film in dogs and cats and the break-up of this stain with time, as observed through a slit lamp biomicroscope using a cobalt blue light source, is used to determine the tear film break-up time (normal 19 seconds), an indicator of tear film quality.

Fluorescein stain is applied to the tear film of dogs to determine patency of the nasolacrimal outflow system. The normal wait time is 2–5 minutes in dogs and up to 10 minutes in cats. A positive test indicates patency of the system. A negative test is not indicative of disease, as the test is negative in a large percentage of normal animals. Fluorescein stain, then, can be added to irrigating solution to flush the nasolacrimal system, making detecting the irrigation solution at the nose more obvious during flushing of the system.

measuring the irrigation solution at the nose more obvious during flushing of the system.

### Suggested Dosages/Precautions/Adverse Effects

Fluorescein stain is applied by dropping a drop of irrigating solution onto the sterile strip and then allowing the drop to fall on the eye. The strip should not contact the cornea or it will cause false positive stain retention at the site of contact with the epithelial cells. Fluorescein impregnated paper strips are preferred to fluorescein solution to insure sterility. After a few seconds, the excess fluorescein is irrigated from the eye, staining areas of full thickness epithelial loss.

For procedures requiring topical anesthesia as well as a disclosing agent, benoxinate is added to fluorescein solutions in a ratio of 0.25% fluorescein to 0.4% benoxinate. These solutions are useful for removal of foreign bodies or sutures, but are not commonly used in veterinary medicine.

Conjunctival or corneal epithelial cells for fluorescent antibody testing should be collected prior to application of fluorescein stain, which can cause a false positive test for several days after application of the stain.

Fluorescein may rarely cause hypersensitivity reactions. Temporary staining of fur and skin may result. Do not use during intraocular surgery.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sterile strips of paper impregnated with fluorescein sodium are the most commonly used form in veterinary medicine. Solutions (2%) of fluorescein are available, however they are not popular following one study indicating that *Pseudomonas* is readily grown in such solutions. Injectable products are also available (for ophthalmic angiography), but are not routinely used in veterinary medicine.

Fluorescein Sodium Strips: 0.6 mg, *Ful-Glo*® (Barnes Hind); 1 mg, *Fluor-I-Strip*®-A.T. (W-A); 9 mg, *Fluor-I-Strip*® (W-A); (all Rx); 1 mg *Bio-Glo*®, 100 ct or 300 ct (Wilson Ophthalmic,) *AK Flor 10% Injection* (Akorn) 5 mL ampules

Fluorescein Sodium: Benoxinate: *Fluress*® (Akorn) 0.25:0.4% Drops in 5 mL, *Flurox*® (Hub) 0.25:0.4% Drops in 5 mL, *Flurate*® (Bausch and Lomb) 0.25:0.4% Drops in 5 mL.

---

### LISSAMINE GREEN

(*lis-ah-meen*)

---

### Indications/Pharmacology

Lissamine green is used for diagnosis of corneal damage and to quantify tear production. These strips work by staining the cornea blue upon instillation, resulting in a “speckling” of the cornea. This speckling marks any corneal ulcerations as well as dry patches from any muco-deficient or damaged corneal cells. A white or blue light may be used on the slit lamp during detection. Lissamine green possesses a therapeutic advantage in that it does not sting the eye like Rose Bengal; however, as interpretation of lissamine green results requires broader experience than that of Rose Bengal and fluorescein, fluorescein staining is considered a more reliable indicator of corneal damage.

### Suggested Dosages/Precautions/Adverse Effects

Lissamine Green impregnated strips are placed in the conjunctival sac and staining is scored based on 6 areas of staining.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

*Lissamine Green Ophthalmic Strips* (Imperial Chemical Industries—available through distributors such as Wilson Ophthalmic) 1.5 mg, 100 individually wrapped strips per box.

---

### PHENOL RED THREAD

(*fee-nol*)

---

### Indications/Pharmacology

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantitatively with either the Schirmer Tear Test or the Phenol Red Thread Test. The Phenol Red Thread (PRT) test is a new, fast and equally accurate method to test tear production as compared to the Schirmer Tear Test. The PRT test has a 75mm long yellow-colored thread that is impregnated with phenol red, a pH sensitive indicator.

### Suggested Dosages/Precautions/Adverse Effects

The 3mm indentation at the end of the thread is inserted into the inferior conjunctival sac for 15 seconds. As tears travel up the thread, the alkaline pH of the tears turns the thread red. The PRT requires only 15 seconds for diagnostic results as opposed to 1 minute for the Schirmer Tear Test in dogs. Normal tear production via PRT in cats at 15 seconds is 18.4 to 27.7 mm/15 seconds and, in dogs, 29.7 to 38.6 mm/15 seconds.

### Dosage Forms/Regulatory Status

VETERINARY-APPROVED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Phenol Red Thread Test: *Zone-QuickDiagnostic Threads*®, 100 per box, (Menicon—available through distributors such as Wilson Ophthalmic)

---

### ROSE BENGAL

(*rose ben-gall*)

---

### Indications/Pharmacology

Rose bengal is a vital stain and stains dead epithelial cells and mucus. Full thickness loss of the corneal epithelium is not necessary (only dead cells need be present) to obtain rose bengal stain uptake. It does not stain epithelial defects and does not pass into intercellular spaces.

Rose bengal is most commonly employed in the detection of the presence of viral keratitis in the cat. Because feline herpes virus tends to infect one cell, moving then to an adjacent cell (causing the so called dendritic tracts in the cornea) without full thickness loss of corneal epithelium initially, rose bengal is an ideal diagnostic agent for this infection. Rose Bengal can also be used to detect damaged corneal epithelium on the dorsal cornea in early cases of keratoconjunctivitis sicca. Rose bengal stain is virucidal although no information is available relative to its use as a therapeutic agent.

### Suggested Dosages/Precautions/Adverse Effects

### Suggested Dosages/Precautions/Adverse Effects

Rose Bengal is applied as a solution (1–2 drops in conjunctival sac before examination) or from an impregnated strip (saturate tip of strip with sterile irrigating solution; touch bulbar conjunctiva or lower fornix with moistened strip; cause patient to blink several times to distribute the stain).

Rose bengal is apparently toxic to the cornea and conjunctiva and should be thoroughly flushed from the eye after use to prevent irritation. Hypersensitivity reactions are possible. May stain clothing.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Rose Bengal Solution: 1% in 5 mL dropper bottles (Spectrum); (Rx)

Rose Bengal Strips: 1.3 mg per strip; *Rosets*® (Akorn); generic (Barnes-Hind); (Rx)

---

### SCHIRMER TEAR TEST

(shir-mer)

---

### Indications/Dosages/Precautions

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantitatively by the Schirmer Tear Test or the Phenol Red Thread Test. The Schirmer Tear Test measures the aqueous aspect of tears and is the most commonly used test for measuring tear production.

### Suggested Dosages/Precautions/Adverse Effects

Because of the risk of false readings, the following should be avoided prior to conducting a Schirmer Tear Test: excessive manipulation of the eyelids, topical anesthesia, and topical or systemic drugs (e.g., tranquilizers and atropine). The round end of the test paper is bent while still in the envelope and positioned to avoid contamination. The bent end should be positioned in the lacrimal lake at the junction of the lateral and middle thirds of the lower eyelid. Most animals will close the eye during the test but this does not affect results. The Schirmer Tear Test should be left in position for one minute as results are not linear and cannot be extrapolated from shorter test times. Schirmer tear test values are as follows for the following species: Dogs:  $21.9 \pm 4.0$  mm wetting per minute, Rabbits:  $5.3 \pm 2.9$  mm wetting per minute, Cats:  $20.2 \pm 4.5$  mm wetting per minute.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

*Schirmer Tear Test*®: 300 individually wrapped strips, (Schering Plough/Intervet)

**HUMAN-LABELED PRODUCTS:**

*Clemente Clarke*® *Schirmer Tear Test Strips*: 50 pair/box, *Schirmer Tear Test Strips*® (Alcon)

### Ocular Anesthetics

Local anesthetic effect is dependent upon chemical structure and concentration. Local anesthetic agents structurally consist of a hydrophobic aromatic ring (benzoic acid derivatives), a linkage site between the aromatic ring and an intermediate chain, and a hydrophilic amine. The hydrophobic portion is essential for activity, as it is the portion that enables diffusion through the lipid membrane of nerves increasing hydrophobicity increases access of the anesthetic to its site of action and decreases its metabolism, thereby increasing potency and duration. Greater hydrophobicity is also associated with increased toxicity. The hydrophilic amine portion may exist in an uncharged, poorly water-soluble form, or as the positively charged ammonium ion.

Topical anesthetics adversely affect the epithelial surface and delay wound healing. Adverse effects range from superficial punctate keratitis, decreased tearing, and decreased blinking, to corneal edema, pain, and diffuse necrotizing keratitis. Long-term administration inhibits cell migration and mitosis leading to retarded wound healing and infection. For this reason, topical anesthetics are never administered therapeutically.

Contraindications to topical anesthetics include liver disease (decreased clearance), concurrent anticholinergic therapy (prevents metabolism of esters), perforating ocular injury, and for collection of ocular surface cultures (due to inhibition of microbial growth.)

---

### PROPARACAINE HCL

(proe-par-a-kane)

---

### Indications/Pharmacology

Proparacaine is a rapid acting topical anesthetic useful for a variety of ophthalmic procedures including tonometry (intraocular pressure measurement), relief of corneal pain to facilitate examination, biopsy/sample collection, and to distinguish between corneal and uveal pain. Proparacaine primarily anesthetizes the cornea; with limited penetration into conjunctiva. Anesthesia is of short duration (5–10 minutes).

### Suggested Doses/Precautions/Adverse Effects

Usual dose is 1–2 drops prior to examination or procedure. For prolonged procedures only requiring local anesthesia; may repeat 1 drop doses every 5–10 minutes for 5–7 doses.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Proparacaine HCl Solution: 0.5% in 15 mL bottles; *Ophthaine*® (Solvay); (Rx). Protect from light. Refrigerate.

**HUMAN-LABELED PRODUCTS:**

Proparacaine HCl Solution: 0.5% in 2 & 15 mL bottles; *Ophthalmic*® (Allergan), *Alcaine*® (Alcon), *Ophthaine*® (Squibb), *AK-Taine*® (Akorn), Generic; (Rx). Protect from light. Some products should be refrigerated; check label.

---

### TETRACAINE HCL

(teh-trah-kane)

---

### Indications/Pharmacology

Tetracaine is more irritating than proparacaine but is sometimes used in veterinary medicine. It is indicated to produce local anesthesia of short duration for ophthalmic procedures including measurement of intraocular pressure (tonometry), removal of foreign bodies and sutures, and conjunctival and corneal scraping in diagnosis and gonioscopy. Tetracaine is also indicated to produce local anesthesia prior to surgical procedures in humans such as cataract extraction and pterygium excision, usually as an adjunct to locally injected anesthetics. Ophthalmic solutions used for intraocular procedures should be preservative-free. Preservatives may cause

damage to the corneal epithelium if a significant quantity of solution enters the eye through the incision.

### Suggested Dosages/Precautions/Adverse Effects

Usual dose is 1–2 drops prior to examination or procedure. The onset of action is about 15 seconds. The duration of action usually extends with repeated applications.

Topical anesthetics should not be used to treat painful eye disease. Prolonged use may retard wound healing and cause corneal epithelial ulcers. Because the blink reflex may be suppressed, the eye should be protected from external injury during use. Repeated use may lead to rapid development of tolerance. Local allergic-type reactions have been rarely reported in humans.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Tetracaine Solution 0.5%: 15 mL; *Ak-Taine*® (Akorn), *Alcaine*® (Alcon), *Ocu-Caine*®, *Ophthaine*®, *Ophthetic*®, *Spectro-Caine*®; (Rx)

Tetracaine Solution 2%: 15 mL and 30 mL bottles; *Pontocaine*® (Hospira); (Rx)

Tetracaine Injection 10 mg/mL; 2 mL ampules; *Pontocaine*® (Hospira); (Rx)

---

## BENOXINATE

(bin-ak-sin-ate)

---

### Indications/Pharmacology

Benoxinate is only available in combination with vital dyes, either sodium fluorescein 0.25% or disodium fluorexon 0.35% (a high-molecular-weight fluorescein that does not stain hydrogel contact lenses, allowing contacts to be worn sooner following administration, without concern of staining). It has a similar onset, intensity, and duration of action to that of tetracaine 0.5% and proparacaine 0.5%. Benoxinate has not been evaluated in veterinary ophthalmology.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fluorescein Sodium: Benoxinate: *Fluress*® (Akorn) 0.25:0.4% Drops in 5 mL, *Flurox*® (Hub) 0.25:0.4% Drops in 5 mL, *Flurate*® (Bausch and Lomb) 0.25:0.4% Drops in 5 mL.

### Ocular Hypotensive Agents, Topical

**Note:** It is important to review the basic pathophysiology of glaucoma in order to understand drug therapy of this disease. Aqueous humor production results from ciliary body secretion and ultrafiltration of plasma. Carbonic anhydrase is a vital enzyme in the production of aqueous humor. Outflow of aqueous humor flows from the posterior chamber into the anterior chamber and exits at the iridocorneal angle, or exits through the iris, ciliary body, choroids, and sclera. The balance of generation and outflow of aqueous humor maintains the intraocular pressure at between 15 and 25 mmHg. By definition, glaucoma is an increase in intraocular pressure with resulting visual deficits. Delayed, inadequate or inappropriate therapy can result in severe pain and irreversible blindness as well as a cosmetically unappealing eye. Generally, once acute congestive primary glaucoma (generally breed-related and hereditary) is noted in one eye in the dog, it is treated as an emergency using a topical prostaglandin such as latanoprost. Surgery may be considered for lasting control of intraocular pressure. The following topical drugs are used “in general” as a preventative measure to prevent the occurrence of primary glaucoma in the unaffected eye in canine patients. Topical ocular antihypertensive medications are sometimes employed for pressure control with secondary glaucomas also. Because primary glaucoma in dogs is a progressive disorder, many patients are initially treated with single agents but combinations of drugs are often ultimately necessary to maintain pressure control.

Primary glaucoma in the feline species is increasingly being recognized in several forms. Although breed-related glaucoma in Siamese and Persian cat breeds has been noted, many veterinary ophthalmologists feel that domestic shorthaired cats are most likely affected. One form involving misdirected flow of aqueous humor into the vitreous, secondarily resulting in a forward displacement of the lens-iris diaphragm, has been described in the literature. The forward displacement of the iris has resulted in an average intraocular pressure of 30 mmHg in most patients. Topical medications have been successful in preventing progressive vision loss in most of these cats. Other forms of feline glaucomas that are presumably genetic are being noted sporadically in clinical practice and most of these cases, in complete contrast with primary glaucoma in the canine, are managed successfully with medications. Pharmacologic agents utilized for medical treatment of glaucoma are noted below categorized by therapeutic class but not by therapeutic priority.

### Parasympathomimetics (Miotics)

The parasympathomimetic nervous system utilizes acetylcholine as the pre- and post-synaptic neurotransmitter. Parasympathomimetic drugs act either directly by mimicking acetylcholine, or indirectly by preventing its breakdown by acetylcholinesterase. Parasympathomimetics are useful ocular therapeutic agents by virtue of inducing contraction of the intraocular smooth muscle (miosis), which reduces intraocular pressure.

---

## CARBACHOL

(kar-beh-call)

---

### Indications/Pharmacology

Carbachol is a direct-acting parasympathomimetic but also has some indirect action through inhibition of acetylcholinesterase. It cannot penetrate intact epithelium and when used topically (rarely), its use must be accompanied with a surfactant (benzalkonium chloride) to enhance penetration.

Carbachol has been used to induce miosis in treatment of glaucoma, but more commonly, is used by veterinary ophthalmologists as an intracameral 0.01% injection at the conclusion of phacoemulsification surgery (cataract removal) to protect against postoperative increases in intraocular pressure (Crasta *et al.* 2010; Stuhr *et al.* 1998).

### Suggested Dosages/Precautions/Adverse Effects

Carbachol 0.75% has been used topically, although rarely, to reduce intraocular pressures in dogs at a dose of 1 drop every 4–8 hours. Carbachol is administered intraoperatively at a dose of 0.5 mL of a 0.01% solution. Carbachol shares the potential for the same adverse effects of all other miotic agents, and in humans has been noted to cause severe headaches and accommodative muscle spasms. Corneal clouding, persistent bullous keratopathy, retinal detachment and postoperative iritis have been reported in humans following intracameral injection of carbachol following cataract extraction.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Carbachol 0.01% Injection, for intraocular use only, 10 × 1 mL ampules, *Carbasta*® (Novartis), *Miostat*® Intraocular (Alcon); (Rx)

Carbachol Ophthalmic Solution: 0.75%, 1.5%, 2.25%, and 3%, in 15 mL plastic dropper bottles; *Isopto Carbachol*® (Alcon), *Carboptic*® (Optopics); (Rx)

## PILOCARPINE HCL

(pye-loe-kar-peen)

---

### Indications/Pharmacology

Pilocarpine is a cholinergic agonist (miotic) that is rarely used in the treatment of canine primary glaucoma. Pilocarpine causes the ciliary body muscle to constrict placing posteriorly directed tension on the base of the iris to mechanically pull open the iridocorneal angle structures. By causing miosis, it may prevent closure of the iridocorneal angle by preventing excess iris tissue from peripherally compromising the outflow of aqueous humor. It should be noted however, that cholinergic agonists reduce uveoscleral outflow, making them less useful in species that are more dependent on uveoscleral outflow for maintenance of intraocular pressure (e.g., horses). Evaluation of pilocarpine 2% to normal mares did not reduce intraocular pressure although it did induce miosis (van der Woerd *et al.* 1998).

Pilocarpine has also been used for diagnostic localization of parasympathetic denervation of the iris sphincter caused by lesions or trauma to Cranial Nerve III. The popularity of treatment of KCS with ophthalmic cyclosporine and tacrolimus has been associated with a decline in the use of pilocarpine for this disease; however, pilocarpine is still used orally as the primary treatment of neurogenic keratoconjunctivitis sicca in dogs as this condition does not respond to cyclosporine or tacrolimus.

Pilocarpine is available in various solutions and gels with a low and potentially irritating pH of 4.5-5.5 in order to maintain drug stability. A buffered-tip formulation of pilocarpine enables administration of a pH 7.0 solution, which may decrease ocular side effects without compromising efficacy.

### Suggested Dosages/Precautions/Adverse Effects

One drop in affected eye(s) 3 times daily. Usually 1% or 2% is most commonly used in veterinary medicine.

Pilocarpine can cause local irritation initially accompanied by a profound miosis that significantly decreases visual acuity, in humans. This irritation reportedly diminishes after 3 days of therapy. It may also cause inflammation of the uveal tract, especially with repeated applications and can cause hyphema. Chronic use may result in an irreversible miosis due to dilator muscle atrophy and sphincter muscle fibrosis. Pilocarpine should not be used in secondary glaucoma cases. With repeated use, pilocarpine may cause systemic effects (vomiting, diarrhea, increased salivation, bronchiolar spasm, and pulmonary edema). Pilocarpine should be avoided in dogs with glaucoma secondary to uveitis as well as in dogs with lens luxation or subluxation due to potential for papillary block.

For diagnosis of parasympathetic denervation or other conditions caused by cranial nerve III lesions, a 0.2% solution of pilocarpine is applied topically. For neurogenic keratoconjunctivitis sicca, a 2% solution of pilocarpine is given orally (in food) at a dose of 2 drops per 20 lbs of body weight twice daily. The dose is increased weekly until signs of toxicity or until control of symptoms is achieved.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pilocarpine HCl Ophthalmic Solution: 0.25%, 0.5%, 1%, 2%, 3%, 4%, and 6% (in addition there are 8% and 10% solutions and a 4% gel is available from Alcon) in 15 mL and 30 mL containers; *Isopto Carpine*® (Alcon); *Ocu-Carpine*® (Iomed); *Piloptic*® (Optopics); *Pilostat*® (Bausch and Lomb), generic; (Rx)

See also the [epinephrine](#) monograph for information on epinephrine/pilocarpine fixed dose combination products.

---

## DEMECARIUM BROMIDE

(deh-meh-kar-ee-um)

---

### Indications/Pharmacology

Demecarium is a potent, long-acting carbamate inhibitor that may reduce intraocular pressures for up to 48 hours in canines. Demecarium reversibly inhibits anticholinesterase thereby causing miosis. Demecarium is generally used in preventive management of the contralateral eye in canine patients after the diagnosis of an acute congestive crisis of primary glaucoma in the other eye. It is not used in secondary glaucoma. Demecarium has the advantage of once or twice daily dosing.

### Suggested Dosages/Precautions/Adverse Effects

One drop once or twice daily. Demecarium is contraindicated during pregnancy. Because of additive effects, demecarium should be used with caution with other cholinesterase inhibitors (e.g., carbamate/organophosphate antiparasiticides), or succinylcholine. Demecarium can cause ciliary body muscle spasm, producing a headache and blurred vision, as well as local inflammation (alleviated by addition of topical corticosteroids) and systemic adverse effects (vomiting, diarrhea, increased salivation, cardiac effects), particularly with high dosages or in very small dogs.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Formerly available as: Demecarium 0.125% or 0.25% in 5 mL dropper bottles; *Humorsol*® (Merck); (Rx). Do not freeze and protect from heat. Demecarium must be obtained from an appropriately qualified compounding pharmacy.

---

## ECHOTHIOPHATE IODIDE

(ek-oh-thye-oh-fate eye-oh-dide)

---

### Indications/Pharmacology

Echothiophate iodide for ophthalmic solution is a long-acting, irreversible cholinesterase inhibitor for topical use that enhances the effect of endogenously liberated acetylcholine in iris, ciliary muscle, and other parasympathetically innervated structures of the eye. It thereby causes miosis, increase in facility of outflow of aqueous humor, fall in intraocular pressure, and potentiation of accommodation. Echothiophate iodide for ophthalmic solution will depress both plasma and erythrocyte cholinesterase levels in most patients after a few weeks of eye drop therapy.

### Suggested Doses/Precautions/Adverse Effects

One drop twice daily. Echothiophate is contraindicated in the presence of active uveal inflammation, and in most cases of angle-closure glaucoma, due to the possibility of increasing angle block. Temporary or permanent discontinuation of the drug may be required if cardiac irregularities, urinary incontinence, diarrhea, muscle weakness, nausea, abdominal cramps, fatigue, weakness or respiratory difficulties occur. Echothiophate should be avoided in patients with asthma, gastric ulcers, bradycardia, hypotension, epilepsy or other disorders that may respond adversely to vagotonic effects. Carbamate and organophosphate pesticides should not be used on patients receiving echothiophate.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ethothiophate Iodide Solution: 0.125% in 5 mL; *Phospholine Iodide*® (Wyeth); (Rx). Store under refrigeration. Once reconstituted, may be stored at room temperature for up to 4 weeks.

### Sympathomimetics (Alpha2-Agonists)

Alpha-agonists reduce intraocular pressure by activation of presynaptic alpha-receptors, inhibiting release of norepinephrine, blocking adrenergic stimulation of the ciliary body and decreasing production of aqueous humor. Chronic use of these agents also results in increased uveoscleral outflow.

---

## APRACLONIDINE

(a-pra-kloe-ni-deen)

---

### Indications/Pharmacology

Apraclonidine is an alpha2 adrenergic agonist used to reduce aqueous humor formation. Apraclonidine is a relatively selective, alpha-adrenergic agonist and does not have significant membrane stabilizing (local anesthetic) activity. The primary ocular side effects noted following use of apraclonidine include conjunctival blanching, eyelid elevation, and mydriasis. While its systemic side effects are relatively mild compared to those of the beta-blockers, apraclonidine can cause dry eye or dry mouth, as well as mild elevations in resting heart rate, blood pressure, and respiration. Chronic use of apraclonidine can lead to decrease in therapeutic response. The onset of action is within 3–5 hours of a single dose. It apparently is less effective than brimonidine in dogs and is very potent, causing vomiting and diarrhea in dogs and cats (Miller & Rhaesa 1996). Severe side effects such as bradycardia, salivation and vomiting preclude use of apraclonidine in cats. Apraclonidine will reduce aqueous production, but it must be combined with other agents for adequate control. Neither the beta-blockers nor alpha-agonists are as effective as the carbonic anhydrase inhibitors in decreasing aqueous production.

### Suggested Dosage/Precautions/Adverse Effects

1% solution applied as 1 drop 2–3 times daily. Apraclonidine should be used with caution in the face of hepatic and renal function impairment (since a structurally related medication, clonidine, is partly metabolized in the liver and undergoes a significant increase in half life in humans with renal impairment). Apraclonidine should not be used in cats due to severe adverse effects including vomiting, diarrhea, bradycardia and salivation. Ironically, in humans the 0.5% concentration is more likely to cause cardiovascular adverse effects than the 1% solution. In humans the following side effects have been noted: For 0.5% ophthalmic apraclonidine: Allergic reaction, abnormal coordination, arrhythmia, asthma, blepharitis, blepharoconjunctivitis, conjunctivitis, blurred vision or change in vision, chest pain, contact dermatitis, corneal erosion, corneal infiltrate, foreign body sensation, keratitis, keratopathy, depression, dizziness, dyspnea, edema of eye, eyelid, or conjunctiva, eye discharge, facial edema, lid retraction, paresthesia, or peripheral edema. For 1% ophthalmic apraclonidine: allergic reaction, arrhythmia, or ocular inflammation or injection.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Apraclonidine 0.5% Solution: 5 mL & 10 mL; 1% *Iopidine*® (Alcon); (Rx). Supplied as follows: 0.1 mL in plastic ophthalmic dispensers, packaged two per pouch. These dispensers are enclosed in a foil overwrap as an added barrier to evaporation.

### References

---

## BRIMONIDINE

(bri-moe-ni-deen)

---

### Indications/Pharmacology

Brimonidine tartrate is an alpha-adrenergic receptor agonist with a greater affinity for alpha2 receptors than apraclonidine. Brimonidine has a longer duration of action than apraclonidine as it binds to melanin, which acts as a reservoir to slowly release brimonidine. When used as a monotherapy, it is recommended that brimonidine be administered every 8 hours. Every 12-hour administration is acceptable when brimonidine is used in combination with timolol or dorzolamide. Brimonidine may also provide a protective effect to the retina and optic nerve (Karakucuk *et al.* 2009). However, this effect has not been clinically explored nor utilized in animals. Fluorophotometric studies in animals and humans suggest that brimonidine tartrate has a dual mechanism of action by reducing aqueous humor production and by increasing uveoscleral outflow. After ocular administration of either a 0.1% or 0.2% solution, plasma concentrations peaked within 0.5 to 2.5 hours and declined with a systemic half-life of approximately 2 hours. In humans, systemic metabolism of brimonidine is extensive. It is metabolized primarily by the liver. Urinary excretion is the major route of elimination of the drug and its metabolites. Approximately 87% of an orally administered radioactive dose was eliminated within 120 hours, with 74% found in the urine.

### Suggested Dosages/Precautions/Adverse Effects

The usual dosage is 1 drop in the affected eye twice daily. Adverse events in humans include: allergic conjunctivitis, conjunctival hyperemia, and eye pruritus, burning sensation, conjunctival folliculosis, hypertension, oral dryness, and visual disturbance. Brimonidine also causes an increase in eyelash growth in humans and it is used in the cosmetic industry for this purpose. Brimonidine appears to be better tolerated in animals than apraclonidine.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Brimonidine 0.15% solution: 5 mL, 10 mL, & 15 mL; *Alphagan P*® (Allergan); various generics as 0.1% and 0.2% solutions; (Rx)

Brimonidine 0.2%/Timolol maleate: 0.5% in 5 mL & 10 mL; *Combigan*® (Allergan); (Rx)

---

## DIPIVEFRIN, TOPICAL

(dye-pi-ve-frin)

---

### Indications/Pharmacology

Dipivefrin is a lipophilic prodrug to epinephrine allowing penetration through the corneal epithelium into the stroma where it is converted to epinephrine by esterases. Once converted to epinephrine, aqueous humor

production is decreased primarily through vasoconstriction of ciliary body vessels and increases outflow through the trabecular meshwork. A study in beagles demonstrated that epinephrine at 1% and 2% and dipivefrin at 0.5% were effective in decreasing intraocular pressure (Gwin *et al.* 1978). While the drug has reasonable efficacy in humans, the associated local adverse effects of burning, hyperemia, hyperpigmentation, and cardiovascular stimulation have caused both epinephrine and dipivefrin to be replaced by the other alpha2 agonists, apraclonidine and brimonidine.

### Suggested Dosage/Precautions/Adverse Effects

Dipivefrin is not recommended for use due to significant local adverse effects including burning, hyperemia, hyperpigmentation, and cardiovascular stimulation.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Dipivefrin 1% solution in 5 mL, 10 mL or 15 mL vials; *Propine*® (Allergan); (Rx)

### References

Gwin, R.M., K.N. Gdin, et al. (1978). Effect of topical 1-epinephrine and dipivefrin on intra-ocular pressure and pupillary diameter in normotensive and glaucomatous beagles. *American Journal of Veterinary Research* 39(1):83-86.

---

## EPINEPHRINE, TOPICAL

(ep-i-nef-rin)

---

### Indications/Pharmacology

Epinephrine is a direct-acting alpha- and beta-agonist. Its primary use in veterinary ophthalmology is for intracameral injection to facilitate mydriasis and prevent bleeding during intraocular procedures. Epinephrine (usually in combination with pilocarpine due to epinephrine's mydriatic effects) is usually used as a preventative measure to prevent glaucoma in the unaffected eye. Epinephrine acts on both alpha and beta adrenergic receptors, thereby causing conjunctival decongestion, transient mydriasis (less so in cats) and decreased IOP (intraocular pressure). Decreased IOP is probably due primarily to increased aqueous humor outflow, but decreased aqueous humor production may occur secondary to vasoconstriction. Epinephrine is ineffective as a sole mydriatic in cats.

### Suggested Dosages/Precautions/Adverse Effects

One drop 2-3 times daily in the unaffected eye. Epinephrine may cause ocular discomfort upon instillation. When injected intracamerally, it may be injected as a 1:10,000 dilution or added to ophthalmic irrigating solutions at a 1:100,000,000 dilution. If used intracamerally, epinephrine solutions should be preservative-free and bisulfate-free to avoid endothelial toxicity.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Epinephrine (HCl) Solution: 0.25%, 0.5%, 1% & 2%: 10 or 15 mL btl; *Epifrin*® (Allergan), *Glaucon*® (Alcon); (Rx)

Epinephrine (Borate) Solution: 0.5%, 1% & 2%: 7.5 mL btl; *Eppy/N*® (Pilkington/Barnes-Hind), *Epinal*® (Alcon); (Rx)

Epinephrine Bitartrate 1% in combination with Pilocarpine HCl Solution: 1%, 2%, 3%, 4% or 6%; *E-Pilo-1*® -2, -3, -4, -6 (Iolab); *PI E1*® (Alcon); (Rx)

### Beta-Adrenergic Antagonists

This class of ocular hypotensive drugs currently consists of both non-selective and beta1-selective agents. At the time of writing, it is not known how blockade of the ciliary body epithelium beta-receptors reduces intraocular pressure. Several mechanisms have been postulated including: beta-blockade of norepinephrine-induced tonic sympathetic stimulation, decreased activation of cAMP in the ciliary body leading to decreased aqueous humor production, inhibition of Na+K+ATPase activity, or action through a vasoactive mechanism. Because beta-blockers significantly affect function of the cardiovascular and pulmonary systems, patients with heart block, bradycardia, heart failure, asthma, chronic bronchitis or other cardiopulmonary conditions are poor candidates for use of topical beta-blockers to reduce intraocular pressure. Topical use of beta-blockers also can affect membrane stabilizing ability and induce local anesthesia. While this property is of no clinical value, adverse effects such as punctate keratitis and epitheliopathies have been reported with chronic use in humans.

---

## BETAXOLOL

(be-tax-oh-lol)

---

### Indications/Pharmacology

Betaxolol HCl is a specific beta1-adrenergic blocking agent that theoretically reduces the potential for beta2-induced adverse pulmonary effects; however, its cardiac effects are the same as non-selective beta-antagonists. Either levobunolol HCl or betaxolol HCl would be the first choice beta-blocking agent in a feline patient with glaucoma and asthma, although a topical carbonic anhydrates inhibitor should be considered before a beta-blocking agent in this situation. Betaxolol and the other beta-blockers should be used with caution in patients with cardiac disease. Betaxolol also inhibits glutamine-induced increases in intracellular calcium thereby providing a potential protective effect against ischemic insult to the retina (Bartlett *et al.* 2008).

### Suggested Dosages/Precautions/Adverse Effects

Like timolol maleate, betaxolol HCl is supplied in a 0.5% and 0.25% solution. Because in animal patients, minimal pressure reduction is noted with concentrations below 0.5% with timolol maleate, many veterinary ophthalmologists only consider use of the 0.5% betaxolol HCl product. One drop of the 0.5% betaxolol HCl solution is instilled twice daily alone or in combination with other glaucoma medications. A study (Miller *et al.* 2000) utilizing 0.5% betaxolol as prophylaxis in the normal eye of dogs with unilateral glaucoma demonstrated a delay in onset of glaucoma in the normal eye relative to dogs who received no prophylaxis (31 months versus 8 months respectively). While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure, although the selective beta1-blocking properties of this particular drug would tend to minimize these risks for patients with pulmonary disease.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Betaxolol HCl 0.5% and 0.25% Solution: 2.5, 5, 10, & 15 mL bottles; *Betoptic*® & *Betoptic-S*® (Alcon); (Rx)

### References

Miler, P.E., G.M. Schmidt, et al. (2000). The efficacy of topical prophylactic antiglaucoma therapy in primary closed angle glaucoma in dogs: A multicenter clinical trial. *Journal of the American Animal Hospital Association* 36(5):431-438.

---

## CARTEOLOL

(kar-tee-oh-loll)

---

### Indications/Pharmacology

Carteolol HCl is a nonspecific beta-adrenergic blocking agent. In addition to the typical therapeutic profile for non-specific beta-blockers, carteolol also possesses intrinsic sympathomimetic activity. This partial agonism of beta-receptors may be advantageous in patients experiencing bradycardia from other non-selective beta-blockade. Carteolol is a suitable substitute for timolol maleate or any of the other beta-blocking agents although it is rarely used in veterinary medicine, and no studies evaluating veterinary use of carteolol have been published. In humans, similar IOP reducing effects have been shown for all members of this class. Substitutes are necessary when one particular product induces topical irritation upon application or when potential beta agonism may be desirable.

### Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 1% solution. While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Carteolol HCl 1% Solution: 5, 10 & 15 mL bottles; *Ocupress*® (Otsuka America); (Rx)

---

### LEVOBUNOLOL HCL

(lee-voe-byoo-noe-lole)

---

### Indications/Pharmacology

Levobunolol HCl is a non-selective beta-blocking agent but without the potential for myocardial depression or airway constriction noted rarely in veterinary medicine and occasionally in human patients. Levobunolol is used in humans with glaucoma responsive to beta adrenergic blocking agents but who suffer cardiac and respiratory side effects associated with timolol. A study (Pugliese *et al.* 2009) comparing 0.5% levobunolol with 0.5% timolol-2% dorzolamide in normal dogs found levobunolol to be less effective than the combination therapy when used twice daily. Levobunolol HCl and then carteolol HCl would be suitable beta-blocking agents for feline patients with glaucoma and asthma, although carbonic anhydrase inhibitors should be used in such cases prior to adding a beta-blocking agent.

### Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.5% concentration. Miosis may develop in veterinary patients after application of topical beta-blocking antiglaucoma medications.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Levobunolol HCl 0.25% or 0.5% solution: 5, 10, & 15 mL. *Betagan*® (Allergan); (Rx)

### References

Pugliese, M.A. ScardBb, et al. (2009). Comparison of effects of topical levobunolol vs combination of timolol-dorzolamide on intraocular pressure and pupal size of healthy dogs. *Veterinary Research Communications* 33: S205-S207.

---

### METIPRANOLOL

(meti-pran-oh-ol)

---

### Indications/Pharmacology

Metipranolol is a nonselective beta-blocking agent and can be used as a substitute for timolol maleate. Pilot studies have suggested that metipranolol is as effective as timolol maleate and is significantly less expensive than trade name timolol preparations, but not the generically labeled products. Metipranolol has been useful for the management of primary open angle glaucoma in cats, however, no studies evaluating veterinary use of metipranolol have been performed.

### Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.3% solution. While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Metipranolol Solution 0.3%: 2, 5, & 10 mL; *OptiPranolol*® (Bausch & Lomb); (Rx)

---

### TIMOLOL

(tye-moe-lole), (teh-moe-loll)

---

### Indications/Pharmacology

Timolol is a non-selective beta-blocker supplied as 0.25% or 0.5% maleate salts, 0.25% or 0.5% hemihydrates salts, 0.47% potassium sorbate, or 0.25% or 0.5% gel-forming solutions. The 0.25% and 0.5% solutions have comparable efficacy in humans, while the potassium sorbate formulation has increased lipophilicity, resulting in greater anterior chamber relative to plasma concentrations (and therefore potentially fewer systemic side effects). Evaluation of 0.25 and 0.5% timolol in normotensive and glaucomatous eyes of Beagles with open-angle glaucoma, caused a reduction of 4-5 mmHg in glaucomatous eyes only (Gum *et al.* 1991). The 0.5% gel-forming solution, applied once daily for seven days, reduced IOP in normotensive dogs by a mean of 5.3 mmHg (Takiyama *et al.* 2006). Timolol has been evaluated in normotensive cats. In a comparison utilizing q12h and q8h administration of 2% dorzolamide with dorzolamide q8h in combination with 0.5% timolol q12h, no greater decrease was found with the addition of timolol compared to the q8h dorzolamide alone (Dietrich *et al.* 2007). Timolol has also been evaluated in horses utilizing a 0.5% solution alone or in combination with 2% dorzolamide and both studies indicate that every 12 hour dosing is preferred utilizing either regimen to effectively reduce intraocular pressure (van der Woerd *et al.* 2000; Willis *et al.* 2001).

Timolol maleate is used primarily to prevent the development of primary glaucoma in the contralateral eye of a dog that has developed primary glaucoma in one eye. It only reduces intraocular pressure 3–10 mmHg and, therefore is of minimal usefulness in patients requiring treatment of primary acute congestive glaucoma. Timolol may cause slight miosis in dogs and cats. It is rarely used alone, but is combined with dorzolamide solution

(*Cosopt*®). Caution is advised with use of beta-blockers in cats with concurrent asthma. As timolol maleate is now available in generic form, it is the primary beta-blocker agent now used.

### Suggested Dosages/Precautions/Adverse Effects

One drop twice daily of the 0.5% solution. The 0.25% concentration has minimal efficacy in animals. While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Timolol Maleate 0.25% (see dosage above) or 0.5% Solution: 2.5, 5, 10, & 15 mL *Ocumeter*® bottles; *Timoptic*® (MSD); Istalol® (ISTA Pharmaceuticals); generic; (Rx)

Timolol Maleate 0.5% and Dorzolamide 2% Solution: 5 mL & 10 mL *Ocumeter*® bottles, *Cosopt*® (MSD); (Rx)

### Carbonic Anhydrase Inhibitors

Carbonic anhydrase is found within the cytosol, mitochondria and salivary glands and catalyzes the conversion of carbon dioxide and water to carbonic acid and free hydrogen molecules. In the eye, bicarbonate ions are then transported into the posterior chamber where water follows the concentration gradient. Inhibition of carbonic anhydrase leads to decreased production of aqueous humor. Carbonic anhydrase inhibitors are most useful in treating primary open-angle glaucoma and secondary glaucomas in humans. Systemic use of these agents has generally been replaced by use of topical carbonic anhydrase inhibitors. For information on systemic carbonic anhydrase inhibitors, see individual monographs for Acetazolamide, Dichlorphenamide, and Methazolamide in the systemic drug monograph section of this reference.

---

### BRINZOLAMIDE HCL

(brin-zoh-la-mide)

---

### Indications/Pharmacology

Brinzolamide is chemically similar to dorzolamide and reduces aqueous humor production by altering H<sup>+</sup>/Na<sup>+</sup> active transport mechanisms associated with aqueous humor production in the ciliary epithelial cells. It can be used as a substitute for dorzolamide and some patients that exhibit excessive topical irritation following application of dorzolamide drops, tolerate brinzolamide better or vice versa. Cats seem to be particularly sensitive to irritation from topical dorzolamide and often brinzolamide can be used in these patients. Comparative data is available suggesting that brinzolamide and dorzolamide are equally effective in animal patients, although brinzolamide has a higher affinity for the carbonic anhydrase enzyme allowing it to be dosed twice daily as compared to 3 times daily for dorzolamide in humans. While there have not been any compelling studies conducted with brinzolamide for dogs and cats, an evaluation of brinzolamide in horses indicated that once daily dosing was equally effective to twice daily dosing with no evidence of ocular or systemic effects (Germann *et al.* 2008).

### Suggested Dosages/Precautions/Adverse Effects

One drop three times daily is the standard treatment frequency, adjusted based on clinical response. Like dorzolamide, may also cause stinging upon application.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Brinzolamide HCl 1% solution: 2.5, 5, 10 & 15 mL containers; *Azopt*® (Alcon); (Rx)

### References

---

### DORZOLAMIDE HCL

(dor-zole-a-mide)

---

### Indications/Pharmacology

Dorzolamide was the first topical carbonic anhydrase inhibitor marketed. Its chemical structure allows it to be both lipophilic and hydrophilic, thereby enabling penetration of the cornea and sclera. It is often used in the contralateral eye of a dog with primary glaucoma to prevent development of bilateral disease. It is also an excellent agent to consider for most secondary glaucomas in dogs and cats because it has no effect on pupil size. Like the related oral carbonic anhydrase inhibitors (dichlorphenamide or *Daranide*®, methazolamide or *Neptazane*®), dorzolamide decreases aqueous humor production by the ciliary body epithelium by altering pH and affecting the H<sup>+</sup>/Na<sup>+</sup> active transport exchange mechanism. Oral carbonic anhydrase inhibitors cause numerous systemic side effects such as metabolic acidosis and panting, diarrhea, vomiting, anorexia and others, all of which can be avoided with topical carbonic anhydrase inhibitors. Investigations of dorzolamide have been conducted to establish efficacy in dogs and cats (McLean *et al.* 2008; Rainbow & Dziezyc 2003). Studies in horses indicate that dorzolamide is an effective monotherapy however, twice daily dosing is required (Willis *et al.* 2001).

### Suggested Dosages/Precautions/Adverse Effects

One drop two to three times daily is the standard treatment frequency, adjusted based on clinical response. Dorzolamide may cause stinging (related to the low pH of the solution) upon topical application, particularly in cats. Superficial punctate keratitis or local hypersensitivity may occur. Approximately 5–10% of humans will experience irritation with use of topical dorzolamide. Systemic effects are not usually associated with topical administration.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dorzolamide HCl 2% Solution: 5, 10 & 15 mL; *Trusopt*® (Merck); (Rx)

Timolol Maleate 0.5% and Dorzolamide 2% Solution: 5 & 10 mL *Ocumeter*® bottles, *Cosopt*® (Merck); (Rx)

### Prostaglandins

Ophthalmic prostaglandin analogues are chemically modified versions of PGE2-alpha, an endogenous inflammatory mediator, that have ocular hypotensive effects. Chemical modification of these agents improves lipi-

Ophthalmic prostaglandin analogues are chemically modified versions of PGF<sub>2</sub>-alpha, an endogenous inflammatory mediator, that have ocular hypotensive effects. Chemical modification of these agents improves lipid solubility and allows them to pass through the epithelium where corneal esterases activate them to the active metabolite, 17-phenyl-PGF<sub>2</sub>-alpha that acts on prostanoid receptors to lower intraocular pressure by effecting extensive uveoscleral matrix remodeling, reducing resistance to outflow. This remodeling is believed to be due to increased levels of metalloproteinases that degrade collagen within the extracellular matrix.

---

## LATANOPROST

(*la-ja-noe-prost*)

---

### Indications/Pharmacology

Latanoprost was the first drug marketed in this class; it is labeled for once daily use in humans. Clinical studies show reduced effectiveness when once daily treatment is exceeded in humans. Although latanoprost is initially dosed once daily in the evening for canine glaucoma, a study (Gelatt & MacKay 2001) was performed evaluating once versus twice daily administration of latanoprost in dogs that demonstrated that twice daily administration of latanoprost produced greater and more significant control of intraocular pressure. The canine uveal tract apparently metabolizes latanoprost at a rate higher than in humans as IOP reduction is profound, but it persists only for 12–15 hours in most dogs. Latanoprost will provide the greatest amount of pressure reduction in canine primary glaucoma cases compared with any other single oral or topical agent and efficacy is even greater when combined with carbonic anhydrase inhibitors. Latanoprost has not been found to be useful in the management of glaucoma in cats (Studer *et al.* 2000). Equine glaucoma is usually secondary to uveitis and latanoprost treatment for glaucoma in horses is not considered effective and is associated with a high incidence of side effects, including ocular discomfort. (Davidson *et al.* 2002; van der Woerd *et al.* 2000).

### Suggested Dosages/Precautions/Adverse Effects

One drop of latanoprost is applied in the PM initially, but with progression of the glaucoma, twice daily treatment schedules will provide additional reduction in intraocular pressure. Latanoprost may cause topical irritation. Conjunctival hyperemia is commonly noted in patients using this medication. A direct stimulation of iris melanocytes results in excess melanin production in the iris of people using this medication, causing an irreversible dark brown color change to the iris, and reversible hyperpigmentation of the eyelid. Hypertrichosis, conjunctival hyperemia, allergy, cystoid macular edema, anterior uveitis, and punctate corneal erosions have also been reported. Profound miosis is noted with the use of latanoprost in dogs. It is not recommended for use in cats and horses due to adverse effects.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Latanoprost 0.005% Solution: 2.5 mL; *Xalatan*® (Pharmacia & Upjohn); (Rx). Store under refrigeration until use; may be stored at room temperature for 6 weeks after opened.

---

## BIMATOPROST

(*bi-ma-toe-prost*)

---

### Indications/Pharmacology

While bimatoprost is grouped in the prostaglandin-analog class, it is considered a synthetic prostamide. It is derived from anandamide, a fatty acid precursor. Prostamides interact only weakly with prostaglandin receptors, and the mechanism of action in reducing intraocular pressure remains unknown. Bimatoprost is available in solutions containing minimal concentrations of benzalkonium chloride and causes less ocular discomfort than latanoprost or travoprost. Bimatoprost also is initially administered once daily in the evening, but an evaluation in dogs (Gelatt & MacKay 2002) demonstrated that twice daily dosing provided for less fluctuation in intraocular pressure. Since latanoprost does not seem to be effective for most forms of feline glaucoma, it is unlikely bimatoprost will prove effective in these cases either.

### Suggested Dosages/Precautions/Adverse Effects

Bimatoprost is dosed 1–2 drops once daily in the evening and increased to twice daily as glaucoma progresses. Bimatoprost shares the same adverse effects profile as latanoprost.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Bimatoprost 0.03% Solution 2.5 mL, 5 mL, 7.5 mL bottles; *Lumigan*® (Allergan); (Rx), *Latisse*® (Allergan); (Rx)

### References

---

## TRAVOPROST

(*tra-vo-prost*)

---

### Indications/Pharmacology

Travoprost is a PGF<sub>2</sub>-alpha analog that is available preserved with benzalkonium chloride as well as in a benzalkonium chloride-free product that avoids the toxic epithelial effects commonly noted with this preservative in humans. As with latanoprost, travoprost is dosed once daily in the evening and produces mean intraocular pressure reductions of 7-8 mmHg. It shares the same adverse effect profile as latanoprost. Since latanoprost does not seem to be effective for most forms of feline glaucoma, it is not likely travoprost will prove effective in these cases either.

### Suggested Dosages/Precautions/Adverse Effects

Travoprost is dosed 1-2 drops in the evening and increased to twice daily dosing with progression of glaucoma.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Travoprost 0.004% Solution; 2.5 mL, 5 mL bottles, *Travatan*® (Alcon); (Rx)

---

## UNOPROSTONE ISOPROPYL

(ooh-no-prah-stone i-so-proe-pel)

---

### Indications/Pharmacology

Unoprostone is a prostaglandin analog that is no longer commercially available in the United States. It is converted by ocular esterases to the active free acid form of isopropyl unoprostone instead of PGF<sub>2</sub>-alpha like other ocular prostaglandin prodrugs. Evaluations of unoprostone in dogs (Ofri *et al.* 2000) demonstrated that once daily evening dosing or twice daily dosing produced the best intraocular pressure control as well as the fewest adverse effects. Like latanoprost, unoprostone did not demonstrate any effects in lowering intraocular pressure in cats (Bartoe *et al.* 2005).

### Suggested Dosages/Precautions/Adverse Effects

Unoprostone is dosed 1–2 drops in the evening and increased to twice daily dosing with progression of glaucoma.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None currently available in the United States, but may be obtained through importation or through the services of appropriately qualified pharmacy.

### Osmotic Agents For Treatment of Glaucoma

Osmotic agents increase the osmotic pressure of plasma and create a concentration gradient that will draw fluid out of the intraocular environment. Effective osmotic agents should be non-toxic, small in molecular weight, and have poor intraocular penetration (else intraocular pressure may increase). These agents are systemically administered with concurrent water deprivation (4–6 hrs) and are indicated only for acute episodes of glaucoma, not maintenance. For further information, see systemic monographs for Mannitol, Glycerin, and Isosorbide.

### Mydriatic-Cycloplegic-Vasoconstrictors

---

## CYCLOPENTOLATE

(sye-kloe-pen-toe-late)

---

### Indications/Pharmacology

Cyclopentolate is an anticholinergic agent that induces relaxation of the sphincter of the iris and the ciliary muscles. When applied topically to the eyes, it causes a rapid, intense cycloplegic and mydriatic effect that is maximal in 15–60 minutes; recovery usually occurs within 24 hours. The cycloplegic and mydriatic effects are slower in onset and longer in duration in animal patients who have darkly pigmented irises. Cyclopentolate is used mainly to produce mydriasis and cycloplegia for diagnostic purposes.

### Suggested Dosages/Precautions/Adverse Effects

1 drop instilled in the eye(s), followed by a second drop 5 minutes later, if necessary. Drops should be administered 40–50 minutes prior to diagnostic procedure. Cyclopentolate increases intraocular pressure and should not be used in animals with glaucoma. Slight stinging is noted with the higher (1%) concentration of the drug.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Cyclopentolate Solution 0.5%, 1%, & 2%: in 2, 5 & 15 mL bottles: *AK-Pentolate*® (Akorn); *Cyclogyl*® (Alcon); generic; (Rx)

---

## PHENYLEPHRINE HCL

(fen-il-ef-rin)

---

### Indications/Pharmacology

Phenylephrine is a direct-acting alpha agonist vasoconstrictor that is most commonly used in veterinary medicine as an adjunct preoperative medication to induce mydriasis prior to phacoemulsification for cataract removal. Phenylephrine is also used prior to minor surface (*e.g.*, conjunctival) procedures to limit bleeding. Phenylephrine can be used to confirm the diagnosis of Horner's syndrome. Dilution of 2.5% phenylephrine solution with saline (1:10) produces a 0.25% solution. Normal eyes will not demonstrate mydriasis in response to this low concentration of phenylephrine. Third order Horner's syndrome of greater than two weeks duration is associated with receptor up regulation and therefore a response to 0.25% phenylephrine is noted. In this way, the diagnosis of Horner's is confirmed and a suggestion as to whether or not the condition is 2nd or 3rd order in nature.

In dogs, maximum mydriasis persists for about 2 hours and effects may last for up to 18 hours. Phenylephrine has significant alpha-adrenergic effects (vasoconstriction and pupillary dilation) and minimal effects on beta-receptors. When used alone, phenylephrine is reportedly not efficacious in the cat unless used with other mydriatics.

### Suggested Dosages/Precautions/Adverse Effects

For diagnosis and characterization of Horner's syndrome: Apply 0.25% solution (see above) in both eyes. If there is a response in the miotic eye, it is 3rd order. If no response in 20–30 minutes, apply 2.5% solution; if there is a response in both eyes it confirms Horner's and probably is 2nd order.

For treatment of Horner's syndrome: Treatment is indicated only if patient experiences visual difficulty because third eyelid is elevated over pupil; then given on an as needed basis with an average duration of effect of 3–6 hours.

Prior to cataract or intraocular surgery: 2.5% or 10% given every 15 minutes for two hours. Smaller animals (*e.g.*, cats and dogs weighing <5kg) are more susceptible to life-threatening systemic effects on blood pressure and cardiac rhythm and preoperative use of phenylephrine in these animals is generally not recommended. In larger animals, repeated dosing is also associated with cardiovascular adverse effects. Phenylephrine is ineffective as a sole mydriatic in cats or horses and it should be combined with atropine to achieve adequate mydriasis.

Local discomfort may occur after instillation and chronic use may lead to inflammation. In some species (cats, rabbits, humans), transient stromal clouding may occur if used when corneal epithelium is damaged.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Phenylephrine HCl 0.12% Solution: 15 mL or 20 mL bottles; generic; (OTC)

Phenylephrine HCl 2.5% Solution: 2, 5 or 15 mL bottles; generic; (Rx)

Phenylephrine HCl 10% Solution: 1, 2, 5 or 15 mL bottles; *Neo-Synephrine*® (Sanofi Winthrop), generic; (Rx)

---

## ATROPINE SULFATE

(a-troe-peen)

---

### Indications/Pharmacology

Atropine is a parasympathetic-antagonist used for therapeutic (not diagnostic) purposes. When used topically on the eye, atropine acts by blocking the cholinergic receptors of the sphincter muscle of the iris and the ciliary body to cause mydriatic-cycloplegic and accommodation paralysis (cycloplegia). Atropine is significantly ionized at physiological pH and it has limited corneal penetration. Atropine controls pain secondary to corneal and uveal disease; to maximally dilate the pupil prior to intraocular surgery; to dilate the pupil and prevent pupillary block in glaucoma and uveitis. In the dog, atropine causes maximal mydriasis in about 1 hour and it may persist for up to 120 hours. Cats also show a delayed onset of action and mydriasis may persist for up to 144 hours (dose dependent). Atropine is particularly long acting in horses and may last days to weeks.

Atropine may be used in combination with 10% phenylephrine to achieve mydriasis and cycloplegia in cases of anterior uveitis. Atropine may also be used in uveitis to break up synechiae.

### Suggested Dosages/Precautions/Adverse Effects

Ointments or drops are routinely used in dogs. One percent is commonly used, but 2% solutions may be required in severe cases of uveitis. Ointments are generally used in cats to prevent hypersalivation associated with the bitter taste of this medication. Dosage frequencies are variable depending on the condition and its severity. Commonly, atropine is given as one drop 2–3 times a day or every other day until pupillary dilation is achieved and once daily thereafter to maintain this response.

Atropine may precipitate acute, congestive primary glaucoma in dogs predisposed to primary glaucoma; do not use in primary glaucoma. Repeated topical application prior to surgery can result in systemic atropine toxicosis (mania, hyperthermia, etc.). Salivation may result in dogs as well as cats (see above) secondary to the bitter taste. Atropine may also decrease tear production in small animals.

Reportedly, very frequent treatment with atropine may induce colic in horses secondary to systemic absorption and atropine's vagal parasympathetic effects. However, clinically this effect is only rarely noted.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Atropine Sulfate Ophthalmic Ointment: 10 mg/gm (1%) in 3.5 gm tubes; *Atrophate*® (Schering-Plough); (Rx)

#### HUMAN-LABELED PRODUCTS:

Atropine Sulfate Ophthalmic Ointment: 5 mg/gm (0.5%), & 10 mg/gm (1%) in 3.5 gm tubes; various trade names & generic; (Rx)

Atropine Sulfate Ophthalmic Solution: 0.5%, 1%, and 2% in unit dose droppers, 2, 5, & 15 mL bottles; various trade names & generic; (Rx)

---

## TROPICAMIDE

(troe-pik-a-mide)

---

### Indications/Pharmacology

Tropicamide, like atropine, causes mydriasis and cycloplegia, but has mydriatic and cycloplegic activity. It has excellent corneal penetration because it is minimally ionized at physiological pH. The action of tropicamide is also less affected by intraocular pigment than are other mydriatics. Tropicamide has a more rapid onset (maximum mydriasis in 15–30 minutes) of action and a shorter duration of action (pupil returns to normal in 6–12 hours in most animals) than does atropine, thereby making it more useful for fundoscopic examinations. In dogs, intraocular pressure is apparently not affected by tropicamide. Tropicamide is also indicated following cataract removal to prevent synechiae formation that is associated with post-cataract atropine administration. As the half-life of tropicamide is shorter than that of atropine, this allows iris contraction preventing synechial adhesions.

### Suggested Dosages/Precautions/Adverse Effects

Once or twice application to eye, prior to exam. Following cataract surgery: apply 2–3 times daily to keep pupil constantly changing in size and reduce formation of synechiae associated with prolonged pupillary dilation (atropine).

Tropicamide is less effective in pain control (cycloplegia) than atropine.

Tropicamide may cause salivation, particularly in cats. It may also sting when applied. Tropicamide may precipitate acute congestive glaucoma in predisposed patients. Tropicamide has been reported to decrease Schirmer Tear Test values for several hours following application in cats and horses.

### Dosage Forms/Regulatory Status

**Veterinary-LaBELED Products:** None

#### HUMAN-LABELED PRODUCTS:

Tropicamide Solution 0.5% and 1%: 2 mL & 15 mL bottles; *Mydrilacyl*® (Alcon), *Opticyl*® (Optopics), *Tropicacyl*® (Akorn), generic; (Rx)

### Anti-inflammatory/Analgesic Ophthalmic Agents

#### Mast Cell Stabilizers, Antihistamines, Decongestants

---

## CROMOLYN SODIUM

(kroe-moe-lin)

---

### Indications/Pharmacology

Cromolyn sodium is a mast cell stabilizing agent that blocks release of histamine and slow-reacting substance of anaphylaxis from mast cells following antigen recognition. Similar to lodoxamine tromethamine, cromolyn sodium has no intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition or other anti-inflammatory properties. Mast cell stabilizing agents are most useful in animal patients suffering from allergic conjunctivitis.

### Suggested Dosages/Precautions/Adverse Effects

For relief of seasonal allergy, one drop 2–6 times daily. A stinging sensation is noted in a low percentage of people using this medication.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Cromolyn Sodium 4% Solution: 2.5, & 10 mL; *Crolom*® (Bausch & Lomb); (Rx)

---

## LODOXAMINE TROMETHAMINE

(loe-dox-a-mide)

---

### Indications/Pharmacology

Lodoxamine tromethamine is a mast cell stabilizer that inhibits Type-I hypersensitivity responses by preventing antigen mediated histamine release. Lodoxamine stabilizes mast cells by blocking calcium influx into the cell upon antigen recognition, thereby blocking histamine release. Lodoxamine has no intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition or other anti-inflammatory properties. Lodoxamine is used in people for management of conjunctivitis associated with seasonal allergy and other histamine mediated disorders. In veterinary medicine, lodoxamine tromethamine has been used in horses and small animal patients with presumed allergic conjunctivitis.

### Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 2–4 times daily. A stinging sensation is noted in a low percentage of people using this medication.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lodoxamine Tromethamine 0.1%: 10 mL; *Alomide*® (Alcon); (Rx)

---

## OLOPATADINE HCL

(oh-loe-pa-ta-deen)

---

### Indications/Pharmacology

Olopatadine HCl is a selective H1 receptor antagonist and inhibitor of histamine release from mast cells. It is marketed for topical use to alleviate symptoms of allergic conjunctivitis in humans and is thought to be safe for use in children three years of age and older. Olopatadine, upon topical application in humans, was shown to have very limited systemic absorption. It was detectable in the milk of nursing rats, after topical application, and like most medications should be avoided in pregnant or nursing animals.

### Suggested Doses/Precautions/Adverse Effects

Olopatadine eye drops are applied as needed in people for temporary relief of itchiness associated with seasonal allergy. They can be used in dogs two to three times daily for allergic conjunctivitis.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Olopatadine HCl ophthalmic solution 0.1%; *Patanol*® (Alcon); (Rx)

---

### Non-Steroidal Antiinflammatory Agents

Non-steroidal anti-inflammatory drugs (NSAIDs), administered topically or systemically, are used in ophthalmology to control inflammation and provide analgesia. However, corticosteroids remain the standard for topical anti-inflammatory effect. NSAIDs are administered perioperatively to induce mydriasis and reduce inflammatory-mediated breakdown of the blood-aqueous barrier during cataract extraction, and postoperatively to reduce inflammation and facilitate corneal healing. NSAIDs are also used in allergic conjunctivitis.

NSAIDs safe for topical ophthalmic use include indole acetic acid, aryl acetic acid, and aryl propionic acid derivatives that are readily formulated as solutions due to their water-soluble nature. Salicylates, fenamates, and pyrazolones are too toxic for topical ocular use. As most NSAIDs are weakly acidic, they exist in their ionized form in the tear film pH and thus only weakly penetrate the cornea. Reducing the pH of topical formulations increases the unionized fractions and intraocular penetration, however it also increases the local irritant effects following administration. Additionally, the anionic nature of NSAIDs favors formation of insoluble complexes with cationic quaternary ammonium preservatives such as benzalkonium chloride.

Adverse effects from topical NSAIDs include local reactions such as hyperemia and contact dermatitis, punctate keratitis (chronic use, especially diclofenac), keratomalacia, corneal toxicity (through disruption of corneal epithelial arachadonic acid metabolism and through disruption of matrix metalloproteinase), and impaired wound healing (particularly products containing thimerosal). Systemic adverse effects may also occur and are associated with an increased risk for gastrointestinal ulceration, altered platelet function, renal damage, bronchospasm, and bone marrow suppression in cats (Giuliano 2004).

---

## BROMFENAC

(brome-fen-ak)

---

### Indications/Pharmacology

Bromfenac is a nonsteroidal anti-inflammatory drug (NSAID) by virtue of its ability to block prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Bromfenac is indicated for treatment of postoperative inflammation in patients who have undergone cataract extraction.

### Suggested Doses/Precautions/Adverse Effects

One drop twice daily.

Bromfenac is contraindicated in patients with known hypersensitivity to any ingredient in the formulation. Bromfenac ophthalmic solution contains sodium sulfite, a sulfite known to cause allergic reactions especially in asthmatic patients. Caution should be exercised when utilizing bromfenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity. There have been reports that ocularly applied NSAIDs may cause increased belled of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or corneal perforation. Use of bromfenac should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown. Post marketing experience with topical NSAIDs suggests that use more than 24 hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Bromfenac should be used with caution in patients with known bleeding tendencies or who

hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Bromfenac should be used with caution in patients with known bleeding tendencies or who are receiving other medications, which may prolong bleeding time. The most commonly reported adverse experiences reported following use of bromfenac include: abnormal sensations in the eye, conjunctival hyperemia, eye irritation (including burning/stinging), eye pain, eye pruritus, eye redness, headache, and iritis. These events were reported in 2–7% of human patients.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Bromfenac 0.09% solution: 7.5 mL & 10 mL; *Xibrom*<sup>®</sup> (ISTA) (Rx). Store at room temperature.

---

#### DICLOFENAC SODIUM

(dye-kloe-fen-ak)

#### Indications/Pharmacology

Diclofenac sodium is a phenylacetic acid that inhibits cyclooxygenase, inhibiting prostaglandin synthesis. Diclofenac sodium topical solution reduces inflammation following cataract extraction in people and counteracts photophobia in humans having refractive corneal surgery. In veterinary medicine, diclofenac sodium is used for treatment of uveitis following surgery on the eye or other causes of uveitis especially when corneal infection is suspected or in diabetic patients whose insulin regulation could be altered by the systemic uptake of topical corticosteroids. Diclofenac can be combined with topical corticosteroids for better control of uveitis in animals when the condition is severe.

#### Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20-minute intervals. One drop four times daily following cataract surgery or for the treatment of uveitis. Caution should be used when applying any anti-inflammatory agent on the cornea in the face of corneal stromal infection because of the positive role inflammation plays in the immune response to microbial invasion of tissue. A stinging sensation is noted in 15% of people using this medication.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Diclofenac Sodium 0.1% Solution: 2.5 & 5 mL; *Voltaren*<sup>®</sup> (Novartis); (Rx)

---

#### FLURBIPROFEN SODIUM

(flure-bi-proe-fen)

#### Indications/Pharmacology

Flurbiprofen is a non-steroidal anti-inflammatory agent that probably acts by inhibiting the cyclo-oxygenase enzyme system, thereby reducing the biosynthesis of prostaglandins. Prostaglandins may mediate certain kinds of ocular inflammation. They may disrupt the blood-aqueous humor barrier, cause vasodilation, increase intraocular pressure and leukocytosis, and increase vascular permeability. Prostaglandins may also cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Flurbiprofen can inhibit this intraocular miosis and it may be useful in the management of uveal inflammation (usually in addition to topical steroids).

#### Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20-minute intervals.

Because flurbiprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with infected corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shunted into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of flurbiprofen prior to cataract surgery has resulted from these studies.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Flurbiprofen Sodium 0.03% Solution: 2.5 mL, 5 mL & 10 mL btl; *Ocuifen*<sup>®</sup> (Allergan); generic; (Rx)

---

#### KETOROLAC TROMETHAMINE

(kee-toe-rol-ak)

#### Indications/Pharmacology

Ketorolac tromethamine is a pyrrolol-pyrrole nonsteroidal anti-inflammatory agent that inhibits prostaglandin formation. Ketorolac tromethamine is marketed for use before cataract extraction in human patients (to prevent miosis during surgery) and for control of post surgical inflammation, especially following cataract surgery. Ketorolac is also effective in treating postoperative cystoid macular edema and ocular surface inflammation. It is also approved for management of conjunctivitis associated with seasonal allergy in people. In veterinary medicine, ketorolac tromethamine is primarily used to control surgical or nonsurgical uveitis particularly in cases with concurrent corneal bacterial infection or ulceration when topical corticosteroids are contraindicated. It is also used in diabetic patients, especially smaller patients, adversely affected by systemic uptake of topically applied corticosteroids. Nonsteroidal agents like ketorolac tromethamine can be combined with topical steroids in patients with severe uveal inflammation.

#### Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20-minute intervals. One drop four times daily; following cataract surgery, treatment of uveitis, or management of allergic conjunctivitis.

The manufacturer indicates that ketorolac tromethamine does not enhance the spread of preexisting corneal fungal, viral or bacterial infections in animal models. Ketorolac tromethamine does not induce postoperative pressure elevation beyond which that frequently follows cataract extraction in people and animals.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ketorolac Tromethamine Solution 0.5%: 3, 5, & 10 mL; *Acular*<sup>®</sup> (Allergan); (Rx)

---

## NEPAFENAC

(ne-pa-fen-ak)

---

### Indications/Pharmacology

Nepafenac is a nonsteroidal anti-inflammatory and analgesic prodrug. After topical ocular dosing, nepafenac penetrates the cornea where it is converted by ocular tissue hydrolases to amfenac, a nonsteroidal anti-inflammatory drug. Amfenac is thought to inhibit the action of prostaglandin H synthase (cyclooxygenase), an enzyme required for prostaglandin production. Nepafenac is indicated for the treatment of pain and inflammation associated with cataract surgery.

### Suggested Dosages/Precautions/Adverse Effects

One drop three times daily. Shake well before use.

Nepafenac is contraindicated in patients who have demonstrated hypersensitivity to any of the ingredients in the formulation or to other NSAIDs. Caution should be exercised when utilizing nepafenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity.

There have been reports that ocularly applied NSAIDs may cause increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or corneal perforation. Use of nepafenac should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown. Post marketing experience with topical NSAIDs suggests that use more than 24 hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Nepafenac should be used with caution in patients with known bleeding tendencies or who are receiving other medications, which may prolong bleeding time. In controlled clinical studies, the most frequently reported ocular adverse events following cataract surgery were capsular opacity, decreased visual acuity, foreign body sensation, increased intraocular pressure, and sticky sensation. These events occurred in approximately 5–10% of patients. Other ocular adverse events occurring at an incidence of approximately 1–5% included conjunctival edema, corneal edema, dry eye, lid margin crusting, ocular discomfort, ocular hyperemia, ocular pain, ocular pruritus, photophobia, tearing and vitreous detachment. Some of these events may be the consequence of the cataract surgical procedure. Non-ocular adverse events reported at an incidence of 1–4% included headache, hypertension, nausea/vomiting, and sinusitis. Nepafenac ophthalmic suspension may be administered in conjunction with other topical ophthalmic medications such as beta-blockers, carbonic anhydrase inhibitors, alpha-agonists, cycloplegics, and mydriatics.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Nepafenac Ophthalmic Suspension: 0.1% in 3 mL; *Nevanac*<sup>®</sup> (Alcon); (Rx). Shake well and store at room temperature.

---

## SUPROFEN

(su-pro-phen)

---

### Indications/Pharmacology

Suprofen is a non-steroidal anti-inflammatory agent similar to flurbiprofen. Suprofen and flurbiprofen are phenylalkanoic acids that inhibit the cyclo-oxygenase enzymes responsible for conversion of arachidonic acid from cell membranes into various prostaglandins. These prostaglandins mediate certain aspects of ocular inflammation including disruption of the blood-aqueous barrier, uveal vasodilation, increases in intraocular pressure, and leakage of white blood cells and protein from uveal vessels into the aqueous humor. Prostaglandins cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Suprofen can inhibit this intraocular miosis and may be useful in the management of uveal inflammation (usually in addition to topical steroids).

### Suggested Dosages/Precautions/Adverse Effects

Prior to surgery: One drop 4 times at 20-minute intervals.

Because suprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with bacterial corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shunted into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of suprofen or flurbiprofen prior to cataract surgery has resulted from these studies.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Suprofen Sodium 1% Solution in 2.5 mL btl; *Profenal*<sup>®</sup> (Alcon); (Rx)

### Steroidal Anti-inflammatory Agents

Topical corticosteroids are used to treat diseases of the eye involving the conjunctiva, sclera, cornea, and anterior chamber. Efficacy of corticosteroids applied topically to the eye is dependent on many patient-related and drug-related factors. Patient factors include frequency and route of administration as well as conditions influencing penetration such as corneal ulceration or ocular inflammation. Topically delivered corticosteroids are best able to penetrate the cornea if they are both hydrophilic and lipophilic. The solubility can be improved by utilizing salts that are more lipophilic in nature (*e.g.* acetates), hydrophilic in nature (*e.g.* sodium phosphate or hydrochloride) or biphasic (*e.g.* alcohol derivatives). Hydrophilic ocular preparations are usually supplied as solutions while lipophilic agents are usually supplied as ointments or suspensions. In order to increase efficacy of topically administered corticosteroids, frequency of administration is increased instead of drug concentration (*e.g.*, prednisolone acetate 1% suspension is equally efficacious as 1.5% and 3% suspensions when used at the same frequency.) Penetration of topically applied corticosteroids into the eyelids is poor as is penetration to the posterior segment of the eye. Corticosteroid-responsive conditions affecting these areas are usually managed with systemically administered agents (with or without adjunctive topically applied medications).

Ocular side effects of ophthalmic corticosteroids can be numerous, including the development of cataracts, increased IOP, infection, decreased wound healing, mydriasis, and calcific keratopathy. While these side effects may be frequent in humans, some are less common in animals. With the exceptions of mydriasis and calcific keratopathy, these side effects may occur in association with systemically administered corticosteroids as well. Systemic side effects of topical ophthalmic corticosteroids include glucocorticoid-induced hepatopathy, suppression of endogenous glucocorticoid production, or local alopecia. It is important to note that such side effects occur more readily with systemic administration of corticosteroids, but occur in a dose and duration-dependent manner following topical ophthalmic administration.

Conjunctivitis in animals is often treated symptomatically, particularly during the first occurrence of the condition for any particular patient. Antibiotic agents with hydrocortisone or dexamethasone, or antibiotic agents alone initially, are used for conjunctivitis in the dog and the horse. Allergic and eosinophilic conjunctivitis are rare diagnoses in the cat. Topically applied corticosteroids should not be used to treat conjunctivitis in cats. Herpes virus is the most common feline conjunctival pathogen and topically applied steroids can induce prolonged disease, steroid dependency and corneal complications including ulcerative keratitis and/or corneal sequestrum formation.

Inflammatory conditions of the canine sclera and episclera include episcleritis, scleritis, nodular granulomatous episclerokeratitis, Collie granuloma and others. Potency and penetration of corticosteroid agents is important in the management of these conditions. Dexamethasone sodium phosphate ointment is often employed and the relatively reduced penetration of the fibrous ocular tunics of this medication compared with that of 1% prednisolone acetate ophthalmic suspension is made up for by increased contact time of the ointment form of this drug and by the increased potency of dexamethasone (30X cortisone) relative to prednisolone (4–5X cortisone). Dexamethasone products alone (without antibiotics) are becoming increasingly scarce in the marketplace and because of this, dexamethasone is often used in combination with an antibiotic for availability reasons only. Four times daily treatment is often the initial frequency with tapering paralleled to clinical response. Topical treatment is often used following subconjunctival injection of corticosteroid agents into or adjacent to the lesion (if focal). Systemic steroid treatment is usually not necessary.

Non-ulcerative inflammatory conditions of the cornea of animals include chronic superficial keratitis (pannus) of the German Shepherd and other breeds, eosinophilic keratitis of the cat and certain, often poorly understood, keratopathies of the equine, including Onchocerca related keratitis. German Shepherd pannus may be better managed using cyclosporine ophthalmic solution or ointment with or without concurrent topical corticosteroids. Eosinophilic keratitis of the cat is best managed with cyclosporine ophthalmic solution or ointment with or without concurrent topical corticosteroids. Eosinophilic keratitis of the horse is best managed with cyclosporine ophthalmic solution or ointment with or without concurrent topical corticosteroids.

steroids initially followed by long term management with cyclosporine ophthalmic alone (see cyclosporine ophthalmic). Eosinophilic keratitis is often treated with subconjunctival corticosteroids in addition to topical 0.1% dexamethasone ophthalmic ointment or solution or 1% prednisolone acetate ophthalmic suspension 4 times daily, tapering the dosage frequency based on clinical response. Recent research reveals that eosinophilic keratitis may be an unusual immune response to latent feline herpes virus in the corneal stroma, calling into question the value of topical steroids in the management of a disease with an infectious etiology. Despite new information pertaining to possible causes of eosinophilic keratitis in the cat, the condition continues to be well managed in most cases with infrequent topical corticosteroid treatment. Non-ulcerative, immune mediated and/or parasitic equine keratopathies are treated with 0.1% dexamethasone ointment 4 times daily with tapering of the treatment frequency based on the clinical response.

Corticosteroids are also used to manage anterior uveal inflammatory disease of companion animals. In small animals, 1% prednisolone acetate ophthalmic suspension is generally used for this purpose because of superior penetration into the anterior segment of the eye in comparison with dexamethasone products. The frequency of treatment depends on the severity of the condition. Severe anterior uveitis can be treated with subconjunctival corticosteroids given in combination with hourly topical corticosteroids with reevaluation performed again 24 hours after beginning treatment. Moderate to mild uveitis and that found following surgery of the anterior segment is often treated initially at the QID level with tapering based on clinical response. Anterior uveitis in animals can often be associated with an underlying systemic infectious or neoplastic condition in animals. Clinicians are advised to evaluate the patient for generalized infectious or neoplastic conditions prior to or concurrent with a course of corticosteroid antiinflammatory therapy, particularly if the condition dictates systemic treatment with these agents in combination with subconjunctival and topical treatment. Uveitis has also been successfully treated utilizing subconjunctival injections of triamcinolone acetate. As commercially available triamcinolone injections are preserved with benzyl alcohol, veterinary ophthalmologists centrifuge triamcinolone injections and remove the alcohol-containing supernatant vehicle. An equal volume of non-preserved sodium chloride injection is then utilized to reconstitute the remaining triamcinolone to provide for an acceptable subconjunctival injection. Uveitis in the equine species is often treated with either 1% prednisolone acetate ophthalmic suspension or with 0.1% dexamethasone ointment. Many clinicians prefer to use the ointment because of increased contact time and potency and the logistics of frequent treatment of this species. 1% prednisolone acetate can be passed through a subpalpebral lavage catheter very frequently to treat equine patients with anterior uveitis when necessary.

Inflammatory conditions of the posterior segment require systemic treatment because of poor penetration of topically applied agents.

---

## PREDNISOLONE

(pred-nis-oh-lone)

---

### Indications/Pharmacology

Prednisolone is an intermediate-acting synthetic corticosteroid available as acetate or phosphate salts. The acetate derivative has superior anti-inflammatory activity in comparison to the phosphate derivative, and it is considered the most effective drug for anterior uveitis. Prednisolone acetate ophthalmic suspension is generally used for anterior uveitis because of superior penetration into the anterior segment of the eye in comparison with dexamethasone products. The frequency of treatment depends on the severity of the condition. Severe anterior uveitis can be treated with subconjunctival corticosteroids given in combination with hourly topical corticosteroids with reevaluation performed again 24 hours after beginning treatment. Moderate to mild uveitis and that found following surgery of the anterior segment is often treated initially at four times daily with tapering based on clinical response.

Other routes of administration: Systemically administered corticosteroids (usually orally) may be indicated for non-infectious inflammatory ocular conditions and following intraocular surgery. Subconjunctival steroids are useful in anterior segment inflammatory disease and following cataract surgery and intraocular glaucoma surgery. Subconjunctival steroids may be absorbed systemically and should be used with caution in patients with endocrinopathies (e.g., diabetes mellitus) or infectious diseases. Even frequent topical steroid application in small animal patients under 20 kg can cause difficulties with diabetes mellitus regulation and after the peak inflammatory response has been suppressed, nonsteroidal antiinflammatory drugs should be considered for ongoing maintenance treatment.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Prednisolone Acetate Drops: 0.12% Suspension: *Pred Mild*® (Allergan); 0.125% Suspension: *Econopred*® (Alcon); 1% Suspension: *Econopred Plus*® (Alcon); *Pred Forte*® (Allergan), generic; (Rx)

Prednisolone Sodium Phosphate Drops: 0.125 & 1% Solution; (various); (Rx)

Prednisolone (0.25%) and Atropine (1%) Drops in 5 mL btl; *Mydrapred*® (Alcon); (Rx)

---

## DEXAMETHASONE

(dex-a-meth-a-sonne)

---

### Indications/Pharmacology

Dexamethasone is a long-acting synthetic corticosteroid, available as alcohol or phosphate derivative suspensions or solutions, or as a phosphate derivative ointment. The anti-inflammatory efficacy of the alcohol is superior to that of the phosphate derivative.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Dexamethasone Sodium Phosphate 0.1% Solution, 5 mL bottles, generic; (Rx)

Dexamethasone Phosphate 0.05% Ointment, 3.5 gram tubes, generic; (Rx)

---

## BETAMETHASONE

(hay-ta-meth-a-sonne)

---

### Indications/Pharmacology

Betamethasone is a long-acting corticosteroid was formerly available as a veterinary-approved antimicrobial-steroid combination (*Gentocin Durafilm*®—Schering).

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Note: Compounding pharmacists can still provide the combination of gentamicin and betamethasone, but this preparation should never be utilized if corneal abrasion or ulceration are suspected, and should not be used to treat herpes keratitis in cats.

---

## FLUOROMETHOLONE

(flor-o-meth-a-lone)

---

### Indications/Pharmacology

Fluorometholone is actually an analog of progesterone instead of cortisol, available in alcohol or acetate salt formulations. Fluorometholone alcohol formulations have less anti-inflammatory effect than prednisolone acetate, but acetate salts have activity comparable to prednisolone acetate suspensions. Higher concentrations of fluorometholone (0.25%) have been noted to raise intraocular pressure (Sendrowski *et al.* 2008).

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fluorometholone 0.1% ointment, 3.5 gram tube: *FML S.O.P.*® (Allergan); (Rx)

Fluorometholone 0.25% alcohol suspension, 5 mL, 10 mL bottles, *FML Forte*® (Allergan); (Rx)

Fluorometholone acetate 0.1% suspension, 5 mL, 10 mL, 15 mL bottles, *FML*® (Allergan); *Flarex*® (Alcon), generic; (Rx)

---

## LOTEPREDNOL

(lo-teh-pred-nal)

---

### Indications/Pharmacology

Loteprednol etabonate is synthesized from an inactive metabolite of the parent drug (*i.e.* a “soft drug”) that is briefly activated to the active metabolite *in vivo*, exerts its pharmacological effects, and then is transformed back to the inactive metabolite. Loteprednol antiinflammatory effect is comparable to other topical corticosteroids and it has a lower risk of raising intraocular pressure.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Loteprednol 0.5% suspension: 2.5 mL, 5 mL, 10 mL, 15 mL bottles; *Lotemax*® (Bausch & Lomb); (Rx)

Loteprednol 0.2% suspension: 5 mL, 10 mL; *Alrex*® (Bausch & Lomb); (Rx)

---

## RIMELOXOLONE

(rem-eh-lox-a-lone)

---

### Indications/Pharmacology

Rimexolone is a topical corticosteroid agent that has comparable anti-inflammatory activity to prednisolone acetate. It is used for treatment of uveitis and is administered in aggressive pulse doses to patients with mild to moderate inflammation.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Rimexolone 1% suspension, 5 mL and 10 mL bottles; *Vexol*® (Alcon); (Rx)

---

### Ophthalmic Analgesics

---

## MORPHINE SULFATE

(mor-feen)

---

### Indications/Pharmacology

A recent study showed that topical use of 1% morphine sulfate solution in dogs with corneal ulcers provided analgesia and did not interfere with normal wound healing. Both *mu* and *delta* opioid receptors were identified in normal corneas of dogs, although the *mu* receptors were present only in small numbers. Dogs treated with morphine sulfate 1% topical solution had significantly less blepharospasm and lower esthesiometer readings than did control dogs. Morphine sulfate is a Schedule II controlled substance.

### Suggested Dosages/Precautions/Adverse Effects

1 drop of 1% morphine sulfate solution in the affected eye(s) three times daily. Preserved solutions of morphine should not be used.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

A 1% morphine sulfate ophthalmic solution may be compounded by utilizing the preservative-free morphine 2.5% injectable solution diluted with sterile saline observing appropriate aseptic technique.

---

## NALBUPHINE

(*nal-byoo-feen*)

---

### Indications/Pharmacology

A review of the literature reveals that solutions of topical nalbuphine were used clinically to provide analgesia and reduce ophthalmic pain in humans as early as 1983. Nalbuphine hydrochloride is a potent analgesic. Its analgesic potency is essentially equivalent to that of morphine on a milligram basis. Receptor studies show that nalbuphine hydrochloride binds to *mu*, *kappa*, and *delta* receptors, but not to *sigma* receptors. Nalbuphine hydrochloride is primarily a *kappa* agonist/partial *mu* antagonist analgesic. Nalbuphine hydrochloride by itself has potent opioid antagonist activity at doses equal to or lower than its analgesic dose. When administered following or concurrent with *mu* agonist opioid analgesics (*e.g.*, morphine, oxymorphone, fentanyl), nalbuphine hydrochloride may partially reverse or block opioid-induced activity from the *mu* agonist analgesic. Nalbuphine hydrochloride may precipitate withdrawal in patients dependent on opioid drugs. Nalbuphine hydrochloride should be used with caution in patients who have been receiving *mu* opioid analgesics on a regular basis. Nalbuphine is not commercially available for ophthalmic use, but may be obtained through appropriately qualified compounding pharmacies.

### Suggested Dosages/Precautions/Adverse Effects

One drop two to six times daily as needed for corneal pain. Do not use in conjunction with topical morphine as nalbuphine will reverse the effects of morphine at the *mu* receptor.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

The 10 mg/mL (1%) nalbuphine injection may be applied as an ophthalmic solution. A 1% nalbuphine ophthalmic solution may also be compounded by utilizing nalbuphine 20 mg/mL injectable solution diluted with 1:1 with sterile saline observing appropriate aseptic technique.

### Antimicrobial Ophthalmic Therapy

#### Antibiotics, Single & Combination Products

Antimicrobials are critical to the management of ocular disease, however several considerations determine appropriate use. For prophylactic use, drugs effective against pathogens likely at the site should be selected as well as potential for microbial resistance or adverse reactions. For therapeutic use, the causative agent should be determined and an appropriate antimicrobial applied again monitoring for development of resistance or adverse effects.

#### Aminoglycosides, Ocular

Aminoglycosides inhibit bacterial protein synthesis via inhibition of the 30S bacterial ribosome and are therefore primarily effective against gram-negative organisms such as *Pseudomonas*, *Proteus*, and *Enterobacter* (with the exception of neomycin which is considered ineffective against *Pseudomonas aeruginosa*). Gram-positive activity is restricted to *Staphylococcus aureus*. Aminoglycosides are not effective against anaerobes. Aminoglycosides are poorly absorbed after oral administration, and use is limited to parenteral or topical administration.

Penicillins and cephalosporins can inactivate aminoglycosides and administration must be separated by a time lapse if concurrently administered.

Aminoglycosides induce ototoxicity (auditory and vestibular) and nephrotoxicity when administered systemically. Topical ophthalmic adverse effects include corneal epithelial damage, conjunctival damage, and hypersensitivity reactions. Intravitreal injection of gentamicin is toxic to the retina and the ciliary body and has been used therapeutically to treat end-stage glaucoma (chemical enucleation). Aminoglycosides should be used carefully and monitored in patients with renal disease.

#### AMIKACIN SULFATE

(*am-eh-kay-sin suhl-fate*)

### Indications/Pharmacology

Although amikacin is not commercially available as a topical preparation, it has been compounded for use in corneal infections caused by gram-negative bacilli that have become resistant to gentamicin or tobramycin. Subconjunctival injection does raise ocular concentrations of amikacin; however, parenteral administration does not demonstrate benefit in treating ocular infections. Of the aminoglycosides, amikacin demonstrates the least retinal toxicity, making it useful in treating endophthalmitis.

### Suggested Dosages/Precautions/Adverse Effects

Amikacin may be compounded to a concentration of 8mg/ml as a sterile, fortified ophthalmic antibiotic solution.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Fortified solutions of amikacin sulfate may be compounded in concentrations of 8 mg/mL.

#### NEOMYCIN SULFATE

(*nee-o-mye-sin suhl-fate*)

### Indications/Pharmacology

Neomycin is commonly included in triple antibiotic formulations. It has minimal corneal penetration in the presence of intact corneal epithelium, but is useful for treatment of superficial corneal ulceration or surface ocular infections.

### Suggested Dosages/Precautions/Adverse Effects

Neomycin may cause contact sensitivity and it is contraindicated in patients with a history of such.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; *Mycitracin*® (Upjohn) (**Note:** contains 500 mg bacitracin/gm); *Neobacimyx*® (Schering); *Trioptic-P*® (Pfizer); *Vetropolycin*® (Dechra); generic; (Rx). Approved for dogs and cats.

Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per mL Ophthalmic Solution: *Optiprime*® (Syntex); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (*e.g.*, gramicidin in place of bacitracin in topical solutions-*Neosporin*® *Ophthalmic Solution*). All of these products require a prescription.

#### GENTAMICIN SULFATE

(*jen-ta-mye-sin suhl-fate*)

### Indications/Pharmacology

Gentamicin may be administered topically or subconjunctivally and is primarily used for keratitis caused by *Pseudomonas aeruginosa*. The commercially available 0.3% solution is generally too dilute to achieve topical

efficacy, and solutions with concentrations greater than 13.6 mg/ml may be compounded for use in ocular infections. The primary antimicrobial spectrum for gentamicin is gram-negative organisms making it less useful for prophylaxis, as agents of concern on the ocular surface tend to be gram-positive organisms. Gentamicin has minimal penetration of intact corneal epithelium but does penetrate in the presence of infection. Subconjunctival injection may increase ocular drug levels, but systemic absorption is a possibility after this route of administration, particularly in smaller patients. Gentamicin is toxic to the intraocular structures (retina and ciliary body) and is used therapeutically for chemical enucleation in end-stage glaucoma.

#### Suggested Dosages/Precautions/Adverse Effects

Three to four times daily as an ointment or solution. For chemical enucleation in end-stage glaucoma: 0.25 mL of gentamicin 100 mg/ml injection.

#### Dosage Forms/Regulatory Status

##### VETERINARY-LABELED PRODUCTS:

Gentamicin Ophthalmic Ointment: 3 mg/gram in 3.5 gm tubes; *Gentocin*® (Schering); (Rx). FDA-approved for use in dogs and cats.

Gentamicin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Gentocin*® (Schering); (Rx). FDA-approved for use in dogs and cats.

##### HUMAN-LABELED PRODUCTS:

Gentamicin Ophthalmic Ointment: 3 mg/gram in 3.5 gm tubes; *Garamycin*® (Schering); *Genoptic*® (Allergan); generic; (Rx)

Gentamicin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Garamycin*® (Schering); *Genoptic*® (Allergan); generic; (Rx)

#### TOBRAMYCIN SULFATE

(*toe-bra-mye-sin suhl-fate*)

#### Indications/Pharmacology

Tobramycin possesses a similar spectrum of activity to that of gentamicin. The commercially available solutions and ointments are sometimes not concentrated enough to achieve therapeutic effect and fortified concentrations of greater than 14.5 mg/mL are compounded for use. Ocular drug levels of tobramycin can be increased with use of subconjunctival injections, however, systemic use of tobramycin does not demonstrate benefit in ocular infections.

#### Suggested Dosages/Precautions/Adverse Effects

Solution: One drop three to four times daily. Ointment: ½ inch strip three to four times daily.

#### Dosage Forms/Regulatory Status

##### VETERINARY-LABELED PRODUCTS: None

##### HUMAN-LABELED PRODUCTS:

Tobramycin Ophthalmic Ointment: 3 mg/gram in 3.5 gm tubes; *Tobrex*® (Alcon); (Rx)

Tobramycin Ophthalmic Drops: 3 mg/mL in 5 mL btl; *Tobrex*® (Alcon); (Rx)

#### Fluoroquinolones, Ocular

Fluoroquinolones (FQNs) are bactericidal through inhibition of bacterial DNA gyrase thereby disrupting bacterial DNA replication. Nalidixic acid is considered the first fluoroquinolone with a spectrum of activity limited to gram-negative organisms and weak activity against *Pseudomonas aeruginosa*. Second generation FQNs (lomefloxacin, norfloxacin, enoxacin, enrofloxacin, ciprofloxacin and ofloxacin) also demonstrate weak activity against *Pseudomonas aeruginosa*, and *Streptococcus* spp are also increasing in resistance to second generation FQN. Third generation FQNs (sparfloxacin, gemifloxacin and levofloxacin) are rarely used in ophthalmology. Fourth generation FQNs (gatifloxacin, moxifloxacin and besifloxacin) have a greater efficacy against gram-positive organisms compared to earlier generation FQNs, but are still relatively ineffective against *Pseudomonas* spp. Moxifloxacin has consistently demonstrated superior ocular penetration when compared to other FQNs (Solomon *et al.* 2005; Yagci *et al.* 2007).

#### References

Solomon, R, ED, Dennenfeld, et al (2005). Penetration of topically applied gatifloxacin 0.3%, moxifloxacin 0.5%, and ciprofloxacin 0.3% into the aqueous humor. *Ophthalmology* 112(3):466-469.

Yagci, R, Y, Oflu, et al (2007). Penetration of second-, third-, and fourth-generation topical fluoroquinolone into aqueous and vitreous humor in a rabbit endophthalmitis model. *Eye* 21(7):990-994.

#### CIPROFLOXACIN

#### GATIFLOXACIN

#### LEVOFLOXACIN

#### MOXIFLOXACIN

#### NORFLOXACIN

#### OFLOXACIN

#### Indications/Pharmacology

These fluoroquinolone ophthalmic antibiotics are primarily useful for established gram-negative corneal infections. They are not recommended for prophylactic use prior to or after surgery. See the main enrofloxacin/ciprofloxacin monograph for additional pharmacologic information.

Clinicians are strongly cautioned regarding the development of retinal neurotoxicity at or above the formerly recommended *systemic* enrofloxacin dosage in cats. There are no reports at the time of writing of retinal toxicity in cats administered topical fluoroquinolone ophthalmic products.

#### Precautions/Adverse Effects

Ciprofloxacin may cause crusting or crystalline precipitates in the superficial portion of corneal defects. Other potential adverse effects with quinolones include: conjunctival hyperemia, bad taste in mouth, itching foreign body sensation, photophobia, lid edema, tearing keratitis and nausea. Allergic reactions have been reported with quinolone eye preps.

#### Dosage Forms/Regulatory Status

##### VETERINARY-LABELED PRODUCTS: None

##### HUMAN-LABELED PRODUCTS:

Ciprofloxacin 3 mg/mL drops in 2.5 & 5 mL btl; *Ciloxan*® (Alcon); (Rx)

Ciprofloxacin: Dexamethasone 0.3%:0.1% drops in 7.5 mL btl; *Ciprodex*® (Alcon); (Rx)

Gatifloxacin 0.3% drops in 5 mL btl; *Zymar*® (Allergan); (Rx)

Levofloxacin 0.5% drops in 5 mL btl, *Quixin*® (JOM); 1.5% drops, 5 mL btl; *Iquix*® (JOM); (Rx)

Moxifloxacin 5 mg/mL drops: 3 mL & 6 mL btl; *Vigamox*® (Alcon); (Rx)

Norfloxacin 3 mg/mL drops in 5 mL btl; *Chibroxin*® (Merck); (Rx)

Ofloxacin 3 mg/mL drops in 5 mL btl; *Ocuflax*® (Allergan); (Rx)

#### Macrolides, Ocular

Macrolides inhibit bacterial growth through binding the bacterial 50S ribosomal subunit preventing protein synthesis. Bacterial resistance to macrolides occurs when bacteria alter ribosomal RNA preventing binding of macrolides to the resulting subunit. Bacterial typically resistant to macrolides include *Staphylococcus aureus*, coagulase-negative Staph spp, and *Streptococcus* spp. While systemic macrolide therapy (azithromycin and clarithromycin) has been used to treat animals with systemic diseases that have ocular manifestations, topical ocular therapy is limited to erythromycin.

#### ERYTHROMYCIN

(*ee-ri-th-rowe-mye-sin*)

## Indications/Pharmacology

Erythromycin has a spectrum against gram-positive organisms except for enterococci. Use of erythromycin in ophthalmology is targeted towards infections caused by *Mycoplasma* spp, *Chlamydia* spp, and *Borrelia burgdorferi*. Resistance to erythromycin is still limited enough that it remains a potentially useful therapeutic option for diseases caused by these organisms.

## Suggested Dosages/Precautions/Adverse Effects

½ inch strip three to four times daily.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Erythromycin 0.5% ophthalmic ointment, 3.5 gram tube, generic (Rx)

## Tetracyclines, Ocular

Tetracyclines exert an antimicrobial effect through inhibition of bacterial protein synthesis at the 30S ribosomal subunit. While tetracyclines have a broad spectrum of antimicrobial coverage, their clinical usefulness is limited by efflux mechanisms in bacteria that actively pump tetracyclines out of cells to create resistant strains. *Pseudomonas* spp are considered resistant to tetracyclines.

Tetracyclines are also useful as anti-inflammatory agents by virtue of their ability to inhibit matrix metalloproteinases (MMP). The role of MMP in destroying corneal collagen can be blocked by tetracyclines administered orally to patients with melting corneal ulcers. Oral administration of doxycycline at doses of 20 mg/kg PO twice daily have resulted in detectable levels of doxycycline in aqueous humor (Davis *et al.* 2006).

## References

Davis JL, JH Salmo, *et al.* (2006). Pharmacokinetics and tissue distribution of doxycycline after oral administration of single and multiple doses in horses. *American Journal of Veterinary Research* 67(2): 310-316.

## OXYTETRACYCLINE

(ox-ee-tet-ra-sye-kleen)

## Indications/Pharmacology

The tetracyclines are most useful in cats for the treatment of Chlamydial and Mycoplasma conjunctivitis as well as nonspecific or symptomatic therapy for undiagnosed (causative organism not determined) conjunctivitis in cats.

## Suggested Dosages/Precautions/Adverse Effects

For Chlamydial/Mycoplasma keratoconjunctivitis: Apply 4 times daily. Dramatic improvement should be noted in 3–4 days, but treatment should continue for 3–4 weeks for Chlamydia to break the reproductive cycle of this organism. Expect potential recurrence after discontinuation of topical treatment from organisms dormant in the nasal passage. As oral doxycycline has been documented to eliminate the carrier state of Chlamydia in cats, better treatment is oral doxycycline 25 mg PO twice daily for three weeks.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 Units/gm: 3.5 gram tubes; *Terramycin® Ophthalmic Ointment* (Pfizer); (Rx)

HUMAN-LABELED PRODUCTS: None

## TETRACYCLINE

(tet-ra-sye-kleen)

## Indications/Pharmacology

The tetracyclines are most useful in cats for the treatment of Chlamydial and Mycoplasma conjunctivitis as well as nonspecific or symptomatic therapy for undiagnosed (causative organism not determined) conjunctivitis in cats.

At the time of writing, there are no commercially available ophthalmic dosage forms of tetracycline.

## Suggested Dosages/Precautions/Adverse Effects

For Chlamydial/Mycoplasma keratoconjunctivitis: Apply 4 times daily. Dramatic improvement should be noted in 3–4 days, but treatment should continue for 3–4 weeks for Chlamydia to break the reproductive cycle of this organism. Expect potential recurrence after discontinuation of topical treatment from organisms dormant in the nasal passage. As oral doxycycline has been documented to eliminate the carrier state of Chlamydia in cats, better treatment is oral doxycycline 25 mg PO twice daily for three weeks.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Formerly available as Tetracycline HCl Ophthalmic Ointment: 10 mg/gram in 3.75 gram tubes; *Achromycin®* (Storz/Lederle); (Rx)

Formerly available as Tetracycline HCl Ophthalmic Suspension: 10 mg/mL in 4 mL bts; *Achromycin®* (Storz/Lederle); (Rx)

## Miscellaneous Antibiotics, Ocular

## BACITRACIN

(bah-si-trey-sun)

## Indications/Pharmacology

Bacitracin inhibits bacterial cell wall synthesis through inhibition of a peptidoglycan precursor, and exhibits a spectrum of action primarily against gram-positive organisms. Bacitracin is unstable in solution, however, it is a common component of combination antibiotic ointments. It is usually combined with polymyxin B and neomycin due to their greater gram-negative activity. This broad spectrum of activity makes triple antibiotic products useful in prophylaxis and therapy for corneal and ocular surface infections. Bacitracin poorly penetrates the cornea and is of limited value in deep corneal or intraocular infections.

## Suggested Dosages/Precautions/Adverse Effects

The primary adverse effect associated with bacitracin is local hypersensitivity.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; *Mycitracin®* (Upjohn) (**Note:** contains 500 mg bacitracin/gram); *Neobacimyx®* (Schering); *Trioptic-P®* (Pfizer); *Vetropolycin®* (Dechra); generic; (Rx). Approved for dogs and cats.

HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (*e.g.*, gramicidin in place of bacitracin in topical solutions-*Neosporin® Ophthalmic Solution*). All these products require a prescription.

## CHLORAMPHENICOL

(klor-am-phen-i-call)

## Indications/Pharmacology

A broad spectrum antibiotic, chloramphenicol has the ability to cross the corneal barrier and enter the anterior chamber. However, very few infections occur in the anterior chamber and if bacteria are actually present, the blood ocular barrier is lost and systemically administered antibiotics can achieve therapeutic levels. Typically, Staph spp. and Strep spp. are susceptible to chloramphenicol while *Pseudomonas* spp. are resistant.

Because of the potential toxicity associated with chloramphenicol to humans, chloramphenicol's use in veterinary ophthalmology is becoming less widespread. It may be useful, however, in treating cats with suspected *Mycoplasma* or chlamydial conjunctivitis, and at the time of printing is one of the few commercially available ophthalmic antibiotics available in an ointment form.

## Suggested Dosages/Precautions/Adverse Effects

For prophylaxis following surgery or for cats with *Mycoplasma* or chlamydial conjunctivitis: One drop (or 1/4 inch strip if using ointment) four times daily. For established corneal infection: Application may be very frequent (up to hourly).

Chloramphenicol exposure in humans has resulted in fatal aplastic anemia. For this reason, this drug should be used with caution in veterinary patients and some ophthalmologists avoid its use entirely. Clients should be cautioned to use appropriate safeguards when applying the drug and avoiding contact with drops or solutions after application.

Labels state to not use longer than 7 days in cats, but three times daily application of ointment for 21 days to cats did not cause toxicity. Must not be used in any food producing animal.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Chloramphenicol 1% Ophthalmic Ointment in 3.5 gm tubes; *Chloromycetin*® (Parke Davis); *Chloroptic*® (Allergan); generic (Rx)

Chloramphenicol 0.5% Ophthalmic Drops in 7.5 mL; *Chloroptic*® (Allergan); generic; (Rx). Refrigerate until dispensed. These products are sporadically available commercially and may need to be compounded by an appropriately qualified compounding pharmacy.

## POLYMYXIN B

(pahl-ee-mix-in-bee)

## Indications/Pharmacology

Polymyxin B is a cationic surfactant (detergent) that disrupts cell membrane integrity through interaction with cell phospholipids. The antimicrobial spectrum is against gram-negative organisms and it is therefore frequently combined with antimicrobials possessing gram-positive activity (e.g. bacitracin).

## Suggested Dosages/Precautions/Adverse Effects

Local reactions can be noted in hypersensitive patients.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 U/gm: 3.5 gm tubes; *Terramycin*® Ophthalmic Ointment (Pfizer); (Rx)

HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (e.g., gramicidin in place of bacitracin in topical solutions-*Neosporin*® Ophthalmic Solution). All are Rx.

## SULFACETAMIDE

(sul-fa-see-ta-mide)

## Indications/Pharmacology

For the treatment of conjunctivitis and other superficial ocular infections due to susceptible microorganisms, and as an adjunctive in systemic sulfonamide therapy of trachoma, *Escherichia coli*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Streptococcus* (viridans group), *Haemophilus Muenzae*, *Klebsiella* species and *Enterobacter* species. Topically applied sulfonamides do not provide adequate coverage against *Neisseria* species, *Serratia marcescens* and *Pseudomonas aeruginosa*. A significant percentage of staphylococcal isolates are completely resistant to sulfa drugs.

## Precautions/Adverse Effects

For conjunctivitis and other superficial ocular infections: Instill one or two drops into the conjunctival sac(s) of the affected eye(s) every two to three hours initially. Dosages may be tapered by increasing the time interval between doses as the patient responds. The usual duration of treatment is seven to ten days. Owners with sulfa allergies should be cautioned to avoid all contact with this medication. Adverse effects seen in animals include gastrointestinal disturbances, allergic skin reactions, renal damage and blood dyscrasias. In dogs, sulfonamides are known to cause keratoconjunctivitis sicca associated with direct toxic effect to the lacrimal acinar cells. This effect is caused by the nitrogen-containing pyridine and pyrimidine rings in sulfonamides and is dose-related. The estimated incidence is 15%-25% in dogs treated with sulfonamides and may occur long after treatment. Dogs demonstrating squinting or excess ocular mucous discharge should be evaluated for this adverse effect, which may be reversible if sulfonamides are discontinued in time.

Sulfonamides are contraindicated in patients with known hypersensitivity or with blood dyscrasias.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sulfacetamide Ophthalmic Solution 10%: 15 mL btl; *Sulf-10*®, *AK-10*® (Akorn); *Bleph-10*® (Allergan); (Rx)

Sulfacetamide Ophthalmic Ointment 10%: *Bleph-10*® (Allergan); (Rx)

## VANCOMYCIN

(vank-o-mye-sin)

## Indications/Pharmacology

Vancomycin inhibits bacterial cell wall synthesis through inhibition of peptidoglycan development. Vancomycin has strong activity against gram-positive organisms, particularly *Staphylococcus* and *Streptococcus* species. Vancomycin is generally reserved for those gram-positive species that have been classified as methicillin-resistant. Vancomycin is used for topical administration in infectious keratitis or bacterial endophthalmitis. An evaluation of vancomycin to treat methicillin-resistant Staph keratitis in rabbits, demonstrated that concentrations of 0.3%-1% vancomycin are effective (Eguchi *et al.* 2009). Injection of vancomycin nanoparticles into the anterior chamber of rabbits demonstrated good prophylactic activity against MRSA with minimal adverse effects (Kodjikian *et al.* 2010).

## Suggested Dosages/Precautions/Adverse Effects

Systemic vancomycin therapy can be associated with ototoxicity, potentially leading to permanent deafness, and nephrotoxicity with resultant fatal uremia.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Vancomycin topical solutions intended for ocular use may be prepared by appropriately qualified compounding pharmacists in concentrations from 0.3%-1%.

## ANTIBIOTIC COMBINATIONS

## Indications/Pharmacology

These combination products exhibit a broad-spectrum of activity and are considered the first choice for symptomatic treatment of conjunctivitis in dogs and for prophylactic treatment of small animals prior to or after eye surgery. These agents are also used prophylactically for corneal injuries/wounds.

## Suggested Dosages/Precautions/Adverse Effects

Usually applied 4 times daily to prevent infection and up to every 30 minutes in established corneal infections. See individual product label information and the information noted previously.

Neomycin has been reported to cause allergic reactions in dogs and cats, particularly after prolonged usage. As noted above, avoid neomycin treatment in cats unless absolutely necessary. Interestingly, anaphylactic reactions in cats have only been associated with neomycin products in ointment form in the absence of cortisone, but not with antibiotic-steroid combination preparations.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Bacitracin zinc 400 Units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units/gram Ophthalmic Ointment: 3.5 gram tubes; *Mycitracin*® (Upjohn) (**Note:** contains 500 mg bacitracin/gm); *Neobacimyx*® (Schering); *Trioptic-P*® (Pfizer); *Vetropolycin*® (Dechra); generic; (Rx). FDA-approved for dogs and cats.

Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 Units/gram Ophthalmic Ointment: 3.5 gm tubes; *Terramycin*® Ophthalmic Ointment (Pfizer); (OTC). FDA-approved for use in dogs, cats, sheep, cattle, and horses.

Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per mL Ophthalmic Solution: *Optiprime*® (Syntex); (Rx). FDA-approved for use in dogs.

### HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (*e.g.*, gramicidin in place of bacitracin in topical solutions-*Neosporin*® Ophthalmic Solution). All these products require a prescription.

## ANTIBIOTIC AND CORTICOSTEROID COMBINATIONS

## Indications/Pharmacology

There are three basic categories of these products that are routinely used in veterinary medicine; antibiotic combinations with hydrocortisone, antibiotic combinations with dexamethasone, and individual antibiotics (*e.g.*, gentamicin or chloramphenicol) with a steroid.

Antibiotic combinations with hydrocortisone (ointment or solution) are used in dogs and horses for conjunctivitis as nonspecific therapy after ruling out other causes for red painful eyes, including glaucoma and anterior uveitis. They generally are applied 4 times daily and then on a tapering schedule based on the response to therapy. The hydrocortisone is relatively weak as an antiinflammatory agent and is not effective for intraocular inflammatory disease such as anterior uveitis. The relative penetration and potency of hydrocortisone in these preparations makes them relatively ineffective for immune mediated extraocular disease including scleritis, episcleritis and nodular granulomatous episclerokeratitis. Anterior uveitis is statistically more common in horses than simple conjunctivitis and the steroid in these agents would not be helpful in improving the clinical signs of immune mediated uveitis.

Antibiotic combinations with dexamethasone are valuable for use in cases of more severe canine or equine conjunctivitis, nonulcerative keratitis and for immune-mediated scleral or corneal conditions such as chronic superficial keratitis (German shepherd pannus), feline eosinophilic keratitis, scleritis, episcleritis and nodular granulomatous episclerokeratitis. For these conditions, the antibiotic agent is not necessary but dexamethasone-only products are not always available. These medications are also used in the equine species with equine uveitis because the ointment forms persist on the cornea longer than drops.

Single agent antibiotic (gentamicin) and potent steroid (betamethasone) combination products (*e.g.*, *Gentocin Durafilm*®) are commonly used in veterinary medicine. However, there are few instances in veterinary ophthalmology in which a very potent corticosteroid agent and an aminoglycoside antibiotic are necessary in combination. Simple conjunctivitis in dogs and horses is adequately treated with antibiotic combinations with hydrocortisone. Avoid use of this agent in cats with conjunctivitis for the reasons noted below.

## Suggested Dosages/Precautions/Adverse Effects

See individual product label information and the information noted above.

Avoid use of antibiotic/steroid combination agents in cats with conjunctivitis as the most common cause of conjunctivitis in the cat is primary or recurring infection with exposure to, or reactivation of, latent feline herpes virus. Recent research indicates that topical steroids increase the length of the typical course of feline herpes virus related conjunctivitis and/or keratitis and can induce corneal involvement in cases that might otherwise have remained confined to conjunctiva. Corneal sequestration has been noted to occur in cats with herpes virus conjunctivitis after treatment with topical steroids. Recommended treatment for feline herpes virus conjunctivitis is tetracycline ointment *QID* during active disease, as this drug is effective against *Mycoplasma* and *Chlamydia* (**Note:** concurrent systemic treatment with doxycycline will likely be necessary to clear *Chlamydia* organisms from the nasal and/or GI passages in cats as discussed above).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

#### *Triple Antibiotic Ointments with Hydrocortisone:*

Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units & Hydrocortisone acetate 1% per gram in 3.5 gm tubes; *Neobacimyx H*® (Schering); *Trioptic-S*® (Pfizer); *Vetropolycin HC*® (Dechra); generic; (Rx). Approved for dogs and cats.

#### *Other Antibiotic/Steroid Ointments:*

Neomycin Sulfate 5 mg & Prednisolone 2 mg (0.2%) per gram in 3.5 gram tubes; *Optison*® (Evsco); (Rx). Approved for use in dogs and cats.

Neomycin Sulfate 5 mg & Isoflupredone acetate 1 mg (0.1%) per gram in 3.5 & 5 gram tubes; *Neo-Predef*® Sterile Ointment (Upjohn); (Rx). Approved for use in horses, cattle, dogs and cats.

Chloramphenicol 1% and Prednisolone acetate 2.5 mg (0.25%) in 3.5 gm tubes; *Chlorasone*® (Evsco) (Rx). Approved for use dogs and cats.

#### *Drops:*

Gentamicin Ophthalmic Drops 3 mg/mL & Betamethasone acetate 1 mg/mL in 5 mL btl.; *Gentocin Durafilm*® (Schering); (Rx). Approved for use in dogs.

### HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic antibiotic/steroid combination products available. Some of the more commonly used combinations include:

#### *Ointments:*

Neomycin/Polymyxin B & Dexamethasone; *Maxitrol*® (Alcon); (Rx)

Neomycin and Dexamethasone; *NeoDecadron*® (Merck); (Rx)

## Antifungals, Ocular

Antifungal agents act primarily by inhibition of fungal cell wall and fall into four classes: polyenes, pyrimidines, azoles, or echinocandins. Polyenes (amphotericin, nystatin and natamycin) bind ergosterol in a dose-related effect causing fungal cell wall leakage and cell death. Fungal keratitis is a serious corneal disease, most commonly reported in the horse. The species selectivity of this disease is related to the environment of this animal, which is often contaminated with fungal elements. An increased incidence of fungal keratitis in people was directly related to the development of multiple topical steroid agents for treatment of eye diseases. In the horse, many cases of fungal keratitis are noted in association with prior treatment of conjunctival and/or corneal diseases with topical steroid agents. Aspergillus is the most common cause of fungal keratitis in the horse, although there is a great deal of variation in fungal isolates from the cornea depending upon geographical location. Studies in people and anecdotal reports from veterinarians suggest that fungal keratitis due to fusarium organisms are more resistant to therapy than are those caused by aspergillus. Most studies in the equine suggest that about 50% of cases of fungal keratitis in the horse result in perforation of the corneal and enucleation of the eye. Medical and surgical therapy (keratectomy, corneal debridement, and conjunctival grafting) are used to treat such cases with the goals of therapy including arresting infection, mechanical removal of organisms from the cornea, and

support of the cornea. All antirungal agents available for use in the equine suffer from poor penetration into the corneal stroma. Conjunctival grating may further hinder drug penetration as a trade off to improving vascular availability to the cornea and mechanical support. Postoperative specimens from horses with fungal keratitis indicate that fungal organisms, unlike bacterial organisms, have a propensity to multiply deep in the stroma, directly adjacent to Descemet's membrane, making corneal penetration an important issue. Because the prognosis for return of vision and saving the globe in cases of fungal keratitis cases is guarded and because treatment is labor intensive, referral to teaching or other hospitals for 24 hour care and observation is recommended.

## AMPHOTERICIN B

(am-foe-ter-i-sin B)

### Indications/Pharmacology

Amphotericin B is a broad spectrum antifungal drug derived from *Streptomyces nodosus*. Originally formulated as a colloidal suspension to overcome poor water solubility, amphotericin frequently caused significant systemic toxicity to kidneys and blood. Amphotericin is now provided in a variety of dosage forms to reduce the risk for systemic toxicity including liposomal injection, lipid complex injection, and colloidal dispersion. No ocular topical dosage form of amphotericin is commercially available, however, the colloidal suspension has been used topically and subconjunctivally to treat cases of equine fungal keratitis. When reconstituting amphotericin, sterile water should be utilized as saline decreases the stability of amphotericin. Resulting dilutions should be refrigerated and protected from light. Amphotericin B is fungistatic or fungicidal depending on the concentration obtained in body fluids and the susceptibility of the fungus. Amphotericin B has been shown to be effective against the following fungi: *Histoplasma capsulatum*, *Coccidioides immitis*, *Candida* species, *Blastomyces dermatitidis*, *Rhodotorula*, *Cryptococcus neoformans*, *Sporothrix schenckii*, *Mucor mucedo*, and *Aspergillus fumigatus*. While *Candida albicans* is generally quite susceptible to amphotericin B, non-albicans species may be less susceptible. *Pseudallescheria boydii* and *Fusarium* spp. are often resistant to amphotericin B.

### Suggested Dosages/Precautions/Adverse Effects

Instill 0.2 mL of a 0.15% solution in the eye or the palpebral lavage catheter every 2–6 hours, or 0.25 mL of a 0.5 mg/mL solution subconjunctivally every 48 hours. There are no commercially available amphotericin B ophthalmic products, but the non-liposomal injectable formulation can be reconstituted with sterile water to make sterile solutions suitable for topical or subconjunctival administration. Amphotericin B should not be reconstituted with sodium chloride containing solutions as this encourages degradation of the drug.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Sterile solutions for topical ophthalmic administration or subconjunctival injection may be prepared by reconstituting commercially available amphotericin B injection lyophilized powder and diluting to appropriate concentrations with sterile water for injection. Chemical stability is concentration dependent, but most resulting solutions may be stored for at least 7 days under refrigeration and protected from light.

## NATAMYCIN

(na-ta-mye-sin)

### Indications/Pharmacology

Natamycin (pimaricin) is a semisynthetic polyene antibiotic and has an improved antimycotic spectrum compared to amphotericin B. It is well-tolerated and induces fewer ocular toxicities compared to amphotericin B. However, natamycin is poorly water-soluble and will not penetrate the intact corneal epithelium. Natamycin is the only antifungal agent approved for use on the eye and the only commercially available eye drug for treatment of fungal keratitis.

### Suggested Dosages/Precautions/Adverse Effects

The product comes as a thick white suspension that complicates the use of subpalpebral lavage apparatus for frequent treatment of the cornea of the horse. This drug will obstruct catheter systems used for medication. It will cause dramatic swelling and pain in the upper eyelid if it leaks out of the tubing into the subcutaneous tissues of the eyelid. Corneal penetration is poor and the medication is very expensive. Fungal keratitis cases are treated aggressively with hourly or bi-hourly treatment the first 1–3 days and gradual reduction in treatment frequency with signs of clinical improvement. Cytology and repeated cultures of the cornea are used to indicate treatment effectiveness. Worsening of the corneal edema and cellular infiltration can be a sign of treatment response. This is thought to be due to antigenic release associated with killing of fungal organisms (like the pulmonary response noted in dogs with institution of antifungal therapy for blastomycosis, etc.). Four to six weeks of treatment is not uncommon for fungal keratitis cases.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Natamycin Ophthalmic Suspension 5%: 15 mL btl; *Natamycin*® (Alcon); (Rx)

## MICONAZOLE

(mi-kon-a-zole)

### Indications/Pharmacology

Miconazole is a broad spectrum imidazole antifungal agent with some antibacterial activity. Miconazole will penetrate the intact corneal epithelium. Topical miconazole therapy has been a favorite first choice agent for treatment of fungal keratitis in the horse by veterinary ophthalmologists for several years. Miconazole may be delivered by subconjunctival route, but with some local irritation, and topical use is the most commonly employed treatment method.

### Suggested Dosages/Precautions/Adverse Effects

Miconazole was formerly available as a 10 mg/mL injectable solution for IV use in humans. It can now only be obtained through s. It is a clear solution readily delivered through subpalpebral lavage apparatus systems. The medication is significantly less expensive compared with natamycin and its corneal penetration is more favorable, although still less than optimal. Treatment is generally delivered hourly or bi-hourly during the first several days of treatment. Once clinical improvement is noted and cytology specimens and repeated cultures indicate eradication of fungal organisms, the treatment frequency is gradually reduced. Most fungal keratitis cases are treated 4–6 weeks.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None suitable for the eye.

All commercially available miconazole topical preparations contain alcohols or other agents that cause corneal damage. It is imperative that a 1% miconazole solution be compounded without alcohols for use on the cornea.

## POVIDONE IODINE

### Indications/Pharmacology

Dilute solutions of povidone iodine (1%–5%) have been utilized for chemical debridement of loose epithelium in canine indolent ulcers. 5% povidone iodine has also been used as an antifungal for fungal keratitis, but must be lavaged from the eye within 5 minutes to prevent damage to corneal epithelium. Generally, povidone iodine is only used once daily and then rinsed off when used in the eye as an anti-fungal. There has also been a renewed interest in utilizing povidone iodine in treating feline herpes keratitis. Solutions of commercially available 10% povidone iodine are diluted in physiologic saline to concentrations of 0.5–1% and applied 1 drop twice to four times daily for treatment of chronic feline herpes keratitis and may also be used prophylactically for feline herpes-virus (FHV) cats with a history of recurring ulcer.

### Suggested Dosages/Precautions/Adverse Effects

Solutions of 1% are applied twice to four times daily for treatment and prophylaxis of feline herpes-virus (FHV) keratitis and for chemical debridement of epithelium for canine indolent ulcers. Solutions of concentration greater than 1% should be lavaged from the eye after no more than 5 minutes to prevent corneal epithelial damage.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Products must be compounded and diluted from the commercially available povidone iodine 10% solutions and diluted to final concentrations of 0.5–1% for antiviral indications and no more than 5% for use as an ophthalmic irrigant.

### SILVER SULFADIAZINE

(sil-ver sul-fa-dye-a-zeen)

#### Indications/Pharmacology

Silver sulfadiazine cream is a broad spectrum agent that covers bacteria (gram-positive and -negative) and fungal agents. It has been used extensively in people suffering from skin burns. It is nontoxic to the skin, conjunctiva and cornea and has been used in the last several years for cases of fungal keratitis. Particularly good results have been noted in cases of superficial keratitis prior to development of advanced disease. Clinical response is better when used early in the course of the disease. Treatment with silver sulfadiazine is considered non-conventional in people. It is gaining in popularity in the treatment of equine fungal keratitis by veterinary ophthalmologists. For medico-legal reasons, in very expensive horses in which litigation may be an issue, treatment with more conventional therapy (natamycin) may be indicated first, or consideration can be given to signed consent regarding treatment with silver sulfadiazine. The initial response to this drug has been promising, however.

#### Suggested Dosages/Precautions/Adverse Effects

The commercially available product is a cream, but can be delivered into the conjunctival sac using a tuberculin syringe, without the needle. A typical treatment dose is 0.2 mL drawn into a syringe. It will not pass through standard sized subpalpebral lavage catheters, although it may be administered through large medication administration systems using red rubber feeding tubes passed through the lid, with variable results getting the medication to pass through the tube. It is probably best applied manually. The cream sticks well to the cornea that probably improves effectiveness, similar to natamycin, as compared to miconazole. Treatment regimes are similar to the other antifungal agents with very frequent applications necessary during the early phases of the treatment and reduction in therapy based upon clinical response. Daily debridement of the necrotic corneal stroma and epithelium will improve penetration of the drug and the clinical response.

The medication is inexpensive and is available from any pharmacy, but it is not labeled for use in eyes. The label (package insert) specifically states “not to be used in eyes” so liability for use in eyes rests solely with the prescribing veterinarian and some pharmacists may be unwilling to dispense this medication for ophthalmic use. Argrysm has been reported in patients receiving topical silver sulfadiazine on a chronic basis.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Silver Sulfadiazine Topical (*not an ophthalmic product*): 10 mg per gram in a water miscible cream base; 20, 50, 400, and 1000 g containers; *Silvadene*® (Marion); *Flint SSD*® (Flint); (Rx). Preferably dispensed aseptically in single use sterile tuberculin syringes for application to the conjunctival sac.

### ITRACONAZOLE

(i-tra-koe-na-zole)

#### Indications/Pharmacology

Itraconazole is a broad spectrum synthetic antifungal agent effective against a wide range of filamentous fungi, dimorphic fungi, and yeasts. It is the most popular systemic antifungal agent for treatment of blastomycosis related and other systemic fungal infections in dogs and people. Itraconazole specifically targets oxidative enzymes of fungal organisms thereby increasing efficacy while lowering toxicity. Itraconazole prepared as a 1% ointment in 30% dimethylsulfoxide (DMSO) is well tolerated in horses with keratomycosis with reported good results. Itraconazole is relatively insoluble in water and must be diluted in DMSO to achieve solution. Itraconazole 1% suspensions in a vehicle of 30% DMSO and 70% artificial tears have also been used successfully to treat fungal keratitis in horses. It is important to note that the DMSO may be topically irritating to many horses. The fungal species most commonly isolated from cases of equine keratomycosis and their particular sensitivity to specific antifungal agents varies greatly by geography in the United States. In vitro sensitivity testing can be done at select laboratories on fungal isolates from the equine eye but this information generally takes several weeks to become available. Because of these considerations, the selection of a particular antifungal drug for an individual case is largely based on local clinical experience and impressions.

#### Suggested Doses/Precautions/Adverse Effects

Compounded itraconazole/DMSO preparation is applied to the cornea frequently in horses with confirmed keratomycosis. Initially, treatment every 2–3 hours is not uncommon; tapering of the treatment based on clinical response. Individuals treating horses need to use routine precautions (gloves) while handling this medication to minimize any skin uptake enhanced by the DMSO solvent.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Compounded product. Must be obtained from an appropriately qualified compounding pharmacy as a 1% suspension or ointment in a DMSO 30% base.

### VORICONAZOLE

(vor-i-kon-a-zole)

#### Indications/Pharmacology

Voriconazole is derived from fluconazole and is considerably more efficacious than amphotericin B for filamentous organisms. Following oral (4 mg/kg) or IV (1 mg/kg) doses to horses, voriconazole demonstrated excellent absorption, bioavailability and tolerance (Davis *et al.* 2006). Although there are currently no approved ocular formulations of voriconazole, compounded solutions of 1% voriconazole have been shown to achieve acceptable ocular concentrations in the aqueous humor (Clode *et al.* 2006).

Voriconazole has been used clinically for the treatment of equine fungal keratitis. Voriconazole is a triazole antifungal agent. The primary mode of action of voriconazole is the inhibition of fungal cytochrome P-450-mediated 14 alpha-lanosterol demethylation, an essential step in fungal ergosterol biosynthesis. The accumulation of 14 alpha-methyl sterols correlates with the subsequent loss of ergosterol in the fungal cell wall and may be responsible for the antifungal activity of voriconazole. Voriconazole has been shown to be more selective for fungal cytochrome P-450 enzymes than for various mammalian cytochrome P-450 enzyme systems. Voriconazole has demonstrated *in vitro* activity against *Aspergillus* (*A. fumigatus*, *A. flavus*, *A. niger* and *A. terreus*), *Candida* (*C. albicans*, *C. glabrata*, *C. krusei*, *C. parapsilosis* and *C. tropicalis*), *Scedosporium apiospermum* and *Fusarium* spp., including *Fusarium solani*. Voriconazole drug resistance development has not been adequately studied *in vitro* against *Candida*, *Aspergillus*, *Scedosporium* and *Fusarium* species. The frequency of drug resistance development for the various fungi for which this drug is indicated is not known. Fungal isolates exhibiting reduced susceptibility to fluconazole or itraconazole may also show reduced susceptibility to voriconazole, suggesting cross-resistance can occur among these azoles. The relevance of cross-resistance and clinical outcome has not been fully characterized. Clinical cases where azole cross-resistance is demonstrated may require alternative antifungal therapy. There are no approved ophthalmic formulations of voriconazole, however, a suitable solution for ophthalmic administration can be prepared by utilizing the approved voriconazole injectable product.

#### Suggested Dosages/Precautions/Adverse Effects

0.2 mL in the eye or palpebral lavage catheter every 2–4 hours. Voriconazole is contraindicated in patients with known hypersensitivity to voriconazole or its excipients. There is no information regarding cross-sensitivity between voriconazole and other azole antifungal agents. Caution should be used when prescribing voriconazole to patients with hypersensitivity to other azoles. Voriconazole treatment-related visual disturbances are common in humans. In therapeutic trials, approximately 21% of patients experienced abnormal vision, color vision change and/or photophobia. The visual disturbances were generally mild and rarely resulted in discontinuation. Visual disturbances may be associated with higher plasma concentrations and/or doses. Since topical administration of voriconazole has not been evaluated in humans, it is not known if this adverse event occurs with topical administration. The mechanism of action of the visual disturbance is unknown, although the site of action is most likely to be within the retina. In a study in healthy volunteers investigating the effect of 28-day treatment with voriconazole on retinal function, voriconazole caused a decrease in the electroretinogram (ERG) waveform amplitude, a decrease in the visual field, and an alteration in color perception. The ERG measures electrical currents in the retina. The effects were noted early in administration of voriconazole and continued through the course of study drug dosing. Fourteen days after end of dosing, ERG, visual fields and color perception returned to normal. Dermatological reactions are also common in human patients treated with voriconazole. The mechanism underlying these dermatologic adverse events remains unknown. In clinical trials, rashes considered related to therapy were reported by 7% (110/1655) of voriconazole-treated patients. The majority of rashes were of mild to moderate severity. Cases of photosensitivity reactions appear to be more likely to occur with long-term treatment. Human patients have rarely developed serious cutaneous reactions, including Stevens-Johnson syndrome, toxic epidermal necrolysis and erythema multiforme during treatment with VFEND. If patients develop a rash, they should be monitored closely and consideration given to discontinuation of VFEND. It is recommended that patients avoid strong, direct sunlight during VFEND therapy. The extent of these adverse drug reactions in animals is unknown at this time.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

## HUMAN-LABELED PRODUCTS: None

There are no commercially available ophthalmic dosage forms of voriconazole. A suitable solution for ophthalmic administration may be prepared by aseptically adding 19 mL of sterile water for injection to a 200 mg vial of *VFend*<sup>®</sup> injection to result in a sterile 1% solution. Resulting solution should be stored under refrigeration and discarded 28 days after reconstitution.

## Antivirals, Ocular

Antiviral drugs are used most commonly in clinical practice for the treatment of feline ocular herpes virus infections. Simple acute conjunctivitis is best managed with symptomatic antibiotic therapy alone (*i.e.*, tetracycline treatment or systemic doxycycline treatment). The development of concurrent corneal disease, however, indicates that consideration should be given to the use of antiviral drugs. Persistent cases of conjunctivitis in the cat due to feline herpes virus infection may also benefit from treatment with topical antiviral drugs. Although *in vitro* studies indicate that trifluridine is the most effective agent against feline herpes virus, idoxuridine is a less irritating, more economical alternative. In general, all antivirals are virustatic (not cidal) and require application every 2 hours for the first 24 hours followed by 5–6 times daily treatment thereafter. While this appendix focuses mostly on topical ophthalmic therapies, it is important to note that studies support use of L-lysine at 500 mg orally twice daily in cats to prevent or reduce the severity of feline herpes virus ocular infections through disruption of viral replication.

### TRIFLURIDINE (TRIFLUOROTHYIMIDINE)

(trye-flure-i-deen)

## Indications/Pharmacology

Trifluridine (trifluorothymidine; *Viropic*<sup>®</sup>) is a pyrimidine nucleoside analog. It is structurally related to 2-deoxythymidine, the natural precursor of DNA synthesis and exerts its effects via inhibition of thymidylate synthetase. An *in vitro* study in which several strains of feline herpes virus were collected from the United States and were used to infect kidney epithelial cells showed that trifluridine was more effective at lower concentrations compared with several other agents. For this reason, trifluridine was the first choice drug employed in the treatment of feline herpes virus ocular disease for many years. Because of the topical toxicity associated with use of trifluridine in cats, its popularity has diminished greatly. In many milder cases, the irritation associated with topical trifluridine is more intense than the inflammation induced by viral infection. Antiviral agents have also been used in the treatment of superficial punctate keratitis in the horse, thought to be associated with equine herpes virus-2 (EHV-2) infection of the cornea.

## Suggested Dosages/Precautions/Adverse Effects

Trifluridine must be applied very frequently. Many veterinary ophthalmologists recommend treatment every 2 hours (waking hours) during the first 2 days of therapy to establish effective corneal drug levels. After this time, treatment 4–6 times daily is indicated. Because trifluridine is virostatic and not viricidal, treatment 1 week beyond the resolution of clinical signs is recommended, to prevent a rebound effect associated with poor surface immunity in combination with residual active viral agents. However, a maximum supply of 3 weeks medication should initially be dispensed as trifluridine is a corneal toxin and can retard corneal epithelial healing. Additionally, if cats do not respond favorably to trifluridine therapy within three weeks, they are not likely to respond with longer durations of therapy. If no improvement is noted in three weeks, trifluridine (or any antiviral) should be discontinued for a rest period and then a different antiviral initiated.

Anecdotal improvement with antiviral agents is noted in about 50% of cats in which the treatment is employed. In some cats, the ocular disease persists despite treatment with antiviral agents. It is not certain if these are truly cases of feline herpes virus infection or other disease. Except in acute cases with respiratory and ocular involvement, the confirmation of feline herpes virus infection is exceedingly difficult in private practice, primarily due to the logistics of performing specific viral isolation tests. Chronic conjunctivitis in the cat seems to be the most resistant to treatment with antiviral agents. Conjunctival and lid margin irritation are commonly reported with trifluridine use.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Trifluridine Ophthalmic Solution: 1% in 7.5 mL btl; *Viropic*<sup>®</sup> (Monarch); (Rx)

### IDOXURIDINE

(eye-dox-yoor-i-deen)

## Indications/Pharmacology

Iodoxuridine (IDU) is chemically similar to thymidine and its substitution into viral DNA causes misreading of the viral genetic code thereby inhibiting viral replication. Because IDU is a non-specific inhibitor of DNA synthesis, it affects any cellular function requiring thymidine and is not suitable for systemic use. Even with topical therapy, corneal toxicity can occur. Like trifluridine, IDU is considered virostatic rather than viricidal. IDU was found to be second to trifluridine in efficacy *in vitro* against common strains of feline herpes virus growing in kidney epithelial cells. IDU is extremely well tolerated in cats and this feature alone makes it the most popular antiviral currently available for use in cats with presumed or established feline herpes virus infection. Although trifluridine was shown to be more effective *in vitro*, the topical irritation it induces in cats frequently negates any beneficial effect that might be noted clinically. Stinging upon application is a rare feature with IDU/artificial tear preparations.

## Suggested Doses/Precautions/Adverse Effects

IDU, like trifluridine, penetrates poorly into the cornea (except in instances of ulceration) and conjunctiva and therefore must initially be applied frequently. Most treatment protocols involve application every two to three hours during waking hours the first two days of acute infection, followed by four to five times daily treatment continued a week beyond resolution of clinical signs.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Formerly approved as *Stoxil*<sup>®</sup> and *Herplex*<sup>®</sup>; must be obtained from appropriately qualified compounding pharmacies as a 0.1% ophthalmic solution or a 0.5% ophthalmic ointment.

### INTERFERON ALPHA

(in-ter-feer-on al-fa)

## Indications/Pharmacology

Interferon alpha-2B is thought to stimulate local immunity against viral infection and has been advocated as an adjunct therapy for treatment of feline herpes viral keratitis. Few peer-reviewed, placebo controlled, prospective clinical trials evaluating interferon administration to FHV cats exist at the time of writing, and until further studies are conducted, the dosage, frequency and efficacy of interferon in FHV cannot be stated. Furthermore, the stability of interferon for long term administration has not been scientifically evaluated. The gastric degradation of interferon by peptidases precludes likely systemic absorption of this drug; however, absorption across the oropharyngeal mucosa may occur and low concentrations of interferon may be amplified via a cascade effect (Weigent *et al.* 1984).

## Suggested Dosages/Precautions/Adverse Effects

It has been used both systemically (30 Units PO q24h) and/or topically (30–50 Units/mL in artificial tears in both eyes 3–5 times daily) for refractory cases of feline herpes keratitis although these doses, routes and frequencies have not been scientifically evaluated.

## Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

The human interferon alpha-2B injection (*Intron-A*<sup>®</sup>—Schering) is diluted to a final concentration of 30–50 Units/mL in saline or artificial tears and administered orally or topically respectively.

### ACYCLOVIR

### VALACYCLOVIR

### FAMCICLOVIR

### GANCICLOVIR

## GANCICLOVIR CIDOFOVIR PENCICLOVIR

### Indications/Pharmacology

These antiviral drugs represent the acyclic nucleoside analogs and require three phosphorylation steps for activation: catalyzation by thymidine kinase, followed by phosphorylation by host enzymes. Because the Feline Herpes virus (FHV) thymidine kinase enzyme is less active than the human Herpes simplex virus (HSV), these agents are not as effective against FHV as they are against HSV.

A 0.5% acyclovir ophthalmic ointment administered 5 times daily demonstrated a mean time of 10 days to resolution of clinical signs (Williams *et al.* 2005). Ophthalmic ganciclovir is available as a 0.15% topical gel for human use, but at the time of writing has not been studied in cats. Systemic anti-retroviral agents have been tried in cats with persistent herpes keratitis, but myelosuppression and nephrotoxicity following systemic use is a serious risk with acyclovir and valacyclovir. Acyclovir should only be used systemically as a last resort and CBC should be monitored weekly in cats receiving this drug. Valacyclovir apparently has no effect on feline herpes replication and should **never** be used in cats due to fatal myeloid dysplasia. The pharmacokinetics of systemic famciclovir in cats are extremely complex and this drug should be used with caution in this species. However, a study of famciclovir administered at 90 mg/kg orally three times daily in experimentally infected FHV cats demonstrated significantly reduced clinical signs, serum globulin concentrations, histologic evidence of conjunctivitis, viral shedding, and serum FHV titers with no evidence of adverse clinical, hematologic or biochemical effects (Thomas *et al.* 2010). As other agents in this drug class are myelosuppressive, extreme caution is recommended regarding famciclovir therapy in cats. Topically administered cidofovir 0.5% solutions have recently been shown to reduce the severity and duration of FHV-1 infections. The *in vitro* efficacy of commonly available antiviral agents for FHV-1 has been studied and is as follows: trifluridine > ganciclovir = idoxuridine = cidofovir = penciclovir = vidarabine > acyclovir >> foscarnet.

### Suggested Doses/Precautions/Adverse Effects

Acyclovir 0.5% ointment applied 5-6 times daily. Cidofovir 0.5% topical solution, 1 drop in each eye twice daily. Until further data is available, systemic use of these agents is not recommended in cats. Topical use of these agents should be conducted with caution in cats as they are likely to groom off medication and experience systemic adverse effects.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Sterile solutions of cidofovir suitable for ophthalmic administration may be prepared by diluting the commercially available injection to a final concentration of 5 mg/mL using 1% carboxymethylcellulose solutions (Fontenelle *et al.* 2008). Acyclovir 0.5% ophthalmic ointment may be obtained from appropriately qualified compounding pharmacies.

### Keratoconjunctivitis Sicca

Keratoconjunctivitis sicca (KCS) is a common ocular disorder in dogs. Recent research efforts indicate that KCS in dogs is an immune mediated disease. It is similar to Sjogren's Syndrome in humans except we do not recognize a connective tissue disorder in the dog compared to this disease in people (man-dry eye, dry mouth, and connective tissue disorder like rheumatoid arthritis; dogs just dry eye). Immune mediated lacrimal adenitis can result in complete destruction of tear producing glands in dogs. Glandular fibrosis produces absolute sicca and these cases may be better managed with a parotid duct transposition surgery because there may be little remaining gland tissue to treat.

## CYCLOSPORINE

(sye-kloe-spor-een)

### Indications/Pharmacology

Cyclosporine is a polypeptide agent first isolated from a fungus. The agent interferes with interleukin synthesis by T-lymphocytes and in so doing, has been employed extensively in people following major organ transplantation to prevent immune rejection. Cyclosporine is extremely hydrophobic and was originally compounded by pharmacists in virgin olive oil or purified corn oil for the topical application to dogs with keratoconjunctivitis sicca. Topical cyclosporine is now commercially available as a 0.2% ointment (*Optimmune*®; Schering). The mechanism of action of cyclosporine in the treatment of keratoconjunctivitis sicca is still not fully understood, although it has been employed in the treatment of KCS in dogs for several years. It stimulates increased tear production in normal dogs and for this reason it is thought to have a direct stimulatory effect on the tear gland. It may do this acting as a prolactin analog, fitting onto lacrimal prolactin receptors. Its interleukin blocking effects likely are the major mechanism of action. Halting local inflammatory mediator production appears to arrest self perpetuating lacrimal adenitis resulting in resumption of normal or improved tear production after several weeks of therapy, however, cessation of therapy results in return of symptoms in a matter of days. Cyclosporine in the cornea appears to have the ability to lessen granulation and pigment development. This property appears to be unrelated to its tear producing ability.

The reported success rate of alleviating the signs of KCS in dogs with treatment with cyclosporine is 75–85%. Some studies indicate that the higher the Schirmer value prior to starting therapy, the more likely that the dog will be well managed with cyclosporine alone. Absolute sicca may be associated with extensive fibrosis of the tear glands, leaving little tissue for stimulation or repair.

Cyclosporine is effective in the management of German Shepherd Pannus or chronic superficial keratitis in the dog. This condition is an immune disease of the cornea and likely is interleukin mediated. Cyclosporine may be preferred for the treatment of pannus because of the lack of systemic side effects noted in dogs with chronic topical administration of cyclosporine. Chronic topical corticosteroid treatment is associated with biochemical changes in the blood of large and small dogs.

Cyclosporine has been tried in the management of the rare case of keratoconjunctivitis sicca in the cat. Dry eye in cats is usually associated with herpes virus destruction of lacrimal epithelial cells and/or stenosis of the ductules or openings of the ductules due to chronic viral conjunctivitis. Preliminary results have not been promising. Topical cyclosporine often aggravates ophthalmic herpes virus infections in people. Cyclosporine has not shown promising effects in the management of feline eosinophilic keratitis, a condition now thought to be related to chronic stromal herpes virus infection in cats.

### Suggested Dosages/Precautions/Adverse Effects

Cyclosporine is an immunosuppressive agent used to facilitate tear production in canine keratoconjunctivitis sicca (KCS). Multiple mechanisms of action have been attributed to cyclosporine. Cyclosporine suppresses T-cell mediated destruction of the lacrimal gland and conjunctival epithelium. Conjunctival mucin stores are also increased leading to improved quality of the tear film and a direct lacrimomimetic effect contributes to the mechanism of action of treating KCS. Cyclosporine is initiated generally as the first course of therapy for confirmed dry eye cases in the dog. The topical half-life of cyclosporine is about 8 hours and most canine cases of KCS are managed with twice daily therapy with 0.2% ointment (*Optimmune*®). Three times a day therapy has been employed during the initial phases of treatment in more difficult or slow responding cases. For unknown reasons (reversal of lacrimal adenitis > reorganization of lacrimal epithelial cell function > formation of secretory granules > tear production) 3–8 weeks of therapy are necessary before a dramatic increase in the Schirmer tear test becomes evident. Patients are generally maintained for life on cyclosporine ophthalmic once or twice daily depending on the response. Discontinuation of therapy is usually associated with the return of clinical signs of KCS within a few days. Reinstitution of therapy, at this time, is usually associated with an almost immediate return of tear production (versus the initial lag phase noted). This likely is related to the degree of inflammatory disease noted with short discontinuation of therapy versus that present initially, prior to the diagnosis of KCS.

If tear production is very low, cyclosporine is often used in combination with artificial tears during the initial phases of therapy. Once tear production is improved, artificial tears can generally be removed completely or their frequency reduced in the treatment plan. After treatment is initiated, reevaluation of tear production in one month is recommended. If ulcerative keratitis complicates keratoconjunctivitis sicca in the dog, more frequent evaluation is necessary. Cyclosporine, although an immunomodulating agent, is considered safe in the face of ulcerative keratitis, with concurrent antibiotic therapy. Caution is advised, however.

When cyclosporine is delivered topically, no systemic toxicity has been noted in dogs given this drug chronically. This is probably associated with the poor absorption of this drug across the GI tract and because it is delivered to the eye at very low concentrations which even if 100% absorbed, when divided over the body weight of the dog is well below even the therapeutic dose. Advanced detection methods have made it possible to measure trace levels of cyclosporine in the blood of dogs being topically treated for dry eye. The clinical implication of this finding is uncertain at this time.

### Dosage Forms/Regulatory Status

*Optimmune*® ointment is the approved formulation of topical cyclosporine for the management of dry eye in dogs. Compounding of topical cyclosporine drops was popular before the introduction, approval, and marketing of *Optimmune*® ointment. Clinicians persistently using compounded formulations of cyclosporine eye drops may be outside of expected ethical and legal standards of practice except under very specific situations. The use of commercially available ophthalmic products instead of compounded medications is highly recommended. *Optimmune*® is first applied 2 or 3 times daily and frequency of daily application is adjusted based on clinical response.

VETERINARY-LABELED PRODUCTS:

Cyclosporine Ophthalmic Ointment 0.2%; *Optimmune*® (Schering-Plough); (Rx)

HUMAN-LABELED PRODUCTS:

Cyclosporine 0.05% Ophthalmic Emulsion; *Restasis*® (Allergan). **Note:** the concentration of this product has not been shown to increase tear production in dogs. Patients failing to respond to the veterinary approved ophthalmic ointment may respond to compounded cyclosporine 1% ophthalmic solution or tacrolimus 0.03% ophthalmic solution.

## TACROLIMUS

### Indications/Pharmacology

Tacrolimus was originally studied at the University of Tennessee College of Veterinary Medicine where investigators found it equally effective as cyclosporine and effective for cyclosporine-resistant cases of KCS. Tacrolimus is a macrolide antibiotic that exerts its effects in KCS through mechanisms similar to that of cyclosporine, however exact mechanisms of action in causing tear production are still being determined.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None appropriate for the eye. At the time of publication, Fujisawa, Inc. has granted exclusive rights to Sucampo, Inc. to study, develop, and market an ophthalmic tacrolimus formulation for use in KCS. **Note:** *Protopic*<sup>®</sup> topical ointment is a topical tacrolimus formulated with propylene carbonate that is known to deplete cholinesterase and to be an ophthalmic irritant and should not be used in the eye. Tacrolimus 0.01–0.03% solutions and ointments should be prescribed through an appropriately qualified compounding pharmacy until a suitable commercially available product is available.

### PIMECROLIMUS

(pee-mek-rowe-li-mus)

### Indications/Pharmacology

Pimecrolimus is similar in mechanism of action to tacrolimus, with a greater sensitivity. An evaluation of pimecrolimus 1% solution given three times daily to KCS patients demonstrated a favorable response (Nell *et al.* 2005). A comparison of pimecrolimus 1% solution to cyclosporine 0.2% ointment in dogs with KCS demonstrated comparable improvement from both drugs over the 8-week study period (Ofri *et al.* 2009).

### Suggested Dosages/Precautions/Adverse Effects

Pimecrolimus should be administered as a 1% ophthalmic solution twice daily.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Compounding pharmacists may prepare a pimecrolimus 1% solution for use in dogs with KCS that are unresponsive to *Optimmune*<sup>®</sup> 0.2% Ophthalmic Ointment.

### Artificial Tear Products/Ocular Lubricants

#### ARTIFICIAL TEARS/OCULAR LUBRICANTS

### Indications/Pharmacology

Various solutions and ointments have been designed to replace (in quality or quantity) the precorneal tear film with the goal of restoring ocular comfort and corneal protection. Artificial tear solutions are aqueous, isotonic, pH buffered viscous solutions with appropriate surface tension that serve as a lubricant for dry eyes and associated eye irritation due to dry eye syndromes. They are often useful adjuncts in keratoconjunctivitis sicca in dogs early in cyclosporine therapy. Most are water-based preparations that may also include polymers (methylcellulose, polyvinyl alcohol, povidone, dextran and propylene glycol) and other agents (gelatin, glycerin, polyethylene glycol, pluronic gel and polysorbate 80) to increase viscosity, lubrication and retention time. Tonicity and pH are achieved through use of sodium chloride, potassium chloride and boric acid. Preservatives may be present or absent, however, preservatives may add to disease through toxicity to the corneal epithelium.

Ocular lubricant ointments are white petrolatum-based products that serve to lubricate and protect eyes. They are particularly useful during anesthetic procedures where animals' eyes may remain open and during which time tear production is dramatically reduced.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

There is a plethora of products available with a variety of formulations and trade names. All are OTC. Some commonly known products include:

Artificial Tear Products (Methylcellulose-based): *Adsorbotear*<sup>®</sup> (Alcon); *Comfort Tears*<sup>®</sup> (Pilkington Barnes Hind); *GenTeal*<sup>®</sup> (Ciba Vision); *Isopto-Tears*<sup>®</sup> (Alcon); *Tears Naturale*<sup>®</sup> (Alcon); *Lacri!*<sup>®</sup> (Allergan)

Artificial Tear Products (Polyvinyl Alcohol-based): *Hypotears*<sup>®</sup> (Iolab); *Liquifilm Tears*<sup>®</sup> (Allergan); *Tears Plus*<sup>®</sup> (Allergan)

Artificial Tear Products (Glycerin-based): *Dry Eye Therapy*<sup>®</sup> (Bausch & Lomb); *Eye Lube A*<sup>®</sup> (Optopics)

Ocular Lubricants (Petrolatum-based): *Lacri-Lube*<sup>®</sup> S.O.P. (Allergan); *Akwa Tears*<sup>®</sup> (Akorn)

#### OPHTHALMIC IRRIGANTS

### Indications/Pharmacology

The primary use of ocular irrigation solutions is during intraocular surgery (cataract removal). Ocular irrigating solutions maintain the shape of the anterior chamber during surgery, cool phacoemulsification handpieces, and lavage emulsified lens and surgical byproducts from the eye. The ideal ocular irrigation solution mimics the composition of the aqueous humor in terms of physiologic pH, osmolality and ion composition. Sterile isotonic solutions are also used for flushing the nasolacrimal system and for removing debris from the eye. They are also used to remove excess stain after diagnostic staining of the cornea. Sterile lactated Ringer's solution (LRS) is well tolerated by the surface of the eye as is a balanced salt solution (BSS). Extraocular irrigating solutions may contain preservatives. Intraocular irrigating solutions (used during surgical procedures) do not contain preservatives and contain electrolytes that are required for normal cell function. Intraocular irrigating solutions may also have added glutathione, which is responsible for stabilizing endothelial cell junctions and intraocular pumping functions. Other additives include heparin, epinephrine, antibiotics and local anesthetics to exert desired pharmacological effects. A study evaluating cooled versus room temperature irrigating solutions have demonstrated no significant adverse effects between the two temperatures (Praveen *et al.* 2009).

### Suggested Dosages/Precautions/Adverse Effects

Extraocular: Use to flush eye as necessary; control rate of flow by exerting pressure on bottle. Intraocular: Refer to both established practices for each surgical procedure as well as the specific manufacturers' recommendations.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

*Eye Rinse*<sup>®</sup> (Butler); (OTC): Contains: water, boric acid, zinc sulfate, glycerin, camphor. Note: This product is not labeled for use as an irrigant per se, but as an aid in cleaning the eye and removing eye stains.

HUMAN-LABELED PRODUCTS:

Common trade name products for extraocular irrigation: *AK-Rinse*<sup>®</sup> (Akorn), *Blinx*<sup>®</sup> (Pilkington Barnes Hind), *Collyrium for Fresh Eyes Eye Wash*<sup>®</sup> (Wyeth-Ayerst), *Dacriose*<sup>®</sup> (Iolab), *Eye Irrigating Solution*<sup>®</sup> (Rugby), *Eye-Stream*<sup>®</sup> (Alcon), *Eye Wash*<sup>®</sup> (several manufacturers), *Eye Irrigating Wash*<sup>®</sup> (Roberts Hauck), *Irrigate Eye Wash*<sup>®</sup> (Optopics), *Optigene*<sup>®</sup> (Pfeiffer), *Star-Optic Eye Wash*<sup>®</sup> (Stellar), *Visual-Eyes*<sup>®</sup> (Optopics). All are OTC.

Common trade name products for intraocular irrigation: **Note:** Most of these products contain Balanced Salt Solution (BSS) = NaCl 0.64%, KCl 0.075%, CaCl<sub>2</sub>•2H<sub>2</sub>O 0.048%, MgCl<sub>2</sub>•6H<sub>2</sub>O 0.03%, Na acetate trihydrate 0.39%, sodium citrate dihydrate 0.17%, sodium hydroxide and/or hydrochloric acid to adjust pH, and water: Balanced Salt Solution (various manufacturers), *BSS*<sup>®</sup> (Alcon), *Iocare Balanced Salt Solution*<sup>®</sup> (Iolab); All are Rx.

BSS + solutions that also contain dextrose, glutathione, bicarbonate, phosphate are also available as: *BSS Plus*® (Alcon) and *AMO Endosol Extra*® (Allergan); All are Rx.

Praven, MR, A.R. Vannada, et al (2009). Effect of room temperature and cooled intracavitary irrigating solution on the corneal and anterior segment inflammation after phacoemulsification: a randomized clinical trial. [Eur J Ophthalmol](#) 23(15):1158-1163.

## Topical Hyperosmotic Agents

### POLYSULFATED GLYCOSAMINOGLYCAN

#### Indications/Pharmacology

Polysulfated glycosaminoglycan (PSGAG) *Adequan*® (Luitpold) inhibits a number of enzymes (lysozyme, hyaluronidase, and serine proteases), decreases prostaglandin E<sub>2</sub> synthesis, reduces production of toxic superoxide radicals, and increases synthesis of collagen proteoglycans and hyaluronic acid. Thus polysulfated glycosaminoglycan, originally developed for use in degenerative osteoarthritis cases, has intriguing properties suggesting usefulness in corneal ulcer management. It has anecdotally been effective in promoting healing of indolent corneal ulcers in dogs but no studies in dogs have been published to date. A Brazilian study reported that when using a 5% PSGAG formulation was applied to indolent ulcers of horses, that 86% of eyes treated were considered healed within 3 weeks of initiation of therapy.

Fibronectin and epidermal growth factors have also been applied in treating indolent ulcers but scientific studies remain to be published regarding efficacy. At the time of publication, surgical keratectomy remains the most reliable treatment for indolent ulcers.

#### Suggested Dosages/Precautions/Adverse Effects

1 drop of a 5% PSGAG solution in artificial tears applied to the affected eye(s) three times daily.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None, however the veterinary approved *Adequan*® injection may be diluted 1:1 with sterile artificial tears to produce a 5% PSGAG solution.

HUMAN-LABELED PRODUCTS: None

### HYPERTONIC SODIUM CHLORIDE

#### Indications/Pharmacology

The stroma of the cornea is the middle layer located between the outer epithelial layer on the surface of the eye and the inner single epithelial layer lining the cornea, called the corneal endothelium. The stroma consists of highly organized collagen bundles and a few keratocytes (fibroblasts). The spacing of the collagen bundles is critical to absolute clarity of the cornea. The spacing of these bundles is disturbed when fluid enters the stroma. Surrounded by water to the exterior (tears) and on the interior (aqueous humor) the relative dehydration of the stroma is maintained by an active ATP-dependent pump mechanism in the corneal endothelial cells. Degeneration of the corneal endothelium is a relatively common eye problem in older dogs and is a known genetic condition in Boston Terrier and Chihuahua dogs. Fluid continuously seeps into the corneal stroma via the tear film and through aqueous humor passing between corneal endothelial cells. When the endothelial pumping capacity deteriorates, fluid retention in the stroma causes two problems. Visual impairment can eventually develop. The other common complication is the development of corneal ulcers. Edema fluid retained in the cornea pools into pockets called bullae which progressively migrate to the surface of the cornea, eventually draining through and disrupting the surface epithelium. This results in very slow healing and painful corneal erosions in dogs (type II refractory ulcers). Hyperosmotic agents applied 2–3 times daily help to prevent recurrence of bullae and subsequent corneal ulcers after the erosions have healed. Because osmotic agents require an intact epithelial barrier in which to induce a pressure gradient (5% NaCl commercial preparation versus 0.9% NaCl body fluids), they are not effective with respect to healing of stubborn corneal ulcers when present. They simply help to prevent re-ulceration once an intact epithelial barrier has been established. It may be said that these agents simply aggravate irritation already present when used in the face of ulcerative keratitis.

#### Suggested Dosages/Precautions/Adverse Effects

5% NaCl (*Muro 128*® or equivalent) eye drops or ointment are applied two to three times daily on an indefinite basis to the surface of eyes with corneal endothelial degeneration to prevent corneal ulceration. In the event of corneal ulceration, treatment is discontinued and substituted for antibiotic and mydriatic treatment in addition to procedures to promote healing of refractory type corneal ulcers. NaCl eye drops are available at a 2% and 5% concentration and ointment is available at a 5% concentration. Because of limited contact time with eye drops, the 2% solution would not be considered for use in animals. Because of prolonged contact time associated with ointments, the 5% ointment is probably the best of the available products for use in animals.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sodium Chloride 2% Ophthalmic Solution in 15 mL btl; *Adsorbonac*® (Alcon), *Muro 128*® (Bausch & Lomb); (OTC)

Sodium Chloride 5% Ophthalmic Solution in 15 mL btl; *Adsorbonac*® (Alcon), *Muro 128*® (Bausch & Lomb), *AK-NaCl*® (Akorn), *Muroptic-5*® (Optopics); (OTC)

Sodium Chloride 5% Ophthalmic Ointment in 15 mL btl; *Muro 128*® (Bausch & Lomb), *AK-NaCl*® (Akorn); (OTC)

#### Viscoelastic Substances

Viscoelastic substances are vital to ocular surgery, minimizing loss of fluid from the anterior chamber while maintaining intraocular space during surgical procedures. The purity and integrity of viscoelastics ensure tissue protection during and after surgery. Viscoelastics generally fall into two categories: cohesives, that tend to stick together, and dispersives, that are more likely to diffuse out into the anterior chamber. Cohesives, in general, create and maintain space very well in the anterior chamber and help stabilize tissue. Such viscoelastics are easily washed away at the end of the case, but are also, unfortunately, all too easily removed during phacoemulsification. Dispersives, that have lower viscosity, remain in the eye more readily, making them well-suited for difficult cases. They are also excellent for various maneuvers, such as retrieving a lost lens fragment, attempting to viscoelevate cortex, or partitioning away a small piece that continues to get caught on the phacoemulsifier tip. Ophthalmic surgeons should be familiar with the advantages and disadvantages of several viscoelastics and realize the limitations encountered if the surgeon chooses to rely on a single viscoelastic. Veterinary ophthalmologist loyalty to brands of viscoelastics is well-earned as newcomer products to this field have frequently resulted in surgical disasters.

Viscoelastics are also vital to tear replacement.

### HYALURONIC ACID

(hye-a-*loo-ron-ik-as-id*)

#### Indications/Pharmacology

Hyaluronic acid is a natural complex sugar of the glycosaminoglycan family and is a long-chain polymer containing repeating disaccharide units of Na-glucuronate-N-acetylglucosamine. Hyaluronic acid is indicated for use as a surgical aid in cataract extraction (intra- and extracapsular), IOL implantation, corneal transplant, glaucoma filtration and retinal attachment surgery. Hyaluronic acid is a naturally occurring polymer and has wound healing properties. In surgical procedures in the anterior segment of the eye, instillation of hyaluronic acid serves to maintain a deep anterior chamber within corneal endothelium and other surrounding tissues. Furthermore, its viscoelasticity helps to push back the vitreous face and prevent formation of a postoperative flat chamber. In posterior segment surgery, hyaluronic acid serves as a surgical aid to gently separate, maneuver and hold tissues. Hyaluronic acid creates a clear field of vision thereby facilitating intra- and post-operative inspection of the retina and photocoagulation.

#### Suggested Dosages/Precautions/Adverse Effects

A sufficient amount of hyaluronic acid (generally 10% concentration) is slowly, and carefully introduced (using a cannula or needle into the anterior chamber. Injection of hyaluronic acid can be performed either before or after delivery of the lens. Injection prior to lens delivery will, however, have the additional advantage of protecting the corneal endothelium from possible damage arising from the removal of the cataractous lens. Hyaluronic acid may also be used to coat surgical instruments and the IOL prior to insertion. Additional hyaluronic acid can be injected during surgery to replace any hyaluronic acid lost during surgical manipulation. Topical solutions of hyaluronic acid are also used to provide a viscoelastic shield to the cornea and provide prolonged relief from ocular surface discomfort.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Hyaluronic acid 10% Solution: 2 mL pre-filled syringe; *Hylartin-V*® (Pfizer Pharmacia); *I-Drop Med*® 0.3% solution, 20 × 1 mL preservative-free unit dose containers; (Rx)

HUMAN-LABELED PRODUCTS:

VETERINARY-LABELED PRODUCTS:  
Hyaluronic acid 10%–23%: *Healon*<sup>®</sup> products (Pfizer); (Rx)

## Cytotoxic Ophthalmic Agents

### CISPLATIN BEADS

(sis-pla-tin)

#### Indications/Pharmacology

Cisplatin 1.6 mg biodegradable beads are used for intralesional chemotherapy in various cutaneous neoplasia including squamous cell carcinoma and sarcoids in equine patients. A recent retrospective case series study demonstrated that implantation of cisplatin beads into cutaneous neoplasia was an effective method of treatment for these tumors. Implantation of commercially available beads is less time consuming and safer than intralesional injection of cytotoxic agents suspended in fixed oils.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: Matrix III Cisplatin Beads: 1.6 mg per 3 mm bead; 3 beads per packet; (Royer Biomedical, Inc.), (Rx) At the time of writing was being considered for approval by FDA.

HUMAN-LABELED PRODUCTS: None

### 5-FLUOROURACIL

(flure-oh-yoor-a-sil)

#### Indications/Pharmacology/Suggested Dosage

5-fluorouracil is a potent cytotoxic chemotherapeutic agent used for the topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

1% solution applied to the affected eye three times daily. **Note:** Ingestion of fluorouracil products by dogs has resulted in significant toxicity and a high rate of mortality. All fluorouracil products should be kept well out of the reach of dogs.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None.

Must be compounded from the injectable product by an appropriately qualified compounding pharmacist in a biological safety cabinet approved for preparation of cytotoxic agents

### MITOMYCIN-C

(mye-toe-mye-sin)

#### Indications/Pharmacology

Mitomycin C is a potent cytotoxic chemotherapeutic agent used for topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

#### Suggested Doses/Precautions

0.4% solution applied initially followed by 0.04% solution applied topically three times daily for 21 days in a cycle of 7 days on followed by 7 days off. Caregivers should be counseled in proper handling of cytotoxic drugs and contact with biological waste from treated patients.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded from the injectable product by an appropriately trained compounding pharmacist in a biological safety cabinet approved for preparation of cytotoxic agents.

## Sympathomimetics

### HYDROXYAMPHETAMINE

(hye-drox-ee-am-fe-ta-meen)

#### Indications/Pharmacology

Hydroxyamphetamine is an indirectly acting alpha-agonist that is used to diagnose Cranial Nerve III denervation syndromes such as Horner's Syndrome. Hydroxyamphetamine stimulates release of norepinephrine from postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denerved neurons.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately qualified compounding pharmacist.

### COCAINE

(koe-kane)

#### Indications/Pharmacology

Cocaine is an indirectly acting sympathomimetic which is used to diagnose Cranial Nerve III denervation syndromes such as Horner's Syndrome. Cocaine prevents reuptake of norepinephrine into postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denerved neurons. Adrenergic agonist activity of cocaine prevents norepinephrine reuptake allowing maintenance of sympathetic stimulation, so it does not localize lesions but confirms diagnosis of sympathetic denervation syndromes.

#### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately qualified compounding pharmacist.

## Anticollagenase Agents

### ACETYLCYSTEINE

(a-se-teel-sis-teen)

#### Indications/Pharmacology

Acetylcysteine is a mucolytic agent that is also used to stop the melting effect of collagenases and proteases on the cornea. Acetylcysteine is useful in halting melting through inhibition of metalloproteinases, but is not felt to be useful for melting caused by infectious agents.

### Suggested Dosages/Precautions/Adverse Effects

Acetylcysteine 5% solution is dosed 1 drop in the affected eye every 1–2 hours for the first 24 hours and then 3–4 times daily for the next 7–10 days. Acetylcysteine solutions are diluted with artificial tears to a final concentration of 5% prior to administration as commercially available solutions of 10% and 20% are topically irritating. Acetylcysteine possesses a foul, sulfur-like smell and owners should be informed that this foul odor does not indicate drug deterioration. Acetylcysteine is unstable at room temperature and solutions should be refrigerated.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None; *Mucomyst*<sup>®</sup> 10% and 20% solution for inhalation may be used to compound a 5% solution in artificial tears.

### EDETATE DISODIUM

(ed-a-tayt)

### Indications/Pharmacology

Edetate Disodium (Sodium EDTA) is a chelating agent that is also used to stop the melting effect of collagenases and proteases on the cornea. EDTA is useful in halting melting through inhibition of matrix metalloproteinases, but is not felt to be useful for melting caused by infectious agents. As the effect of EDTA on metalloproteinases is reversible, it must be administered several times daily to be effective.

### Suggested Dosages/Precautions/Adverse Effects

0.05%-1% solution applied as 1 drop in the affected eye several times daily.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

EDTA solutions must be compounded by an appropriately qualified compounding pharmacist.

### Fibrinolytics/Antifibrinolytic Agents, Ocular

Fibrin clot formation results from activation of the clotting cascade in an effort to control hemorrhage. Intraocular fibrin formation can result in complications (synechia formation, pupillary seclusion, occlusion of gonioimplants, formation of traction bands) that compromise ocular integrity and vision, so lysis of the clot before these complications occur is essential. Agents developed for fibrinolysis in humans include urokinase, streptokinase and tissue plasminogen activator (tPA). At the time of writing, tPA is the only fibrinolytic commercially available for intraocular use.

Antifibrinolytic agents can be useful to inhibit the breakdown of fibrin clots when control of intraocular bleeding is desired. These agents are used particularly as antidotes following overdosage of fibrinolytics.

### Fibrinolytic Agents

### TISSUE PLASMINOGEN ACTIVATOR (tPA)

(tiss-u plaz-men-o-jen ak-tiv-ate-or)

### Indications/Pharmacology

Recombinant human tPA is a fibrinolytic agent that is injected by the intracameral route to achieve lysis of intraocular clots. Intracameral injection of tPA in humans following cataract removal in doses of 10 micrograms dissolved fibrin clots, reduced posterior synechiae, and did not result in any re-bleeding (Heiligenhaus *et al.* 1998). Topical application of tPA to dogs does not result in therapeutic aqueous humor concentrations (Gerding *et al.* 1994). Intracameral injection of 25 micrograms of tPA caused fibrinolysis without corneal toxicity in dogs and cats, while doses of 50 micrograms have led to corneal endothelial toxicity (Gerding *et al.* 1992; Hrach *et al.* 2000).

### Suggested Dosages/Precautions/Adverse Effects

Tissue Plasminogen Activator, reconstituted to 250 micrograms/mL is injected intracamerally at 0.1 mL per dose. Adverse effects include repeat bleeding and profound hypotonia and corneal epithelium toxicity at doses equal to or greater than 50 micrograms.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Tissue Plasminogen Activator Lyophilized Powder for Injection: 2 mg, 50 mg, 100 mg, *Activase*<sup>®</sup> (Genentech); (Rx)

### References

### Antifibrinolytic Agents

### AMINOCAPROIC ACID

(a-mee-no-ka-pro-ik-ass-id)

### Indications/Pharmacology

Aminocaproic acid may be administered systemically or topically. Systemic administration significantly decreases intraocular re-bleeding episodes, but side effects can be severe and include nausea, dizziness, hypotension, and thrombosis of retinal vessels. Topical administration achieves therapeutic concentrations in aqueous humor in rabbits and humans, but clinical antifibrinolytic efficacy by this route is variable. Aminocaproic acid has also been used in patients with persistent corneal ulceration in order to maintain Fibronectin in the wound promoting re-epithelialization (Regnier *et al.* 2005).

### Suggested Dosages/Precautions/Adverse Effects

If administered topically, aminocaproic acid is compounded in a concentration of 30% in 2% carboxypolymethylene gel.

### Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Aminocaproic acid 30% solution in 2% carboxypolymethylene gel may be compounded by an appropriately qualified compounding pharmacist.

### References

- Regnier, A., G. Chabot, *et al.* (2005). Topical treatment of non-healing corneal epithelial ulcers in dogs with aminocaproic acid. *Veterinary Record* 157(17):510–513.

## Principles of Compounding Ophthalmic Products

GIGI DAVIDSON, DICVP

### Physiochemical Considerations for Compounding Ophthalmic Preparations

The availability of suitable commercially available products for every veterinary ophthalmic indication is highly unlikely. Many agents used in veterinary ophthalmology are no longer or never were commercially available.

Examples of agents that are commonly used by veterinarians but are no longer commercially available currently include oxytetracycline ophthalmic ointment, idoxuridine ophthalmic solution and ointment, miconazole solution, vidarabine ophthalmic solution, trifluridine ophthalmic solution, tetracycline ophthalmic solution, rose bengal solution, and chloramphenicol ophthalmic ointment. Even if commercially available, products may be of inappropriate concentration to achieve a therapeutic effect in a given patient (e.g., cyclosporine A) or may have agents and excipients that have adverse effects in animal patients (e.g., neomycin sulfate in cats). In other cases, no product is commercially available and must be compounded from other non-ophthalmic drugs or from bulk chemicals (e.g., acetylcysteine ophthalmic solution and disodium edetate ophthalmic solution). For these reasons, pharmacists are frequently called upon to compound products to be used in the animal eye. These products may be administered topically in the form of solutions, suspensions or ointments, by periocular or intraocular injection, by drug-implanted collagen shields, or by drug-impregnated disposable contact lens delivery systems. The quality and sterility of these products is critical. To ensure adequate stability, uniformity, and sterility, both the American Society of Health-Systems Pharmacists and the United States Pharmacopoeial (USP) Convention have published guidelines for pharmacy-prepared ophthalmic products. These guidelines address the following areas of concern.

#### Validation of Formulation:

Before compounding any product for ophthalmic use, the pharmacist should obtain documentation that substantiates the stability, safety and benefit of the requested formulation. Pharmacists may call the manufacturer of the drug, refer to primary literature, call regional eye centers, or call professional compounding organizations to obtain such information. If no such documentation is available, the pharmacist must employ professional judgment in determining a suitable formulation for ophthalmic administration. Factors to consider when making this judgment include: sterility, tonicity, pH and buffering, toxicity of the drug, need for preservatives, solubility, stability in the chosen vehicle, viscosity, packaging, and any precautions necessary to keep drug residues from occurring in any food-producing animals.

#### Documentation:

A written procedure for each ophthalmic product compounded should be recorded and kept in a readily retrievable place. This master formulation sheet should indicate the name of the product, the dosage form, the specifications and source of each ingredient used, the weights and measures of each ingredient used, the equipment required, a complete description of each step in the compounding process with special notation of aseptic techniques utilized and which method of terminal sterilization is appropriate, beyond-use dating, storage requirements, specific packaging requirements, sample label and auxiliary labeling, quality control testing performed, and references for formula. Production records for each batch should include the date of compounding, lot or batch number assigned, the manufacturer and lot number and expiration date of each ingredient used, a sign-off provision for compounder and checker, the amount compounded, and the projected beyond-use date for the batch compounded.

#### Sterility:

Ophthalmic dosage forms must be compounded in aseptic conditions. Sterile Compounding Guidelines should be consulted in the United States Pharmacopeia General Chapter <797>. Sterility is the most important consideration for ophthalmic products. Contaminated ophthalmic products can result in eye infections leading to blindness or even loss of the eye, especially if pathogens such as *Pseudomonas* are present. Eye infections from contamination can also lead to systemic infections requiring hospitalization and may even result in death. All ophthalmics should be compounded in a laminar flow hood that has undergone annual checkups and certification of acceptable performance. It is also important to note that the laminar flow hood does not guarantee sterility. The compounding pharmacist must also use impeccable aseptic technique when handling products intended for use in the eye. All products must be rendered sterile after formulation in the laminar flow hood. Sterilization of the final product is most easily achieved through filtration through 0.2µm filters, which also remove particulate matter. This method is obviously only suitable for ophthalmic solutions. Ophthalmic suspensions and ointments must be sterilized by other means to avoid filtering out active drug. Other methods of sterilization available to the pharmacist include dry heat, autoclaving, and ethylene oxide gas sterilization. Gamma radiation is also commercially available for bulk sterilization, but is very expensive. Preservatives may also be added to prevent bacterial growth, especially if the container is intended for multiple use. The preservative selected must be compatible with the active drug and excipients as well as non-toxic to the eye or to the patient. A description of commonly used ophthalmic preservatives and maximal concentrations is provided in [Table 1](#).

**Table 1. Agents used for preserving ophthalmic products.**

Agent	Maximum concentration (%)*
Benzalkonium chloride	0.01
Benzethonium chloride	0.01
Phenylmercuric acetate	0.004
Phenylmercuric nitrate	0.004
Methylparaben	0.2
Propylparaben	0.04
Thimerosal	0.01
Chlorobutanol	0.5

\*As recommended by FDA Advisory Review Panel on OTC Ophthalmic Drug Products

#### Clarity:

Drugs prepared as ophthalmic solutions should be free from foreign particles. This can be accomplished through filtration with a 0.45µm filter needle attached to a sterile syringe, or through the use of clarifying agents such as polysorbate 20 (maximum of 1%) and polysorbate 80 (maximum of 1%). Drugs prepared as ophthalmic suspensions, obviously cannot be filtered, but must be of a particle size that does not irritate or scratch the cornea. A micronized form of the drug is required. The use of an ointment mill is highly recommended to decrease particle size for ophthalmic ointments.

#### Tonicity:

Ophthalmic products do not need to be isotonic if the contact time with the cornea is only for a few minutes. The eye can tolerate a range of 200–600 mOsm/L for short periods of time. For ointments, irrigations and products that will remain in contact with the eye longer than a few minutes, isotonic products should be used. Hypotonic agents may cause corneal edema and hypertonic agents may dehydrate the cornea and cause pain. Tear fluid and normal saline have identical osmotic pressures making 0.9% sodium chloride an excellent vehicle for ophthalmic products. For products that are hypotonic, sodium chloride equivalencies can be used to determine how much sodium chloride to render the product isotonic.

#### Buffering and pH:

Ophthalmic preparations are generally buffered in a range from 4.5–11.5. Buffering is necessary to provide maximal stability of the drug or for comfort and safety of the patient. Alkaloids such as atropine and pilocarpine are usually buffered. If the activity and stability of the drug are not pH dependent, and the pH of the product is not irritating, then buffers may be omitted from the formulation. Commonly used buffers for ophthalmic preparations include Palitzsch buffer, boric acid buffer, boric acid/sodium borate buffer, sodium acetate/boric acid buffer, Sorensen's modified phosphate buffer, Atkins and Pantin buffer solution, Feldman buffer, and Gilford ophthalmic buffer. Formulations for these solutions and ratios required to achieve a desired pH are referenced in the International Journal of Pharmaceutical Compounding, Vol. 2, No. 3 May/June 1998.

#### Viscosity Enhancers:

Because tears and blinking reflexes reduce the total amount of drug available for penetration, an increase in residence time in the eye will increase drug absorption. Increasing the viscosity of the drug is the most common way to prolong contact time. Methylcellulose is the most commonly used agent and is generally formulated at a concentration of 0.25%. Hydroxypropylmethylcellulose is used in concentrations of 0.5–1%. Polyvinyl alcohol has also been used in concentrations of 0.5–1% w/v. Agents used to increase the viscosity of ophthalmic products are shown in [Table 2](#).

**Table 2. Agents used to increase viscosity of ophthalmic solutions and suspensions.**

Agent	Maximum Concentration (%)
Hydroxyethylcellulose	0.8
Hydroxypropylmethylcellulose	1.0
Methylcellulose	2.0
Polyvinyl alcohol	1.5
Polyvinylpyrrolidone	1.7

#### Quality Control:

Finished products should be thoroughly inspected visually for clarity and uniformity of suspension. The pH of the final product should always be checked and the value recorded on the master formula record for that batch. Most compounded products should have a pH of 5–7 unless otherwise indicated for stability or penetration of ocular tissue. Practitioners compounding large volumes of ophthalmic products should periodically perform testing to ensure sterility. Various agencies provide this service. The nearest college of pharmacy can be consulted for a list of providers of this service.

**Packaging:**

Ophthalmic preparations should be packaged in sterile dropper bottles (glass or plastic), or individual doses can be placed in sterile syringes with sterile tip caps. Ointments should be packaged in sterile ointment tubes and heat-sealed.

**Beyond Use Dating:**

The USP/NF standards for preparation of ophthalmic medications indicate that, unless otherwise documented, the beyond-use date for water containing formulations is 14 days. For non-aqueous liquids, the recommendation is not more than 25% of the time remaining until the expiration date of the starting product or six months, whichever is earlier. For all other products, the expiration dating should be the duration of therapy or 30 days whichever is shorter. These beyond-use recommendations can be extended in the face of supporting, valid, scientifically conducted stability information.

**Considerations for use of ophthalmics in veterinary patients:**

Veterinary patients experience many of the same ophthalmic diseases and conditions as humans, and treatments are often based on human therapy. Animals, however, have a variety of species-related characteristics that might cause human-designed therapies to fail or be toxic. Behavioral characteristics such as grooming may significantly reduce the contact time of ophthalmic agents with the eye, and increase systemic exposure through ingestion. Anatomical differences such as size must be considered. Horses and other large animals may simply elevate their eyes out of a caregiver’s reach if ophthalmic treatments are objectionable. Specialized delivery devices have been created to treat these patients. Subcutaneous palpebral lavage systems are tunneled under the skin over the animal’s brow and allow for passage of medication through long catheters that are easily reachable by caregivers. Food-producing animals require special consideration. Systemic absorption of ophthalmic agents in food-producing animals could result in violative drug residues in food intended for human consumption.

**General Principles of Ocular Penetration**

**Corneal penetration:**

Drugs must generally be administered topically to treat corneal and intraocular conditions. While the eye would appear to be an easy target for topical administration, the eye has several anatomical barriers to prevent penetration by foreign substances. Instantaneous tear production, strong blinking reflexes, and alternating layers of lipophilic and hydrophilic tissue all work in conjunction to prevent entry of foreign substances. The clear tissue known as the cornea covers the visible outer surface of the eye between the lids. The cornea must be clear in order to allow for vision, and nature has accomplished this by omitting blood vessels in the cornea. Because of this lack of vascular tissue, systemically administered drugs do not penetrate into the cornea. The cornea is composed of several layers of lipophilic (outer layers) and hydrophilic (inner layer) tissue. For a topically administered drug to fully penetrate the cornea, the drug must be able to exist in ready equilibrium between both ionized and non-ionized forms (e.g., chloramphenicol, atropine, and pilocarpine). Most antibiotics are water-soluble and will not penetrate the lipophilic outer layer of the cornea unless ulcers are present. Small molecular weight (<350) and high local concentration of drugs will also increase penetration even if the drugs are ionized and hydrophilic. Topical administration is ideal as it allows for very high local concentrations of drug on the cornea. For a topically administered drug to reach the anterior chamber and bind to intraocular structures (e.g., ciliary body, iris, aqueous humor), the drug must pass through the cornea. Drugs may also reach the anterior chamber to some extent by passive absorption through the conjunctiva.

Key points for corneal penetration of drugs:

- lipophilic
- equilibrium between ionized and non-ionized forms
- small molecular weight (<350)
- high local concentrations

**Intravitreal Penetration:**

Topically administered drugs reach the vitreous only in very small concentrations. To treat severe conditions of the anterior chamber (uveitis) as well as intravitreal conditions, drugs must be administered by periocular or intraocular injection. The periocular routes include subconjunctival injection and sub-Tenon’s membrane injection while the intraocular routes are intracameral injection (directly into the aqueous humor) or intravitreal injection (directly into the vitreous humor). Periocular injections can be administered under sedation and topical anesthesia. Intraocular injections are usually only performed in the operating room while the patient is completely anesthetized. These routes bypass the outermost chemical and physical ocular defenses and allow for better concentration of drug in the vitreous. The volume of administration for these routes is relatively small. Periocular injections should not exceed 0.5–1.0 mL in small animals and 2 mL in large animals. Intraocular injections should not exceed 0.1 mL in small animals and 0.25 mL in large animals due to the risk in increasing intraocular pressure. Drugs injected into the eye should be free of preservatives and buffers.

**Route of Therapy for Given Ocular Target:**

Tissue	Routes of Administration
Eyelids	Topical, systemic
Corneal surface	Topical
Anterior segment	Topical if good penetration or mild disease Systemic if poor penetration or severe disease
Posterior segment	Systemic or intraocular injection (rarely)
Any site where multiple dosing is impractical	Subconjunctival depot injection

**Questions to Ponder Prior to Compounding Ophthalmic Products:**

1. Where is the target of therapy? (eyelids, corneal surface, cornea, anterior segment, posterior segment)
2. What is the character of the drug?
  - Lipophilic? Hydrophilic?
  - What is the molecular weight?
  - What is the inherent toxicity of the drug to the eye (gentamicin)? To the caregiver (chloramphenicol); to the patient (neomycin sulfate in cats)?
  - Is there data to support what concentration is necessary for corneal penetration?
  - Is the drug soluble in a vehicle that is not toxic to the eye?
  - If not soluble, will the particle size of the suspension or the ointment scratch the corneal or conjunctiva?
  - What is the pH of the final product? Is this in an acceptable range to avoid irritation (4.5–11.5)?
  - What is the tonicity of the final product? Hypertonic? Hypotonic? How long will the product be in contact with the cornea if not isotonic?
  - Will the viscosity need to be enhanced in order to prolong contact with the eye? Which agent is compatible?
  - What is the duration of therapy? Will the product require preservation if long term multiple use? Which preservative is compatible?

**Dermatological Agents, Topical**

The following section lists many of the active ingredients and corresponding preparations used topically for their local action in veterinary medicine. It includes both veterinary-labeled dermatological products and some potentially useful human-labeled products. Active ingredients are listed by therapeutic class. The drug sponsor, availability and formulation of these products tend to change rapidly in the marketplace so this listing should be used as a basic guide.

Products that are applied topically, but are absorbed systemically and used primarily for their systemic effects are found in the general monograph section. For veterinary products, refer to the complete label for additional information.

Portions of this section are adapted from: Koch, Torres, & Plumb. (2011). *Canine and Feline Dermatology Drug Handbook*. IN PRESS. Wiley-Blackwell. This reference provides additional detail on these, and other compounds and products.

**Note:** While many of these products do not legally require a prescription (OTC), they are often marketed as “Sold only through licensed veterinarians” or “Sold by professionals only.”

**Antipruritics/Antiinflammatories, Topical  
Non-Corticosteroids**

**ALUMINUM ACETATE SOLUTION (BUROW'S SOLUTION OR MODIFIED BUROW'S SOLUTION)**

(ah-loo-mi-num ass-ih-tate)

For otic use, refer to the Otics section

**Indications/Actions**

An astringent antipruritic agent, aluminum acetate solution (Buwrow's solution, modified Buwrow's solution) can be useful for adjunctive treatment of minor skin irritations such as insect bites, and localized inflamed and exudative skin conditions, including acute moist dermatitis, fold dermatitis (intertrigo) and contact dermatitis. It can also be used for the treatment of otitis externa (see Otics section).

In addition to Buwrow's solution's astringent and antipruritic actions, it also has acidifying effects and it mildly antiseptic. The exact mechanisms of action for these effects are not fully understood.

**Suggested Dosages/Use**

Topical use of Buwrow's solution (alone) is usually as a wet compress, dressing or soak. Application for 15–30 minutes is generally recommended and the affected area is air-dried between applications. Use can be as often as necessary, but every 4–6 hours is often employed. The veterinary-labeled products containing hydrocortisone may be directly applied. As Buwrow's solution products come in various dosage forms (powder or tablets for dissolving, liquid); refer to package directions for proper dilutions. Dilutions of 1:40, 1:20, or 1:10 are commonly used.

**Precautions/Adverse Effects**

Do not use plastic or any occlusive dressing material to prevent evaporation. Use room temperature water for dissolving and application. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Buwrow's solution may cause dry skin or skin irritation on some patients.

**Veterinary-Labeled Aluminum Acetate Solution Products**

Product (Company)	Form: Concentration All contain: Hydrocortisone 1%; Aluminum Acetate 2%	Label Status	Other Ingredients; Comments; Size(s)
<b>Cort/Astrin Solution</b> <sup>®</sup> (Vedco)	Solution	OTC	1 oz. dropper btl, 16 oz.
<b>Corti-Derm Solution</b> <sup>®</sup> (First Priority)	Solution	OTC	1 oz.
<b>Hydro-Plus</b> <sup>®</sup> (Phoenix)	Solution	OTC	1, 2, 16 oz.
<b>Bur-O-Cort 2:1</b> <sup>®</sup> (Q.A. Labs)	Solution	OTC	1, 16 oz.
<b>Hydro-B 1020</b> <sup>®</sup> (Butler)	Solution	OTC	1, 2, 16 oz.

**Human-Labeled Aluminum Acetate Solution Products**

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Domeboro Powder</b> <sup>®</sup> (Bayer)	Powder Packets: Aluminum sulfate and Calcium acetate	OTC (Human)	Packets of 12 or 100/box. One packet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Buwrow's sol.
<b>Pedi-Boro Soak Paks</b> <sup>®</sup> (Pedinol)	Powder Packets: Aluminum sulfate and Calcium acetate 2.7 g	OTC (Human)	Packets of 12 or 100/box. One packet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Buwrow's sol.
<b>Domeboro Tablets</b> <sup>®</sup> (Bayer)	Effervescent Tablets: Aluminum sulfate and Calcium acetate	OTC (Human)	Tablets of 12 or 100/box. One tablet dissolved in 16 oz (480 mL) of water makes a 1:40 (2.5%) modified Buwrow's sol.
<b>Buwrow's Solution</b> (various)	Solution: Aluminum acetate (Buwrow's)	OTC (Human)	480 mL bottles

**COLLOIDAL OATMEAL**

(ko-lay-d-al ote-meel)

**Indications/Actions**

Colloidal oatmeal is used topically as an antiinflammatory and antipruritic, but an exact mechanism for this effect is not known. It is thought that as the concentration of oatmeal increases, both its drying and antipruritic effects increase; it has been suggested that it may inhibit prostaglandin synthesis.

**Suggested Dosages/Use**

Spray can be used 2–3 times per day as needed for itching or pain. Shampoo or conditioner is usually used once a day to once a week. Shampoo should be in contact with skin for at least 10 minutes and then rinsed well. Refer to each product's label for further details.

**Precautions/Adverse Effects**

Other than the potential for increased drying of already dry skin, colloidal oatmeal is very safe. In humans, there are some reports of contact dermatitis associated with its use.

**Veterinary-Labeled Colloidal Oatmeal Products**

**Note:** Products listed are those containing only colloidal oatmeal as the principle active ingredient. For other products that contain colloidal oatmeal, see [Diphenhydramine](#), [Pramoxine](#), [Hydrocortisone](#), [Permethrin](#), or [Pyrethrins](#) listings.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Dermallay<sup>®</sup> Oatmeal Spray</b> (Dechra)	Leave-On Spray; 0.75%	OTC	12 oz; 1 gal
<b>Dermallay<sup>®</sup> Conditioner</b> (Dechra)	Conditioner; 0.75%	OTC	8 oz; 1 gal
<b>Epi-Soothe<sup>®</sup> Cream Rinse</b> (Virbac)	Cream Rinse; 1%	OTC	Lactic acid. 8, 16 oz; 1 gal
<b>ResiSoothe<sup>®</sup> Leave-On Lotion</b> (Virbac)	Lotion; % not listed	OTC	Sunflower oil (omega 6 FA's), vitamin E. 8 oz. Shake well.
<b>Aloe &amp; Oatmeal Skin and Coat Conditioner<sup>®</sup></b> (Vet Solutions, Vetoquinol)	Conditioner; % not listed	OTC	Aloe vera gel, vitamins A, D & E, chamomile. 16 oz; 1 gal.
<b>Dermallay<sup>®</sup> Oatmeal Shampoo</b> (Dechra)	Shampoo; 2%	OTC	12 oz; 1 gal
<b>Epi-Soothe<sup>®</sup> Shampoo</b> (Virbac)	Shampoo; 2%	OTC	Chitosanide, glycerin. Ingredients in free form and in Spherulites <sup>®</sup> . 8, 16 oz; 1 gal
<b>Cortisoothe Shampoo<sup>®</sup></b> (Virbac)	Shampoo: Colloidal Oatmeal % not listed; Hydrocortisone 1%	Rx	8, 16 oz Labeled for dogs and cats.
<b>Hartz Soothing Botanicals Skin Moisturizing Shampoo<sup>®</sup></b> (Hartz Mountain)	Shampoo; % not listed	OTC	Aloe vera. 15 oz

<b>Hartz Groomer's Best Oatmeal Shampoo*</b> (Hartz Mountain)	Shampoo: % not listed	Rx	18 oz
<b>Aloe &amp; Oatmeal Shampoo*</b> (Sogeval, Vet Solutions, Vetoquinol)	Shampoo: % not listed	Rx	Aloe vera. 16 oz; 1 gal.
<b>Foaming Silk Bath*</b> (AAH)	Shampoo: % not listed	Rx	Aloe vera, vitamins A & E. 16 oz

### Human-Labeled Colloidal Oatmeal Products

**Note:** There are several human products available containing colloidal oatmeal, including creams, lotions and products to be added to the bath. Common trade names include: *Aveeno*®, *Geri SS*®, and *Actibath*®.

### ESSENTIAL FATTY ACIDS, TOPICAL

For systemic use of essential fatty acids, refer to the *Fatty Acids, Essential monograph found in the main section.*

### Indications/Actions

Essential fatty acids are indicated primarily for pruritic and inflammatory conditions such as atopic dermatitis and sebaceous adenitis, and keratinization disorders such as seborrhea. They may also be used to improve coat quality and ameliorate dry skin. Some of these products may contain other active ingredients, including other natural oils, which may have other adjunctive indications.

The exact mechanism of action of essential fatty acids is not well understood. However, essential fatty acids affect the arachadonic acid levels in plasma lipids and platelet membranes. They affect production of inflammatory prostaglandins in the body, thereby reducing inflammation and pruritus. Essential oils may also play a role in restoring the skin barrier.

### Suggested Uses/Dosages

If using spray: up to 2–3 times applications a day or as needed. If spot-on: treatment may vary from weekly to every 2 weeks or monthly. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

### Precautions/Adverse Effects

No specific precautions or adverse effects are described for these products.

### Veterinary-Labeled Topical Essential Fatty Acids Products

Product (Company)	Form: Concentration	Label Status	Ingredients; Comments; Size(s)
<b>Dermoscent® Atop7</b> (Animal Dermo-Care)	Spray	OTC	Capparis spinosa extract, essential fatty acids from hemp and neem, essential oils of cajputi and melaleuca. Indicated for itchy or allergy prone skin. Labeled for dogs. 75 mL
<b>Dermoscent® Cicafolla</b> (Animal Dermo-Care)	Spray	OTC	Cajputi essential oil and Amazonian Croton lechleri sap extract, peptides, Margosa's essential fatty acids, gamma oryzanol and silicon. Labeled for dogs and cats. 30 mL
<b>HyLyt® EFA Bath Oil</b> (DVM)	Spray	OTC	Omega 6 fatty acids. Labeled for dogs and cats. 8 oz
<b>Dermoscent® Essential 6 Spot-On</b> (Animal Dermo-Care)	Spot on	OTC	Essential oils of rosemary, lavender, melaleuca, cedar, oregano, essential fatty acids from hemp grain and neem, vitamin E. Labeled for dogs and cats. Pipettes of 0.4, 0.6, 1.2, & 2.4 mL depending package labeling.
<b>Dermoscent® Essential Mousse</b> (Animal Dermo-Care)	Mousse	OTC	Oils and polyunsaturated fatty acids as well as soothing Cucurbitine®. Soap free. Labeled for dogs and cats. 150 mL.
<b>HyLyt® EFA Shampoo</b> (DVM)	Shampoo	OTC	Omega 6 fatty acids. Soap free. Labeled for dogs and cats. 8, 12 (spray) oz; 1 gal.
<b>Dermoscent® EFA Treatment Shampoo</b> (Animal Dermo-Care)	Shampoo	OTC	Essential fatty acids from hemp grain, Cucurbitine (lichen plant extract), Niaouli essential oil. Soap free. Labeled for dogs and cats. 200 mL.
<b>DermaLyt® Shampoo</b> (Dechra)	Shampoo	OTC	Omega 6 fatty acids, Vitamin E, Coconut oil. Soap free. 1 oz pouch, 12 oz; 1 gal.
<b>Hyliderm® Shampoo</b> (Sogeval)	Shampoo	OTC	Omega 6 fatty acids. Soap free. Labeled for dogs and cats. 2, 8, 16 oz; 1 gal.
<b>Allermyl® Shampoo</b> (Virbac)	Shampoo	OTC	Omega 6 fatty acids (linoleic acid), Ceramides 1, 3 and 6, Cholesterol, L-thiamine, D-mannose, D-galactose; polysaccharide: alkyl polyglucoside. Fragrance free. Indicated for control of pruritus, specifically labeled for management of allergic skin conditions in dogs and cats. Also has skin barrier restoring properties. 8, 16 oz
<b>Allerderm Spot-on*</b> (Virbac)	Spot-on	OTC	Free fatty acids, Ceramides 1, 3 and 6, Cholesterol. Indicated specifically for allergic dermatitis, contact allergies, keratinization disorders and chronic microbial infections. May also be used for the treatment of sebaceous adenitis. 2 mL, 4 mL.
<b>HyLyt® EFA Crème Rinse</b> (DVM)	Crème Rinse	OTC	Labeled for dogs and cats. 8 oz; 1 gal.

### Human-Labeled Topical Essential Fatty Acids Products

**Note:** Several human over-the-counter products are available in the USA but may contain other ingredients. They are generally not used in dogs and cats.

### DIPHENHYDRAMINE HCL, TOPICAL

(dye-fen-hye-dra-meen) Benadryl®

For systemic use, see the monograph found in the main section

### Indications/Actions

A first generation antihistamine, diphenhydramine has some local anesthetic activity that probably is its main antipruritic mechanism of action. Diphenhydramine may be absorbed in small amounts transdermally, but should not cause systemic side effects.

### Suggested Dosages/Use

Topical creams, gels, lotion or sprays are usually applied 2–3 times a day. The shampoos and conditioners are generally used once a day to once a week after bathing. Shampoos should remain in contact with skin for at least 10 minutes prior to rinsing.

### Precautions/Adverse Effects

Avoid contact with eyes or mucous membranes. Do not apply to blistered or oozing areas of skin. Clients should wash hands after application or wear gloves when applying.

Prolonged use could potentially cause local irritation and/or hypersensitization. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>ResiHist® Leave-On Lotion</b> (Virbac)	Lotion: 2%	Rx	Water, cetyl alcohol base. 8 oz Labeled for use on dogs and cats

### Human-Labeled Topical Diphenhydramine Products

Product (Company)	Forms: Concentration	Label Status	Other Ingredients; Comments; Size(s)
Products include: <b>Benadryl®</b> , <b>Dermamycin®</b> , <b>Dermarest®</b> , <b>Ziradryl®</b> (various manufacturers and additional trade name modifiers such as Maximum Strength, etc may be found)	Spray: 1%, 2% Lotion: 0.5%, 1% Gel: 1%, 2% Cream 1%, 2%, 4%	OTC (Human)	These products may also contain astringents (calamine, zinc oxide or acetate), other antihistamines (pyrilamine, tripelemamine), and/or counter irritants (menthol, camphor)

### LIDOCAINE, TOPICAL

#### LIDOCAINE/PRILOCAINE (EMLA CREAM)

(*lye-doe-kane; pry-loe-kane*)

For systemic use of [lidocaine](#), see the monograph found in the main section

### Indications/Actions

Lidocaine is used topically as a dermal anesthetic or antipruritic and is included in several products used for acute moist dermatitis, pruritic lesions, or painful skin conditions. When combined with prilocaine (commonly called EMLA cream), it may be useful for dermal anesthesia prior to painful or invasive procedures (e.g., catheter placement, etc).

Lidocaine exerts its anesthetic properties via alteration of cell membrane ion permeability, thereby inhibiting conduction from sensory nerves.

### Suggested Dosages/Use

Thin layers can be applied every 3-4 hours as needed.

### Precautions/Adverse Effects

Topical lidocaine may be absorbed systemically, but systemic toxicity is unlikely to occur unless used on a significant percentage of body area, for prolonged times or at high concentrations. Be extra vigilant in patients also receiving Class-I antiarrhythmics (e.g., lidocaine, mexiletine). Avoid contact with eyes and do not use in ears, unless specifically labeled for such. Clients should wash hands after application or wear gloves when applying.

Hypersensitivity reactions or skin irritation (burning, tenderness, etc.) are possible, but apparently do not occur commonly. Products containing prilocaine (EMLA) may be more likely to cause methemoglobinemia or systemic toxicity, but these occur rarely.

### Veterinary-Labeled Topical Lidocaine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Allercaïne®</b> (Tomlyn)	Spray: 2.4%	OTC	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%. Do not apply to entire body or to large areas of broken skin. 4, 12 oz.
<b>Allerspray®</b> (Vetoquinol)	Spray: 2.4%	OTC	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%, aloe vera gel, allantoin, PEG-75 lanolin. 4 oz.
<b>Dermacool w/ Lidocaine Spray®</b> (Virbac)	Spray: 1.5%	OTC	Hamamelis extract, lactic acid, colloidal oatmeal, PCMX. 4 oz
<b>Hexa-Caine®</b> (PRN Pharmacal)	Spray: 2.4%	OTC	Denatonium benzoate (bittering agent), Benzalkonium Chloride 0.1%, aloe vera gel, allantoin, lanolin. 4, 8, 16 oz.
<b>Blocain®</b> (Tomlyn)	Lotion: 2%	OTC	<i>Bittran®</i> II (bittering agent), Benzalkonium Chloride 0.1%. 2, 4 oz.

### Human-Labeled Topical Lidocaine Products

There are also several topical OTC products listed for human use, including sprays (2–2.5%), liquids (2–4%), creams (0.5–2%), gels (0.5–2.5%) and topical patches.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>EMLA®</b> (Astra)	Cream: Lidocaine 2.5%; Lidocaine/Prilocaine Cream (Generic): Prilocaine 2.5%	Rx (Human)	Depending on manufacturer: 5, 15, 30 g. various)

### PHYTOSPHINGOSINE

(*fy-e-tos-fin-joe-seen*) DOUXO®

### Indications/Actions

The *Douxo® Calm* products containing phytosphingosine are labeled as indicated for localized and generalized inflammatory conditions that may be associated with pruritus including allergic diseases such as atopic dermatitis. *Douxo Gel®* is also indicated as a liquid wound dressing for localized inflammation and after surgery (can be sprayed on sutures). There are also products marketed for seborrheic conditions and an otic cleanser.

Phytosphingosine is a modified pro-ceramide with salicylic acid and a key molecule in the natural defense mechanism of the skin. Ceramides comprise 40-50% of the main lipids responsible for maintaining the cohesion of the stratum corneum, therefore; restoring the skin lipid barrier, controlling local flora (antibacterial and antifungal effects), and maintaining the correct moisture balance. It is also anti-inflammatory as it has anti-IL-1 activity, impairing the production of PGE2 and inhibits kinase protein C.

### Suggested Dosages/Use

If using spray or gel: up to 2–3 times a day as needed for itching/pain relief. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

### Precautions/Adverse Effects

Skin redness or irritation may occur.

### Veterinary-Labeled Phytosphingosine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>DOUXO® Calm Gel</b> (Sogeval)	Gel: 0.1%	OTC	Hinoktiol 0.2%, Raspberry seed oil, natural tocopherol, extract of creosote bush. 2 oz.
<b>DOUXO® Calm Micro-emulsion Spray</b> (Sogeval)	Spray: 0.05%	OTC	Hinoktiol 0.1%, Raspberry seed oil. 6.8 oz.
<b>DOUXO® Calm Shampoo</b> (Sogeval)	Shampoo: 0.05%	OTC	Hinoktiol 0.1%, Raspberry seed oil, allantoin, lipidure C. 6.8, 16.9 oz, 3L.
<b>DOUXO® Seborrhea Shampoo</b> (Sogeval)	Shampoo: 0.1%	OTC	Fomblin (stabilizer), cationic conditioners; 6.8 oz
<b>DOUXO® Chlorhexidine PS</b> (Sogeval)	Shampoo: Chlorhexidine 3% Phytosphingosine 0.05%	OTC	<i>Lipicid®</i> C8G; 6.8 oz
<b>DOUXO® Seborrhea MicroEmulsion Spray</b> (Sogeval)	Spray: 0.2%	OTC	Boswellia serrata extract, glycerin; 6.8 oz
<b>DOUXO® Seborrhea Spot-on</b>	Spot-on Solution: 1%	OTC	Transcutol (surface diffuser)

## Human-Labeled Phytosphingosine Products

**Note:** There are several over-the-counter human cosmetic products containing phytosphingosine in the USA. These products target mostly lipid barrier restoration and are generally not used in dogs and cats.

### PRAMOXINE HCL

(pra-moks-een)

#### Indications/Actions

Pramoxine is a surface and local anesthetic affecting peripheral nerves. It is not related structurally to procaine-type anesthetics. Pramoxine is often combined with other topical medications to reduce pain and/or itching. Precise mechanism of action is not known.

#### Suggested Dosages/Use

Depending on the product labeling, pramoxine 1% may be applied every 3–4 hours. Peak local anesthetic effects occur within 3–5 minutes of application. It provides only temporary effects. Shampoos are used once daily to once weekly and should remain in contact with the skin for at least 10 minutes prior to rinsing well.

#### Precautions/Adverse Effects

Avoid contact with eyes; pramoxine is too irritating for ophthalmic use. Depending on product labeling, clients should wash hands after application or wear gloves when applying. Adverse effects are unlikely, but localized dermatitis is possible.

#### Veterinary-Labeled Pramoxine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Micro-Pearls Advantage Dermal-Soothe<sup>®</sup></b> <b>Anti-Itch Spray</b> (Vetoquinol)	Spray: 1%	OTC	Lactamide monoethanolamine and Novasome <sup>®</sup> microvesicles. 12 oz. Shake well and repeat as necessary.
<b>Relief<sup>®</sup> Spray</b> (DVM)	Spray: 1%	OTC	Colloidal oatmeal. 8 oz. For dogs or cats.
<b>Relief<sup>®</sup> HC Spray</b> (DVM)	Spray: Hydrocortisone 1% Pramoxine 1%	Rx	Colloidal oatmeal. 8 oz.
<b>Pramoxine Anti-Itch<sup>®</sup> Spray</b> (Davis)	Spray: 1%	OTC	8 oz. For dogs or cats. Labeled for daily use or as directed by DVM
<b>Pramosoothe<sup>®</sup> HC Spray</b> (Sogeval)	Spray: Hydrocortisone 1% Pramoxine 1%	Rx	Colloidal oatmeal, essential fatty acids. 8 oz.
<b>Resiprox<sup>®</sup> Leave-On Lotion</b> (Virbac)	Lotion: 1.5%	Rx	Water, cetyl alcohol, stearyl alcohol base. 8 oz. Shake well. Use daily or as directed by DVM
<b>Micro-Pearls Advantage Dermal-Soothe<sup>®</sup></b> <b>Anti-Itch Shampoo</b> (Vetoquinol)	Shampoo: 1%	OTC	Colloidal Oatmeal, Novasome <sup>®</sup> microvesicles, Skin respiratory factor. 12 oz, 1 gal. Labeled for dogs, cats, horses.
<b>Pramoxine Anti-Itch<sup>®</sup> Shampoo</b> (Davis)	Shampoo: 1%	OTC	Colloidal oatmeal, emollients. 12 oz, 1 gal. Labeled for dogs, cats, puppies, kittens
<b>Relief<sup>®</sup> Shampoo</b> (DVM)	Shampoo: 1%	OTC	Colloidal oatmeal, Omega-6 FAs. 8, 12 oz, 1 gal.
<b>Micro-Pearls Advantage Dermal-Soothe<sup>®</sup></b> <b>Anti-Itch Cream Rinse</b> (Vetoquinol)	Rinse: 1%	OTC	Colloidal Oatmeal, Novasome <sup>®</sup> microvesicles, Skin respiratory factor. 12 oz, 1 gal. Labeled for dogs, cats, & horses.
<b>Pramoxine Anti-Itch<sup>®</sup> Creme Rinse</b> (Davis)	Rinse: 1%	OTC	Colloidal oatmeal, emollients, Omega-6 FAs. 12 oz, 1 gal. Labeled for dogs, cats, puppies, kittens
<b>Relief<sup>®</sup> Creme Rinse</b> (DVM)	Rinse: 1%	OTC	Colloidal oatmeal, emollients, Omega-6 FAs. 8, 12 oz, 1 gal.

#### Human-Labeled Pramoxine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>AmLactin<sup>®</sup> AP</b> (UpsherSmith)	Cream: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
<b>Prax<sup>®</sup></b> (Ferdale)	Lotion: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
<b>Tronothane<sup>®</sup></b> (Abbott)	Lotion: 1%	OTC (Human)	Usually used for extremely dry, painful or itchy skin in humans.
<b>Itch-X<sup>®</sup></b> (Ascher)	Spray: 1%	OTC (Human)	Benzyl alcohol 10%, aloe vera gel. 60 mL
<b>Itch-X<sup>®</sup></b> (Ascher)	Gel: 1%	OTC (Human)	Benzyl alcohol 10%, aloe vera gel. 35.4 g.
<b>PrameGel<sup>®</sup></b> (GenDerm)	Gel: 1%	OTC (Human)	0.5% menthol, emollient base, benzyl alcohol. 118 g.

### PHENOL/MENTHOL/CAMPHOR

(fee-nol; men-thol; kam-for)

#### Indications/Actions

When used in low concentrations, these agents can be used as counterirritants and may be added to proprietary or compounded products primarily as antipruritics. Camphor and phenol may also have some antiseptic properties.

#### Precautions/Adverse Effects

These compounds may cause local irritation and should not be used around, or in eyes. Products containing phenol should not be used on cats.

#### Veterinary-Labeled Phenol, Menthol, or Camphor Products

**Note:** There are also several over the counter products not listed containing menthol, phenol or camphor used primarily on equine patients for overexertion, soreness, or stiffness. These include a variety of liniments (e.g., white liniment, Choate's liniment) or gels (e.g., *Cool Gel*<sup>®</sup>, *Ice-O-Gel*<sup>®</sup>, *Shin-O-Gel*<sup>®</sup>, etc.).

Product (Company)	Form/Concentration	Label Status	Other Ingredients; Size(s)
<b>Scarlet Oil Pump Spray</b> (Dominion)	Spray: Menthol, Phenol, Oil of Camphor, Oil of Eucalyptus & Oil of Pine each at 7.5mg/mL; Oil of Thyme 2.8mg/mL; Peru Balsam 1.5mg/mL; Biebrich Scarlet Red 100 ppm.	OTC	Labeled for superficial cuts, wounds, bumps, etc. for horses and mules. Shake well, 500 mL.

### ZINC GLUCONATE (NEUTRALIZED), TOPICAL

For otic use, refer to the Otics section.

#### Indications/Actions

Can be used alone for mild itching or as adjunctive treatment for more serious pruritic conditions, mild bacterial infections, or dry skin. It can be used for minor skin irritations such as insect bite reactions, acute moist dermatitis, acral lick dermatitis, fold dermatitis (intertrigo), feline acne and post surgery wounds.

Exact mechanism of action is unknown. Zinc plays a role in extra-cellular matrix remodeling, wound healing, connective tissue repair, inflammation, and cell proliferation. Zinc also has antiseptic and astringent properties.

### Suggested Dosages/Use

May be applied to affected areas 2 times a day or as needed to relief itching and soothe the skin. Refer to product label for details on individual use.

### Precautions/Adverse Effects

Avoid contact with eyes.

### Veterinary-Labeled Topical Neutralized Zinc Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s);
<b>Max/Guard<sup>®</sup> ZN7</b> Derm (Addison)	Solution and Spray: Zinc gluconate 0.9-1.1%	OTC	Taurine, L-lysine, glycerin. 2 oz btl.

### Human-Labeled Topical Neutralized Zinc Products

There are several OTC zinc gluconate or zinc oxide products available for use in humans, and many of the products contain other ingredients. A common trade name is *Calamine lotion*, which contains zinc oxide and 0.5% iron(III) oxide.

### Corticosteroids, Topical

**Note:** There are at least 20 chemical entities (plus a variety of salts) used in humans for topical corticosteroid therapy. The following section includes many veterinary topical products and some human products that may be of use in veterinary medicine. Also, see the *Otics* section for more products.

#### BETAMETHASONE, TOPICAL

(bet-ah-meth-ah-zone)

For systemic use, see the [monograph](#) found in the main section

### Indications/Actions

Considered a high potency topical corticosteroid, betamethasone may useful for adjunctive treatment of localized pruritic or inflammatory conditions. Because risks associated with betamethasone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, betamethasone products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products are in combination with gentamicin and labeled indications are for treatment of infected superficial lesions caused by bacteria sensitive to gentamicin. Additional otic products are available that contain gentamicin and clotrimazole, but these can be used in an extra-label manner for treating mixed bacterial and yeast infections when strong antiinflammatory activity is desired. Sole ingredient betamethasone topical forms are available with human labeling.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (*e.g.*, histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

### Suggested Dosages/Use

Betamethasone formulations are best suited for focal (*e.g.*, pedal) or multifocal lesions for relatively short durations (*e.g.*, less than 2 months). Initially, topical corticosteroids are usually used sparingly 1–4 times per day and then frequency is tapered when control is achieved. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible. Refer to individual product labeling for actual dosing recommendations for veterinary products.

### Precautions/Adverse Effects

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20–30 minutes after application.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy (skin fragility, alopecia, localized pyoderma and comedones are other possible complications) occur as product concentration and duration of use increases. Betamethasone may delay wound healing particularly if used longer than 7 days in duration. Vomiting and diarrhea have been reported with use of the products containing betamethasone. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

### Veterinary-Labeled Topical Betamethasone Products

**Note:** At time of writing there are no veterinary-labeled sole active ingredient betamethasone products in the USA.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Gentocin Topical Spray<sup>®</sup></b> (Intervet/Schering)	Spray (all products listed): Gentamicin 0.57 mg/mL;	All are Rx	Depending on product: 15 & 30 g, 60, 72, 120, 240 mL
<b>Gentaspray<sup>®</sup></b> (Butler)	Betamethasone (as valerate)		
<b>Betagen Topical Spray<sup>®</sup></b> (Med-Pharmex)	0.284 mg/mL		
<b>Gentamicin Topical Spray<sup>®</sup></b> (RXV)			
<b>Gentaved Topical Spray<sup>®</sup></b> (Vedco)			
<b>Otomax<sup>®</sup> Ointment</b> (Intervet/Schering)	Ointment (otic): All Products contain: Gentamicin 3 mg/g;	Rx	Mineral oil base. Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; 7.5, 10, 15, 20 and 215 g bottles or tubes
<b>DVMAX<sup>®</sup> Ointment</b> (DVM)	Gentamicin 3 mg/g;		
<b>Vetromax<sup>®</sup> Ointment</b> (Dechra)	Betamethasone (as valerate)		
<b>MalOtic<sup>®</sup> Ointment</b> (Vedco)	1 mg/g; Clotrimazole 10 mg/g		
<b>Fuciderm Gel<sup>®</sup></b> (Dechra)	Gel: Betamethasone valerate 0.1% Fusidic acid 0.5%	Rx (not in USA); available in EU and Canada	Labeled for dogs. Can be used extra-label in cats. 15, 30 g tubes.

### Human-Labeled Topical Betamethasone Products

**Note:** Partial listing; there are also topical branded products (two common trade names are *Diprosone<sup>®</sup>* and *Maxivate<sup>®</sup>*) available with betamethasone dipropionate. Do not confuse products containing *augmented* betamethasone dipropionate (*Diprolene<sup>®</sup>*, etc.) with betamethasone dipropionate. Augmented betamethasone dipropionate is not equivalent with betamethasone dipropionate as it is more potent. For more information on human-labeled betamethasone products, refer to a comprehensive human drug reference (*e.g.*, *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s); Comments
<b>Betamethasone Dipropionate Ointment</b>	Ointment: 0.05%	Rx (Human)	15, 45 g.
<b>Betamethasone Dipropionate Cream</b>	Cream: 0.05%	Rx (Human)	15, 45 g.
<b>Betamethasone Dipropionate Lotion</b>	Lotion: 0.05%	Rx (Human)	20, 30, 60 mL
<b>Diprosone<sup>®</sup></b> (Westwood Squibb)	Aerosol Spray: 0.1%	Rx (Human)	85 g. 10% isopropyl alcohol, mineral oil
<b>Clotrimazole &amp; Betamethasone Diprop.</b> (Fougera)	Lotion: Clotrimazole 1%	Rx (Human)	30 mL
<b>Lotrisone<sup>®</sup></b> (Schering)	Betamethasone dip. 0.05%		
<b>Clotrimazole &amp; Betamethasone Diprop.</b> (Fougera)	Cream: Clotrimazole 1%	Rx (Human)	15, 45 g.
<b>Lotrisone<sup>®</sup></b> (Schering)	Betamethasone dip. 0.05%		

## HYDROCORTISONE, TOPICAL

(hye-droe-kor-ti-zone)

### Indications/Actions

Considered a low potency topical corticosteroid, hydrocortisone may be useful for adjunctive treatment of localized pruritic and/or inflammatory conditions. Because risks associated with hydrocortisone are significantly less when compared to higher potency corticosteroids, hydrocortisone is a reasonable first choice, particularly when treating large areas, or when used on smaller patients. Some products also contain the astringent Burow's solution, which may have additional antipruritic effects.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

### Suggested Dosages/Use

Hydrocortisone formulations are best suited for focal (e.g., pedal) or multifocal lesions for relatively short durations (e.g., less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. In contrast to some of the more potent topical corticosteroids, hydrocortisone can be applied more frequently and over a greater surface area without undue risk for local or systemic adverse effects. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible.

Shampoos containing hydrocortisone are generally used once a day to once a week. They should remain in contact with skin for at least 10 minutes prior to rinsing. Refer to individual product labeling for actual dosing recommendations for veterinary products.

### Precautions/Adverse Effects

Several veterinary topical products list tuberculosis of the skin or pregnancy as contraindications. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20-30 minutes after application.

Local skin reactions are possible, but unlikely to occur. Atrophy associated with skin fragility, superficial follicular cysts (milia) and comedones may be seen with long term, frequent use, but this occurs more commonly when using more potent, topical corticosteroids. Although systemic absorption is rare with hydrocortisone, long term use may lead to HPA axis suppression.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

### Veterinary-Labeled Topical Hydrocortisone Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Comments: Size(s)
<b>Corticalm Lotion*</b> (DVM)	Lotion: 1%	Rx	3, 6 oz.
<b>Sulfodene HC Anti-Itch Lotion*</b> (Farnam)	Lotion: 0.5%	OTC	1.5 oz.
<b>Zymox Topical Cream*</b> (PKB)	Cream: 1%	Rx	Lactoperoxidase, lysozyme, lactoferrin, 1 oz.
<b>Zymox Topical Wipes*</b> (PKB)	Wipes: 1%	Rx	Lactoperoxidase, lysozyme, lactoferrin, 30 count jar.
<b>Malacetic HC Wipes*</b> (Dechra)	Wipes: Hydrocortisone 1% Acetic Acid 1% Boric Acid 1%	Rx	25 count jar.
<b>Relief* HC Spray</b> (DVM)	Spray: Hydrocortisone 1% Pramoxine 1%	Rx	Colloidal oatmeal, 8 oz.
<b>Pramosothe* HC Spray</b> (Sogeval)	Spray: Hydrocortisone 1% Pramoxine 1%	Rx	Colloidal oatmeal, essential fatty acids, 8 oz.
<b>Cortispray*</b> (DVM)	Spray: 1%	Rx	Labeled for use on dogs, cats, and horses. 60 mL
<b>Dermacool HC Spray*</b> (Virbac)	Spray: 1%	Rx	Colloidal oatmeal, hamamelis extract, lactic acid, menthol, propylene glycol, 2, 4 oz.
<b>Hartz Advanced Care Hydrocortisone Spray w/ Aloe*</b> (Hartz Mountain)	Spray: 0.5%	OTC	Aloe, 5 oz.
<b>Zymox Topical Spray*</b> (PKB)	Spray: Hydrocortisone 1%	Rx	Lactoperoxidase, lysozyme, lactoferrin, 2 oz.
<b>Malacetic Ultra Spray*</b> (Dechra)	Spray: Hydrocortisone 1% Ketoconazole 0.15%	Rx	Acetic Acid 1%, Boric Acid 2%; 8 oz.
<b>Cort/Astrin Solution*</b> (Vedco)	Solution: Hydrocortisone 1%	OTC	Depending on product: 1, 2, 16 oz btl
<b>Corti-Derm Solution*</b> (First Priority)	Hydrocortisone 1%		
<b>Hydro-Plus*</b> (Phoenik)	Burow's Solution 2%		
<b>Bur-O-Cort 2:1*</b> (Q.A. Labs)			
<b>Hydro-B 1020*</b> (Butler)			
<b>Cortisothe Shampoo*</b> (Virbac)	Shampoo: Hydrocortisone 1% Colloidal oatmeal 1%	Rx	Labeled for dogs and cats. 8, 16 oz.
<b>Chlorhexidine 4% HC Shampoo</b> (Sogeval)	Chlorhexidine 4% Hydrocortisone 1%	Rx	Labeled for dogs and cats. 8, 16 oz.
<b>Malacetic Ultra Shampoo*</b> (Dechra)	Hydrocortisone 1% Ketoconazole 0.15% Acetic Acid 1% Boric Acid 2%	Rx	Labeled for dogs and cats. 8 oz.
<b>Resicort Leave-On Lotion*</b> (Virbac)	Lotion: 1%	Rx	8, 16 oz.

### Human-Labeled Topical Hydrocortisone Products

**Note:** Partial listing; there are many branded products available with hydrocortisone. For more information on human-labeled hydrocortisone products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s)
<b>Hydrocortisone Ointment</b>	Ointment: 0.5, 1%	OTC/Rx (Human). Status determined by labeling	15, 20, 28.4, 30, 60, 120, 454 g.
<b>Hydrocortisone Ointment</b>	Ointment: 2.5%	Rx (Human)	20, 30 g
<b>Hydrocortisone Cream</b>	Cream: 0.5, 1%	OTC/Rx (Human). Status determined by labeling	1 g pkts, 15, 20, 28.4, 30, 60, 120, 454 g.

<b>Hydrocortisone Solution; Liquid</b>	Solution: 1%, 2.5%	Rx (Human)	30, 45, 60, 75, 120, 600 mL
<b>Hydrocortisone Spray</b>	Spray: 1%	OTC (Human)	45 mL

### Indications/Actions

Considered a high potency topical corticosteroid, isoflupredone in combination with neomycin and tetracaine may be useful for adjunctive treatment of otic or topical localized pruritic or inflammatory conditions that may be associated with a bacterial skin infection and pain. Because risks associated with isoflupredone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, these products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products (*Tritop® Ointment* and *Neo-Predew/Tetracaine Powder®*) have labeled indications for conditions associated with neomycin-susceptible organisms and/or allergy with anesthetic properties due to tetracaine, or as a superficial dressing applied to minor cuts, wounds, lacerations, and abrasions, and for post-surgical pain application where reduction in pain and inflammatory response is deemed desirable. In addition, *Tritop® Ointment* is also labeled for acute (and possibly chronic) otitis externa, acute moist dermatitis and anal sac inflammation/infection, and *Neo-Predew/Tetracaine Powder®* for acute otitis externa, acute moist dermatitis and interdigital dermatitis in dogs and cats.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

### Suggested Dosages/Use

Labeled dose for *Tritop®* when used on skin or mucous membranes: Cleanse area, apply a small amount and spread and rub in gently. Involved area may be treated 1–3 times daily and continued in accordance with clinical response.

Labeled dose for *Neo-Predew/Tetracaine Powder®*: Cleanse area, apply by compressing bottle with short, sharp squeezes; once daily application usually sufficient, but may use 1–3 times as required.

### Precautions/Adverse Effects

Several veterinary topical products containing corticosteroids list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20-30 minutes after application. Isoflupredone may delay wound healing particularly if used longer than 7 days in duration.

Use care when treating large areas, or when used on smaller patients. Treat for only as long as necessary on as small an area as possible. Risk for HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy increase with prolonged duration of use. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur. Hypersensitivity reactions to neomycin and/or tetracaine are possible.

### Veterinary-Labeled Topical Isoflupredone Products

**Note:** At time of writing there are no veterinary-labeled sole active ingredient isoflupredone products in the USA.

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Comments: Size(s)
<i>Tritop®</i> (Pfizer)	Ointment: Isoflupredone acetate 0.1%; Neomycin sulfate 0.5%; Tetracaine HCl 0.5%	Rx	10 g. tube. Labeled for dogs and cats.
<i>Neo-Predew w/ Tetracaine Powder®</i> (Pfizer)	Powder: Isoflupredone acetate 1mg/g; Neomycin Sulf. 5 mg/g; Tetracaine HCl 5 mg/g	Rx	Myristyl-gamma-picolinium Cl (germicidal surfactant) 0.2 mg/g. 15 g. insufflator bottle. Store in dry place, do not allow tip of bottle to contact moisture. Labeled for use on dogs and cats.

### Human-Labeled Topical Isoflupredone Products

None

### MOMETASONE FUROATE

(moe-met-a-zone fyur-ob-ate)

For otic use, refer to the Otics section.

### Indications

Considered a highly potent topical corticosteroid, mometasone furoate may be useful for adjunctive treatment of pruritic and/or inflammatory conditions that may be associated with bacterial and/or yeast skin infections. Because risks associated with mometasone (HPA axis suppression, skin atrophy) are greater than with hydrocortisone, mometasone products are generally reserved for more serious pruritic conditions or when hydrocortisone is not effective. Mometasone is found in a veterinary-labeled suspension (*MoMetaMax®*) in combination with gentamicin and clotrimazole indicated for otic use. It can also be used extra-label for yeast and/or bacterial skin infections sensitive to clotrimazole and gentamicin, when a strong anti-inflammatory effect is also needed.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

### Suggested Dosages/Use

Initially, topical corticosteroids are usually used sparingly 1–2 times per day, then tapered to less frequent use. Mometasone formulations are best suited for focal (e.g. pedal) or multifocal lesions and for relatively short durations (e.g., less than 2 months). However, clinicians must tailor the frequency and duration of application to the severity of clinical signs. Refer to the actual product labeling for additional usage information.

### Precautions/Adverse Effects

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and cutaneous atrophy associated with skin fragility, alopecia, localized pyoderma, superficial follicular cysts (milia) and comedones occur as product concentration and duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur. Mometasone may delay wound healing particularly if used longer than 7 days in duration.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

### Veterinary-Labeled Mometasone Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Comments: Size(s)
<i>MoMetaMax Otic Suspension®</i> (Intervet/Schering-Plough)	Suspension (otic): Per gram: Mometasone 1 mg; Gentamicin 3 mg; Clotrimazole 10 mg	Rx	Mineral-oil base. Approved for otic use in dogs, but used extra-label (see above). In 7.5, 15, 30, 215 g tubes

### Human-Labeled Topical Mometasone Products

**Note:** Partial listing; for more information on human-labeled mometasone products (nasal, etc), refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Comments: Size(s)
<i>Elocon®</i> (Schering-Plough); generic	Cream, Ointment, Lotion: 0.1%	Rx	Cream: stearyl alcohol. 15, 45 g. Ointment: 15, 45 g. Lotion: Propylene glycol, isopropyl alcohol. 30, 60 mL

### TRIAMCINOLONE ACETONIDE, TOPICAL

(trye-am-sin-oh-eh-one ass-si-toe-nide)

For systemic use, see the [monograph](#) found in the main section.

## Indications/Actions

Considered a medium potency topical corticosteroid when used at concentrations less than 0.5% (high potency), triamcinolone acetonide may be useful for adjunctive treatment of pruritic conditions. Because risks associated with triamcinolone (HPA axis suppression, skin atrophy) are greater than with hydrocortisone, triamcinolone acetonide products are generally reserved for more serious pruritic conditions or when hydrocortisone is not effective. Triamcinolone can be found in a veterinary-labeled sole agent cream (*Medalone*®) or spray (*Genesis*®). It is also an ingredient in combination with antibiotics and anti-yeast ingredients in several veterinary products (*e.g.*, *Panalog*®) that are labeled for otic use. However, these products can be used in an extra-label manner to treat bacterial and yeast skin infections sensitive to gentamicin and nystatin, including pododermatitis and anal sac disease, when a strong anti-inflammatory effect is needed.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (*e.g.*, histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

## Suggested Dosages/Use

Triamcinolone formulations are best suited for focal (*e.g.*, pedal) or multifocal lesions for relatively short durations (*e.g.*, less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible. Refer to individual product labeling for actual dosing recommendations for veterinary products.

## Precautions/Adverse Effects

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20-30 minutes after application.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy (skin fragility, alopecia, localized pyoderma and comedones are other possible complications) occur as product concentration and duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

## Veterinary-Labeled Topical Triamcinolone Acetonide Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<i>Medalone Cream</i> * (Med-Pharmex) <i>Cortalone Cream</i> * (Vedco)	Cream: 0.1%	Rx	7.5, 15 g. Approved for dogs. Indications include allergic dermatitis and summer eczema.
<i>Genesis Spray</i> * (Virbac)	Spray: 0.015%	Rx	16 oz spray bottle. Approved for dogs. Indication is for control of pruritus associated with allergic dermatitis. Bacterial skin infection needs to be resolved prior to use. Strongly recommend referring to the package insert information for maximum allowable dosages, treatment durations, etc.
<i>Derma-Vet Cream</i> * (Med-Pharmex)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx	Aqueous vanishing cream. 7.5, 15 g. Panalog and Derma-Vet labeled for use in dogs or cats. Cortalone labeled for dogs only.
<i>Panalog Ointment</i> * (Pfizer) <i>Animax Ointment</i> * (Pharmaderm) <i>Quadratop Ointment</i> * (Butler) <i>Derma-Vet Ointment</i> * (Med-Pharmex) <i>Dermalog Ointment</i> * (RXV) <i>Dermalone Ointment</i> * (Vedco)	Ointment: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx	Labeled for use in dogs or cats. 7.5, 15, 30, 240 mL

## Human-Labeled Topical Triamcinolone Acetonide Products

**Note:** Partial listing; there are several topical branded products (two common trade names are *Aristocort*® and *Kenalog*®) available with triamcinolone. For more information on human-labeled triamcinolone products, refer to a comprehensive human drug reference (*e.g.*, *Facts and Comparisons*) or contact a pharmacist.

Product (Company)	Form: Concentration	Label Status	Size(s); Comments
<i>Triamcinolone Acetonide Ointment</i>	Ointment: 0.025, 0.1, 0.5%	Rx (Human)	15, 20, 28.4, 30, 60, 120, 454 g.
<i>Triamcinolone Acetonide Cream</i>	Cream: 0.025, 0.1, 0.5%	Rx (Human)	15, 20, 30, 60, 120, 240 454 g.
<i>Triamcinolone Acetonide Lotion</i>	Lotion: 0.025, 0.1%	Rx (Human)	15, 60 mL
<i>Kenalog</i> * (Westwood Squibb)	Aerosol Spray: 0.1%	Rx (Human)	23, 63 g. 10.3% alcohol
<i>Nystatin-Triamcinolone Acetonide</i> (various)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 0.1%	Rx (Human)	Depending on product: 1.5 g. pkts, 15, 30, 60, 120 g.

## Antimicrobials, Topical

### Antibacterial Agents

See also the [Sulfur](#) listing the keratolytic section

### BACITRACIN AND BACITRACIN COMBINATIONS, TOPICAL

(bass-ih-trase-in)

## Indications/Actions

Bacitracin is used topically to prevent infection after dermal lacerations, scrapes or minor burns. Bacitracin acts by inhibiting cell wall synthesis of susceptible bacteria and is either bactericidal or bacteriostatic depending on drug concentration and bacterial susceptibility. Bacitracin is primarily active against gram-positive bacteria, but *Staphylococci* spp. are becoming increasingly resistant. Bacitracin activity is not impaired by blood, pus, necrotic tissue or large inocula. Bacitracin is not recommended in the treatment of ulcerated and chronic canine dermatoses (sensitization may occur).

## Suggested Dosages/Use

May be applied up to 3 times daily and be covered by a suitable dressing. Use is usually not recommended to continue more than one week.

## Precautions/Adverse Effects

Bacitracin topical ointment should not be used in or around eyes, for the treatment of ulcerated lesions, or in patients known to be hypersensitive to it. There have been anecdotal reports of cats developing fatal anaphylactic reactions after administered ophthalmic "triple" antibiotic ointment. Deep puncture wounds, animal bites or deep cutaneous infections may require systemic antibiotic therapy. While topical administration generally results in negligible systemic levels, if used over large areas of the body or on serious burns or puncture wounds, measurable absorption and potential toxicity may occur. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application. Clients should wash hands after application or wear gloves when applying.

## Veterinary-Labeled Bacitracin Topical Products

Veterinary-labeled bacitracin formulations for topical use are not available. However, ophthalmic preparations containing bacitracin in combination with other antibiotics w/ or w/o hydrocortisone could be used in an extra-label manner.

### Human-Labeled Topical Bacitracin Products

Bacitracin ointment is available alone as 500 Units/g in various tube sizes. There are many OTC human products available with formulas equivalent to the formally available veterinary-labeled triple antibiotic preparations that contained neomycin, polymyxin B, and bacitracin. A well-known trade name is *Neosporin*® or it is available generically as Triple Antibiotic Ointment. When combined with only polymyxin B, a common trade name is *Polysporin*®.

Product (Company)	Form; Concentration	Label Status	Other Ingredients; Size(s)
<i>Bacitracin</i> (various generic)	Ointment; 500 Units/gram	OTC (Human)	Depending of manufacturer: white petrolatum, mineral oil. 14, 28, 120 g. tubes, 1 lb. jars

### BENZOYL PEROXIDE

(ben-zoyl per-oxs-ide)

#### Indications/Actions

Benzoyl peroxide products are used topically either as gels or in shampoos. Shampoos are generally used for oily and scaly skin (seborrhea oleosa), superficial and deep pyodermas, crusty pyodermas (such as seborrheic dermatitis/pyoderma commonly seen in Cocker Spaniels), furunculosis, and as adjunctive therapy for generalized demodicosis and Schnauzer comedo syndrome. Gels may be useful for treating localized superficial and deep pyodermas, chin acne, fold pyodermas, and localized Demodex lesions.

Benzoyl peroxide possesses antimicrobial (especially antibacterial), comedolytic ("follicular flushing"), keratolytic and antiseborrheic actions. It also has some mild antipruritic activity and wound healing effects, and is thought to increase follicular flushing. Benzoyl peroxide's antimicrobial activity is due to the oxidative benzoyl peroxy radicals formed that disrupt cell membranes.

#### Suggested Dosages/Use

Gels are usually recommended for use once to twice daily and shampoos up to once daily. Shampoos should remain in contact with skin for at least 10 minutes before rinsing. For veterinary products, refer to product label for details on use.

#### Precautions/Adverse Effects

Avoid contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Benzoyl peroxide will bleach colored fabrics, jewelry, clothing or carpets and may bleach the patient's fur. Clients should be advised to keep treated animals away from fabrics during treatment. Do not let animal lick or chew at affected areas for a few minutes after application.

Benzoyl peroxide can be drying or irritating (erythema, pruritus, pain) in some patients particularly at higher (>5%) concentrations. Reducing frequency of use, application of emollients after bathing, or using shampoos with moisturizing microvesicles may alleviate or prevent this problem. Benzoyl peroxide shampoos do not lather well.

#### Veterinary-Labeled Topical Benzoyl Peroxide Products

Product (Company)	Form; Active Ingredients; Concentration	Label Status	Other Ingredients; Comments; Size(s)
<i>Pyoben Gel</i> ® (Virbac)	Gel; 5%	Rx	Labeled for dogs and cats and for use once or twice daily after cleaning. 30 g
<i>Oxydex Gel</i> ® (DVM)	Gel; 5%	Rx	Labeled for dogs and cats and for use once or twice daily after cleaning. Rub in well so that no residue remains. Prevent pet from licking area until dries (1–2 minutes). 30 g
<i>Micro-Pearls Advantage Benzoyl-Plus</i> ® (Vetoquinol)	Shampoo; 2.5%	Rx	<i>Novasome</i> ® microvesicles. Labeled for dogs & cats. Shake well; wear gloves. May be used up to once daily as directed. 12 oz, 1 gal
<i>Benzoyl Peroxide Shampoo</i> ® (Davis)	Shampoo; 2.5%	OTC	Labeled for OTC use. 12 oz, 1 gal
<i>OxyDex Shampoo</i> ® (DVM)	Shampoo; 2.5%	OTC	Labeled for OTC use. 8, 12 oz, 1 gal.
<i>Pyoben Shampoo</i> ® (Virbac)	Shampoo; 3%	Rx	<i>Spherulites</i> ® microcapsules, chitosanide. Labeled for dogs and cats. Use initially 2–3 times/week, then once a week or as directed by DVM. 8, 16 oz.
<i>Vet Solutions BPO-3</i> ® Shampoo (Vetoquinol)	Shampoo; 3%	Rx	Labeled for dogs and cats. 16 oz; 1 gal.
<i>Sulf OxyDex Shampoo</i> ® (DVM)	Shampoo; Benzoyl Peroxide 2.5% Sulfur (micronized) 2%	OTC	Shake well. May be used pm or as directed by DVM. 8, 12 oz, 1 gal
<i>Oxyderm</i> ® Shampoo (Sogeval)	Shampoo; Benzoyl peroxide 3% Sulfur 2% Salicylic acid 2% Phytosphingosine	OTC	Labeled for dogs and cats. 8, 16 oz.
<i>DermaBess</i> ® Shampoo® (DermaPet)	Shampoo; Benzoyl peroxide 2.5%, Sulfur 1%, Salicylic Acid 1%	OTC	Moisturizing factors, Vitamin E. 8 oz, 1 gal

#### Human-Labeled Topical Benzoyl Peroxide Products

There are many human products available containing benzoyl peroxide (2.5%-10%), but with the possible exception of the 5% gel products, the veterinary formulations would be more suitable for use on dogs or cats. Benzoyl peroxide 5% gel can be labeled as either Rx or OTC depending on product and are available as generics or with the following trade names: *Benzac*®, *Desquam-X*®, or *PanOxyl*®.

### CLINDAMYCIN, TOPICAL

(klin-da-mye-sin) Cleocin®, ClinzGard®

For systemic use, see the monograph found in the main section

#### Indications/Actions

Topical clindamycin may be used for the treatment of feline acne or other localized skin infections caused by bacteria susceptible to it. The veterinary product (*ClinzGard*®) is labeled as indicated for the treatment of anal sac and tissue abscesses, puncture wounds and surgical incisions. It has been recommended by some veterinary dermatologists that topical clindamycin only be used when other topical antibiotics such as gentamicin have failed. Ideally, treatment should be based on culture and susceptibility results.

Clindamycin inhibits bacterial protein synthesis by binding to the 50S ribosome; primary activity is against anaerobic and gram-positive aerobic bacteria. For more information on the pharmacology of clindamycin, refer to the monograph for systemic use found in the main section.

#### Suggested Dosages/Use

When used for feline acne, topical clindamycin is generally applied in a thin film once to twice daily. *ClinzGard*® is used as a single application that has sustained-release over 7-10 days. It must be applied to cleaned and, if necessary, debrided surfaces.

#### Precautions/Adverse Effects

Topical clindamycin should not be used in patients with a history of hypersensitivity to clindamycin or lincomycin. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Contact reactions (pain, burning erythema, itching, drying, peeling) are possible. Clindamycin lotions and gels may cause less burning than the topical solutions or foams. As clindamycin can be absorbed through the skin, systemic adverse effects are possible. Antibiotic associated diarrheas are potentially possible, but severe, life-threatening diarrheas (so-called Pseudomembranous colitis) are thought to occur very rarely in animal patients when clindamycin is used systemically.

#### Veterinary-Labeled Topical Clindamycin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>ClinzGard®</b> (TriLogic)	Gel: 1%	Rx	Labeled for dogs and cats. Sterile single-dose syringes (box with 4 units).

## Human-Labeled Topical Clindamycin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Clindamycin Phosphate</b> (various generic)	Lotion: 1%	Rx (Human)	30, 60 g.
<b>Cleocin T®</b> (Pharmacia Upjohn)	Lotion: 1%	Rx (Human)	Cystostearyl alcohol, glycerin, methylparaben. 60 mL
<b>Clindamax®</b> (PharmaDem)	Lotion: 1%	Rx (Human)	Cystostearyl alcohol, glycerin, methylparaben. 60 mL
<b>Clindamycin Phosphate</b> (various generic)	Gel: 1%	Rx (Human)	30, 60 g.
<b>Cleocin T®</b> (Pharmacia Upjohn)	Gel: 1%	Rx (Human)	Methylparaben. 30, 60 g.
<b>Clindagel®</b> (Galderma)	Gel: 1%	Rx (Human)	Methylparaben. 7.5, 42 & 77 g.
<b>Clindamax®</b> (PharmaDem)	Gel: 1%	Rx (Human)	Methylparaben. 30, 60 g.
<b>Clindamycin Phosphate</b> (various generic)	Solution: 1%	Rx (Human)	30, 60 mL
<b>Cleocin T®</b> (Pharmacia Upjohn)	Solution: 1%	Rx (Human)	Isopropyl alcohol 50%. Single-use pledgets 30 & 60 mL
<b>Clindets®</b> (Stiefel)	Pledgets: 1%	Rx (Human)	Isopropyl alcohol 52%. 1 mL pledgets
<b>Evoclin®</b> (Connetics)	Aerosol Foam: 1%	Rx (Human)	Cetyl alcohol, ethanol 58%, stearyl alcohol, propylene glycol. 50 g.

## GENTAMICIN SULFATE, TOPICAL

(jen-ta-mye-sin sul-fate) Gentocin®

For systemic use, see the monograph found in the main section.

## Indications/Actions

Topical gentamicin can be useful for treating both primary and secondary superficial bacterial skin infections caused by bacteria susceptible to it. It can also be used prophylactically after lacerations/abrasions or after minor surgery. In small animal medicine, topical gentamicin is usually used in combination with the corticosteroid betamethasone to treat superficial lesions, including “hot spots” (acute moist dermatitis, pruritic lesions).

The products containing betamethasone or mometasone and clotrimazole are labeled for otic use, but can also be used in an extra-label manner for yeast and/or bacterial skin infections sensitive to gentamicin and clotrimazole, when an anti-inflammatory effect is also desired. Formulations containing betamethasone or mometasone are best suited for focal (*e.g.*, pedal) or multifocal lesions for relatively short durations (*e.g.*, less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. Sole ingredient gentamicin sulfate topical forms are available with human labeling.

Gentamicin has activity against many Streptococci, Staphylococci (coagulase negative/positive and some penicillinase-producing strains) and gram-negative bacteria including many Klebsiella, *E. coli*, and some strains of Pseudomonas. Gentamicin-resistant strains of Pseudomonas are an ongoing issue.

## Suggested Dosages/Use

Topical gentamicin/betamethasone sprays are labeled for use 2–4 times day for up to 7 days. Topical gentamicin creams and ointments are generally applied to affected areas up to four times daily. Creams are generally used for secondary or greasy infections; ointments on dry skin infections.

## Precautions/Adverse Effects

Topical gentamicin may be absorbed systemically if used on ulcers, burned or denuded skin. Creams are more likely to be absorbed than are ointments. Systemic toxicity is unlikely to occur unless used on a significant percentage of body area or for prolonged times. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

With products containing betamethasone or mometasone, long-term or frequent use can cause HPA axis suppression. Risk can be reduced by treating for only as long as necessary on as small an area as possible. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Refer to individual product labeling for actual dosing recommendations for veterinary products.

## Veterinary-Labeled Topical Gentamicin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Gentocin Topical Spray®</b> (Intervet Schering-Plough)	Spray (all products listed): Gentamicin 0.57 mg/mL;	Rx	All products listed are labeled for dogs and contain isopropyl alcohol, propylene glycol and parabens.
<b>Gentaspray®</b> (Butler)	Betamethasone (as valerate)		
<b>Betagen Topical Spray®</b> (Med-Pharmex)	0.284 mg/mL		Sizes range from 60 mL to 240 mL
<b>Gentamicin Topical Spray®</b> (RXV; Priority Care 1)			
<b>Gentaved Topical Spray®</b> (Vedco)			
<b>GenOne Spray®</b> (VetOne)			
<b>Otomax® Ointment</b> (Schering)	Ointment (otic): Gentamicin 3 mg/g;	Rx	Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or Malassezia dermatitis; Depending on product: 7.5, 15, 20 g tubes & 215 g bottles
<b>DVMAX® Ointment</b> (DVM)	Betamethasone 1 mg/g;		
<b>Vetromax® Ointment</b> (Dechra)	Clotrimazole 10 mg/g		
<b>MoMetaMax Otic Suspension®</b> (Intervet Schering-Plough)	Suspension (otic): Gentamicin 3 mg/g; Mometasone 1 mg/g; Clotrimazole 10 mg/g	Rx	Mineral oil based. Approved for otic use in dogs. Extra label use in dogs and cats with localized inflamed or infected cutaneous lesions ( <i>e.g.</i> , bacterial skin lesions or Malassezia dermatitis.) 7.5, 15, 30, 215 g tubes.

## Human-Labeled Topical Gentamicin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Gentamicin</b> (various generic)	Cream: 0.1% (as base) Ointment: 0.1% (as base)	Rx (Human)	Cream may contain propylene glycol and parabens. 15 g tubes Ointment may contain white petrolatum and parabens. 15 g. tubes

## MUPIROCIN (PSEUDOMONIC ACID A)

(myoo-pye-roe-sin) Bactroban®, Bactoderm®

## Indications/Actions

Mupirocin is FDA-approved for treating infections in dogs (*e.g.*, superficial pyoderma, fold pyoderma, interdigital cysts/draining tracts, acne, pressure point pyodermas, etc) caused by susceptible strains of *Staphylococcus aureus* or *Staphylococcus (pseudo)intermedius*, including beta-lactamase producing and methicillin-resistant strains. It may also be of use in other species and conditions (*e.g.*, feline acne, equine pyoderma, superficial pyoderma, interdigital abscesses, pressure point pyodermas, etc). It may also be of use in feline acne. It also shows activity against other gram-positive pathogens, including strains of *Corynebacterium*, *Clostridium*, *Proteus* and *Actinomyces*.

Mupirocin is not related structurally to other commercially available antibiotics and acts by inhibiting bacterial protein synthesis by binding to bacterial isoleucyl transfer-RNA synthetase. While bacterial resistance is rare, resistant strains of *Staphylococcus aureus* have been identified and resistance transference is thought to be plasmid-mediated. It is thought that resistance occurs more frequently when mupirocin is used over a prolonged period and over larger areas of skin, therefore; it may be best to use mupirocin for short-term treatment and on small, localized areas. Cross-resistance with other antimicrobials has not been identified. Mupirocin also has activity against some gram-negative bacteria, but it is not used clinically for gram-negative infections. *Pseudomonas* is particularly resistant to mupirocin.

Mupirocin is not significantly absorbed through the skin into the systemic circulation, but does penetrate well into granulomatous deep pyoderma lesions. It is not suitable for application to burns.

### Suggested Dosages/Use

Mupirocin is labeled for twice daily application on dogs. It requires 10 minutes of contact time to be active. In cats with feline acne, once a course of once to twice daily mupirocin therapy has been completed (control attained), some cats can be maintained with 1–2 applications per week.

### Precautions/Adverse Effects

Mupirocin is contraindicated in patients with a history of hypersensitive reactions to or other ointments containing polyethylene glycol. Because the ointment has a polyethylene glycol base, the manufacturer warns that nephrotoxicity may potentially develop if used on extensive deep lesions. Avoid contact with eyes.

Mupirocin appears to be very well tolerated; contact reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use. Anecdotally, very rare renal toxicity has been reported.

### Veterinary-Labeled Topical Mupirocin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Muricin</b> <sup>®</sup> (Dechra)	Ointment: 2%	Rx	Labeled for use on dogs; Polyethylene glycol base. 15 g.

### Human-Labeled Topical Mupirocin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Mupirocin</b> (various generic)	Ointment: 2%	Rx (Human)	Polyethylene glycol base. 22 g.
<b>Bactroban<sup>®</sup> Ointment</b> (GlaxoSmithKline)	Ointment: 2%	Rx (Human)	Polyethylene glycol base. 22 g.
<b>Centany<sup>®</sup></b> (Medimetrix)	Ointment: 2%	Rx (Human)	Castor oil, hard fat base. 30 g
<b>Bactroban<sup>®</sup> Cream</b> (GlaxoSmithKline)	Cream: 2%	Rx (Human)	Oil/water base. 15 & 30 g

## NITROFURAZONE, TOPICAL

(nye-troe-fur-ah-zone) Furazone<sup>®</sup>

### Indications/Actions

Nitrofurazone is a nitrofurantoin antibacterial that can be used topically as an antibacterial for treating or preventing superficial infections. It is bactericidal for many bacteria, including *E. coli*, *S. aureus*, etc. Clinical efficacy demonstrating efficacy for the treatment of minor burns or surface bacterial infections is apparently unavailable.

Nitrofurazone's mechanism of action is thought to be associated with inhibiting bacterial enzymes that primarily degrade glucose and pyruvate.

### Suggested Dosages/Use

Apply once daily until lesions resolve or as directed by the veterinarian. For veterinary products, refer to product label for details on individual use.

### Precautions/Adverse Effects

As nitrofurazone has been shown to cause mammary tumors when fed in high doses to rats and ovarian tumors in mice, **U.S.A. federal law prohibits the use of nitrofurazone products in (or on) food animals, including horses to be used for food.**

The soluble dressing contains polyethylene glycols and if used on large areas of denuded skin significant amounts of polyethylene glycol could be absorbed and cause nephrotoxicity.

Avoid ointment contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Do not allow animal to lick or chew treated area for at least 30 minutes. Avoid exposure to sunlight, strong fluorescent lighting, excessive heat, or alkaline materials.

Topical nitrofurazone appears to be well tolerated; hypersensitivity or skin reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use.

### Veterinary-Labeled Topical Nitrofurazone Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Nitrofurazone Soluble Dressing</b> (Generic; Med-Pharmex, AgriLabs, Vedco, etc.) Also available under a variety of trade names.	Ointment (soluble): 0.2%	OTC	Water-soluble or polyethylene glycol base. 1 lb. jars.
<b>NFZ<sup>®</sup> Puffer</b> (AgriLabs, Durvet, Aspen, etc)	Soluble Powder: 0.2%	OTC	Labeled for eye and ear infections, surface wounds, cuts and abrasions in dogs and cats. Shake or rotate to loosen powder. Restricted drug in California. 45 g.

### Human-Labeled Topical Nitrofurazone Products

None. Nitrofurazone products are apparently no longer available with human labeling in the USA.

## SILVER SULFADIAZINE (SSD)

(sil-ver sul-fa-dye-ah-zeen) Silvadene<sup>®</sup>

### Indications/Actions

Topical silver sulfadiazine (SSD) is labeled (human) for topical prophylaxis and treatment of 2<sup>nd</sup> and 3<sup>rd</sup> degree burns. In veterinary medicine, it is can be useful in treating localized bacterial skin infections, particularly those caused by *Pseudomonas* spp.

SSD has extensive antimicrobial activity and is bactericidal for yeasts and many gram-negative and gram-positive bacteria. SSD acts by disrupting microbial cell membranes and cell walls; this differs from the antibacterial actions of silver nitrate or sodium sulfadiazine. It can enhance epithelization, but can retard granulation.

### Suggested Dosages/Use

When used for burns SSD is applied once to twice daily at a thickness of approx. 1/16<sup>th</sup> of an inch (1–2 mm). Dressings may be applied over the cream. When used for localized bacterial infections once to twice daily treatment with the cream rubbed in is suggested.

### Precautions/Adverse Effects

Patients hypersensitive to sulfonamides may also react to SSD. Risks of continued treatment must be weighed against the risks of not treating with SSD. Patients with significant hepatic or renal dysfunction may accumulate drug, particularly when used over large areas. Because SSD can retard granulation, avoid use in non-granulated wounds. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Adverse effects associated with sulfonamides (*e.g.*, KCS in dogs, blood dyscrasias in dogs/cats, etc.) are possible particularly when used over large areas or for extended periods. Refer to the Sulfadiazine/Trimethoprim monograph in the main section of the reference for more information.

### Veterinary-Labeled Silver Sulfadiazine Products

There are no topical products labeled for veterinary patients. An otic preparation (*Baytril Otic*<sup>®</sup>) contains SSD. See the Otics section for more information.

### Human-Labeled Silver Sulfadiazine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Silvadene®</b> (Hoechst MR)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 20, 50, 85, 400 & 1000 g.
<b>SSD AF Cream®</b> (Boots)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 50, 400 & 1000 g.
<b>Thermazene®</b> (Sherwood)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing white petrolatum, stearyl alcohol, methylparaben. 50, 400 & 1000 g.
<b>SSD Cream®</b> (Boots)	Cream: 1% (10 mg/gm)	Rx (Human)	Water-miscible base containing cetyl alcohol, white petrolatum, stearyl alcohol, methylparaben. 25, 50, 85, 400 & 1000 g.

## Antiseptics

### ACETIC ACID/BORIC ACID

(ah-see-ik ass-id; Bor-ik ass-id)

#### Indications/Actions

Indicated for the treatment of skin infections caused by bacteria including *Staphylococcus* spp., *Pseudomonas* spp. and yeast such as *Malassezia* spp. Also indicated for fold dermatitis, acute moist dermatitis, pododermatitis, and seborrhea oleosa. Some products contain other antimicrobials such as chlorhexidine and ketoconazole or antiinflammatory agents such as hydrocortisone for anti-pruritic effects.

Acetic and boric acids are potent antibacterial and antifungal agents with a rapid killing effect. They also possess ceruminolytic, keratolytic, keratoplastic, and astringent activities.

#### Suggested Uses/Dosages

If using spray or wipes: up to 2–3 times a day. If shampoo or conditioner: daily to weekly baths/after baths according to the veterinarian's recommendations. Leave shampoos in contact with the skin for at least 10 minutes prior to rinsing. Refer to the product for individual label directions.

#### Precautions/Adverse Effects

Skin redness and irritation may occur. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

#### Veterinary-Labeled Topical Acetic and Boric Acid Products

Product (Company)	Form: Active Ingredients; Concentration	Label Status	Other Ingredients; Comments; Size(s);
<b>Malacetic Ultra Spray®</b> (Dechra)	Spray: Acetic Acid 1% Boric Acid 2% Ketoconazole 0.15% Hydrocortisone 1%	OTC	Labeled for dogs and cats. 8 oz.
<b>Mal-A-Ket Wipes®</b> (Dechra)	Wipes: Acetic Acid 2% Chlorhexidine 2% Ketoconazole 1%	OTC	Labeled for dogs and cats. 50 count jar.
<b>Malacetic HC Wipes®</b> (Dechra)	Wipes: Acetic Acid 1% Boric Acid 1% Hydrocortisone 1%	OTC	Labeled for dogs and cats. 25 count jar.
<b>Malacetic Wet Wipes®</b> (Dechra)	Wipes: Acetic Acid 1% Boric Acid 1%	OTC	Labeled for dogs and cats. Indicated for anal sac expression, skin folds and cleaning of ears. 25 and 100 count jars and 25-count brick pack.
<b>Malacetic Spray®</b> (Dechra)	Leave-on Spray: Acetic Acid 2% Boric Acid 2%	OTC	Labeled for dogs and cats. 8, 16 oz.
<b>Malacetic Shampoo®</b> (Dechra)	Shampoo: Acetic Acid 2% Boric Acid 2%	OTC	Labeled for dogs and cats. 12, 16 oz; 1 gal.
<b>Malacetic Ultra Shampoo®</b> (Dechra)	Shampoo: Ketoconazole 0.15% Hydrocortisone 1% Acetic Acid 1% Boric Acid 2%.	Rx	Labeled for dogs and cats. 8 oz.
<b>Mal-A-Ket® Shampoo</b> (Dechra)	Shampoo: Ketoconazole 2% Acetic Acid 2% Chlorhexidine 2%	Rx	Labeled for dogs and cats. 1 oz pouch, 8 oz; 1 gal.

#### Human-Labeled Topical Acetic and Boric Acid Products

There are several OTC human products available containing acetic acid or boric acid (alone or containing other ingredients). For more information on human-labeled acetic acid or boric acid products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

### CHLORHEXIDINE

(klor-heks-ih-deen) Nolvasan®

#### Indications/Actions

A topical antiseptic, chlorhexidine has activity against many bacteria, but apparently, it is not predictably active against *Pseudomonas* or *Serratia* spp. It is available with veterinary labels in many different forms (solutions, shampoos, scrubs, ointments, sprays, etc).

Because it causes less drying and is usually less irritating than benzoyl peroxide, it is sometimes used in patients that cannot tolerate benzoyl peroxide. However, it does not have the keratolytic, comedolytic or degreasing effects of benzoyl peroxide. Chlorhexidine possesses some residual effects and can remain active on skin after rinsing. Chlorhexidine products may also contain other ingredients such as antifungals (ketoconazole and miconazole), salicylic acid, phytosphingosine, etc.

At usual concentrations, chlorhexidine acts by damaging bacterial cytoplasmic membranes. Antifungal activity can be obtained with 2% or higher concentrations.

#### Suggested Dosages/Use

For wound irrigation or foot soaking, 0.05–0.1% dilution in water is recommended. If using spray or wipes/pads: 1-2 times a day. If using shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

#### Precautions/Adverse Effects

Keep away from eyes as chlorhexidine products can damage eyes. Clients should wash hands after application or wear gloves when applying. Chlorhexidine is safe used on cats, although irritation and corneal ulcers have been reported.

Hypersensitivity and local skin irritant reactions are possible. Likelihood of irritation increases with increased concentrations. Chlorhexidine may retard wound healing; not recommended for long-term use particularly on granulating lesions.

#### Veterinary-Labeled Topical Chlorhexidine Products

There are also a several teal dip and udder wash products, a lubricant, and oral rinses are available. There are several trade names used for chlorhexidine products, including *Novasan*®, *Chlorhexiderm*®, *Dermachlor*®, *Chlorasan*®, *Chloradine*®, *Privasan*®, and *Chlorhex*®.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Chlorhexidine Spray</b> (various manufacturers and trade names)	Spray: 4%	OTC	Aloe. 8 oz. Shake well. Labeled for dogs, cats, & horses

<b>Ketochlor Shampoo®</b> (Virbac)	Shampoo: Chlorhexidine 2.3% Ketoconazole 1%	Rx	Spherulites® Microcapsules. Glycotechnology (monosaccharides: L-thamnose, D-mannose, D-galactose; polysaccharide: alkyl polyglycoside), chitosanide. Labeled for dogs and cats. 8, 16 oz, 1 gal.
<b>Malaseb Shampoo®</b> (DVM)	Shampoo: Miconazole nitrate 2% Chlorhexidine 2%	OTC	8, 12 oz, 1 gal.
<b>Malaseb® Concentrate Rinse</b> (DVM)	Rinse: Miconazole nitrate 5.2% Chlorhexidine 5.9%	OTC	Labeled for use on dogs, cats, & horses. Must be diluted before use. Do not allow animal to lick the treated areas until dry. 8, 32 oz.
<b>TrizChlor 4® Shampoo</b> (Dechra)	Shampoo: Chlorhexidine 4% TrizEDTA	OTC	Labeled for dogs and cats. 8 oz, 1 gal.
<b>ResiKetoChlor Leave-On Conditioner®</b> (Virbac)	Conditioner: Chlorhexidine 4% Ketoconazole 1%	OTC	Spherulites® Microcapsules. Glycotechnology (monosaccharides: L-thamnose, D-mannose, D-galactose; polysaccharide: alkyl polyglycoside), chitosanide. Labeled for dogs and cats. 8 oz.
<b>Chlorhexidine Scrub</b> (various)	Scrub: 2%, 4%	OTC	1 gal.
<b>ChlorhexDerm® Plus Scrub</b> (DVM)	Scrub: 2%	OTC	Labeled for dogs and cats. 1 gal.

#### Human-Labeled Topical Chlorhexidine Products

There are several topical skin cleansers available in the 2–4% range. Trade names include: *Hibiclens*®, *Hibistat*®, *Betasept*®, *Exidine*®, *Dyna-Hex*® and *BactoShield*®.

For otic use, refer to the Otics section

### Indications/Actions

Chloroxylenol is an antimicrobial disinfectant with demonstrated efficacy against gram-negative and gram-positive bacteria, in addition to a wide variety of fungal organisms, and against RNA and DNA viruses. It can be used in pre-surgical preparation of skin, cleaning wounds and in the treatment of bacterial, fungal and yeast skin infections.

Chloroxylenol, also known as PCMX, is a chlorinated phenolytic antiseptic. Its antibacterial action is due to disruption of bacterial cytoplasmic membranes by blocking production of adenosine triphosphate.

### Suggested Uses/Dosages

If using shampoo, leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. Refer to product label for details on individual use.

### Precautions/Adverse Effects

May cause skin irritation.

### Veterinary-Labeled Topical Chloroxylenol Products

This list contains only products where chloroxylenol is one of the main active ingredients. For more products containing chloroxylenol (PCMX), see other topical compounds in this section.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Chloroxylenol Scrub*</b> (Vedco)	Scrub: 2%	OTC	Propylene glycol, citric acid. Used for surgical scrub and preoperative skin preparation. Use full strength. Do not dilute. Labeled for dogs and cats. 1 gal.
<b>Medicated Shampoo*</b> (Sogeval)	Shampoo: Chloroxylenol 2% Salicylic acid 2% Sodium thiosulfate 2%	OTC	Propylene glycol, citric acid. Also has antiseborrheic effect. Labeled for dogs and cats. 16 oz; 1 gal.
<b>Vet Solutions Sebozole Shampoo*</b> (Vetoquinol)	Solution: Chloroxylenol 1% Miconazole nitrate 1%	OTC	Also has antimycotic effect. Labeled for dogs and cats. 8, 16 oz; 1 gal.
<b>Vet Solutions Universal Medicated Shampoo*</b> (Vetoquinol)	Solution: Chloroxylenol 2% Salicylic acid 2% Sodium thiosulfate 2%	OTC	Propylene glycol, citric acid. Also has antiseborrheic effect. Labeled for dogs and cats. 16 oz.
<b>VPS Medicated Shampoo*</b> (Jeffers)	Solution: Chloroxylenol 2% Salicylic acid 2% Sodium thiosulfate 2%	OTC	Also has antiseborrheic effect. Labeled for dogs and cats. 16 oz; 1 gal.

### Human-Labeled Topical Chloroxylenol Products

There are several topical products available containing chloroxylenol usually combined with other ingredients such as hydrocortisone, menthol, pramoxine, and benzocaine. They are presented in different forms (creams, ointments, lotions and shampoos), but are not commonly used in dogs and cats. Trade names include: *Aurino*®, *Calamycin*®, *Cortamax*®, *Cortane-B*®, *Dermacoat*® and *Foille*®

### ENZYMES, TOPICAL (LACTOPEROXIDASE, LYSOZYME, LACTOFERRIN)

For otic use, refer to the Otics section

### Indications/Actions

These products may be useful for bacterial and fungal skin infections and are reported to be effective against *Staphylococcus* spp., *Pseudomonas* spp., *Malassezia* spp., *Candida albicans*, *Microsporum* spp. They can be used alone, or especially with products containing hydrocortisone, for mild itching or as an adjunctive treatment for more pruritic conditions such as atopic dermatitis.

The veterinary products contain the milk-derived enzymes lactoperoxidase, lysozyme and lactoferrin. These enzymes are reported to be effective against bacterial, fungal and viral microorganisms. Lactoperoxidase combined with hydrogen peroxide, thiocyanate, and/or iodide produce hypothiocyanate or hypiodite ions that are bactericidal by oxidizing components of bacterial cell walls. Hypiodite also is fungicidal. Lactoferrin acts as a bacteriostatic agent against many bacteria by depriving them of iron.

### Suggested Uses/Dosages

If using spray, cream or wipes: 1–2 times a day applications. If shampoo or rinse: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. May be applied to affected areas 2 times a day or as needed to relieve itching and soothe the skin. Refer to product label for details on individual use.

### Precautions/Adverse Effects

Overall appears to be safe. No reported side effects, but skin irritation is possible.

### Veterinary-Labeled Topical Products

Product (Company)	Form: Concentration	Label Status	Ingredients; Comments; Size(s)
<b>Zymox Topical Spray*</b> (PKB)	Spray	OTC	Lactoperoxidase, lysozyme, lactoferrin. Available with and without Hydrocortisone 1%. 2 oz.
<b>Zymox Topical Cream*</b> (PKB)	Cream	OTC	Lactoperoxidase, lysozyme, lactoferrin. Available with and without Hydrocortisone 1%. 1 oz.
<b>Zymox Topical Wipes*</b> (PKB)	Wipes	OTC	Lactoperoxidase, lysozyme, lactoferrin. Available with and without hydrocortisone 1%. 30 wipes.
<b>Zymox Enzymatic Shampoo*</b> (PKB)	Shampoo	OTC	Lactoperoxidase, lysozyme, lactoferrin. 12 oz.
<b>Zymox Enzymatic Rinse*</b> (PKB)	Rinse	OTC	Lactoperoxidase, lysozyme, lactoferrin. 12 oz.

### Human-Labeled Topical Products

None

### ETHYL LACTATE

(eth-*il* lak-tate) Etiderm®

### Indications/Actions

Ethyl lactate shampoos can be used for bacterial skin infections, including surface and superficial pyodermas. It also has a keratoplastic effect, which provides anti-seborrheic activity.

A lipid soluble compound, ethyl lactate rapidly penetrates hair follicles and sebaceous glands where bacterial lipases convert it into lactic acid and ethanol, which are responsible for its antibacterial action. Ethanol helps solubilize fats and reduces sebaceous secretions. It is not as active as benzoyl peroxide against staphylococcal organisms, but it is less irritating and drying.

### Suggested Dosages/Use

Daily to 2–3 weekly baths. Shampoo should remain in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

### Precautions/Adverse Effects

Ethyl lactate shampoos are often used in conjunction with oral antibiotics and are usually used 2–3 times per week initially; frequency of use may be reduced when pyoderma is under control.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Adverse effects are unlikely, but local effects (erythema, pain, itching) are possible.

#### Veterinary-Labeled Topical Ethyl Lactate Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Etiderm Shampoo</b> <sup>®</sup> (Virbac)	Shampoo: 10% (in Spherulite <sup>®</sup> and free form)	OTC	Chitosanide (in Spherulite <sup>®</sup> and free form), benzalkonium chloride (in encapsulated form), lactic acid, propylene glycol in a shampoo base. Labeled for dogs & cats. Shake well. 8, 16 oz, 1 gal.

#### Human-Labeled Topical Ethyl Lactate Products

None

#### HYPOCHLOROUS ACID SODIUM HYPOCHLORITE

(hye-poe-klor-us-ass-id)

#### Indications/Actions

The proprietary products, *Vetericyn*<sup>®</sup> and *Microcyn*<sup>®</sup> contain hypochlorous acid and sodium hypochlorite and are labeled for the management of wounds, abscesses, cuts, abrasions, skin irritations, ulcers, post surgical incision sites, burns and wound odors and to accelerate healing. It may be used for prevention of bacterial skin infections or as an adjunctive topical therapy for bacterial skin infections, including Methicillin-Resistant *Staphylococcus* spp. and *Pseudomonas* spp. Hypochlorous acid also has anti-fungal and antiviral properties and is reported to reduce inflammation, pain and itching.

These products are a proprietary formulation and have broad-spectrum antimicrobial activity and act rapidly against gram-positive and gram-negative bacteria and fungal/yeast organisms. They may also be effective against viruses. The products *Vetericyn*<sup>®</sup> and *Microcyn*<sup>®</sup> contain oxochlorine (bleach-like) compounds and have a neutral pH. Mode of action is to disrupt the cellular membrane of single cell organisms. Because mode of action is primarily chemical in nature, resistance does not appear to be an issue.

#### Suggested Dosages/Use

Clip hair if necessary and apply spray or gel to affected areas up to 3 times a day; may be used with dressing applications on wounds. Refer to product label for details on individual use. No rinsing is required. Labeled as safe to use around eyes, nose and mouth.

#### Precautions/Adverse Effects

No precautions or adverse effects reported. Reported as non-toxic; does not sting or irritate the skin, however treated area may become reddened secondary to increased blood flow.

#### Veterinary-Labeled Topical Hypochlorous Acid Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Vetericyn<sup>®</sup> VF</b> (Innovacyn)	Spray/liquid: Hypochlorous Acid <0.1% Sodium hypochlorite 0.001%	OTC	Labeled for dogs and cats, including puppies and kittens. 4, 8, 16 oz.
<b>Vetericyn<sup>®</sup> VF Hydrogel</b> (Innovacyn)	Spray/gel: Hypochlorous Acid <0.1% Sodium Hypochlorite 0.001% Boric Acid 0.5%	OTC	Labeled for dogs and cats, including puppies and kittens. 4, 8, 16 oz.
<b>Vetericyn<sup>®</sup> Wound and Infection Treatment</b> (Innovacyn) <b>Vetericyn<sup>®</sup> Hot Spot Spray</b> (Innovacyn) <b>Vetericyn<sup>®</sup> Wound and Infection Treatment</b> (Innovacyn)	Spray/liquid: (all products contain the same formula): Hypochlorous Acid <0.01% Sodium Hypochlorite 0.001%	OTC	Depending on product, labeled for dogs, cats, horses, or all animals. 4, 8, 16 oz.

#### Human-Labeled Topical Hypochlorous Acid Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Microcyn<sup>®</sup> Skin &amp; Wound HydroGel</b> <b>Microcyn<sup>®</sup> Dermatology HydroGel</b> <b>Microcyn<sup>®</sup> Dermatology Spray</b> <b>Microcyn<sup>®</sup> Solution with Preservatives</b> <b>Microcyn<sup>®</sup> Skin and Wound Care</b> <b>Microcyn<sup>®</sup> Negative -Pressure Wound Therapy Solution</b> <b>Puracyn<sup>®</sup> Wound and Skin Care</b> All products are by: Oculus Innovative	All products contain: Hypochlorous Acid 0.008% Sodium Hypochlorite 0.002%	Depending on labeling either OTC or Rx	Product sizes range from 1.5 oz to 990 mL
<b>Myclins<sup>®</sup> Spray</b> (Union Spring)	Spray: Hypochlorous Acid 0.00025% Sodium Hypochlorite 0.0036%	OTC	pH: 6.2-7.8. 2 oz.

#### POVIDONE IODINE

(poe-vi-done-eye-oh-dine) Betadine<sup>®</sup>

#### Indications/Actions

Povidone iodine can be used as a topical pre-surgical skin cleanser/antiseptic and may be used for superficial pyoderma and *Malassezia* dermatitis, however; it is infrequently used in small animal dermatology due to its drying, irritating and staining effects.

An iodophore antiseptic, povidone iodine is rapidly bactericidal (against gram-positive and -negative bacteria) at low concentration. It is also fungicidal and sporicidal (as a 1% aqueous solution). Povidone acts by slowly releasing iodine to tissues. It has prolonged activity (4–6 hours), but not as long as chlorhexidine. Povidone iodine also has mild degreasing and debriding activity.

#### Suggested Dosages/Use

For veterinary products, refer to product label for details on individual use

#### Precautions/Adverse Effects

Povidone may be drying, irritating and staining to skin, hair and fabrics. Can be extremely irritating to the scrotal skin and external ears. Use with emollients may alleviate the drying effects. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Systemic absorption can result in renal and thyroid dysfunction.

#### Veterinary-Labeled Topical Povidone Iodine Products

There are several trade names used for povidone iodine products, including *Povidern*<sup>®</sup>, *Prodine*<sup>®</sup>, *Vetadine*<sup>®</sup>, *Betadine*<sup>®</sup>, *Lanodine*<sup>®</sup>, *Viodine*<sup>®</sup> and *Povidine*<sup>®</sup>. There are also (not listed) hoof dressings, teat dips, and udder washes available that contain povidone iodine.

**Note:** 10% povidone iodine yields 1% titratable iodine and so forth. Labels may be confusing.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Povidern Medicated Shampoo</b> <sup>®</sup> (Butler)	Shampoo: 5%	OTC	8 oz, 1 gal.
<b>Viodine Medicated Shampoo</b> <sup>®</sup> (Farnam)	Shampoo: 5%	OTC	1 pt.
<b>Povidone Iodine Solution</b> (various manufacturers and trade names)	Solution: 10%	OTC	1 qt, 1 gal

<b>Povidone Iodine Ointment</b> (various manufacturers and trade names)	Ointment: 10%	OTC	1 lb.
<b>Povidone Iodine Surgical Scrub</b> (various manufacturers and trade names)	Scrub: 7.5%	OTC	1 gal

### Human-Labeled Topical Povidone Iodine Products

There are several trade names used for povidone iodine products, including *Betadine*®, *Betagen*®, *Biodine*®, *Etodine*®, *Mallisol*®, *Minidyne*®, *Polydine*® and *Povidine*®. There are also (not listed) vaginal gels, swabs, and foaming skin cleansers available.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Povidone Iodine Solution</b> (various manufacturers and trade names)	Solution: 10%	OTC (Human)	15, 30, 120 mL, 1 pt, 1 qt, 1 gal
<b>Povidone Iodine Spray</b> (various manufacturers and trade names)	Spray: 10% Aerosol: 5%	OTC (Human) OTC (Human)	30, 60 mL, 1 pt, 1 gal 89 mL
<b>Povidone Iodine Surgical Scrub</b> (various manufacturers and trade names)	Scrub: 5.5–7.5%	OTC (Human)	15 mL, 1 pt, 1 gal
<b>Povidone Iodine Ointment</b> (various manufacturers and trade names)	Ointment: 10%	OTC (Human)	1 g pkts, 30, 120 g, 1 lb.

### TRICLOSAN (IRGASAN)

(trye-klose-san)

#### Indications/Actions

Found in several products, often with other active ingredients, triclosan's antibacterial effects may be useful in treating superficial pyodermas. Veterinary products labeled for small animals containing triclosan as the sole active ingredient are all shampoos.

Triclosan is a bis-phenol disinfectant/antiseptic. It has activity against a wide range of organisms, including both gram-positive and gram-negative bacteria and acts via inhibiting bacterial fatty acid synthesis leading to disruption of cell membrane integrity. Triclosan reportedly is not effective against *Pseudomonas* spp. and may be less effective against staphylococci than either chlorhexidine or ethyl lactate.

#### Suggested Dosages/Use

Daily to weekly baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

#### Precautions/Adverse Effects

Triclosan should not be used on burned or denuded skin, or mucous membranes. Avoid contact with eyes.

Triclosan is not recommended as a surgical scrub. Clients should wash hands after application or wear gloves when applying. Allergic contact reactions may occur.

### Veterinary-Labeled Triclosan Products

There are also triclosan products labeled for use as teat sealants (*Uddergold Dry*®) in cattle.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Sebalyt Shampoo</b> ® (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC	Labeled for dogs and cats. 8, 12 oz, 1 gal.
<b>Triclosan Shampoo</b> (Davis)	Shampoo: % not listed	OTC	12 oz, 1 gal.

### Human-Labeled Triclosan Products

There are several human triclosan products labeled as hand, face or body washes for acne treatment. Trade names include *Septisofl*®, *Clearasil Antibacterial*®, *Clearasil Daily Face Wash*®, *Stri-Dex*®, *Oxy Medicated Soap*®, and *ASC*®.

#### Antifungals

### CLOTRIMAZOLE, TOPICAL

(kloe-trye-ma-zole) *Lotrimin*®

#### Indications/Actions

Topical clotrimazole has activity against dermatophytes and yeasts; it may be useful for localized lesions associated with *Malassezia*. It is not very effective in treating dermatophytosis in cats. Most veterinary products contain gentamicin and either, betamethasone or mometasone, and are labeled for otic use. However, these products may be used in an extra-label manner for bacterial and yeast skin infections with concurrent inflamed/pruritic skin.

Clotrimazole inhibits the biosynthesis of ergosterol, a component of fungal cell membranes leading to increased membrane permeability and probable disruption of membrane enzyme systems.

#### Suggested Dosages/Use

If sprays, twice daily applications are usually recommended. Ointments are generally applied to affected areas up to four times daily. For veterinary products, refer to product label for details on individual use.

#### Precautions/Adverse Effects

*Products with clotrimazole alone:*

Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible, but unlikely to occur with products containing only clotrimazole.

*If using products containing betamethasone or mometasone:*

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20–30 minutes after application. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing's, gastrointestinal effects) and skin atrophy (skin fragility, alopecia, localized pyoderma and comedones are other possible complications) occur as product concentration and duration of use increases. Betamethasone may delay wound healing particularly if used longer than 7 days in duration. Vomiting and diarrhea have been reported with use of the products containing betamethasone. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

### Veterinary-Labeled Topical Clotrimazole Products

**Note:** There are several products containing clotrimazole for otic use; refer to that section for more information.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Clotrimazole Solution</b> (Vet Solutions, Butler, Vedco)	Spray or Solution: 1%	Rx	30 mL
<b>Otomax</b> ® Ointment (Intervet/Schering)	Ointment (otic):	Rx	Mineral oil base. Approved for otic use in dogs; used in extra-label manner for bacterial skin lesions or <i>Malassezia</i> dermatitis; 7.5, 10, 15, 20 and 215 g bottles or tubes
<b>DVMAX</b> ® Ointment (DVM)	All Products contain: Gentamicin		
<b>Vetromax</b> ® Ointment (Dechra)	3 mg/g; Betamethasone (as valerate)		
<b>MalOtic</b> ® Ointment (Vedco)	1 mg/g; Clotrimazole 10 mg/g		
<b>MoMetaMax Otic Suspension</b> ®	Suspension (otic):	Rx	Mineral-oil base. Approved

(Intervet/Schering-Plough)	Per gram: Mometasone 1 mg; Gentamicin 3 mg; Clotrimazole 10 mg	for otic use in dogs, but used extra-label (see above). In 7.5, 15, 30, 215 g tubes.
----------------------------	---	--

### Human-Labeled Topical Clotrimazole Products

In addition to the products listed below, there vaginal creams and suppositories, and oral 10 mg troches.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Clotrimazole</b> (various); <b>Cruex</b> ® (Novartis); <b>Lotrimin AF</b> ® (Schering-P); <b>Desenex</b> ® (Novartis)	Solution: 1%	OTC/Rx (Human). Status determined by labeling	Depending on product: 105-113 mL
<b>Lotrimin AF</b> ® (Schering-P);	Lotion: 1%	OTC (Human)	20 mL
<b>Clotrimazole &amp; Betamethasone Diprop.</b> (Fougera) <b>Lotrisone</b> ® (Schering)	Lotion: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	30 mL
<b>Clotrimazole</b> (various); <b>Lotrimin AF</b> ® (Schering)	Cream: 1%	OTC/Rx (Human). Status determined by labeling	Depending on product: 10, 30 mL
<b>Clotrimazole &amp; Betamethasone Diprop.</b> (generic) <b>Lotrisone</b> ® (Schering)	Cream: Clotrimazole 1% Betamethasone dip. 0.05%	Rx (Human)	15, 45 g.

### ENILCONAZOLE

(ee-nil-kon-a-zole)

#### Indications/Actions

Although no dosage forms are currently commercially available for topical use in the USA, enilconazole is used topically for treating dermatophytosis in small animals and horses using compounded products. A commercially available topical rinse *Imaverol*® (Janssen) 10% is available with canine, bovine and equine use labeling in many countries. Intranasal instillation of enilconazole after plaque debridement has also been shown useful in treating nasal aspergillosis in small animals.

Use of topical enilconazole on cats with dermatophytosis is somewhat controversial as there are apparently no products with feline labeling available in Europe or Canada. There are reports of safely and successfully using enilconazole on dermatophytic cats alone, or in combination with oral itraconazole.

A topical product and a poultry environmental disinfectant product (*Clinafarm EC*®) are available in the USA. This formulation has been used off-label to treat dermatophytosis at a dilution of 55.6 ml per gallon water as a topical antifungal. However, it is technically illegal to use this product other than it is labeled, as it is an EPA-licensed product in the USA.

#### Suggested Dosages/Use

Using *Imaverol*®: dilute as directed and wash or dip 4 times, at 3-day intervals or as directed by veterinarian. Refer to product label for details on individual use.

#### Precautions/Adverse Effects

Avoid contact with eyes. Clients should wear gloves when applying and use eye protection.

When used topically in cats, hypersalivation, vomiting, anorexia/weight loss, muscle weakness, and a slight increase in serum ALT levels have been reported.

#### Veterinary-Labeled Topical Enilconazole Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Imaverol</b> ® (Janssen)	Concentrate: 10%	Not available in USA	Concentrate is diluted to 0.2% (1 part concentrate to 50 parts water). For Dogs: Dilute as directed and wash 4 times, at 3-day intervals. May also use as a dip. Not labeled for use on cats. 100 mL
<b>Clinafarm EC</b> ® (Schering Plough)	Emulsifiable Concentrate: 13.8%	OTC-EPA Pesticide	Labeled for the control of <i>Aspergillus fumigatus</i> contamination in poultry hatchery equipment. It is a violation of US Federal Law to use this product in a manner inconsistent with its labeling. Corrosive; may cause irreversible eye damage. Labeling includes several warnings on ingestion or exposure. 750 mL

#### Human-Labeled Topical Enilconazole Products

None

### KETOCONAZOLE, TOPICAL

(kee-toe-kah-na-zole) Nizoral®, Ketochlor®

For systemic use, see the [monograph](#) found in the main section

For otic use, see the [Otics](#) section

#### Indications/Actions

Topical ketoconazole has activity against dermatophytes and yeasts and ketoconazole shampoos can be effective treatment for *Malassezia* dermatitis. Patients with severe, generalized infections may require additional systemic therapy. Topical ketoconazole shampoos are generally ineffective (or minimally effective) when used alone for dermatophytosis.

#### Suggested Dosages/Use

If using spray or wipes/pads: 1–2 times a day. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

#### Precautions/Adverse Effects

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible.

#### Veterinary-Labeled Topical Ketoconazole Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Ketoseb-D® Spray</b> (Sogeval)	Spray: Chlorhexidine 2% Ketoconazole 1%	Rx	Labeled for dogs and cats. 8 oz.
<b>Mal-A-Ket Plus TrizEDTA Spray</b> ® (Dechra)	Leave-on Spray: Chlorhexidine 2% Ketoconazole 1% TrizEDTA	Rx	Labeled for dogs and cats. 8 oz.
<b>Malacetic Ultra Spray</b> ® (Dechra)	Spray: Ketoconazole 0.15% Hydrocortisone 1% Acetic Acid 1% Boric Acid 2%	Rx	Labeled for dogs and cats. 8 oz.
<b>Ketoseb-D® Wipes</b> (Sogeval)	Wipes: Chlorhexidine 2% Ketoconazole 1%	Rx	Labeled for dogs and cats. 50 count jar.

<b>Mal-A-Ket® Wipes</b> (Dechra)	Wipes: Chlorhexidine 2% Ketoconazole 1% Acetic Acid 2%	Rx	Labeled for dogs and cats. 50 count jar.
<b>Mal-A-Ket Plus TrizEDTA® Flush</b> (Dechra)	Flush: Chlorhexidine 0.15% Ketoconazole 0.15% TrizEDTA	Rx	A multicleanse flush to aid in the treatment of bacterial and fungal (dermatophytosis and malassezia) infections. pH 8. Labeled for dogs and cats. 4, 12 oz.
<b>Ketoseb-D® Flush</b> (Sogeval)	Flush: Chlorhexidine 2% Ketoconazole 1%	OTC	Labeled for dogs and cats. 4, 16 oz.
Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Mal-A-Ket® Shampoo</b> (Dechra)	Shampoo: Ketoconazole 2% Acetic Acid 2% Chlorhexidine 2%	Rx	Labeled for dogs and cats. 1 oz pouch, 8 oz; 1 gal.
<b>Ketochlor Shampoo®</b> (Virbac)	Shampoo: Chlorhexidine 2.3% Ketoconazole 1%	Rx	<i>Spherulites®</i> Microcapsules. Glycotechnology (monosaccharides: L-thamnose, D-mannose, D-galactose; polysaccharide: alkyl polyglucoside), chitosanide. Labeled for dogs and cats. 8, 16 oz, 1 gal.
<b>ResiKetoChlor Leave-On Conditioner®</b> (Virbac)	Conditioner: Chlorhexidine 4% Ketoconazole 1%	OTC	<i>Spherulites®</i> Microcapsules. Glycotechnology (monosaccharides: L-thamnose, D-mannose, D-galactose; polysaccharide: alkyl polyglucoside), chitosanide. Labeled for dogs and cats. 8 oz.

#### Human-Labeled Topical Ketoconazole Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Nizoral A-D®</b> (McNeil)	Shampoo: 1%	OTC (Human)	207 mL
<b>Nizoral®</b> (McNeil)	Shampoo: 2%	Rx (Human)	Aqueous suspension. 120 mL
<b>Ketoconazole</b> (Clay-Park)	Shampoo: 2%	Rx (Human)	118 mL
<b>Ketoconazole</b> (Teva)	Cream: 2%	Rx (Human)	Aqueous vehicle containing cetyl alcohol, stearyl alcohol, sodium sulfite. 15, 30 60 g.
<b>Nizoral®</b> (McNeil)	Cream: 2%	Rx (Human)	15, 30, 60 g.

#### LIME SULFUR (SULFURATED LIME SOLUTION)

(*lyme sul-fur*) LymDyp®

#### Indications/Actions

Lime sulfur applications are very effective and relatively inexpensive as a generalized topical treatment for dermatophytosis. Both lime sulfur and enilconazole are thought to have the most topical activity against *M. canis* of commercially available compounds. In addition, it is the most efficacious treatment of surface demodicosis (*Demodex gato*) in cats. Lime sulfur can also be useful in the adjunctive treatment of Malassezia dermatitis, Cheyletiellosis, Chiggers, Sarcoptic and Notoedric mange, fur mites, lice, canine demodicosis and sarcoptic mange.

Lime sulfur has antibacterial and antifungal (and some anti-yeast) properties secondary to the formation of pentathionic acid and hydrogen sulfide after application. Both lime sulfur and enilconazole are thought to have the most topical activity against *M. canis*. Lime sulfur may also have keratolytic, keratoplastic, antiparasitic, and antipruritic effects.

#### Suggested Dosages/Use

Labeled dose for *LymDyp®* and *Vet Solutions Lime Sulfur Dip®*: Shake well; dilute 4 oz. of concentrate in one gal of water. Mix well. Apply as a rinse or dip at 5–7 day intervals. Do not rinse. For more chronic or resistant cases, may be used at 8 oz per gal.

Labeled dose for *LimePlus Dip®* and *Lime Sulfur Dip®*: Pour 4 oz. of concentrate in one gal of water. Mix well. Bathe animal prior to application. Rinse off shampoo. Pour entire contents of diluted *LimePlus Dip®* onto pet and work into skin. Apply as a rinse, spray or dip at 5–7 day intervals. Allow to dry on the animal. Do not rinse. When used for dermatophytosis, once to twice weekly treatments have been recommended, if patients can tolerate the treatment's irritating effects, until 2 consecutive negative cultures are obtained. When used for confirmed cases of feline surface demodicosis, applications are recommended every 5–7 days for a total of 6 treatments. If using lime sulfur as a treatment trial for surface demodicosis, 3 applications should be performed and if there is significant improvement in clinical signs, 3 more applications should be performed to complete treatment. If no significant improvement is seen after 3 applications, demodicosis should be ruled out and other diagnosis should be considered.

#### Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Can stain porous surface (*e.g.*, concrete, porcelain) or permanently discolor jewelry. Clients should wear gloves and protect skin and eyes from solution. Because of its very unpleasant odor, application should be performed in a well-ventilated area or clients should wear a protective (respirator-type) mask.

While reasonably non-toxic, lime sulfur may cause skin irritation or drying. Adding mineral oil to the solution may reduce its drying effects. Lime sulfur can stain (temporarily) light colored fur and rarely cause hair loss on the pinnae in cats. Lime sulfur's odor may persist on treated animals, but generally is tolerable once the patient dries. Oral ingestion can rarely cause nausea and oral ulcers, mainly in cats; an Elizabethan collar may help prevent this from occurring.

#### Veterinary-Labeled Lime Sulfur Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>LymDyp®</b> (DVM)	Concentrate: 76.9%	OTC	Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above). 16 oz, 1 gal.
<b>LimePlus Dip®</b> (Dechra)	Concentrate: 97.8%	OTC	Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above). 4, 16 oz., 1 gal.
<b>Vet Solutions Lime Sulfur Dip®</b> (Vetoquinol)	Concentrate: 97.8%	OTC	Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above). 4, 16 oz.
<b>Lime Sulfur Dip®</b> (DVMs)	Concentrate: 97.8%	OTC	Labeled for dogs, puppies, kittens and cats. Shake well and dilute before use (see dosages above). 16 oz.
<b>LymDyp® Spray</b> (DVM)	Solution: 76.9%	Rx	Labeled for dogs, puppies, kittens and cats. Scented (less strong odor compared to concentrated solutions). Already diluted and ready to use. 16 oz.

#### Human-Labeled Lime Sulfur Products

None

#### MICONAZOLE, TOPICAL

(*mye-kah-nah-zole*)

For otic use, refer to the Otics section

#### Indications/Actions

Topical miconazole has activity against dermatophytes and yeast. It is especially effective for the treatment of *Malassezia* dermatitis. Patients with severe, generalized infections may require systemic therapy. Lotions, sprays and creams are generally used for localized lesions associated with *Malassezia* sp. or dermatophytes. Topical miconazole products are generally ineffective (or minimally effective) when used alone for dermatophytosis.

ointments are generally used for localized lesions unless oral or dermatophyte topical miconazole products are generally ineffective (or primarily effective) when used alone for dermatophytosis. adjunctive systemic treatment is usually required.

Miconazole's actions are a result of altering permeability of fungal cellular membranes and interfering with peroxisomal and mitochondrial enzymes, leading to intracellular necrosis. Miconazole products are fungicidal with repeated application.

### Suggested Dosages/Use

If using spray, creams, lotions or wipes/pads: 1–2 times a day applications. If using a shampoo or conditioner: daily to weekly baths; leave in contact with skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

### Precautions/Adverse Effects

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Do not allow animal lick or chew at affected areas for at least 20-30 minutes after application.

Skin irritation is possible, but unlikely to occur, but in very inflamed, eroded to ulcerated skin, the pledgets, wipes, towelettes, and spray containing alcohol (*Malaseb*®) can be severely irritating.

### Veterinary-Labeled Topical Miconazole Products

**Note:** Miconazole nitrate is the salt generally used in pharmaceutical products. While technically, a 1% concentration of miconazole nitrate contains less than 1% miconazole, the following products are rounded to the closest full percent regardless of how much miconazole base is actually in each product.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Micro-Pearls Advantage Miconazole 1% Spray</b> ® (Vetoquinol)	Spray: 1%	Rx	Labeled for dogs, cats, & horses. 4 oz.
<b>Conofite Spray</b> ® 1% (Intervet/Schering-Plough)	Spray: 1%	Rx	Labeled for dogs and cats. 60 mL
<b>Micaved Spray</b> ® 1% (Vedco)	Spray: 1%	Rx	Labeled for use on dogs and cats. 60 mL
<b>Malaseb</b> ® Spray (DVM)	Spray: Miconazole nitrate 2% Chlorhexidine 2%	OTC	Alcohol 30%. Labeled for use in dogs, cats, & horses. 8 oz.
Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Micazole Spray</b> ® (Butler)	Spray: 1%	Rx	Labeled for use on dogs and cats. 120, 240 mL
<b>Malaseb</b> ® Flush (DVM)	Flush: Miconazole nitrate 2% Chlorhexidine 2%	OTC	Labeled for use on dogs and cats. 4, 12 oz.
<b>Malaseb</b> ® Concentrate Rinse (DVM)	Rinse: Miconazole nitrate 5.2% Chlorhexidine 5.9%	Rx	Labeled for use on dogs, cats, and horses. Must be diluted before use. 8, 32 oz.
<b>Malaseb</b> ® Pledgets (DVM)	Pledget (medicated pad): 17.4 Miconazole 20 mg Chlorhexidine	OTC	Alcohol 30%. Labeled for use in dogs, cats, & horses. 60 per container.
<b>Malaseb</b> ® Towelettes (DVM)	Towelettes: Miconazole 20 mg Chlorhexidine 20 mg	OTC	Alcohol 30%. Labeled for dogs, and cats. 12 and 60 count jars.
<b>Conofite Cream</b> ® 2% (Intervet/Schering-Plough)	Cream: 2%	Rx	Labeled for use on dogs and cats. 15 g
<b>Resizole Leave-On Lotion</b> ® (Virbac)	Lotion: 2%	Rx	Labeled for use on dogs and cats. 8 oz.
<b>Priconazole Lotion</b> ® 1% (First Priority)	Lotion: 1%	Rx	Polyethylene glycol, ethyl alcohol. Labeled for dogs and cats. 60 mL
<b>Miconosol Lotion</b> ® 1% (Med-Pharmex)	Lotion: 1%	Rx	Labeled for use on dogs and cats. 60 mL
<b>Conofite Lotion</b> ® 1% (Intervet/Schering-Plough)	Lotion: 1%	Rx	Labeled for use on dogs and cats. 30 mL
<b>Micaved Lotion</b> ® 1% (Vedco)	Lotion: 1%	Rx	Labeled for use on dogs and cats. 60 mL
<b>Micazole Lotion</b> ® 1% (Butler)	Lotion: 1%	Rx	Labeled for use on dogs and cats. 60 mL
<b>Sebazole</b> ® Shampoo (Vet Solutions)	Shampoo: Miconazole 2%, Chloroxyleneol 1%	Rx	Salicylic acid, sodium thiosulfate. Labeled for dogs, cats, and horses. 8, 12 oz, 1 gal.
<b>Dermazole Shampoo</b> ® (Virbac)	Shampoo: Miconazole 2%, Salicylic Acid 2%	Rx	Labeled for use on dogs and cats. 6, 16 oz.
<b>Malaseb Shampoo</b> ® (DVM)	Shampoo: Miconazole 2%, Chlorhexidine 2%	OTC	Labeled for dogs, cats, and horses. 8, 12 oz, 1 gal.

### Human-Labeled Topical Miconazole Products

In addition to the products listed below, there are 2% topical vaginal creams, vaginal suppositories, 2% powders and spray powders available. Most human-labeled products are OTC.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Micatin</b> ® (Ortho); <b>Neosporin AF</b> ® (Pfizer); <b>Lotrimin AF</b> ® (Schering); <b>Prescription Strength Desenex</b> ® (Ciba)	Spray (liquid): 2%	OTC (Human)	Depending on product: 90-115 mL
<b>Tetterline</b> ® (SSS Co.)	Ointment: 2%	OTC (Human)	30 g.
<b>Zeosorb-AF</b> ® (Stiefel)	Gel: 2%	OTC (Human)	24 g.
<b>Miconazole Nitrate</b> (Taro); <b>Micatin</b> ® (Ortho); <b>Monistat-Derm</b> ® (Ortho); <b>Neosporin AF</b> ® (Pfizer)	Cream: 2%	OTC (Human)	Depending on product: 15, 30, 90 g

### NYSTATIN

(nye-sta-tin)

For oral use, see the [monograph](#) found in the main section.

### Indications/Actions

Because of limited dosage forms and other alternative antiyeast medications readily available, nystatin is not usually used alone in small animal medicine. The combination products (*e.g.*, *Panalog*®, etc.) can be useful for topical lesions caused by yeasts or yeast-like organisms; they have been used for mixed otitis infections for many years.

Nystatin has efficacy against many yeasts and yeast-like organisms (*Malassezia*). Its mechanism of action is believed secondary to binding to sterols in the fungal cell membranes thereby increasing membrane permeability with leakage of intracellular components. Nystatin does not have activity against bacteria and is ineffective against other fungi.

### Suggested Dosages/Use

Nystatin (topical) is rarely used alone in veterinary medicine. In humans, the cream is usually used instead of the ointment in treating candidal-infections involving intertriginous areas; nystatin topical powder is best used for very moist lesions.

Nystatin products that contain triamcinolone are best suited for focal (*e.g.*, pedal) or multifocal lesions for relatively short durations (*e.g.*, less than 2 months). Initially, topical corticosteroids are usually used sparingly 1–4 times per day and then frequency is tapered when control is achieved.

## Precautions/Adverse Effects

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Nystatin alone is very safe, although hypersensitivity reactions are possible. The combination veterinary products are usually well tolerated when used on skin. Neomycin can cause localized sensitivity and those containing glucocorticoids can potentially cause cutaneous atrophy HPA-axis suppression.

## Veterinary-Labeled Nystatin-Containing Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Derma-Vet Cream</b> <sup>®</sup> (Med-Pharmex)	Cream: Nystatin 100,000 units/g Triamcinolone Acet. 1 mg Neomycin Sulf. 2.5 mg Thiostrepton 2,500 units	Rx	Aqueous vanishing cream. Labeled for use in dogs or cats. 7.5, 15 g.
<b>Panalog Ointment</b> <sup>®</sup> (Pfizer)	Ointment:	Rx	Labeled for use in dogs or cats. 7.5, 15, 30, 240 mL
<b>Animax Ointment</b> <sup>®</sup> (Dechra)	Nystatin 100,000 units/g		
<b>Quadrapot Ointment</b> <sup>®</sup> (Butler)	Triamcinolone Acet. 1 mg		
<b>Derma-Vet Ointment</b> <sup>®</sup> (Med-Pharmex)	Neomycin Sulf. 2.5 mg		
<b>Demalog Ointment</b> <sup>®</sup> (RXV)	Thiostrepton 2,500 units		

## Human-Labeled Topical Nystatin Products

In addition to the products listed below, there are vaginal tablets and oral products. Oral products are found in the main section.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Nystatin</b> (various)	Powder: 100,000 units/g	Rx (Human)	Depending on product: 15, 30, 60 g.
<b>Nystatin</b> (various)	Ointment: 100,000 units/g	Rx (Human)	Depending on product: 15, 30 g.
<b>Nystatin</b> (various)	Cream: 100,000 units/g	Rx (Human)	Depending on product: 15, 30, 240 g.
<b>Nystatin-Triamcinolone Acetonide</b> (various)	Ointment: Nystatin 100,000 units/g	Rx (Human)	Depending on product: 15, 30, 60, 120 g.
<b>Mycogen II</b> <sup>®</sup> (Goldline)	Triamcinolone Acet. 0.1%		
<b>Mycolog-II</b> <sup>®</sup> (Bristol Meyers Squibb)			
<b>Myco-Triacet II</b> <sup>®</sup> (Lemmon)			
<b>Nystatin-Triamcinolone Acetonide</b> (various)	Cream: Nystatin 100,000 units/g	Rx (Human)	Depending on product: 1.5 g. pkts, 15, 30, 60, 120 g.
<b>Mycogen II</b> <sup>®</sup> (Goldline)	Triamcinolone Acet. 0.1%		
<b>Mycolog-II</b> <sup>®</sup> (Bristol Meyers Squibb)			
<b>Myco-Triacet II</b> <sup>®</sup> (Lemmon)			
<b>Myconel</b> <sup>®</sup> (Mamel)			

## SELENIUM SULFIDE

(si-leeen-ee-um sul-fide)

## Indications/Actions

Selenium sulfide may be useful in seborrheic disorders (mainly for seborrhea oleosa) and for adjunctive treatment of *Malassezia* dermatitis, particularly in dogs exhibiting signs of waxy, greasy or scaly (seborrheic) dermatitis. There may be some residual activity on the skin.

Selenium sulfide possesses antifungal (including sporocidal activity), keratolytic, keratoplastic and degreasing properties. It affects cells of the epidermis and follicular epithelium (alters the epidermal turnover) and interferes with hydrogen bond formation of keratin thereby reducing corneocyte production. Selenium sulfide's antifungal mechanism of action is not well understood.

## Suggested Dosages/Use

Frequency of shampooing will vary according to the patient's needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3–5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

## Precautions/Adverse Effects

Selenium sulfide products should **not be used on cats**. Avoid contact with eyes. Selenium sulfide can discolor jewelry. Clients should wear gloves when using these products.

Selenium sulfide can be irritating, cause excessive drying and hair-coat staining. Mucous membranes and scrotal areas may be particularly sensitive to the irritating effects of the drug.

After discontinuation, a rebound seborrhea can occur where signs could be worse than prior to treatment. Gastrointestinal effects (nausea, vomiting, diarrhea) may occur selenium sulfide is ingested orally. Neurologic signs are possible if large quantities are ingested. Contact an animal poison center if a substantial oral ingestion occurs.

## Veterinary-Labeled Topical Selenium Sulfide Products

There apparently are no labeled veterinary products containing selenium sulfide currently available in the USA; *Selen*<sup>®</sup> may be available in other countries.

## Human-Labeled Topical Selenium Sulfide Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Selenium Sulfide</b> (various)	Shampoo/Lotion: 1%	OTC (Human)	210 mL
<b>Selsun Blue Medicated Treatment</b> <sup>®</sup> (Chatterm)	Shampoo/Lotion: 1%	OTC (Human)	Menthol. 325 mL
<b>Head &amp; Shoulders Intensive Treatment</b> <sup>®</sup> (P&G)	Shampoo/Lotion: 1%	OTC (Human)	400 mL
<b>Selenium Sulfide</b> (various)	Lotion: 2.5%	Rx (Human)	120 mL
<b>Selsun</b> <sup>®</sup> (Abbott)	Lotion: 2.5%	Rx (Human)	120 mL

## TERBINAFINE HCL, TOPICAL

(ter-bin-a-feeen) Lamisil<sup>®</sup>

For systemic use, see the [monograph](#) found in the main section

## Indications/Actions

An allylamine antifungal agent, terbinafine may be useful for localized lesions associated with *Malassezia*. With its current topical dosage forms, it does not appear to be very useful for treating dermatophytosis in cats.

Terbinafine inhibits the biosynthesis of ergosterol, but its mechanism for inhibiting ergosterol is different from the azole antifungals. Terbinafine inhibits the fungal squalene epoxidase enzyme. The resultant depletion of ergosterol within the fungal cell membrane and the intracellular accumulation of squalene are believed to be responsible for the fungicidal effect of terbinafine. It is fungicidal against dermatophytes, but may only be fungistatic against yeasts.

## Suggested Dosages/Use

Topical terbinafine is not commonly used in veterinary medicine at present, but it could be used topically to affected areas once to twice a day.

## Precautions/Adverse Effects

Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible, but unlikely to occur.

## Veterinary-Labeled Topical Terbinafine Products

None

## Human-Labeled Topical Terbinafine Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Lamisil ATB</b> (Ciba-Geigy) <sup>®</sup> topical	Cream: 1%	OTC (Human)	15, 30 g.

<b>Lamisil AT*</b> (Ciba-Geigy), generic	Cream: 1%	OTC (Human)	15, 30 g
<b>Lamisil*</b> (Ciba-Geigy)	Solution: 1%	Rx (Human)	Alcohol, 30 mL
<b>Lamisil AT*</b>	Spray: 1%	OTC (Human)	Ethanol, benzyl alcohol, 30 mL
<b>Lamisil Advanced*</b> (Ciba-Geigy)	Gel: 1%	OTC (Human)	Ethanol, propylene glycol, 6 & 12 g

## Keratolytic Agents

Also see the:

- **BENZOYL PEROXIDE** monograph in the Antibacterials section
- **PHYTOSPHINGOSINE** monograph in the Non-Corticosteroid Antipruritic/Antiinflammatories section
- **SELENIUM SULFIDE** monograph in the Antifungals section

## SALICYLIC ACID

(sal-i-sil-ic acid)

### Indications/Actions

Often combined with sulfur, salicylic acid shampoos are employed to treat patients with seborrheic disorders (seborrhea sicca and oleosa) exhibiting mild to moderate scaling, with mild waxy and keratinous debris. When combined with benzoyl peroxide, salicylic acid and sulfur containing shampoos can also be used to manage seborrhea oleosa. In higher concentrations, topicals such as *Kerasolv® Gel* (6.6% salicylic acid) can be used to remove localized excessive tissues associated with hyperkeratotic disorders, such as calluses and idiopathic thickening of the planum nasale and footpads.

Salicylic acid has mildly antipruritic, antibacterial (bacteriostatic), keratoplastic and keratolytic actions. Lower concentrations are primarily keratoplastic and higher concentrations, keratolytic. Salicylic acid lowers skin pH, increases corneocyte hydration and dissolves the intercellular binder between corneocytes. Salicylic acid and sulfur are thought to be synergistic in their keratolytic actions.

### Suggested Dosages/Use

Frequency of shampooing will vary according to the patient's needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3-5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

### Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Burning, itching, pain, erythema, swelling can occur from salicylic acid, particularly when used in higher concentrations (> 2%). A rebound seborrheic effect can occur.

### Veterinary-Labeled Topical Salicylic Acid Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Kerasolv Gel*</b> (DVM)	Gel: 6.6%	OTC	Labeled for use on dogs, cats, & horses. Other ingredients (humectants): sodium lactate and urea, propylene glycol. Rub in well. Usually used once daily initially, may reduced to 2-3 times per week once remission occurs. Often requires life-long treatment. 30 mL
<b>Derma-Cleans* Cream</b> (Pfizer)	Cream: Salicylic acid, Benzoic acid, Malic acid, Concentrations not listed (proprietary).	OTC	Labeled as an acidic cleansing cream for use on wounds, abrasions, burns, and other dermatological conditions. 1oz, 14 oz.
<b>Dermazone Shampoo*</b> (Virbac)	Shampoo: Miconazole 2% Salicylic Acid 2%	Rx/OTC	6, 16 oz.
<b>Sebalyt Shampoo*</b> (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC	8, 12 oz, 1 gal.
<b>Nova Pearls Medicated Dandruff Shampoo*</b> (Tomlyn)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC	<i>Novasome*</i> moisturizers. 12 oz, 1 gal.
<b>Keratolux Shampoo*</b> (Virbac)	Shampoo: Salicylic Acid 1% Zinc Gluconate 0.5% Pyridoxine 0.5%	OTC	<i>Spherulites*</i> , fatty acids, tea tree leaf oil. Shake well; wear gloves. 8, 16 oz; 1 gal
<b>Sebolux Shampoo*</b> (Virbac)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC	Chitosanide, urea, glycerin. Ingredients in free form and in <i>Spherulites*</i> . Shake well; wear gloves. 8, 16 oz; 1 gal
<b>Oxiderm* Shampoo</b> (Sogeval)	Shampoo: Salicylic acid 2% Benzoyl peroxide 3% Sulfur 2%	OTC	8, 16 oz.
<b>Oxiderm* Shampoo + PS</b> (Sogeval)	Shampoo: Salicylic acid 2% Benzoyl peroxide 3% Microsized sulfur 2% Phytosphingosine HCl 0.05%	OTC	8, 16 oz, 1 gal
<b>Micro Pearls Advantage Seba-Moist Shampoo*</b> (Vetoquinol)	Shampoo: Salicylic Acid 2% Sulfur 2%	Rx	<i>Novasome*</i> microvesicles. Labeled for dogs and cats. Shake well; wear gloves. 12 oz, 1 gal.
<b>Micro Pearls Advantage Seba-Hex Shampoo*</b> (Vetoquinol)	Shampoo: Chlorhexidine 2% Salicylic Acid 2% Sulfur 2%	Rx	<i>Novasome*</i> microvesicles. Labeled for dogs, cats and horses. Shake well; wear gloves. 12 oz, 1 gal.
<b>Vet Solutions Universal Medicated Shampoo*</b> (Vetoquinol)	Solution: Chloroxylenol 2% Salicylic acid 2% Sodium thiosulfate 2%	OTC	Propylene glycol, citric acid. Also has antiseborrheic effect. Labeled for dogs and cats. 16 oz.
<b>NuSal-T*</b> (DVM)	Shampoo: Salicylic acid 3%, Coal Tar 2%, menthol 1%	OTC	Labeled for dogs; in 237 mL, 355 mL & 3.78 L

### Human-Labeled Topical Salicylic Acid Products

**Note:** There are many topical salicylic acid products labeled for human use, including topical creams, ointments, transdermal patches, liquids and gels that are principally labeled for wart removal. Except for one product (*Salex®*; 6% cream), they are available OTC. There are also many OTC skin cleansers and shampoos containing salicylic acid and usually sulfur (sometimes coal tar or menthol). As there are several similar products formulated and labeled for animal use, human products will not be listed. For more information on these products, refer to a comprehensive human drug reference or contact a pharmacist.

## Indications/Actions

Often combined with salicylic acid, sulfur-containing shampoos are often employed to treat patients with seborrheic disorders exhibiting mild to moderate scaling, with mild waxiness and keratinous debris.

Sulfur has keratoplastic and keratolytic actions. Lower concentrations of sulfur are primarily keratoplastic secondary to assisting conversion of cysteine to cystine, thought an important factor in the maturation of corneocytes. Like salicylic acid, sulfur's keratolytic effects increase with concentration. Salicylic acid and sulfur are believed synergistic in their keratolytic actions. Sulfur also has mild degreasing effects and can be mildly antipruritic.

Sulfur also has antibacterial, antifungal, and antiparasitic effects secondary to sulfur conversion to hydrogen sulfide and pentathionic acid by bacteria and keratocytes.

## Suggested Dosages/Use

Frequency of shampooing will vary according to the patient's needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3-5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

## Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Sulfur can be drying, cause pruritus and be irritating. Residual odor is often bothersome to clients. Sulfur may stain fabrics and hair. A rebound seborrheic effect can occur when using shampoo products containing sulfur.

## Veterinary-Labeled Topical Sulfur Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Sebalyt Shampoo*</b> (DVM)	Shampoo: Triclosan 0.5% Sulfur 2% Salicylic acid 2%	OTC	8, 12 oz, 1 gal.
<b>Micro Pearls Advantage Seba-Hex Shampoo*</b> (Vetoquinol)	Shampoo: Chlorhexidine 2% Salicylic Acid 2% Sulfur 2%	Rx	Novasome® microvesicles. Labeled for dogs, cats and horses. Shake well; wear gloves. 12 oz, 1 gal.
<b>Micro Pearls Advantage Seba-Moist Shampoo*</b> (Vetoquinol)	Shampoo: Salicylic Acid 2% Sulfur 2%	Rx	Novasome® microvesicles. Labeled for dogs and cats. Shake well; wear gloves. 12 oz, 1 gal.
<b>Sebolux Shampoo*</b> (Virbac)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC	Chitosanide, urea, glycerin. Ingredients in free form and in <i>Spherulites</i> ®. Shake well; wear gloves. 8, 16 oz; 1 gal
<b>Oxiderm® Shampoo</b> (Sogeval)	Shampoo: Sulfur 2% Salicylic acid 2% Benzoyl peroxide 3%	OTC	8, 16 oz
<b>Oxiderm Shampoo + PS</b> (Sogeval)	Shampoo: Microsized sulfur 2% Salicylic acid 2% Benzoyl peroxide 3% Phytosphingosine HCl 0.05%	OTC	8, 16 oz, 1 gal
<b>Keratolux Shampoo*</b> (Virbac)	Shampoo: Salicylic Acid 1% Zinc Gluconate 0.5% Pyridoxine 0.5%	OTC	<i>Spherulites</i> ®, fatty acids, tea tree leaf oil. Shake well; wear gloves. 8, 16 oz, 1 gal
<b>Dermapet Demasebs Shampoo*</b> (Dermapet)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC	8 oz, 1 gal
<b>Nova Pearls Medicated Dandruff Shampoo*</b> (Tomlyn)	Shampoo: Salicylic Acid 2% Sulfur 2%	OTC	Novasome® moisturizers. 12 oz, 1 gal.
<b>Paraguard Shampoo*</b> (First Priority)	Shampoo: Captan 2% Sulfur 1%	OTC	Labeled as an anti-ringworm, antifungal, antibacterial shampoo for dogs, cats & horses. 32 oz.
<b>Sulf OxyDex Shampoo*</b> (DVM)	Shampoo: Benzoyl peroxide 2.5% Sulfur (micronized) 2%	Rx	8, 12 oz, 1 gal.
<b>Medicated Shampoo</b> (Vet Solutions, Sogeval)	Shampoo: Sodium Thiosulfate 2% (source of soluble sulfur) Salicylic Acid 2% Chloroxylenol 2%	OTC	16 oz, 1 gal

## Human-Labeled Topical Sulfur Products

**Note:** There are several topical products containing sulfur labeled for human use, including topical creams, lotions, shampoos, soaps and masks that are principally labeled for acne or dandruff. For more information on these products, refer to a comprehensive human drug reference (*e.g., Facts and Comparisons*) or contact a pharmacist.

## COAL TAR

(*cole tar*)

## Indications/Actions

Use of coal tar containing shampoos in veterinary medicine is somewhat controversial, particularly since almost all veterinary-labeled products have been withdrawn from the market. However, coal tar shampoos have been used in dogs for treating greasy dermatoses (seborrhea oleosa) for many years.

Coal tar possesses keratoplastic, keratolytic, vasoconstrictive, antipruritic, and degreasing actions. Coal tar's mechanism of keratoplastic (keratoregulating) action is probably secondary to decreasing mitosis and DNA synthesis of basal epidermal cells.

## Suggested Dosages/Use

Frequency of shampooing will vary according to the patient's needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3-5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

## Precautions/Adverse Effects

The carcinogenic risks associated with coal tar products are hotly debated. At present, most (including the FDA) believe that coal tar products with concentrations of 5% or less are safe for human use. However, should they be used on animals, clients should wear gloves when applying and wash off any product that contacts their skin. Carcinogenic risk assessment for dogs using coal tar products was not located.

Coal tar products should **not be used on cats**, patients who have prior sensitivity reactions to tar products or have dry scaling dermatoses.

Be careful in comparing coal tar concentrations on labels. Coal tar solution contains approximately 20% coal tar extract or refined tar. For example, a 10% coal tar solution contains approximately 2% coal tar (refined).

Photosensitization, skin drying and skin irritation are possible with tar therapy. Adverse effects are more likely with tar concentrations greater than 3%. Residual odor is often bothersome to clients. Tar may stain fabrics or haircoats and discolor jewelry.

## Veterinary-Labeled Coal Tar-Containing Products

Product (Company)	Form: Concentration (Concentrations listed as refined tar or extract)	Label Status	Other Ingredients; Size(s)
-------------------	--	--------------	----------------------------

<b>NuSal-T® (IVX)</b>	Shampoo: Coal Tar 2%, Salicylic acid 3%, menthol 1%	OTC (Human)	Labeled for dogs; in 237 mL, 355 mL & 3.78 L
-----------------------	---	-------------	--

## Human-Labeled Coal Tar-Containing Products

There several products labeled for human use that contain coal tar, including ointments, lotions, creams, and shampoos available in concentrations ranging from 0.5%-5% coal tar (not coal tar extract).

## Antiseborrheic Products

See the:

## Immunomodulators, Topical

### IMIQUIMOD, TOPICAL

(*imi-i-kwi-mod*) Aldara®

## Indications/Actions

An immune response modifier, imiquimod may be useful in the treatment of a variety of topical conditions in animals. It is labeled for use on humans as a treatment for genital or perianal warts, superficial basal cell carcinomas and actinic keratoses of the face and scalp. In dogs and cats, imiquimod potentially may be of benefit in treating feline herpes virus dermatitis, actinic keratosis, squamous cell carcinoma and Bowen's disease, papillomas virus lesions, and localized solar dermatitis or solar carcinoma *in situ*. Many of these indications are based upon anecdotal evidence, as there are very few studies published for veterinary use. In horses, imiquimod has been anecdotally used with success in treating sarcoids.

Imiquimod stimulates the patient's own immune system to release a variety of cytokines including interferon-alpha and interleukin-12. This locally generated cytokine milieu induces a Th1-immune response with the generation of cytotoxic effectors. Imiquimod itself does not have *in vitro* activity against wart viruses, but stimulates monocytes and macrophages to release cytokines that induce a regression in viral protein production.

## Suggested Dosages/Use

Use in animals is still rather limited and ongoing research on this agent is being performed. Doses and treatment regimens will vary depending on the disease treated and tolerance to the drug. At present, dosing ranges from applying a thin film once daily to 2–3 times weekly or every-other-week. Treatment duration and frequency may need to be adjusted depending on patient response and adverse reactions.

## Precautions/Adverse Effects

Clients administering the drug should wear gloves when handling or applying the cream. It is advised to avoid getting in eyes or on mucous membranes; but dogs with oral mucosal papillomas have been treated without significant problems. While there are low chances the drug would be absorbed systemically, do not allow animal to groom/lick the applied site; occlusive dressings should not be used over the treatment site. Application site should not be touched after application. Avoid exposure of the site to sunlight; there is concern that there may be an increased risk for sunburn after use (not proven).

Local skin reactions are common with imiquimod therapy and include application site reactions: erythema, burning, tenderness, pain, irritation, oozing/exudate and erosion. Treatment duration and frequency may need to be adjusted depending on response and irritant reactions. Depigmentation and hair loss may occur at application sites as post-treatment sequelae.

## Veterinary-Labeled Imiquimod Products

None

## Human-Labeled Imiquimod Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Aldara®</b> (Graceway)	Cream: 5%	Rx (Human)	Cetyl alcohol, stearyl alcohol, white petrolatum, benzyl alcohol, parabens. Single use 250 mg packets in boxes of 12.

### PIMECROLIMUS, TOPICAL

(*pim-e-kroe-li-mus*) Elidel®

## Indications/Actions

A relatively new addition to the human topical armamentarium, pimecrolimus cream may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease or other cutaneous vasculopathies, alopecia areata, vitiligo, perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy), and for feline proliferative and necrotizing otitis externa. Unlike topical corticosteroids, pimecrolimus does not have atrophogenic or metabolic effects associated with long-term or large area treatment.

Pimecrolimus acts similarly as cyclosporine and tacrolimus, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils. Pimecrolimus may not have identical mechanisms of action as tacrolimus, as it did not impair the primary immune response (as did tacrolimus) in mice after a contact sensitizer was applied. Both drugs did impair the secondary response however. Any clinical significance associated with this difference is not yet clear.

## Suggested Dosages/Use

Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled, then reduce application frequency to the fewest times that allow control of the disease.

## Precautions/Adverse Effects

Both tacrolimus and pimecrolimus have FDA-mandated "black box" warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (*e.g.*, a Q-tip) when applying the cream. The long-term adverse effects of topical pimecrolimus are currently unknown; therefore, it is prudent to avoid using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that keeps the disease under control.

Topical pimecrolimus appears well tolerated in dogs, but localized irritation and pruritus have been reported in humans and dogs using the drug. Early anecdotal reports state that pimecrolimus may be less irritating than tacrolimus in dogs, but that it also may not be as effective. The cost of the medication may be prohibitive for some clients.

## Veterinary-Labeled Topical Pimecrolimus Products

None

## Human-Labeled Topical Pimecrolimus Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Size(s)
<b>Elidel®</b> (Novartis)	Cream: 1%	Rx (Human)	30, 60, 100 g.

### TACROLIMUS, TOPICAL

(*ta-kroe-li-mus*) Protopic®

## Indications/Actions

Tacrolimus ointment may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo and for perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy). Unlike topical corticosteroids, tacrolimus or pimecrolimus do not have atrophogenic or metabolic effects associated with

long-term or large area treatment.

Tacrolimus acts similarly as cyclosporine, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils.

### Suggested Dosages/Use

Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled, then reduce application frequency to the fewest times that allow control of the disease.

### Precautions/Adverse Effects

Both tacrolimus and pimecrolimus have FDA-mandated “black box” warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (*e.g.*, a Q-tip) when applying the ointment. The long-term adverse effects of topical tacrolimus are currently unknown; therefore, it is prudent to avoid using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that keeps the disease under control.

The commercially available ointment should not be used as, or compounded into an ophthalmic preparation for treating KCS in dogs as it contains propylene carbonate, a known ocular toxin.

Thus far, topical tacrolimus appears to be well tolerated in dogs, but localized irritation and pruritus have been reported in humans and dogs using the drug. Early anecdotal reports state that pimecrolimus may be less irritating than tacrolimus in dogs, but that it may also not be as effective. The cost of the medication may be cost prohibitive for some clients.

### Veterinary-Labeled Topical Tacrolimus Products

### Human-Labeled Topical Tacrolimus Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Size(s)
<b>Protopic®</b> (Astellas Pharma)	Ointment: 0.03, 0.1%	Rx (Human)	30, 60, 100 g.

### Retinoids, Topical

#### TRETINOIN (TRANS-RETINOIC ACID; VITAMIN A ACID)

(*tret-in-oin*) Retin-A®

### Indications/Actions

Topical tretinoin may be useful in treating localized follicular or hyperkeratotic disorders such as acanthosis nigrans, idiopathic nasal and footpad hyperkeratosis, callous pyodermas, or chin acne.

Tretinoin’s exact mechanism of action is not well understood, but it stimulates cellular mitotic activity, increases cell turnover, and decreases the cohesiveness of follicular epithelial cells.

### Suggested Dosages/Use

In small animals, topical tretinoin gel is usually used initially at a concentration of 0.05% and is applied once daily. Treatment continues as long as the animal tolerates the treatment or until controlled. Once controlled, usage is then reduced to as needed. In animals unable to tolerate therapy, concentration may be reduced to 0.025–0.01% in an attempt to balance efficacy with adverse effects.

### Precautions/Adverse Effects

Avoid sun exposure during treatment with tretinoin. Avoid contact with eyes, nostrils, inner ears, or mouth. Clients should wear gloves when applying the product.

Adverse effects can include hypersensitivity reactions or local irritation (erythema, dryness, peeling, pruritus).

### Veterinary-Labeled Topical Tretinoin Products

<b>Retin-A Micro®</b> (Ortho)	Gel: 0.05%	Rx (Human)	Microspheres. 20, 45 g.

### Antiparasitic Agents, Topical

For agents such as [eprinomectin](#), [ivermectin](#), [levamisole](#), [moxidectin](#) and [selamectin](#) that may be administered topically, but absorbed through the skin to treat internal parasites as well as external parasites, refer to the monographs in the main (systemic drugs) section of the Handbook. Also see monographs in the main section for those products administered orally for their external parasitic actions, including [lufenuron](#), [nitenpyram](#), [milbemycin](#), and [spinosad](#).

#### AMITRAZ

(*a-mi-traz*) Mitaban®, Taktic® EC, Preventic®, ProMeris® for Dogs

### Indications/Actions

In dogs, amitraz solution is used topically primarily in the treatment of generalized demodicosis. A topical spot-on solution (*ProMeris® for Dogs*) and a collar (*Preventic®*) are available for treatment and prevention of flea and tick infestation. It is also used as a general insecticidal/miticidal agent in several other species (see label information). The pharmacologic action of amitraz is not well understood, but it is a monoamine oxidase (MAO) inhibitor (in mites) and may have effects on the CNS of susceptible organisms. It apparently also possesses alpha-2 adrenergic activity and inhibits prostaglandin synthesis. Amitraz can cause a significant increase in plasma glucose levels, presumably by inhibiting insulin release via its alpha2-adrenergic activity. Yohimbine (alpha2 blocker) or atipamezole can antagonize this effect.

### Suggested Dosages/Use

#### ■ DOGS:

For treatment of generalized demodicosis:

**Note:** The general rule of thumb for therapy duration independent of the protocol chosen involves treating for 30 days past two consecutive negative skin scrapings.

#### Labeled Dose Protocol

Long and medium haired dogs should be clipped closely and given a shampoo with mild soap and water prior to first treatment. Topically treat at a concentration of 250 ppm (one 10.6 mL bottle of *Mitaban®* in 2 gallons of warm water), by applying to entire animal and allowing to air dry. DO NOT rinse or towel dry. Use a freshly prepared dilution for additional dogs or additional treatments. Repeat every 14 days for 3–6 treatments (continue until six treatments done or two successive skin scrapings demonstrate no live mites). Chronic cases may require additional courses of therapy. (Package Insert; *Mitaban®*—Upjohn)

#### Extra-label Protocols:

1) For dogs whose owners accept the risk of using the drug in an “unlicensed” manner with the goal of increasing efficacy, first try the 250 ppm solution (as above) *once weekly* for 4 weeks. If positive response is seen, continue treatment for an additional 30 days after obtaining two consecutive negative skin scrapings (rule of thumb). If weekly 250 ppm application fails, a 500 ppm solution may be tried (1 bottle in 1 gallon of water) weekly as above. In dogs failing 500 ppm, 1000 ppm may also be attempted, but likelihood of toxicity increases and the authors have no experience using this high concentration. If these methods fail, the dog is unlikely to be cured using amitraz.

2) Prepare a 0.125% solution by diluting 1 mL of the 12.5% commercially available large animal product (*Taktic®*) in 100 mL of water. Using a sponge rub the diluted solution (0.125%) *daily onto one-half of the dog’s*

body and alternate sides on a daily basis. Air dry. During the first week of therapy, keep dog hospitalized and observe for adverse effects.

Follow rule of thumb above for duration of therapy.

Dogs with severe pododemodicosis should be also treated with daily foot soaks of the 0.125% solution. Dogs with otic demodicosis can be treated with a diluted solution of amitraz (1 mL of Tactic in 8.5 mL of mineral oil) every 3–7 days unless irritation develops. Owners accepting the extra-label therapy, must be carefully screened and trained to carefully handle the amitraz solutions.

#### ■CATS:

For follicular demodicosis (*Demodex cati*) (**Note:** extra-label; not labeled for use on cats): Dilute amitraz to 0.0125% (125 ppm) and apply every 7–14 days. Monitor cats very closely for potential side effects. Place an Elizabethan-collar until the solution is completely dry.

For surface demodicosis (*Demodex gatoi*) (**Note:** extra-label; not labeled for use on cats): Dilute amitraz to 0.0125% (125 ppm) and apply every 7 days for 12 weeks. Monitor cats very closely for potential side effects. Place an Elizabethan-collar until the solution is completely dry. (Saari S. AM. et al. Acta Veterinaria Scandinavica; 51:40, 2009).

#### ■Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:

1.4 mL per liter topically every 2 weeks (q14 days) for 3–6 treatments. **Caution:** Not recommended in young animals or rabbits. (Adamcak, A. & B. Otten (2000). Rodent Therapeutics. Vet Clin NA: Exotic Anim Pract 3:1(Jan): 221-240)

#### Precautions/Adverse Effects/Drug Interactions

Amitraz liquid concentrates are flammable until diluted with water. Do not stress animals for at least 24 hours after application of *Mitaban*®. When mixing with water, protect exposed skin with rubber gloves, etc. After application to animal, wash hands and arms well. Dispose of unused diluted solution by flushing down the drain. Rinse *Mitaban*® container with water and dispose; do not re-use. Do not re-use collar or container; wrap in newspaper and throw in trash. Avoid inhalation of vapors. Animals treated may exhibit signs of sedation; if animal is un-arousable or sedation persists for longer than 72 hours, contact your veterinarian.

Safety has not been demonstrated in dogs less than 4 months of age. The manufacturer of *Mitaban*® does not recommend use in these animals. Toy breeds may be more susceptible to CNS effects (transient sedation); lower dose rates (½ of recommended) have been recommended in these breeds. Because of the drug's effects on plasma glucose, use with caution in brittle diabetic patients. Reproductive safety has not been established. Use only when benefits outweigh potential risks of therapy

The most commonly reported adverse effect after amitraz topical administration is transient sedation that may persist for up to 72 hours (24 hours is usual). If treating around eyes, use an ophthalmic protectant (e.g., petrolatum ophthalmic ointment) before treating. Do not use if dog has deep pyodermas with drainage tracts; postpone application until lesions improve after treating with antibiotic and shampoo therapy. Other adverse effects include: ataxia, bradycardia, vomiting, diarrhea, hypothermia and a transient hyperglycemia. Rarely, seizures have been reported. Topical effects can include edema, erythema and pruritus. Adverse effects are more likely to be seen in debilitated, geriatric, or very small breed dogs.

Amitraz can be toxic to cats and rabbits and it is probably best to avoid its use in these species, although amitraz has been used safely in cats in diluted form for the treatment of demodicosis.

Amitraz may be toxic if swallowed (by either animals or humans). Beagles receiving 4 mg/kg PO daily for 90 days, demonstrated transient ataxia, CNS depression, hyperglycemia, decreased pulse rates and lowered body temperature. No animals died.

Amitraz toxicity can be significant if amitraz-containing insecticide collars are ingested. Treatment should consist of emesis, retrieval of the collar using endoscopy if possible and administration of activated charcoal and a cathartic to remove any remaining collar fragments. Because of the risk of an increased chance of gastric dilatation, gastrotomy may not be a viable option. Yohimbine at a dose of 0.11–0.2 mg/kg IV (start with low dosage) may be of benefit for overdose effects. Because yohimbine has a short half-life it may need to be repeated, particularly if the animal has ingested an amitraz-containing collar that has not been retrieved from the GI tract. Atipamezole has also been used to treat amitraz toxicity; refer to that monograph for more information. Contact a poison center for more information, if necessary.

Because of their immunosuppressive effects, **corticosteroids** and **other immunosuppressant drugs** (e.g., azathioprine, cyclophosphamide, etc) should not be used in animals with demodicosis.

Amitraz may interact with other MAO inhibitors (including **selegiline**) or tricyclic antidepressants (**amitriptyline**, **clomipramine**). Concomitant use is not recommended.

Clients should wear gloves when applying and wash off any product that contacts their skin.

#### Veterinary-Labeled Amitraz Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients: Comments: Size(s)
<b>Mitaban</b> ® (Pfizer) <b>Note:</b> This product's availability has been undependable in past years; may not be available	Solution for Dilution: 19.9%	Rx	10.6 mL btt. FDA labeled and approved for use on dogs. <b>Note:</b> Liquid is flammable until diluted.
<b>Taktic</b> ®EC (Intervet)	Solution (emulsifiable concentrate) for Dilution: 12.5%	OTC-EPA	760 mL cans. EPA labeled for use on swine, dairy or beef cattle. Label states not to use on dogs or horses.
<b>ProMeris</b> ® for Dogs (BIVI)	Spot-On Solution: amitraz 150 mg/mL; metaflumizone 150 mg/mL	OTC-EPA	For dogs and puppies 8 weeks of age or older. Must not be used on cats. See the product label for more information. Packaged in 5 different sizes according to dog's weight.

#### Human-Labeled Amitraz Products

None

#### CROTAMITON

(kroe-ta-mye-ton) Eurax®

#### Indications/Actions

Crotamiton is a topical miticide/scabicide and has been used primarily for adjunctive treatment (with ivermectin) for treating mite infections (e.g., Knemidoptotes) in birds. Crotamiton has both miticidal and antipruritic actions, but the mechanism for each is not known.

#### Suggested Dosages/Use

Once to twice daily applications are usually recommended.

#### Precautions/Adverse Effects

Do not apply around eyes or mouth. Little is known of the compound's safety profile; irritation or hypersensitivity reactions are possible.

#### Veterinary-Labeled Crotamiton Products

None

<b>Eurax</b> ® (Ranbaxy)	Lotion: 10%	Rx (Human)	Cetyl alcohol, emollient base. 60, 454 g.

#### DELTAMETHRIN

(del-ta-meeth-rin)

#### Indications/Actions

In the United States, deltamethrin-impregnated collars are labeled for killing fleas and ticks on dogs. In countries where leishmaniasis is a problem, deltamethrin-impregnated collars are also indicated for repelling and killing the phlebotomine sandfly vectors.

Deltamethrin is a synthetic pyrethroid and acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

#### Suggested Dosages/Use

The manufacturer recommends applying a new collar every 6 months and claims that maximum effect may not occur before 2 to 3 weeks after collar placement. Follow label for specific use instructions.

### Precautions/Adverse Effects

Collars containing deltamethrin should not be used in dogs younger than 12 weeks of age. Avoid contact with eyes, skin or clothing. Consult a veterinarian before using on debilitated, pregnant, nursing, old or medicated animals. Skin reactions at the application site may occur. Mammalian exposure to deltamethrin is classified as safe; however, it should be used very carefully around water because deltamethrin is highly toxic to aquatic animals, especially fish

### Veterinary-Labeled Deltamethrin Products

### DINOTEFURAN + PYRIPROXYFEN (± PERMETHRIN)

### Indications/Actions

The product containing dinotefuran and pyriproxyfen (*Vectra*®) labeled for dogs and cats is used for control of adult and all immature flea stages including eggs, larvae and pupae. The exclusive dog product contains in addition to dinotefuran and pyriproxyfen, permethrin (*Vectra 3D*®), which kills and repels adult and immature fleas, ticks and mosquitoes.

Dinotefuran is a nitroguanidine, neonicotinoid insecticide with a structure similar to acetylcholine. It permanently binds to the same insect receptor sites as acetylcholine and activates the nerve impulse at the synapse causing stimulation, which results in tremors, incoordination and insect death. Dinotefuran does not bind to mammalian acetylcholine receptor sites.

The commercially available products also contain pyriproxyfen (a second-generation insect growth regulator) and, in the case of *Vectra 3D* (for dogs only), permethrin.

### Suggested Dosages/Use

Refer to the package information for specific instructions on application and dosages of dinotefuran-containing products. Monthly applications are recommended for dogs and cats. It is labeled for cats and kittens 8 weeks of age or older and dogs or puppies 7 weeks of age or older. Apparently bathing or swimming does not interfere with efficacy; however, the authors do not recommend bathing the pet until two days after application.

### Precautions/Adverse Effects

The dog product containing permethrin (*Vectra 3D*®) **must not be used on cats or on dogs that cohabit with a cat**. The manufacturer recommends not using *Vectra 3D*® or *Vectra*® on debilitated, aged, medicated, pregnant or nursing animals and animals known to be sensitive to pesticide products. Mild transitory skin erythema may occur at the application site. Avoid eye and oral contact since Dinotefuran can cause substantial, but temporary eye irritation.

### Veterinary-Labeled Topical Dinotefuran Products

### Human-Labeled Dinotefuran Products

None

### FIPRONIL ± (S)-METHOPRENE±

(*fip-roe-nil*; *meth-oh-preen*) **Frontline®, Frontline® Plus**

### Indications/Actions

In the USA, Fipronil is indicated for the treatment of fleas, ticks and chewing lice infestations in dogs and cats. It has also been used successfully for *Trombicula autumnalis* (chigger) infestation, sarcoptic mange, cheyletiellosis, chewing lice and otoacariosis.

Fipronil is a phenylpyrazole antiparasitic agent that in invertebrates interferes with the passage of chloride ions in GABA regulated chloride channels, thereby disrupting CNS activity causing death of the flea or tick. The manufacturer states that fipronil collects in the oils of the skin and hair follicles and continues to be released over a period a time resulting in long residual activity. Topically applied, the drug apparently spreads over the body in approximately 24 hours via translocation.

When fipronil is combined with the insect growth regulator (S)-methoprene (*Frontline® Plus*), additionally flea eggs and flea larvae are killed. (S)-methoprene mimics flea juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced.

### Suggested Dosages/Use

#### For fleas, ticks or chewing lice:

Monthly treatments are usually recommended when used for fleas, ticks or chewing lice. See product labels for specific directions on administration and recommendations on bathing/swimming, etc after administration.

#### For *Trombicula autumnalis* infestation:

Fipronil *spray* (0.25%) is recommended Monthly applications throughout the trombiculid season at the dose of 3 to 6 mL/kg. It is important to thoroughly wet the coat with special emphasis on the areas typically affected (feet, ears, face, perineum and tail). In some cases, the interval between applications needs to be shortened to every 14 days.

#### For otoacariosis:

Apply 0.05 mL of fipronil solution inside each ear canal and 0.4 mL between the shoulder blades. Resolution of clinical signs can be seen as early as seven days post-treatment. Additional applications may be needed. Fipronil needs to be applied in the ear canals to be effective.

### Precautions/Adverse Effects

Do not use on puppies or kittens less than 8 weeks of age. This product is reportedly contraindicated in rabbits as deaths have occurred with the spray. Do not apply or spray in eyes. While temporary irritation may occur at the site of administration, animals that have demonstrated sensitivity reactions to fipronil or any of the ingredients in the product should probably not be retreated.

The manufacturer recommends consulting a veterinarian before using on debilitated, aged, or medicated patients.

Do not contaminate food or water and dispose of container properly. Avoid human contact with skin, eyes or clothing and wear gloves when applying/spraying. If using spray, do so in a well ventilated area. Avoid contact with animal until dry. Wash well with soap and water if contact occurs.

contact with animal unit(s); wash well with soap and water if contact occurs.

Product is labeled as remaining effective after bathing (but do not shampoo within 48 hours of application), water immersion, or exposure to sunlight. Spotted areas may appear wet or oily for up to 24 hours after application.

Temporary irritation may occur at the site of administration. Rarely, hypersensitivity has been reported.

#### IMIDACLOPRID

#### IMIDACLOPRID WITH PERMETHRIN

#### IMIDACLOPRID WITH MOXIDECTIN

(eye-mi-da-kloe-prid, per-meth-rin, mox-ih-dek-tin) Advantage®, K9 Advantix®, Advantage®, Advocate®

#### Indications/Actions

Imidacloprid topical solution (*Advantage*®) is indicated for the treatment of adult and larval stage fleas in dogs and cats. The combination product with permethrin (*K9 Advantix*®) is indicated for adulticide/larvicide for fleas, to repel and kill ticks, and mosquitoes in dogs only. The canine combination product with moxidectin (*Advantage*® *Multi for Dogs* in USA and *Advocate*® in Europe) is indicated for the prevention of heartworm disease, adult fleas, adult and immature hookworms, adult roundworms, and adult whipworms. It has been also used successfully for the treatment of sarcoptic mange, cheyletiellosis and mild cases of demodicosis.

The feline combination product (*Advantage*® *Multi for Cats*) is indicated for the prevention of heartworm disease, adult fleas, ear mites, adult and immature hookworms, and adult roundworms.

Imidacloprid's mechanism of action as an insecticide is to act on nicotinic acetylcholine receptors on the postsynaptic membrane causing CNS impairment and death. Certain insect species are more sensitive to these agents than are mammalian receptors. This is a different mechanism of action than other insecticidal agents (organophosphates, pyrethrins, carbamates, insect growth regulators (IGR's) and insect development inhibitors (IDI's)). The manufacturer states that imidacloprid is non-teratogenic, non-hypersensitizing, non-mutagenic, non-allergenic, non-carcinogenic, and non-photosensitizing. The manufacturer states that when applied topically the compound is not absorbed into the bloodstream or internal organs. One combination product for dogs (*K9 Advantix*®) also contains permethrin, a pyrethroid (synthetic pyrethrin) that will kill and repel ticks and mosquitoes. Permethrin's insecticidal activity is as a neurotoxin in susceptible species by slowing sodium ions through sodium channels in neuron membranes. Moxidectin is found in combination products (*Advantage*® *Multi for Dogs* and *Cats*) with imidacloprid. Moxidectin is a macrocyclic lactone that binds to the glutamate-gated ion channels specific to parasites thereby increasing the influx of chloride ions resulting in hyperpolarization of neuronal cells causing paralysis and death.

#### Suggested Dosages/Use

Refer to the package information for specific instructions on application of imidacloprid products. They are generally administered once monthly. While swimming, bathing, and rain do not apparently significantly affect the duration of action, repeated shampooing may require additional treatment(s) before the monthly dosing interval is completed. Do not reapply more often than once weekly for these animals.

#### Precautions/Adverse Effects

The manufacturer lists the following contraindications for imidacloprid (alone): Do not use in puppies younger than 7 weeks old or kittens younger than 8 weeks old. The manufacturer recommends consulting a veterinarian before using on debilitated, aged, pregnant, or nursing animals or those on medication.

The combination product with permethrin (*K9 Advantix*®) **must not be used on cats**. Use with caution in households with both dogs and cats, particularly if cats are in close contact or will groom dogs in the household.

When used as directed, adverse effects are unlikely. Because the drug is bitter tasting, oral contact may cause excessive salivation. Do not get product in eyes. If eye contact occurs (human or animal), flush well with ophthalmic irrigation solution or water. While gloving is not mandated it should be encouraged, as contact with skin should be avoided. Wash hands with soap and water after handling. Keep out of reach of children and do not contaminate feed or food. Dispose of product carefully (in the trash); the permethrin-containing product is extremely toxic to fish.

Imidacloprid topical solutions are usually very well tolerated. Dermal irritation has been reported at the site of application. Hypersalivation, tremors, vomiting and reduced appetite may occur in cats after oral exposure to *Advantage Multi*®. Uncommon to rare adverse reactions reported in dogs treated with *Advantage Multi*® in a field study included pruritus, lethargy, reduced appetite and hyperactivity.

#### Overdoses/Acute Toxicity

Most problems are seen following oral dosing of topical products. Signs include hypersalivation and vomiting, oral ulcers have been rarely reported in cats. There were 119 exposures to imidacloprid reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 57 were dogs with 25 showing clinical signs, 60 cases were cats in which 42 showed clinical signs, 1 case was a turtle that showed clinical signs and the remaining case was a lagomorph that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, hypersalivation, and trembling. Common findings in cats recorded in decreasing frequency included hypersalivation, vomiting, lethargy, and hiding.

#### Veterinary-Labeled Imidacloprid Topical Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Advantage® For Dogs</b> (Bayer)	Topical Solution: imidacloprid 9.1%	OTC-EPA	Flea adulticide/larvicide for use on dogs and puppies 7 weeks of age and older. In cards of 4 or 6 tubes: Under 10 lb. = 0.4 mL (green) 11–20 lb. = 1 mL (teal) 21–55 lb. = 2.5 mL (red) Over 55 lb. = 4 mL (blue)
<b>Advantage® for Cats</b> (Bayer)	Topical Solution: imidacloprid 9.1%	OTC-EPA	Flea adulticide/larvicide for use on cats and kittens 8 weeks of age and older. In cards of 4 or 6 tubes: 9 lb and under = 0.4 mL (orange) Over 9 lb. = 0.8 mL (purple)
<b>K9 Advantix®</b> (Bayer)	Topical Solution: imidacloprid 8.8%, permethrin 44%	OTC-EPA	Flea adulticide/larvicide, tick and mosquito repellent and treatment. For use on dogs and puppies 7 weeks of age and older. In cards of 4 or 6 tubes: Under 10 lb. = 0.4 mL (green) 11–20 lb. = 1 mL (teal) 21–55 lb. = 2.5 mL (red) Over 55 lb. = 4 mL (blue)
<b>Advantage Multi® for Dogs</b> (Bayer)	Topical Solution: imidacloprid 10%, moxidectin 2.5%	Rx	Approved for use on dogs 7 weeks of age or greater, and more than 3 lb body weight
<b>Advantage Multi® for Cats</b>	Topical Solution:	Rx	Approved for use on cats 9 weeks of age or greater,

**Human-Labeled Imidacloprid Products**

None

**METAFLUMIZONE**

(met-ah-floo-mih-zone) ProMeris®

**Indications/Actions**

The canine product (*ProMeris® For Dogs*) contains metaflumizone and amitraz (see amitraz monograph for more information) and is labeled for control of fleas (*Ctenocephalides* spp.), ticks, chewing lice and Demodectic mange mites on dogs and puppies 8 weeks of age and older. The feline product (*ProMeris® For Cats*) is labeled for control of fleas (*Ctenocephalides* sp.) on cats and kittens 8 weeks of age and older.

Metaflumizone blocks the influx of sodium required to propagate a nerve impulse along the axon and dendrite of the neuron causing a reduction in feeding, loss of coordination, paralysis and death of the parasite. Amitraz is a formamidine compound that acts by inhibiting mixed function oxidases in addition to monoamine oxidase. It apparently also has alpha2 adrenergic activity and inhibits prostaglandin synthesis.

**Suggested Dosages/Use**

Refer to the package information for specific instructions on recommended dosages and application of metaflumizone products. For cats, the label states that a single dose is effective for up to 7 weeks in controlling fleas. Apply a single dose prior to exposure. Reapplication at monthly intervals may be appropriate depending upon the level of flea challenge and animal sensitivities (*i.e.* flea allergy dermatitis). Do not apply more than once monthly.

For dogs, the product's label states: A single dose is effective for up to 6 weeks in controlling fleas and up to 4 weeks for ticks. Apply a single dose prior to exposure. Monthly application is recommended for effective control of fleas, ticks, chewing lice and Demodectic mange mites and to prevent re-infestation of fleas, ticks and chewing lice. Do not apply more than once monthly.

**Precautions/Adverse Effects**

The manufacturer does not recommend using in lactating/nursing dogs or cats until at least 5 days post delivery. However, it can be used in breeding dogs (males and females) as well as in pregnant dogs and cats. **The canine formulation must not be used in cats** because it contains amitraz. The manufacturer recommends consulting a veterinarian before applying these products in aged or debilitated animals or animals on medications. The manufacturer also advises contacting a veterinarian if skin irritation, behavior changes, vomiting or diarrhea occurs and persists after application of these products.

Adverse application site events such as focal inflammation, pruritus or alopecia are uncommon. A subset of dogs treated with the combined product may experience clinical signs similar to pemphigus foliaceus (pemphigus-like disease) after one or multiple applications of the product. Lesions may be limited to the application site and surrounding skin or be present at distant sites such as face and feet.

Accidental oral exposure of the combined product containing amitraz (*ProMeris® For Dogs*) may result in decreased activity.

**Veterinary-Labeled Topical Metaflumizone Products**

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<i>ProMeris® for Cats</i> (Pfizer)	Topical Solution: Metaflumizone 9.1%	OTC-EPA	For use on cats and kittens 8 weeks of age and older. Product comes in two sizes: for cats less than 9 lbs, and for those over 9 lbs.
<i>ProMeris® for Dogs</i> (Pfizer)	Spot-On Solution: amitraz 14.34%; metaflumizone 14.34% mg/mL	OTC-EPA	For dogs and puppies 8 weeks of age or older. Must not be used on cats. See the product label for more information. Packaged in 5 different sizes according to dog's weight.

**Human-Labeled Metaflumizone Products**

None

**(S)-METHOPRENE COMBINATIONS**

(meth-oh-preen)

Also see the [Fipronil ± \(s\)-Methoprene](#) listing**Indications/Actions**

Methoprene is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability prevent maturation of eggs or larva.

(s)-methoprene mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (*e.g.*, permethrin, fipronil, phenothrin) all stages of the parasite are killed and re-infestation is less likely.

**Suggested Dosages/Use**

For specific use and dosage recommendations, refer to the actual product's label.

**Precautions/Adverse Effects**

Methoprene may be found in products also containing **permethrin or phenothrin, which can be toxic to cats**, particularly small kittens. **Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats.** Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes.

Methoprene (used alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur. As methoprene is broken down by UV light, protect unused product from light.

**Veterinary-Labeled (s)-Methoprene Topical Products**

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<i>Adams Spot On® Flea &amp; Tick Control</i> (Farnam)	Topical Solution: (s)-Methoprene: 3% Permethrin: 45%	OTC-EPA	Kills and repels adult fleas, ticks and mosquitoes. It also prevents flea eggs from developing into adult fleas. For dogs 6 months of age or older. Must not be used on cats or on dogs that cohabit with a cat. Packaged and labeled by the dog's weight in tubes of 3: <15-30 lbs = 0.034 oz; 31-60 lbs = 0.068 oz; > 60 lbs = 0.101 oz
<i>Bio Spot On® Flea &amp; Tick Control For Dogs</i> (Farnam)	Topical Solution: (s)-Methoprene: 3% Permethrin: 45%	OTC-EPA	Kills and repels adult fleas, ticks and mosquitoes. It also prevents flea eggs from developing into adult fleas. For dogs 6 months of age or older Must not be used on cats or on dogs that cohabit with a cat. Packaged and labeled by the dog's weight in tubes of 3: <15-30 lbs = 0.034 oz; 31-60 lbs = 0.068 oz; > 60 lbs = 0.101 oz
<i>Frontline® Plus for Cats and Kittens</i> (Merial)	Topical Solution: (s)-Methoprene: 11.8%, Fipronil: 9.7%	OTC-EPA	Labeled for use on cats or kittens 8 weeks of age or older. Single dose applicators 50 mL in 3's & 6's.
<i>Frontline® Plus for Dogs &amp; Puppies</i> (Merial)	Topical Solution: (s)-Methoprene: 8.8%, Fipronil: 9.7%	OTC-EPA	Single dose applicators in 3's and 6's; Labeled for dogs or puppies 8 weeks of age or older. For dogs weighing 11–22 lb.: 0.67 mL For dogs weighing 23–44 lb.: 1.34 mL For dogs weighing 45–88 lb.: 2.68 mL For dogs weighing 89–132 lb.: 4.02 mL
<i>Hartz UltraGuard Plus® Flea &amp; Tick Drops for Dogs and Puppies®; Hartz UltraGuard Plus® (Hartz Mountain)</i>	Topical Solution: (s)-Methoprene: 2.3% Phenothrin: 85.7%	OTC-EPA	<b>Note:</b> Phenothrin is a pyrethroid similar to permethrin; refer to the permethrin monograph for more information. For dogs 12 weeks of age and older as weighing more than 4 pounds

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Hartz UltraGuard One Spot® Treatment for Cats and Kittens®</b> (Hartz Mountain)	Topical Solution: (s)-Methoprene: 2.9%	OTC-EPA	and older or weighing more than 4 pounds. Kills fleas, ticks, mosquitoes and flea eggs for 30 days; repels fleas and ticks. Must not be used on cats or on dogs that cohabit with a cat. Packaged and labeled by dogs weight in tubes of 3: 4–15 lb. = 1.1 mL; 16–30 lb. = 1.3 mL; 31–60 lb. = 4.1 mL; > 60 lb. = 5.9 mL
<b>Hartz UltraGuard Plus® Drops for Cats; Hartz UltraGuard Pro®</b> (Hartz Mountain)	Topical Solution: (s)-Methoprene: 3.6% Etofenprox: 40%	OTC-EPA	For kittens 12 weeks of age and older. Kills fleas, flea eggs and deer ticks; kills and repels mosquitoes. 1.8 mL applicators.
<b>Bio-Spot® Flea &amp; Tick Spray for Dogs and Puppies</b> (Farnam)	Topical Spray: (s)-Methoprene: 0.27% Pyrethrins: 0.2% Piperonyl Butoxide: 0.37%	OTC-EPA	Kills and repels fleas, ticks and mosquitoes. Prevents flea eggs from hatching. For dogs 12 weeks of age or older. 24 oz.

#### Human-Labeled (s)-Methoprene Products

None

#### PERMETHRIN

(per-meth-rin)

Also see the [Imidacloprid ± Permethrin](#) listing

#### Indications/Actions

Permethrin is synthetic pyrethroid that acts as an adulticide insecticide/miticide. It has knockdown activity against fleas, lice, ticks, and certain mites (e.g., *Cheyletiella*, *Sarcoptes scabiei*). Permethrin also has repellent activity. In small animal medicine, it is used primarily for fleas and ticks on dogs. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use for flies, lice, mites, mosquitoes, ticks and keds.

Permethrin acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

#### Suggested Dosages/Use

For specific dosage recommendations, refer to the actual product's label.

#### Precautions/Adverse Effects

**Permethrin and other synthetic pyrethroids can be toxic to cats**, particularly small kittens. **Only use products containing pyrethroids labeled for use on cats on this species.** Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes. Clients should wear gloves when applying and wash off any product that contacts their skin.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

#### Veterinary-Labeled Topical Permethrin Products

Not inclusive; many shampoos, pour-ons, sprays, dusts are available.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Adams Spot On® Flea &amp; Tick Control</b> (Farnam)	Topical Solution: Permethrin: 45% (s)-Methoprene: 3%	OTC-EPA	Kills and repels adult fleas, ticks and mosquitoes. It also prevents flea eggs from developing into adult fleas. For dogs 6 months of age or older. Must not be used on cats or on dogs that cohabit with a cat. Packaged and labeled by the dog's weight in tubes of 3: <15-30 lbs = 0.034 oz 31-60 lbs = 0.068 oz > 60 lbs = 0.101 oz
<b>Bansect® Squeeze-On Flea &amp; Tick Control for Dogs®</b> (Sergeant's)	Topical Solution: Permethrin 45%	OTC-EPA	Kills and repels fleas and ticks. For dogs, older than 6 months old. Must not be used on cats or on dogs that cohabit with a cat. Individual packaging for dog's weighing: < 33 lb. = 1.5 mL >33 lb. = 3 mL 3 per package.
<b>Bio Spot On® Flea &amp; Tick Control For Dogs</b> (Farnam)	Topical Solution: Permethrin: 45% (s)-Methoprene: 3%	OTC-EPA	Kills and repels adult fleas, ticks and mosquitoes. It also prevents flea eggs from developing into adult fleas. For dogs 6 months of age or older. Must not be used on cats or on dogs that cohabit with a cat. <b>Flea Halt® Flea and Tick Spray for Dogs</b> (Farnam)	Topical Spray: Permethrin 0.1% Pyrethrins 0.05% Piperonyl Butoxide 0.5%	OTC-EPA	Kills and repels fleas, ticks, flies, mosquitoes, gnats, chiggers and lice. For dogs older than 3 months of age. Must not be used on cats or on dogs that cohabit with a cat. 32 oz bottle.
<b>Freedom® 45 Spot-On for Dogs</b> (Star Horse)	Topical Solution Permethrin 45%	OTC-EPA	Kills fleas, ticks, mosquitoes, lice and mites. For dogs 12 weeks of age or older. It cannot be used on cats or on dogs that cohabit with a cat. In cards of 2 to 3 tubes 33 lbs and under = 1.5 cc applicators 33 to 66 lbs = 3 cc applicators Over 66 lbs = 6 cc applicators
<b>K9 Advantix®</b> (Bayer)	Topical Solution: Permethrin 44% Imidacloprid 8.8%	OTC-EPA; Manufacturer restricts sales to licensed veterinarians	Flea adulticide/larvicide, tick and mosquito repellent. For use on dogs and puppies 7 weeks of age and older. It cannot be used on cats or on dogs that cohabit with a cat. In cards of 4 or 6 tubes: Under 10 lb. = 0.4 mL (green) 11–20 lb. = 1 mL (teal) 21–55 lb. = 2.5 mL (red) Over 55 lb. = 4 mL (blue)
<b>Liberty 50 Plus IGR Spot-On®</b> (Star Horse)	Topical Solution: Permethrin 50% Pyrproxifen 1.2%	OTC-EPA	Kills and repels fleas, ticks, mosquitoes, lice and mites. Kills flea larvae and prevents eggs from hatching. For use on dogs over 12 weeks of age. Must not be used on cats or on dogs that cohabit with a cat. Available for extra small, small, large and extra large dogs.

<b>ProTicall® Insecticide for Dogs</b> (Intervet-Schering-Plough)	Spot-On Liquid: Permethrin 65%	EPA	Kills and repels fleas, ticks and mosquitoes. Dosing amounts vary with dog weight; refer to directions. Labeled for use on puppies over 4 weeks of age. Must not be used on cats or on dogs that cohabit with a cat. 6 X 1 mL applicators.
<b>Scratchex® Flea &amp; Tick Spray For Dogs and Cats</b> (Farnam)	Topical Spray: Permethrin 0.05% Pyrethrins 0.056% Related compounds 0.004%	OTC-EPA	Kills and ticks. For dogs and cats 12 weeks of age or older. 7 oz bottle.
<b>Vectra 3D®</b> (Summit VetPham)	Topical Solution: Permethrin 36.08%, Pyriproxyfen 0.44%, Dinotefuran, 4.95%	OTC-EPA	For use on dogs over 7 weeks old only. Must not be used on cats or on dogs that cohabit with a cat. In 4 different package sizes for dogs weighing >2.5. lb.
<b>Virbac Long Acting Knockout®</b> (Virbac)	Topical Spray: Permethrin 2 % Pyriproxyfen 0.05%	OTC-EPA	Kills adult and immature fleas and ticks. Use only on dogs 12 weeks of age or older. Re-apply every 2 months. It cannot be used on cats or on dogs that cohabit with a cat. 16 oz.

## Human-Labeled Topical Permethrin Products

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
Generic (various), <b>Elimite®</b> (Allergan), <b>Acticin®</b> (Bertek)	Cream: Permethrin 5%	Rx (Human)	Used for treating scabies in humans. 60 g.
Generic (various)	Lotion/Cream Rinse: Permethrin 1%	OTC (Human)	Used for treating head lice in humans. 60 mL

## PYRETHRINS AND PYRETHRIN COMBINATIONS, TOPICAL

(pye-ree-thrins)

For otic use, refer to the Otics section

### Indications/Actions

Pyrethrins are naturally derived insecticides that act as adulticide insecticides/miticides. They have knockdown activity against fleas, lice, ticks, and Cheyletiella. In small animal medicine, pyrethrins are used primarily for fleas and ticks on dogs and cats. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use.

Pyrethrins act by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death. Pyrethrins are often found in combination with the insect growth regulators, methoprene or pyriproxyfen and with the synergist piperonyl butoxide. Piperonyl butoxide inhibits insect metabolic enzymes (P450 system) allowing a lower dose of primary insecticide to be used.

### Suggested Dosages/Use

For specific dosage recommendations, refer to the actual product's label.

### Precautions/Adverse Effects

Pyrethrins are among the safest insecticidal products available, but cats should not be allowed to groom wet product after using dips or sprays. Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes. Avoid hypothermia when using liquid products (sprays, dips, etc), particularly in small animals and when ambient temperatures are low.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

Clients should wear gloves when applying and wash off any product that contacts their skin.

### Veterinary-Labeled Pyrethrin Products

Not an inclusive list, but representative of the types of products available; many shampoos, pour-ons, sprays, dusts, ointments are available.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Adams Flea &amp; Tick Dust II®</b> (VPL)	Dust: Pyrethrins 0.1% Carbaryl 12.5% Piperonyl butoxide 1%	OTC-EPA	Silica gel 10%. Odorless. Labeled for dogs, cats, puppies, & kittens over 12 weeks old. 3 oz.
<b>Adams Flea &amp; Tick Mist with IGR®</b> (Farnam) <b>Adams Flea &amp; Tick Mist for Cats®</b> (Farnam)	Topical Spray: Pyrethrins 0.18% Pyriproxyfen 0.125%	OTC-EPA	N-octyl bicycloheptane dicarboxamide 1% (insecticide synergist). For dogs and cats. 16, 32 oz.
<b>Vet-Kem Ovitrol Plus Flea, Tick &amp; Bot Spray®</b> (Wellmark)	Topical Spray: (s)-Methoprene: 0.27% Pyrethrins: 0.2% Piperonyl Butoxide 0.37%	OTC-EPA	N-octyl bicycloheptane dicarboximide: 0.62%. 16 oz., 1 gal. Labeled for use on dogs, cats, puppies, kittens, horses, and ponies. Not for puppies or kittens less than 12 weeks old.
<b>Bio-Spot® Flea &amp; Tick Spray for Dogs and Puppies</b> (Farnam)	Topical Spray: Pyrethrins: 0.2% Piperonyl Butoxide: 0.37% (s)-Methoprene: 0.27%	OTC-EPA	Kills and repels fleas, ticks and mosquitoes. Prevents flea eggs from hatching. For dogs 12 weeks of age or older. 24 oz.
<b>Bio-Spot® Flea &amp; Tick Repellent for Puppies</b> (Farnam)	Topical Spray: Pyrethrins: 0.2% Piperonyl Butoxide: 0.37% (s)-Methoprene: 0.1%	OTC-EPA	Kills fleas and ticks and prevents flea eggs from hatching. For puppies 12 weeks of age or older. 16 oz.
<b>Flea Halt® Flea and Tick Spray for Dogs</b> (Farnam)	Topical Spray: Pyrethrins 0.05% Permethrin 0.1% Piperonyl Butoxide 0.5%	OTC-EPA	Kills and repels fleas, ticks, flies, mosquitoes, gnats, chiggers and lice. For dogs older than 3 months of age. Must not be used on cats or on dogs that cohabit with a cat. 32 oz bottle.
<b>Scratchex® Flea &amp; Tick Spray For Dogs and Cats</b> (Farnam)	Topical Spray: Pyrethrins 0.056% Permethrin 0.05%	OTC-EPA	Kills fleas and ticks. For dogs and cats 12 weeks of age or older. 7 oz bottle.
<b>Bio Spot Shampoo® for Dogs and Puppies</b> (Farnam)	Shampoo: Pyrethrins 0.15% (s)-methoprene 0.1% Piperonyl butoxide 1.5%	OTC-EPA	For dogs and cats 12 weeks of age or older. 12 oz.
<b>Adams® Plus Flea &amp; Tick Shampoo with Insect Growth Regulator (IGR)</b> (Farnam)	Shampoo: Pyrethrins 0.075% Pyriproxyfen 0.086% Piperonyl butoxide 0.75%	OTC-EPA	Kills fleas, ticks and lice. Prevent flea eggs from hatching. For dogs and cats. 12 oz.
<b>Vet-Kem Ovitrol Plus Flea &amp; Tick Shampoo®</b> (Wellmark)	Shampoo: (s)-Methoprene: 1.1% Pyrethrins: 0.15% Piperonyl butoxide:1.05%	OTC-EPA	12 oz. Not for puppies or kittens less than 12 weeks old.
<b>Ectokyl 3X Flea &amp; Tick Shampoo®</b> (DVM)	Shampoo: Pyrethrins: 0.15% Piperonyl butoxide:1% N-octyl bicycloheptene dicarboxamide 0.5% Di-n-propyl isocinchomerate 0.5%	OTC-EPA	Oatmeal, aloe. Not for puppies or kittens less than 12 weeks old. 8 oz, 1 gal.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Ecto-Sooth® 3X Shampoo</b> (Virbac)	Shampoo: Pyrethrins 0.15%	OTC-EPA	N-octyl bicycloheptane dicarboxamide (MGK 264) 0.5%. Kills ticks, fleas, and

	Piperonyl butoxide 1.5% Spherulite® microcapsules		lice. For dogs and cats 12 weeks of age or older. 8 oz, 16 oz, 1 gal.
<b>Vet-Kem Ovitrol Plus Flea &amp; Tick Shampoo®</b> (Wellmark)	Shampoo: Pyrethrins: 0.15% Piperonyl butoxide: 1.05% (s)-Methoprene: 1.1%	OTC-EPA	Kills adult fleas, ticks and lice and prevents flea larvae from hatching. Not for puppies or kittens less than 12 weeks old. 12 oz.
<b>Adams Pyrethrin Dip®</b> (Farnam)	Dip: Pyrethrins: 0.97% Piperonyl butoxide: 3.74%	OTC-EPA	N-octyl bicycloheptene dicarboxamide 5.7% Di-n-propyl isocinchomerate 1.94%. Kills and repels fleas, ticks, lice, gnats, mosquitoes and flies. Not for puppies or kittens less than 12 weeks old. Must be diluted before use. 4 oz.
<b>Blo Spot® Pyrethrin Dip</b> (Farnam)	Dip: Pyrethrin 0.97% Piperonyl butoxide 3.74%	OTC-EPA	N-octyl bicycloheptene dicarboxamide 5.7% Di-n-propyl isocinchomerate 1.94%. Kills and repels fleas, ticks, lice, gnats, mosquitoes and flies. For dogs and cats over 12 weeks of age. 4 oz.
<b>Pyrethrins Dip and Spray®</b> (Davis)	Dip & Spray: Pyrethrins 3% Piperonyl butoxide 30%	OTC-EPA	Petroleum distillate 12%. Kills fleas, ticks and lice. For puppies or kittens over 6 weeks old. Must be diluted before use. Keep away from open flame. 16 oz, 1 gal.

#### Human-Labeled Pyrethrin Products

None

#### PYRIPROXYFEN & PYRIPROXYFEN COMBINATIONS, TOPICAL

(pye-ri-proks-i-fen) Nylar®

Also see to the [Dinotefuran](#) listing

#### Indications/Actions

Pyriproxyfen is a second-generation insect growth regulator and is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability to prevent maturation of eggs or larva.

Pyriproxyfen mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (e.g., permethrin, fipronil) all stages of the parasite are killed and re-infestation is less likely. It is more resistant to UV light than is methoprene.

#### Suggested Dosages/Use

For specific dosage recommendations, refer to the actual product's label.

#### Precautions/Adverse Effects

Pyriproxyfen may be found in products also containing **permethrin, which can be toxic to cats**, particularly small kittens. **Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats.**

Pyriproxyfen (used alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur.

Clients should wear gloves when applying products containing permethrin or other insecticides and wash off any product that contacts their skin.

#### Veterinary-Labeled Topical Pyriproxyfen Products

Not necessarily inclusive, there are premise sprays and other topical products containing pyriproxyfen.

Product (Company)	Form: Concentration	Label Status	Other Ingredients; Comments; Size(s)
<b>Adams® Plus Flea &amp; Tick Mist with Insect Growth Regulator (IGR)</b> (Farnam)	Topical Spray: Pyriproxyfen 0.125% Pyrethrins 0.18%	OTC-EPA	Kills and repels fleas, ticks and mosquitoes. Also kills flea eggs and larvae. For dogs and cats. N-octyl bicycloheptane dicarboxamide 1% (insecticide synergist). 16 and 32 oz.
<b>Adams® Flea &amp; Tick Mist for Cats</b> (Farnam)	Topical Spray: Pyriproxyfen 0.125% Pyrethrins 0.18%	OTC-EPA	Kills and repels fleas, ticks and mosquitoes. Also kills flea eggs and larvae. For cats. N-octyl bicycloheptane dicarboxamide 1% (insecticide synergist). 16 oz.
<b>Adams® Plus Flea &amp; Tick Shampoo with Insect Growth Regulator (IGR)</b> (Farnam)	Shampoo: Pyriproxyfen 0.086% Pyrethrins 0.075% Piperonyl butoxide 0.75%	OTC-EPA	Kills fleas, ticks and lice. Prevent flea eggs from hatching. For dogs and cats. 12 oz.
<b>Blo Spot® Shampoo</b> (Farnam)	Shampoo: Pyriproxyfen 0.01% Pyrethrins 0.1% Piperonyl butoxide 0.5%	OTC-EPA	Kills adult and larval fleas, and ticks. For dogs only. 12 oz.
<b>Liberty® 50 Plus IGR Spot-On</b> (Star Horse)	Topical Solution: Pyriproxyfen 1.2% Permethrin 50%	OTC-EPA	Kills and repels fleas, ticks, mosquitoes, lice and mites. Kills flea larvae and prevents eggs from hatching. For use on dogs over 12 weeks of age. It must not be used on cats or on dogs that cohabit with a cat. Available for extra small, small, large and extra large dogs. Available in three dosage sizes: < 33 lbs; 33-66 lbs.; >66 lbs
<b>TriForce® Canine Squeeze-On</b> (Tridewinds)	Topical Solution: Pyriproxyfen 2% Cyphenothrin 40%	OTC-EPA	Kills and repels fleas, ticks and mosquitoes. Kills flea larvae and prevents eggs from hatching. For use on dogs 12 weeks of age or older. Must not be used on cats or on dogs that cohabit with a cat. Available in four dosage sizes: 9-20 lbs; 21-39 lbs; 40-60 lbs; 61 lbs and over

#### Human-Labeled Pyriproxyfen Topical Products

None

#### SPINETORAM

#### Indications/Actions

Topical spinetoram is labeled for the prevention and treatment of flea infestations in cats and kittens 8 weeks of age or older.

Spinetoram is a spinosyn compound related to spinosad. It activates the nicotinic acetylcholine receptors (nAChRs) causing the death of fleas.

#### Suggested Dosages/Use

One low-volume dose of all sizes cats of weights. The manufacturer applying the tube content topically to the skin at the base of the cat's neck once monthly. The manufacturer claims that the product starts working within 30 minutes and kills 98%–100% of fleas within 12 hours.

### Precautions/Adverse Effects

None reported by the manufacturer.

### Veterinary-Labeled Spinetoram Products

Product (Company)	Ingredients	Label Status	Size
<b>Assurity*</b> (Elanco)	Spinetoram 39.6%	OTC-EPA	Do not use on kittens less than eight (8) weeks of age. One applicator tube contains 0.019 oz (0.57 mL). Single-dose and six-dose dispensing packs.

### Human-Labeled Spinetoram Products

None

### Otic Preparations

While not a complete list, the following examples are representative of the types of topical otic preparations available to veterinarians. Included are both veterinary-labeled and human-labeled products that may be of use in veterinary medicine. Much of this section is adapted from: Koch, Torres, & Plumb. (2011). *Canine and Feline Dermatology Drug Handbook* IN PRESS. Wiley-Blackwell. This reference provides additional detail on these, and other related compounds and products.

### Ceruminolytic Agents

Ceruminolytic products emulsify and remove ceruminous and purulent exudate by providing a surfactant, detergent and bubbling activity. They work best if applied 10–15 minutes prior to cleaning. Ceruminolytic agents should not be used with ruptured tympanic membrane because of potential for ototoxicity (be especially careful in cats with ruptured tympanum). If they are needed during in-hospital ear flushing procedures, their use should be followed by multiple flushes with warm sterile isotonic saline. Docusate sodium (DSS), calcium sulfosuccinate, and urea (carbamide) peroxide are considered potent ceruminolytic agents. Squalene, triethanolamine polypeptide elite condensate and hexamethyltetracosane are less potent agents. Propylene glycol, glycerin and oil are considered very mild ceruminolytic agents. Urea peroxide containing products will release oxygen when activated and produce a foaming action that helps breakdown down cerumen. This product however, can be irritating to already inflamed ears. If mild ceruminolytic products will be used at home by the client (intact tympanic membrane), it is important to demonstrate the cleaning technique in the examination room. Advise the client to discontinue product application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

Trade Name (Manufacturer)	Ingredients	Sizes
<b>ADL Foaming Ear Cleanser*</b> (ADL)	Cocamidopropyl betaine, isosteramidopropyl morpholine lactate, salicylic acid, eucalyptol	4 oz, 8 oz
<b>Cerumene*</b> (Vetoquinol)	25% squalene in isopropyl myristate liquid, petrolatum base	4 oz
<b>ClearX Ear Cleaning Solution*</b> (DVM)	Docusate (DSS) 6.5%; urea (carbamide) peroxide 6%	4 oz
<b>Corium-20*</b> (Virbac)	Purified water, SDA-40B 23%, glycerol	8 oz
<b>KlearOtic* Ear Cleanser</b> (Dechra)	Squalene 22%	4 oz
<b>Douxo* Micellar Solution</b> (Sogeval)	Phytosphingosine, polysorbate, propylene glycol, poloxamer 184, imidazolidin urea, polidocanol, polysaccharides, alcohol, light fragrance	4.2, 8.4 oz
<b>Ear Cleansing Solution*</b> (Vet Solutions)	De-ionized water, aloe vera gel, SD alcohol 40-2, propylene glycol, lactic acid, glycerin, docusate (DSS), salicylic acid, fragrance, benzoic acid and benzyl acid	8, 16 oz
<b>Earoxide Ear Cleanser*</b> (Tomlyn)	Carbamide peroxide 6.5% in a glycerin base	2, 4 oz
<b>OtiFoam*</b> (DVM)	Water, cocamidopropyl betaine, PEG-60 almond glycerides, mackalene 426, salicylic acid and oil of eucalyptus.	8 oz
<b>OtiRinse* Solution</b> (DVM)	Salicylic acid, benzoic acid, docusate sodium (DSS), aloe vera	8 oz
<b>Vet Solutions Ear Cleansing Solution for Dogs and Cats*</b> (Vetoquinol)	Docusate sodium (DSS), ethanol, aloe vera	4, 8, 16 oz, 1 gal

### Cleaning/Drying Agents

Cleaning and drying agents are typically used after debris or exudate has been removed from the ear canals with a ceruminolytic agent. Their ingredients are usually an acid or isopropyl alcohol. Cleaning and drying ear solutions can be used on a maintenance regimen to help prevent ear infections and after bathing or swimming to keep the external ear canals water free. It is important to demonstrate the cleaning technique in the examination room. Advise the client to discontinue application and contact the veterinarian if the ears become more red or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

Trade Name (Manufacturer)	Ingredients	Sizes
<b>ADL Ear Flushing Drying Lotion*</b> (ADL)	Isopropyl alcohol, salicylic acid, eucalyptol, acetamine MEA, propylene glycol, acetic acid, aluminum acetate, hydrolyzed oat protein, wheat amino acids	8 oz
<b>Alocetic Ear Rinse*</b> (DVM)	Water, acetic acid, nonoxynol-12, fragrance, methylparaben, DMDM hydantoin, aloe vera gel	4, 12 oz
<b>Clearx Ear Drying Solution*</b> (DVM)	Acetic acid, colloidal sulfur, hydrocortisone	4 oz
<b>Corium-20*</b> (Virbac)	SDA-40B 23%, glycerol	8 oz
Trade Name (Manufacturer)	Ingredients	Sizes
<b>Domeboro* Otic</b> (Miles) <b>Note:</b> human product	Acetic acid 2%, aluminum acetate	2 oz
<b>Ear Cleaning Solution*</b> (Vetoquinol)	Aloe vera gel, SD alcohol 40-2, propylene glycol, lactic acid, glycerin, docusate sodium (DSS), salicylic acid, fragrance, benzoic acid and benzyl acid	8, 16 oz
<b>Epi-Otic* Cleanser with Spherulites</b> (Virbac)	Lactic acid 2.5%, salicylic acid 0.1%, Spherulites* microcapsules, encapsulated chitosanide, docusate sodium, propylene glycol, PCMX	4, 8, 16 oz
<b>Epi-Otic Advanced*</b> (Virbac)	Salicylic acid 0.2%, disodium EDTA, docusate sodium, PCMX, a monosaccharide complex, odor neutralizer	4, 8 oz
<b>Euclens Otic Cleanser*</b> (Butler Schein)	Propylene glycol, malic acid, benzoic acid, eucalyptus oil	4, 16 oz
<b>Gent-L-Ciens*</b> (Intervet/Schering-Plough)	Lactic acid, salicylic acid in propylene glycol	4 oz
<b>MalAcetic Otic*, MalAcetic Otic* AP (contains apple fragrance)</b> (Dechra)	Acetic acid 2%, boric acid 2%	4, 8, 16 oz
<b>Oti-Calm*</b> (DVM)	Benzoic acid, malic acid, salicylic acids; oil of eucalyptus	4 oz, 12 oz
<b>Oti-Ciens*</b> (Pfizer)	Propylene glycol, malic acid, benzoic acid, salicylic acid	4 oz
<b>Oti-Soothe*+ PS with Aloe Vera</b> (Sogeval)	Aloe vera gel, lactic acid, salicylic acid, benzoic acid, propylene glycol, SD alcohol 40, glycerin, docusate (DSS), fragrance, benzyl alcohol; phytosphingosine: 0.01%	4, 8, 16 oz & 1 gallon
<b>Oti-Soothe* + PS with Cucumber Melon</b> (Sogeval)	Aloe vera gel, lactic acid, salicylic acid, benzoic acid, propylene glycol, SD alcohol 40, glycerin, docusate sodium (DSS), fragrance, benzyl alcohol	4, 8, 16 oz & 1 gallon
<b>OtiRinse* Solution</b> (DVM)	Salicylic acid, benzoic acid, docusate (DSS), aloe vera	8 oz
<b>Otocetic Solution*</b> (Vedco)	Acetic acid 2%, hamamelis, anodyne with surfactants	4, 16 oz

### Antiseptic Agents

Topical antiseptic ear flushes include acetic acid, chlorhexidine and ketoconazole containing products. These products are typically used as adjunctive therapy for ear infections (e.g., bacterial and/or yeast) but can also be used as sole treatment in mild, first time infections. Acetic acid works as an acidifying and antimicrobial agent. Chlorhexidine has activity against gram-positive and gram-negative bacteria and fungi. Chlorhexidine containing products should be used cautiously in ear canals with ruptured tympanic membranes and antimicrobial potential for ototoxicity. Ketoconazole is a fung-static antifungal. When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become more red or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

Trade Name (Manufacturer)	Active Ingredients	Sizes
<b>Bausch &amp; Lomb Acetic Acid 2% in Aqueous Aluminum (B&amp;L)</b>	Acetic acid, aluminum acetate	60 mL
<b>MalAcetic Otic<sup>®</sup></b>	Acetic acid 2%, boric acid 2%; MalAcetic <sup>®</sup> Otic AP contains	4, 8, 16 oz
<b>MalAcetic Otic<sup>®</sup> AP (Dechra)</b>	apple fragrance	
<b>MalAcetic<sup>®</sup> Ultra Otic (Dechra)</b>	acetic acid 1%, boric acid 1%, ketoconazole 0.15%, Hydrocortisone 1%	2, 8 oz
<b>Mal-A-Ket Plus TrizEDTA Flush<sup>®</sup> (Dechra)</b>	Ketoconazole (0.15%), chlorhexidine 0.15%, tris-EDTA	4, 12 oz
<b>Otocetic Solution<sup>®</sup> (Vedco)</b>	Acetic acid 2%, hamamelis	4, 16 oz

### Antibiotic Potentiating Agents

Tromethamine-ethylenediaminetetraacetic acid (tris-EDTA) has antimicrobial and antibiotic potentiating activity. It is alkalizing (pH8), blocks the *Pseudomonas* efflux pump, potentiates antibiotics such as enrofloxacin and aminoglycosides, disrupts the bacterial cell wall by chelating metal ions and making it more porous, inhibits the effects of ulcerating bacterial enzymes. Tris-EDTA is non-ototoxic and safe to use in the middle ear. Tris-EDTA containing products when applied 15-30 minutes before the topical antibiotic.

Products containing tris-EDTA are available as a sole ingredient or combined with chlorhexidine or ketoconazole. When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

Trade Name (Manufacturer)	Active Ingredients	Sizes
<b>KetoTris Flush + PS<sup>®</sup> (Sogeval)</b>	Ketoconazole 0.1%, EDTA, phytosphingosine 0.01%	4, 16 oz
<b>KetoTris Flush<sup>®</sup> (Sogeval)</b>	Ketoconazole 0.1%, EDTA	4, 16 oz
<b>Mal-A-Ket Plus TrizEDTA Flush<sup>®</sup> (Dechra)</b>	Ketoconazole 0.15%, chlorhexidine 0.15%, tris-EDTA	4, 12 oz
<b>TrizEDTA<sup>®</sup>, Aqueous or Crystals (Dechra)</b>	tris-EDTA	4, 16 oz
<b>TrizULTRA + Keto<sup>®</sup> (Dechra)</b>	tris-EDTA, ketoconazole 0.15%	4, 12 oz
<b>TrizCHLOR<sup>®</sup> (Dechra)</b>	tris-EDTA, chlorhexidine 0.15%	4 oz
<b>T8 Keto<sup>®</sup> Flush (DVM)</b>	tris-EDTA, ketoconazole 0.1%	4, 12 oz
<b>T8 Solution<sup>®</sup> Ear Rinse (DVM)</b>	tris-EDTA, benzyl alcohol, nonoxonyl 12, lanolin	4, 12 oz

### Corticosteroid Preparations

Corticosteroid-containing ear medications are used in cases of acute or chronic otitis with the goal of reducing inflammation, edema, tissue hyperplasia, pain and pruritus. In addition, they are helpful in decreasing secretions from sebaceous and apocrine glands thereby reducing the build up of debris in ear canals. Ear cleaning solutions that contain glucocorticoids without an antibiotic can be used as maintenance therapy in cases of allergic otitis, but use the least potent glucocorticoid at the lowest possible frequency to balance efficacy and prevent undesirable side effects.

Trade Name (manufacturer)	Active Ingredients	Sizes
<b>Clearx Drying Solution<sup>®</sup> (DVM)</b>	Hydrocortisone 1%, acetic acid, colloidal sulfur.	1 oz
<b>Cort/Astrin Solution<sup>®</sup> (Vedco)</b>	Hydrocortisone 1%, Burow's solution	1, 16 oz
<b>MalAcetic<sup>®</sup> Ultra Otic (Dechra)</b>	Hydrocortisone 1%, boric acid 2%, acetic acid 1%, ketoconazole 0.15%	2, 8 oz
<b>Synotic Otic Solution<sup>®</sup> (Pfizer)</b>	Fluocinolone 0.01%; DMSO 60%	8 & 60 mL

### Antibacterials

Refer also to *Corticosteroid Preparations and Injectable Antimicrobial (Antibacterial) Preparations*

Antibacterial ear preparations are commonly used to treat infections caused by *Staphylococcus* spp. or *Pseudomonas* spp. Very few otic products containing solely an antibiotic are commercially available to treat bacterial otitis; therefore, the clinician often must use ophthalmic or injectable antibiotics directly into the ear canals to treat these infections. When using acidifying ear cleansers and with an aminoglycoside- or fluoroquinolone-containing agent, it is recommended to use these products about one hour apart since low pH can decrease the activity of aminoglycosides and fluoroquinolones. When treating a *Pseudomonas* ear infection, culture and susceptibility should be performed to select the appropriate antibiotic as resistance is a major concern.

These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more red or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.

Trade Name (Manufacturer)	Active Ingredients	Sizes
<b>Baytril Otic<sup>®</sup> (Bayer)</b>	Enrofloxacin 0.5%, Silver sulfadiazine (SSD) 1%	15 mL, 30 mL
<b>Gentocin<sup>®</sup> Ophthalmic Solution (Schering-Plough) generic</b>	Gentamicin sulfate 0.3%	5 mL
<b>Tobrex<sup>®</sup> Ophthalmic Solution (Alcon Ophthalmic)</b>	Tobramycin 0.3%,	5 mL

### Antifungals

Refer also to the *Corticosteroid + Antimicrobial* section

Antifungal ear preparations are used to treat *Malassezia* otitis and rarely otic candidiasis. Most of the commercially available products also contain an antibiotic and/or a glucocorticoid. Listed here are exclusively the products without an antibiotic agent.

These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more red or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.

Trade Name (Manufacturer)	Active Ingredients	Sizes
<b>Clotrimatop<sup>®</sup> Solution (Butler)</b>	Clotrimazole 1%	30 mL
<b>Clotrimazole Solution (VET Solutions)</b>	Clotrimazole 1%	30 mL
<b>Lotrimin<sup>®</sup> Solution (Schering-Plough); Generics</b>	Clotrimazole 1%	10 mL, 30 mL
<b>MicaVed<sup>®</sup> Lotion (Vedco)</b>	Miconazole 1%	120 mL
<b>Micazole<sup>®</sup> Lotion (Butler)</b>	Miconazole 1%	60 mL
<b>Miconosol<sup>®</sup> Lotion (Med Pharmex)</b>	Miconazole 1%	60 mL
<b>Priconazole<sup>®</sup> Lotion 1% (Priority Care)</b>	Miconazole 1%	30 mL, 60 mL

### Corticosteroid + Antimicrobial Preparations

Most otic antimicrobial preparations commercially available combine an antifungal, an antibiotic and a glucocorticoid agent

These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more red or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.

Trade Name (Manufacturer)	Active Ingredients	Size(s)
<b>Antibiotic Ear Solution<sup>®</sup> (Rugby)</b>	Neomycin sulfate 3.5 mg/mL, Polymyxin B 10,000	7.5 mL or 10 mL
<b>Cortisporin<sup>®</sup> Otic Suspension (Monarch)</b>	Units/mL, Hydrocortisone 10 mg/mL	depending on brand
<b>Cortomycin<sup>®</sup> (Major)</b>		
<b>Oti-Sone<sup>®</sup> Otic Suspension (Ocumed)</b>		
<b>Pediolic<sup>®</sup> Otic Suspension (GlaxoSmithKline)</b>		
<b>Generics</b>		
<b>Betagen<sup>®</sup> Otic Solution (Med-Pharmex)</b>	Gentamicin sulfate 3 mg/mL, Betamethasone	Depending on brand:
<b>GenOne Otic Solution<sup>®</sup> (VetOne)</b>	valerate 1 mg/mL	7.5, 15, & 240 mL
<b>Genotic<sup>®</sup> (Butler)</b>		

Trade Name (Manufacturer)	Active Ingredients	Dose/Use	Comments: Size(s)
<b>GentaVed Otic Solution*</b> (Vedco)			
<b>Topagen® Ointment</b> (Intervet/Schering-Plough)			
<b>Animax® Ointment</b> (Dechra)	Nystatin 100,000 Units/mL, Neomycin sulfate	Depending on brand:	
<b>Derma Vet® Ointment</b> (Med-Pharmex)	0.25%, Thiostrepton 2,500 Units, Triamcinolone	7.5, 15, 30, & 240 mL	
<b>Dermalog Ointment®</b> (RXV)	acetamide 0.1%		
<b>Dermalone Ointment®</b> (Vedco)			
<b>Quadrilop® Ointment</b> (Butler)			
<b>Panolog® Ointment</b> (Pfizer)			
<b>MoMetaMax® Otic Suspension</b> (Schering-Plough)	Gentamicin 3 mg/gram, Mometasone 1 mg/gram, Clotrimazole 10 mg/gram	15, 30 g	
<b>DVMax® Ointment</b> (DVM)	Clotrimazole 1%, Gentamicin sulfate 0.3%, Betamethasone valerate 0.1%	Depending on brand:	
<b>Gentizol® Ointment</b> (VetOne)		7.5, 10, 15, 20, 25, 30 & 215 g

<b>Vetromax®</b> (Dechra)			
<b>Posatex® Otic Suspension</b> (Intervet)	Posaconazole 0.1%, Orbifloxacin 1%, Mometasone furoate monohydrate 0.1%	7.5, 15 & 30 g	
<b>Quadrilop® Ointment</b> (Vetus)	Nystatin 100,000 units/mL, Neomycin sulfate 2.5 mg/mL, Thiostrepton 2,500 units/mL, Triamcinolone acetamide 1.0 mg/mL	240 mL	
<b>Surolan® Otic Suspension</b> (Vetoquinol)	Miconazole 23 mg/mL, Polymyxin B 0.5293 mg/mL, Prednisolone acetate 5 mg/mL	15 & 30 mL	
<b>Tresaderm®</b> (Merck)	Neomycin 0.25%, Dexamethasone 0.1%, Thiabendazole 4%	7.5 mL, 15 mL	
<b>Tritop® Ointment</b> (Pfizer)	Neomycin sulfate 0.5%, Isoflupredone acetate 0.1%, Tetracaine hydrochloride 0.5%	10 g	
<b>TobraDex® Ophthalmic Solution</b> (Alcon); Generics	Tobramycin 0.3%, Dexamethasone 0.1%	2.5, 5 mL	
<b>Zymox® Otic</b> (Three Point Enzyme System)	Lysozyme, Lactoferrin, Lactoperoxidase, Hydrocortisone 1%	36.96 mL	

## Antiparasitic Preparations

Refer also to the Selamectin and Fipronil monographs

Included are only preparations labeled to be applied directly into the ear canals for the treatment of otocariosis. However, parasiticides with systemic or more generalized effect such as, selamectin or fipronil are preferred because *Otodectes cynotis* mites are known to also live outside ear canals and can re-infest the ears.

Trade Name (Manufacturer)	Active Ingredients	Dose/Use	Comments: Size(s)
<b>Acarexx® Otic Suspension</b> (Ilex)	0.01% ivermectin	Clean ear and apply 0.5 mL in each ear; repeat one time if necessary	For ear mite infestation in cats or kittens four weeks of age or older. 12 foil pouches with 2 ampules per foil pouch containing 0.5 mL.
<b>Adams Pene-Mite®</b> (Farnam)	Pyrethrins 0.05%, Piperonyl butoxide 0.5%	Clean ear and apply every-other-day for 12 days	Recommended for dogs and cats 12 weeks of age or older. 0.5 oz
<b>Cerumite 3x®</b> (Vetoquinol)	Pyrethrins 0.15%, Piperonyl butoxide 1.5%	Clean ear and apply a sufficient amount to coat the ear canals not more frequent than twice a week	N-octyl bicycloheptene dicarboximide. For ear mite infestation in dogs and cats. 0.5 oz
<b>Cooper's Best Ear Mite Lotion®</b> (Aspen)	Oil of pennyroyal, Oil of lemongrass, Oil of lavender	Clean ear and apply daily for 7 to 10 days. Repeat the procedure in two weeks if needed.	Aloe. For ear mite infestation on dogs and cats. 6 oz
<b>Ear Mite Solution®</b> (Durect)	Rotenone 0.12%	Clean ear and apply twice allowing one day interval.	Associated resins 0.16%. For ear mite infestation on dogs and cats 12 weeks of age or older. 4 oz
<b>Ear Mitecide®</b> (Phenik)	Rotenone 0.12%	Clean ear and apply twice allowing one day interval.	Associated resins 0.16%. For ear mite infestation on dogs and cats 12 weeks of age or older. 2 oz
<b>EarMed Mite Lotion®</b> (Davis)	Oil of pennyroyal, Oil of lemongrass, Oil of lavender	Clean ear and apply once daily for 7-10 days. Repeat in two weeks if needed.	Aloe. For ear mite infestation on dogs and cats. 2 oz
<b>Eradimate®</b> (Pfizer)	Pyrethrins 0.15%, Piperonyl butoxide 1.5%	Clean ear and apply once daily every 2 days until resolution of infestation	For ear mite and spinose ear tick infestation on dogs and cats. 1 oz
<b>Happy Jack Mite®</b> (Happy Jack)	Pyrethrins 0.05%, Piperonyl butoxide 0.5%	Clean ear and apply once daily for 7-10 days. Repeat in two weeks if needed.	For ear mite infestation on dogs and cats. 0.5, 1 oz
<b>Hartz Advanced Care® Ear Mite Treatment</b> (Hartz)	Pyrethrins 0.05%, Piperonyl butoxide 0.5%	Clean ear and apply once daily for 7-10 days. Repeat in two weeks if needed.	Aloe. For ear mite infestation on cats 12 weeks of age or older. 3 mL
<b>MilbeMite® Otic</b> (Novartis)	Milbemycin oxime 0.1%	Clean ear and apply entire contents of tube in external ear canal, one tube per ear. Repeat in 30 days if recommended by the veterinarian.	For ear mite infestation on cats or kittens four weeks of age or older. Box of 10 pouches of 2 tubes of 0.25 mL each
<b>Mite-Clear® Lotion</b> (Pfizer)	Pyrethrins 0.15%, Technical piperonyl butoxide 1.5%	Clean ear; instill enough to wet ear canal and massage. Retreat in 7 days.	N-octyl bicycloheptene dicarboximide 0.5%, di-n-propyl isocinchomeronate 1%. For ear mite infestation on dogs and cats. 22 mL
<b>Otomite Plus®</b> (Virbac)	Pyrethrins 0.15%, Technical piperonyl butoxide 1.5%	Clean ear and instill enough to wet ear canal and massage. Retreat in 7 days.	N-octyl bicycloheptene dicarboximide 0.5%, di-n-propyl isocinchomeronate 1%. For ear mite infestation on dogs and cats. 15 mL
<b>Performer Ear Mite Killer®</b> (Aglilabs)	Pyrethrins 0.15%, Piperonyl butoxide 1%	Apply daily for 7 to 10 days.	N-Octyl bicycloheptene dicarboximide 0.5%, di-n-propyl isocinchomeronate 1%. For ear mite infestation on dogs and cats 12 weeks of age or older. 6 oz
<b>QuadroClear® Ear Drops®</b> (Van Bock)	Pyrethrin 0.61 mg/mL, Sesquiterpenoid 25 mg/mL, Salicin 0.61 mg/mL, Proprietary blend of carvacrol 58 mg/mL	Clean ears and apply twice daily for 7-10 days.	1-8 cineol, thymol, menthol, cinnamic aldehyde. For ear mite infestation on dogs and cats. Other manufacturer's recommendations include: bacterial and yeast ear infections. 1 oz
<b>Sentry HC EARMITEfree Ear Mitecide for Dogs®</b> (Sergeant)	Pyrethrins 0.06%, Piperonyl butoxide 0.6%	Clean ears and apply twice daily until the infestation is resolved.	For mite and tick ear infestation on dogs 12 weeks of age or older. 1 oz
<b>Sentry HC EARMITEfree Ear Mitecide for Cats®</b> (Sergeant)	Pyrethrins 0.06%, Piperonyl butoxide 0.6%	Clean ears and apply twice daily until the infestation is resolved.	For mite and tick ear infestation on cats 12 weeks of age or older. 1 oz
<b>Sergeant's Vetscription Ear Mite and Tick Treatment®</b> (Sergeant)	Pyrethrins 0.06%, Piperonyl butoxide 0.6%	Clean ears and apply twice daily until the infestation is resolved.	For use on cats 12 weeks of age or older. 3 oz

## Overdose and Toxin Exposure Decontamination Guidelines

CAMILLE DECLEMENTI, VMD, DABT  
ASPCA Animal Poison Control Center

All patients should be stabilized prior to attempts at decontamination. Once stabilization has been accomplished, decontamination should be considered to prevent systemic absorption of the toxicant. The specific method of decontamination chosen in each case must be guided by the species exposed and the exposure circumstances. When a patient has ingested a potentially toxic dose of a substance, the clinician has many options for decontamination including dilution, induction of emesis, gastric lavage, the use of adsorbents, cathartics, and administration of enemas. In many cases, the best treatment plan will include more than one of these methods.

**Dilution** using a small amount of milk or water is recommended in cases where irritant or corrosive materials have been ingested. A dose of 2-6 mL/kg is suggested (Mathews, 2006), which for an average-sized cat, would

be approximately only 1–2 teaspoons. Using only a small amount is important since using excessive amounts could lead to vomiting and re-exposure of the esophagus to the damaging material (Rosendale, 2002). Juicy fruits and vegetables can be fed to accomplish dilution in some patients, especially birds and reptiles. Dilution is not appropriate in patients who are at an increased risk for aspiration, including those who are actively seizing or obtunded (Rosendale, 2002). Dilution with milk, yogurt and cottage cheese has been useful in cases of oral irritation following ingestion of plants containing insoluble calcium oxalate crystals (Philodendron species, for example) (Means, 2004).

**Emetics** are usually most effective if used within 2–3 hours after the ingestion (Rosendale, 2002) but in some cases, emesis may be effective even after that time frame. If the substance ingested could coalesce to form a bezoar in the stomach or a timed-released medication was ingested, emesis may be effective later than 3 hours after the ingestion. Chocolate (Albretsen, 2004) and chewable medications are examples of products, which may form bezoars. Emetics generally empty 40–60% of the stomach contents (Beasley and Dorman, 1990). Feeding a small moist meal before inducing vomiting can increase the chances of an adequate emesis.

Animals that are able to vomit safely include dogs, cats, ferrets, and potbelly pigs. Emetics should not be used in birds, rodents, rabbits, and horses or ruminants. Rodents are unable to vomit. Rabbits have a thin-walled stomach putting them at risk for gastric rupture if they vomit (Donnelly, 2004).

Induction of emesis is *contraindicated* with ingestion of corrosive agents including alkalis and acids. The protective epithelial lining of the esophagus may be damaged initially when one of these products is swallowed. The muscular layer of the esophagus may be exposed and at risk for ulceration, perforation and scarring if vomiting does occur (Beasley and Dorman, 1990). Emesis is also not recommended after petroleum distillate ingestion due to the risk of aspiration. The clinician must also take into account when deciding whether to induce emesis, any pre-existing conditions of the patient that can cause vomiting to be hazardous including severe cardiac disease or seizure disorder. In all instances the attending veterinarian must carefully weigh the benefits of emesis against the risks. Emesis may not be needed if the animal has already vomited and is not appropriate if the animal is already exhibiting clinical signs such as coma, seizures or recumbency, which make emesis hazardous. Additionally, if the patient has ingested a CNS stimulant and is already agitated, the additional stimulation of vomiting could lead to seizures (Rosendale, 2002).

Hydrogen peroxide, apomorphine hydrochloride and xylazine hydrochloride are commonly used emetics in the veterinary clinical setting. Preliminary data obtained from the ASPCA Animal Poison Control's toxicology database indicate that hydrogen peroxide and apomorphine are effective emetics in dogs. Emesis was successful in ninety-two percent of dogs when administered either 3% hydrogen peroxide or apomorphine. No significant adverse effects were reported in dogs after emetic use. Apomorphine was poorly effective as an emetic in cats and using it in cats is controversial. Xylazine was an effective emetic in only fifty-seven percent of cats. When emesis was successfully induced, sixty-eight percent of patients vomited some portion of the ingested toxicant (Khan, 2009). Please see the monographs in the text for additional information on using these as emetics.

Several other agents have been suggested by various sources as emetics. These include table salt, liquid dishwashing liquid, syrup of ipecac and powdered mustard. They are not as effective as those mentioned, and salt and syrup of ipecac may cause significant adverse effects. Table salt (sodium chloride) has been associated with hypernatremia and CNS dysfunction (Beasley and Dorman, 1990) and there are concerns that syrup of ipecac can be cardiotoxic (Rosendale, 2002). Human pediatricians no longer routinely recommend syrup of ipecac for home use and The American Association of Poison Control Centers reported in 2001 that the use of ipecac in human exposures has fallen by more than 95% over a 15-year period (Shannon, 2003). An October 12, 2010 bulletin by the American Society of Health-System Pharmacists indicates that syrup of ipecac has been discontinued (<http://goo.gl/dwbY2>).

**Gastric lavage** can be considered in cases where emesis is contraindicated, not possible or has been unsuccessful. For example, lavage is an option if the patient is agitated, seizing or recumbent or has other health concerns, such as recent abdominal surgery, that increase the risks associated with induction of emesis. Gastric lavage should be considered in rabbits and rodents, which are unable to vomit safely. Lavage is unlikely to be as effective as emesis (Beasley and Dorman, 1990) and is associated with significant potential risks (Rosendale, 2002). For these reasons, it should not be chosen routinely as a decontamination method over emesis. Lavage should also not be used to remove caustic materials or volatile hydrocarbons for the same reasons emesis is contraindicated in such cases (Rosendale, 2002).

The patient should be under general anesthesia when performing gastric lavage unless the patient is comatose. In all instances, a cuffed endotracheal tube should be in place to prevent aspiration. If the patient is a species with cheek pouches, the cheek pouches should be emptied gently with a finger or swab prior to the lavage. Risks associated with gastric lavage include esophageal or stomach damage or perforation, electrolyte abnormalities, hypothermia and the accidental placement of the tube in the trachea and the instillation of fluid into the patient's lungs (Rosendale, 2002).

**Adsorbents** may be utilized instead of or in addition to using an emetic or performing gastric lavage to prevent further systemic absorption of a toxicant. These agents act by adsorbing to a chemical or toxicant in the gastrointestinal tract and facilitating its excretion in the feces. Activated charcoal is the most commonly used adsorbent.

Activated charcoal is composed of large porous particles that adsorb to and therefore trap a wide range of organic compounds within the gastrointestinal tract. It is created from materials such as coal, wood, rye starch and coconut shells through a process using acid and steam treatments. The surface binding area of activated charcoal is large, in the range of 900–1500 m<sup>2</sup>/g (Rosendale, 2002). Charcoal tablets and capsules available over the counter, which are used to control flatulence, and bloating are not likely to be as effective adsorbents as the commercially prepared products (Buck and Bratich, 1986). The concentration of charcoal in the capsules is often low and the binding area much smaller.

Repeated doses of activated charcoal should be considered in some instances where toxicants are known to undergo enterohepatic recirculation. In enterohepatic recirculation, the toxicant is first carried to the liver by either the portal vein after absorption from the gastrointestinal tract or via the systemic circulation. Once in the liver, the toxicant enters the bile and is excreted into the gastrointestinal tract where it is again available for absorption. Examples of toxicants known to undergo this type of recycling include most NSAIDs, marijuana and digoxin.

Another instance where multiple doses of activated charcoal are appropriate is in the treatment of ivermectin toxicosis. Ivermectin is a substrate for the P-glycoprotein pump that transports drugs across cell membranes. This pump is found in various cells including intestinal epithelial cells and brain capillary endothelial cells. In the intestine, ivermectin is absorbed into the enterocyte. However, once in the cell, the P-glycoprotein pump acts to move the ivermectin back into the gastrointestinal lumen. This cycling allows the ivermectin molecules to have multiple opportunities to bind with the repeated doses of activated charcoal (DeClementi, 2007). Other P-glycoprotein substrates include loperamide, diltiazem and doxorubicin (Mealey, 2006).

When repeated doses are indicated, half the original dose should be given at 4 to 8 hour intervals (Peterson, 2006). It is important to mention that if medications are excreted in the bile, activated charcoal can be beneficial regardless of the route the medication was administered. Thus if a patient received an overdose of injectable ivermectin subcutaneously, use of activated charcoal will still be a very useful (DeClementi, 2007).

Administration of activated charcoal does carry some risks and it does not bind all compounds equally. Some chemicals that are not bound effectively include: ethanol, methanol, fertilizer, fluoride, petroleum distillates, most heavy metals, iodides, nitrites, sodium chloride, and chlorate. Activated charcoal should not be given to animals that have ingested caustic materials. It is unlikely to bind them, can be additionally irritating to the mucosal surfaces, and make visualization of oral and esophageal burns difficult (Buck and Bratich, 1986). Activated charcoal can cause a false positive on an ethylene glycol test since propylene glycol is found in many formulations. Additionally, the timing of the activated charcoal administration should be taken into account when deciding on dosing of other oral medications since the charcoal can also bind them.

Activated charcoal administration carries a significant risk of aspiration. If a patient does aspirate the charcoal, the prognosis is poor, hence proper placement of the stomach tube and a protected airway are required in symptomatic patients. Constipation and black bowel movements are possible making it difficult to determine if melena is present. If the activated charcoal resides within the gastrointestinal tract for a significant period, it may release the compound it has adsorbed. It is for this reason that activated charcoal is frequently administered with a cathartic. Many commercially available preparations do contain a cathartic such as sorbitol.

Hypernatremia is another possible adverse effect of activated charcoal administration. In humans, hypernatremia has been reported primarily in children when multiple doses of a charcoal-sorbitol mixture were administered. The mechanism for hypernatremia is attributed to a water shift from the intracellular and extracellular spaces into the gastrointestinal tract as a result of the osmotic pull of the sorbitol cathartic (Allerton and Strom, 1991). The ASPCA Animal Poison Control Center (APCC) has also received reports of elevated serum sodium following activated charcoal administration in dogs. Hypernatremia appears to be reported more often in small dogs receiving multiple doses of activated charcoal, but it has also been reported in large dogs and in cases receiving only a single dose. Furthermore, unlike the human reports, elevated serum sodium has also been noted in cases where no cathartic was present in the charcoal (APCC unpublished data). In hypernatremia cases, the APCC has found that administration of a warm water enema is effective at lowering the serum sodium and controlling the resultant central nervous system effects (DeClementi, 2007).

**Cathartics** enhance elimination of substances, including administered activated charcoal, by promoting their movement through the gastrointestinal tract. Activated charcoal only binds to toxicants by weak chemical forces, so without cathartics the bound toxicant can eventually be released and reabsorbed (Rosendale, 2002). When used with activated charcoal, the cathartic is given immediately following or mixed with the charcoal. Cathartics are *contraindicated* if the animal is dehydrated, has diarrhea, if ileus is present, or if intestinal obstruction or perforation are possible (Peterson, 2006).

There are bulk, osmotic, and lubricant cathartics. The most commonly used bulk cathartic is psyllium hydrophilic mucilloid (*e.g.*, *Metamucil*®). Another bulking cathartic that can be used in dogs and cats is unspiced canned pumpkin. In birds and reptiles, dilute peanut butter, fruit or vegetables can also be used as bulking agents. Timothy hay can be utilized in rabbits. Osmotic cathartics have limited absorption from the gastrointestinal tract so they are able to pull water into the gastrointestinal tract, thereby increasing the fluid volume and stimulating motility to hasten expulsion in the feces.

There are saline and saccharide osmotic cathartics. Sorbitol is the most commonly used saccharide osmotic cathartic; it is the cathartic of choice and is frequently combined with activated charcoal in commercially prepared charcoal products. The saline cathartics include sodium sulfate (Glauber's salts) and magnesium sulfate (Epsom salts). Saline cathartics *should not* be used in patients with renal insufficiency or in birds or reptiles.

Of the lubricant cathartics, mineral oil is the most often used. Mineral oil is *not recommended following activated charcoal administration* as the mineral oil may render the charcoal less effective (Buck and Bratich, 1986; Gale, 1992). Since all cathartics alter the water balance in the gastrointestinal tract, electrolyte abnormalities, especially hypernatremia, are a potential risk to their use. Hydration status should be monitored frequently and fluids administered, intravenously or via an enema as needed.

**Enemas** may be indicated when elimination of toxicants from the lower gastrointestinal tract is desired (Beasley and Dorman, 1990). Medications formulated as extended-release or controlled-release are absorbed from the entire gastrointestinal tract, including the colon (Buckley et al., 1995). An enema can be used to move those medications through the colon quickly and lessen additional systemic effects. The general technique is to use plain warm water or warm soapy water. Phosphate enema solutions should be avoided due to the risk of electrolyte and acid-base disturbances (Beasley and Dorman, 1990). In reptiles, enemas may be useful since ingested materials often lag for prolonged periods in the colon. Enemas are *not recommended for birds* since they already have a rapid gastrointestinal transit time.

## ARCI UCGFS Classifications

The Association of Racing Commissioners International, Inc. is a non-profit corporation whose mission and vision is: To protect and uphold the integrity of the pari-mutuel sports of horse racing, dog racing and jai-alai through an informed membership, by encouraging forceful and uniform regulation, by promoting the health and welfare of the industry through various programs and projects. In the ARCI classification system, Class 1 drugs have the most potential to affect performance; subsequent classes have less potential. The information in the monographs is taken from the Uniform Classification Guidelines for Foreign Substances and Recommended Penalties and Model Rule document (April 2005). See the ARCI website for the most up-to-date information at <http://www.arci.com>.

## Importation of Unapproved New Animal Drugs into the USA

As of October 2009, the Food and Drug Administration's Center for Veterinary Medicine is no longer accepting requests nor issuing "no-objection" letters facilitating veterinarians' personal importation of foreign animal drugs that are not approved for use in the United States. FDA previously allowed licensed veterinarians to apply for permission to import small amounts of unapproved animal drugs under the Medically Necessary Personal Import Policy (a 13 step letter detailing the intended use for a specific patient under specific circumstances, such as when the drug posed no threat to human or animal health and there were no adequate drug substitutes available.) The burden of importation now appears to rest upon the exporter in completing necessary Customs and Border Patrol (CBP) documents that will allow the drugs to clear US Customs upon entry into the United States. It is important to note that drug shipments may still be seized by US Customs and returned to the exporter in spite of efforts to provide necessary documentation.

Veterinarians seeking to import these types of foreign animal drugs are now directed to FDA's guidance on the Coverage of Personal Importation, which is available at: <http://goo.gl/GiWys>

This supplier from the U.K. has been recommended to the author and may be able to assist U.S. veterinarians in obtaining medically necessary products from abroad:

### Abbreviations Used in Prescription Writing

**A warning and the strange case of S.I.D.:** Although prescription abbreviations are used throughout many references and they are generally fairly well recognized, they do increase the potential for mistakes to occur. When writing a prescription, this author recommends writing out the directions in plain English and avoiding the use of abbreviations entirely. If abbreviations are to be used, definitely avoid q.d., q.o.d., q.i.d. and s.i.d. because they can be easily confused with other abbreviations.

S.I.D. is an abbreviation virtually unknown to health professionals outside of veterinary medicine and the vast majority of pharmacists have never seen it. **S.I.D. should be eliminated from all veterinary usage and replaced with "once a day."** The additional time to write out "once a day" versus "SID" is approximately 3 seconds, but by doing so, a potentially serious, avoidable error could be prevented.

a.c.	before meals
a.d.	right ear
a.s.	left ear
a.u.	both ears
amp.	ampule
b.i.d.	twice a day
c.	with
cap.	capsule

### Solubility Definitions

The following definitions are used throughout the book in the chemistry section for each agent:

<i>Descriptive Term</i>	<i>Parts of Solvent for 1 Part of Solute</i>
Very Soluble	Less than 1
Freely Soluble	From 1 to 10
Soluble	From 10 to 30
Sparingly Soluble	From 30 to 100
Slightly Soluble	From 100 to 1000
Very Slightly Soluble	From 1000 to 10,000
Practically Insoluble, or Insoluble	More than 10,000

### Conversion: Weights; Temperature; Liquids

- 1 pound (lb) = 0.454 kg = 454 grams = 16 ounces
- 1 kilogram (kg) = 2.2 pounds = 1000 grams
- 1 grain (gr.) = 64.8 mg (often rounded to 60 or 65 mg)
- 1 gram = 15.43 grains = 1000 mg
- 1 ounce = 28.4 grams
- 1 gram = 1000 mg
- 1 milligram (mg) = 1000 mcg (µg)
- 1 microgram (mcg or µg) = 1000 nanograms (ng)

### TEMPERATURE CONVERSION:

- $9 \times (^{\circ}\text{C}) = (5 \times ^{\circ}\text{F}) - 160$
- $^{\circ}\text{C to } ^{\circ}\text{F} = (^{\circ}\text{C} \times 1.8) + 32 = ^{\circ}\text{F}$
- $^{\circ}\text{F to } ^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times 0.555 = ^{\circ}\text{C}$

### LIQUID MEASURE:

- 1 gallon (gal.) = 4 qts. = 8 pts. = 128 fl. oz. = 3.785 liters = 3785 mL
- 1 quart (qt) = 2 pints = 32 fl. oz. = 946 mL
- 1 pint = 2 cups = 16 fl. oz. = 473 mL
- 1 cup = 8 fl. oz = 237 mL = 16 tablespoons
- 1 tablespoon = 15 mL = 3 teaspoons
- 1 teaspoon = 5 mL
- 4 liters = 1.057 gals.
- 1 liter = 1000 mL = 10 deciliters
- 1 deciliter (dl) = 100 mL
- 1 milliliter (mL) = 1 cubic centimeter (cc) = 1000 microliters (µl; mcl)

### Milliequivalents & Molecular Weights

Milliequivalents: The term milliequivalents (mEq) is usually used to express the quantities of electrolytes administered to patients. A mEq is 1/1000 of an equivalent (Eq). For pharmaceutical purposes an equivalent may be thought of as equal to the equivalent weight of a given substance. This, in practical terms, is the molecular weight of the substance divided by the valence or the radical. For example:

How many milligrams are equivalent to 1 mEq of potassium chloride (KCl)?

1. Determine the equivalent weight = gram atomic weight ÷ valency. Molecular weight of KCl = 74.5; Valence = 1 (K<sup>+</sup>; Cl<sup>-</sup>). Equivalent weight = 74.5 ÷ 1 = 74.5 grams

1. Determine the equivalent weight = gram atomic weight ÷ valence; molecular weight of KCl = 74.5; valence = 1 (K<sup>+</sup>, Cl<sup>-</sup>); Equivalent weight = 74.5 ÷ 1 = 74.5 grams
2. Determine the mEq weight: Equivalent weight ÷ 1000; 74.5 ÷ 1000 = 74.5 mg = 1 mEq of KCl = 1 mEq of K<sup>+</sup> & 1 mEq of Cl<sup>-</sup>
- If the substance would have been CaCl<sub>2</sub>, the process would be identical using the gram molecular weight of CaCl<sub>2</sub> (MW 111 if anhydrous; 147 if dihydrate) and a valence of 2.

Listed below are several commonly used electrolytes with their molecular weights and valences in parentheses:

<b>Electrolyte</b>	<b>Molecular Weight (valence)</b>
Sodium Chloride	58.44 (1)
Sodium Bicarbonate	84 (1)
Sodium Acetate, anhydrous	82 (1)
Sodium Acetate, trihydrate	136 (1)
Sodium Lactate	112 (1)
Potassium Chloride	74.55 (1)
Potassium Gluconate	234.25 (1)
Calcium Gluconate	430.4 (2)
Calcium Lactate, anhydrous	218.22 (2)
Calcium Chloride, anhydrous	111 (2)
Calcium Chloride, dihydrate	147 (2)
Magnesium Sulfate, heptahydrate	246.5 (2)
Magnesium Sulfate, anhydrous	120.4 (2)
Magnesium Chloride, anhydrous	95.21 (2)
Magnesium Chloride, hexahydrate	203.3 (2)

## “Normal” Vital Signs

<b>Temperature</b>	<b>Celsius (°C)</b>	<b>Fahrenheit (°F)</b>
Dog	37.5–39.2	99.5–102.5
Cat	37.8–39.5	100–102.5
Ferret	37.8–39.2	100–102.5
Cattle, up to one year old	38.6–39.4	101.5–103.5
Cattle, over one year old	37.8–39.2	100–102.5
Horse, adult	37.2–38.5	99–101.3
Horse, foal	37.5–39.3	99.5–102.7
Goat	38.5–40.2	101.3–104.5
Sheep	38.5–40	101.3–104
Swine, piglet	38.9–40	102–104
Swine, adult	37.8–38.9	100–102
Rabbit	38.5–39.3	100.4–105

Temperature (Rectal): Temperatures will normally fluctuate over the course of the day. The following may increase body temperature: Time of day (evening), food intake, muscular activity, approaching estrus, during gestation, high external temperatures. The following may decrease body temperature: intake of large quantities of cool fluids, time of day (morning), and low atmospheric temperature. Small breed dogs tend to have higher normal temperatures than large breeds.

<b>Pulse Rates</b>	<b>BPM</b>
Cattle, calves	100–120
Cattle, adults	55–80
Cat, young	130–140
Cat, old	100–120
Dog, young	110–120
Dog, adult large breed	80–120
Ferret	300
Goat	70–120
Horse, adult	28–40
Horse, 3 months–2 years	40–80
Horse, foals–3 months	64–128
Rabbit	120–150
Sheep	66–115
Swine, young	100–130
Swine, adult	60–90

Pulse Rates (resting and healthy) in beats per minute (BPM). Pulse rates for very young animals are usually in the higher ranges and older animals in the lower ranges of those values listed.

<b>Respiratory Rates</b>	<b>RPM</b>
Cattle, young	15–40
Cattle, adults	10–30
Cats	20–30
Dog	15–30
Ferret	33–36
Horse	10–14
Swine	8–18
Rabbit	50–60
Sheep, Goat	10–30

## Estrus and Gestation Periods for Dogs &amp; Cats

	Dog	Cat
Appearance of first estrus at the age of:	7–9 months	4–12 months
Estrous cycle in animals not served:	Mean = 7 months Range = every 5–8 months	Every 4–30 days (14–19 day model) if constant photoperiod
Duration of estrus period:	7–42 days (proestrus plus estrus)	2–19 days
First occurrences after parturition:	Pregnancy does not alter interval	7–9 days
Gestation Period	Mean = 63 days; Range 58–71 days	Mean = 63 days; Range 58–70 days
Number of Young	8–12 Large Breeds 6–10 Medium Breeds 2–4 Small Breeds	4–6
Suckling Period	3–6 weeks	3–6 weeks

## Conversion of Conventional Chemistry Units to SI Units

The Système Internationale d'Unités (SI), or the International System of Units was recommended for use in the health professions by the World Health Assembly in 1977. It is slowly being adopted in the United States and many journals now require its use. The following is an abbreviated table of conversion values for some of the more commonly encountered tests that may now be reported in SI Units.

	Chemistry Units to SI Units
Albumin	g/dl x 10 = g/L
Ammonia	mg/dl x 0.5872 = mmol/L
Bilirubin	mg/dl x 17.10 = mmol/L
Calcium	mg/dl x 0.2495 = mmol/L
Cholesterol	mg/dl x 0.02586 = mmol/L
CO <sub>2</sub> pressure, pCO <sub>2</sub>	mmHg x 0.1333 = kPa
Creatinine	mg/dl x 88.4 = mmol/L
Glucose	mg/dl x 0.05551 = mmol/L
Lactate	mg/dl x 0.111 = mmol/L
Magnesium	mg/dl x 0.4114 = mmol/L
O <sub>2</sub> pressure, pO <sub>2</sub>	mmHg x 0.1333 = kPa
Phosphorus	mg/dl x 0.3229 = mmol/L
Protein	g/dl x 10 = g/L
Urea Nitrogen	mg/dl x 0.7140 = mmol/L
Amylase	IU/L = U/L
AST (SGOT)	IU/L = U/L
ALT (SGPT)	IU/L = U/L
Lipase	IU/L = U/L
ALP	IU/L = U/L
SDH (Sorbitol)	IU/L = U/L

Bicarbonate, Chloride, CO<sub>2</sub> (total), Potassium, & Sodium do not require conversion from conventional to SI units.

## Reference Laboratory Ranges

**Note:** The following reference ranges are as a general reference only; refer to the “normals” for the laboratory you are using

## Chemistry: Canine, Feline, Bovine, Equine

Values are from: Marshfield Clinic Laboratories, Veterinary Diagnostic Service; <http://www.marshfieldlabs.org/veterinary/> Data accessed: 2011

Test	Units	Canine	Feline	Bovine	Equine
Glucose	mg/dl	74–145	56–153	50–79	52–121
AST (SGOT)	Units/L	13–81	14–54	57–108	156–597
ALT (SGPT)	Units/L	14–151	26–128	11–47	3–60
Alkaline phosphatase	Units/L	13–289	14–102	26–78	86–262
Total bilirubin	mg/dL	0.1–0.5	0.0–0.2	0.1–0.4	0.4–3.3
Cholesterol	mg/dL	98–300	71–218	112–331	59–125

### Governmental Veterinary Drug-Related Websites

#### Food and Drug Administration Center for Veterinary Medicine (FDA-CVM)

Call to report an adverse effect for a pharmaceutical, etc. 888-463-6332 (888-INFO-FDA); Emergency: 866-300-4374. After hours call and leave a recorded message. May also file a report on-line [www.fda.gov/cvm/](http://www.fda.gov/cvm/)

#### U.S. Department of Agriculture (USDA)

For adverse effect reporting on biologics: 800-752-6255. May also file a report on-line at: <http://goo.gl/5hoCO>

#### U.S. Environmental Protection Agency (EPA)

Most of the products used topically for the control of ectoparasites and insects on animals are regulated by the Environmental Protection Agency (EPA) under the Federal Insecticide Fungicide and Rodenticide Act. The EPA may be reached at 800-858-7378.

The National Pesticide Information Center has a hotline and an online site for veterinarians or their staff to report adverse effects of topical pesticides: 800-858-7378; <http://pi.ace.orst.edu/vetrep/>

#### Food Animal Residue Avoidance & Depletion Program (FARAD)

1-888-USFARAD (1-888-873-2723)

<http://www.farad.org/>

#### Drug Enforcement Administration (DEA)

800-882-9539 Toll-free number for registration information. [www.deadiversion.usdoj.gov/](http://www.deadiversion.usdoj.gov/)

#### OUTSIDE OF USA:

Australia: APVMA Website: <http://www.apvma.gov.au/>

Canada: Health Canada website with many veterinary links: <http://goo.gl/cGDua>

New Zealand: NZFSA Ag Compounds and Vet Medicines website: <http://goo.gl/UvHLA>

United Kingdom: Veterinary Medicines Directorate website: <http://www.vmd.gov.uk/>

### Drug Shortage Websites

The Food and Drug Administration (FDA) maintains a drug shortage web page. E-mail notification service is available: <http://goo.gl/16ICZ>

The American Society of Health-System Pharmacists (ASHP) has a website for drug shortages (human drugs): <http://www.ashp.org/shortages>

### Animal Poison Centers

#### ASPCA Animal Poison Control Center

1-888-426-4435

[www.apcc.aspc.org](http://www.apcc.aspc.org)

A consultation fee may be applied to a credit card.

#### Pet Poison HELPLINE

1- 800-213-6680

[www.petpoisonhelpline.com](http://www.petpoisonhelpline.com)

A consultation fee may be applied to a credit card.

#### Angell Poison Control Hotline

1-877-2ANGELL

<http://goo.gl/oJ8jX>

A consultation fee may be applied to a credit card.

There are many regional poison centers that may be of assistance with animal poisonings; refer to your local poison center for more information.

### Animal Blood Banks

#### Animal Blood Resources

Michigan: 517-851-8244

California: 800-243-5759

**Systemic Drugs Sorted by Therapeutic Class or Major Indication**

The following lists systemic drugs by their therapeutic class or major indication, followed by species where dosages are listed, and the page number for the monograph. The following species codes are used in parentheses after the drug name:

= Avian; Pet Bird  
B = Bovine, Cattle  
C = Cat, Feline  
D = Dog, Canine  
Fer = Ferret  
Fi = Fish  
H = Horse, Equine  
L = Llama, Alpacas, Camelids  
Po = Pocket Pets, Rabbits, Small Lab Animals  
O = Ostrich, Ratite  
R = Reptiles/Amphibians  
Sh = Sheep/Goats; Ovine/Caprine  
Sw = Swine, Pigs  
Z = Wildlife/Zoo Animals

Note: As some drugs have multiple indications, there may not be a specific dosage listed for that indication for every species noted.

#### Antihistamines

[Cetirizine](#) (D, C, H)  
[Chlorpheniramine](#) (D, C, Fer, A)  
[Clemastine Fumarate](#) (D, C)  
[Cyproheptadine](#) (D, C, H)  
[Diphenhydramine](#) (D, C, Fer, Po, A, H, B)  
[Doxepin](#) (D, C, A)  
[Hydroxyzine](#) (D, C, Fer, H, A)  
[Meclizine](#) (D, C, Po)  
[Promethazine](#) (D, C)  
[Pyrilamine](#) (D, B, H, Sh, Sw)  
[Trimeprazine](#) (D)  
[Tripeleminamine](#) (D, C, B, H, Sw)

#### Central Nervous System Drugs

(including antiinflammatories, analgesics, muscle relaxants)

#### CNS/RESPIRATORY STIMULANTS

[Doxapram](#) (D, C, Po, B, Sw, H, A, R)

#### ANALGESICS, OPIOID AGONISTS

[Alfentanil](#) (D)  
[Codeine Phosphate](#) (D, C, Po)  
[Fentanyl](#) (D, C, Fer, Po, H, Sh, Sw)  
[Hydromorphone](#) (D, C, Fer, Po)  
[Meperidine](#) (D, C, Fer, Po, Sh, Sw, B, H)  
[Methadone](#) (D, C, H)  
[Morphine](#) (D, C, Po, H, Sw, Sh, L, Z)  
[Oxymorphone](#) (D, C, Fer, H, Sw, Po, Z)  
[Sufentanil](#) (D, C)  
[Tramadol](#) (D, C, H, Z)

#### ANALGESICS, OPIOID AGONIST/ANTAGONISTS

[Buprenorphine](#) (D, C, Po, Fer, H, Z)  
[Butorphanol](#) (D, C, Fer, Po, B, H, A, L, R, Z)  
[Pentazocine](#) (D, C, Po, Fer, H)

#### ANALGESICS, OTHER

[Amantadine](#) (D, C, H)  
[Clonidine](#) (B)  
[Gabapentin](#) (D, C)  
[Ketamine](#) (D, C, Po, Fer, B, H, Sw, Sh, L, R, A, Z)  
[Pregabalin](#) (D, C)

#### NONSTEROIDAL ANTIINFLAMMATORY/ANALGESIC AGENTS

[Acetaminophen](#) (D, Po)  
[Aspirin](#) (D, C, Po, Fer, B, H, Sw, A)  
[Carprofen](#) (D, C, Po, H, B, A, R, Z)  
[Colchicine](#) (D, A)  
[Deracoxib](#) (D)  
[Diclofenac](#) (H)  
[Dimethyl Sulfoxide](#) (D, H)  
[Etodolac](#) (D)  
[Firocoxib](#) (D, C, H)  
[Flunixin](#) (D, Fer, Po, B, H, Sh, Sw, A, Z)  
[Ketoprofen](#) (D, C, Fer, Po, H, A, Z)  
[Ketorolac Tromethamine](#) (D, C, Sh, Po)  
[Mavacoxib](#) (D)  
[Meloxicam](#) (D, C, H, B, Sw, Fer, A, Z)  
[Naproxen](#) (D, Po, H)  
[Phenylbutazone](#) (D, B, H, Sw)  
[Piroxicam](#) (D, C, H, Po)  
[Robenacoxib](#) (D, C)  
[Tepoxalin](#) (D)  
[Tolfenamic Acid](#) (D, C, B, Sw)

#### BEHAVIOR-MODIFYING AGENTS

[Amitriptyline](#) (D, C, A)

[Guspirone](#) (D, C)  
[Clomipramine HCl](#) (D, C, A)  
[Clorazepate](#) (D, C)  
[Diazepam](#) (D, C, Fer, Po, B, H, Sw, Sh, A, Z)  
[Fluoxetine](#) (D, C)  
[Fluvoxamine](#) (D, C)  
[Imipramine](#) (D, C, H)  
[Lorazepam](#) (D, C)  
[Methylphenidate](#) (D)  
[Paroxetine HCl](#) (D, C)  
[Pheromones](#) (D, C, H)  
[SAMe](#) (D, C)  
[Sertraline](#) (D, C)  
[Trazodone](#) (D)

#### TRANQUILIZERS/SEDATIVES

[Acepromazine](#) (D, C, Fe, P, B, H, Sw, Sh, Z)  
[Alprazolam](#) (D, C)  
[Azaperone](#) (Sw)  
[Chlordiazepoxide](#) (D, C)  
[Detomidine](#) (H, B, Sh, L, A)  
[Dexmedetomidine](#) (D, C)  
[Diazepam](#) (D, C, Po, Fer, A, B, H, Sw, Sh, Z)  
[Doxepin](#) (D, C, A)  
[Lorazepam](#) (D, C)  
[Medetomidine](#) (D, C, Po, Fer, A, R, Z)  
[Midazolam](#) (D, C, Po, A, H, Z)  
[Romifidine](#) (D, C, H, B)  
[Tiletamine/Zolazepam](#) (D, C, Po, B, Sh, Fer, H, R, A, Z)  
[Xylazine](#) (D, C, Fer, Po, A, B, H, Sh, L, Z)

#### ANESTHETIC AGENTS, BARBITURATES

[Methohexital Sodium](#) (D, C)  
[Pentobarbital](#) (D, C, Po, B, H, Sw, Sh)  
[Thiopental](#) (D, C, Po, B, H, Sw, Sh)

#### ANESTHETIC AGENTS, INHALANTS

[Desflurane](#)  
[Halothane](#) (D, C, Po, H)  
[Isoflurane](#) (D, C, Po, R, A)  
[Sevoflurane](#) (D, C)

#### ANESTHETIC AGENTS, MISCELLANEOUS

[Alfaxalone](#) (D, C, Po)  
[Alfentanil](#) (D)  
[Etomidate](#) (D, C, Fe, Po)  
[Fentanyl](#) (D, C, Fer, Po, H, Sh, Sw)  
[Ketamine](#) (D, C, Po, Fer, B, H, Sw, Sh, L, R, A, Z)  
[Propofol](#) (D, C, Po, R, Z)  
[Remifentanyl](#) (D, C)  
[Sufentanil](#) (D, C)  
[Tiletamine/Zolazepam](#) (D, C, Po, B, Sh, Fer, H, A, R, Z)  
[Xylazine](#) (D, C, Po, Fer, A, B, H, Sh, L, Z)

#### REVERSAL AGENTS

[Atipamezole](#) (D, C, Po, B, Sh, A, R, Z)  
[Flumazenil](#) (D, C, Z)  
[Naloxone](#) (D, C, Po, H)  
[Naltrexone](#) (D, C, Z)  
[Neostigmine](#) (D, C, B, H, Sw, Sh)  
[Tolazoline](#) (D, C, H, L, A, Sh, B, Z)  
[Yohimbine](#) (D, Po, A, B, H, L, Z)

#### ANTICONVULSANTS

[Bromides](#) (D, C)  
[Carbamazepine](#) (D, H)  
[Clonazepam](#) (D, C)  
[Clorazepate](#) (D, C) 328  
[Diazepam](#) (D, C, Po, Fer, A, B, H, Sw, Sh, Z)  
[Felbamate](#) (D)  
[Gabapentin](#) (D, C)  
[Levetiracetam](#) (D, C)  
[Lorazepam](#) (D, C)  
[Phenobarbital](#) (D, C, Fer, B, H)  
[Phenytoin](#) (D, C, H)  
[Pregabalin](#) (D, C)  
[Primidone](#) (D, C)  
[Topiramate](#) (D, C)  
[Valproic Acid](#) (D)  
[Zonisamide](#) (D, C)

#### MUSCLE RELAXANTS, SKELETAL

[Atracurium](#) (D, C, Po, H)  
[Baclofen](#) (D)  
[Dantrolene](#) (D, C, H, Sw)  
[Guaiifenesin](#) (D, B, H, L, Sh)

[Methocarbamol](#) (D, C, B, H)  
[Pancuronium](#) (D, C, Po)  
[Rocuronium](#) (D, C, H)  
[Succinylcholine](#) (D, C, H, R)  
[Vecuronium](#) (D, C)

**Euthanasia Agents**  
[Pentobarbital/Phenytoin](#) (D, C)

#### Cardiovascular Agents

##### INOTROPIC AGENTS

[Digoxin](#) (D, C, Fer, Po, B, H, A)  
[Dobutamine](#) (D, C, H)  
[Inamrinone Lactate](#) (D, C)  
[Pimobendan](#) (D, C)

##### ANTIARRHYTHMIC DRUGS

[Amiodarone](#) (D, H)  
[Disopyramide](#) (D)  
[Lidocaine](#) (D, C, H)  
[Mexiletine](#) (D)  
[Procainamide](#) (D, C, H)  
[Quinidine](#) (D, C, H)  
[Verapamil](#) (D, C, H, Po)

##### ANTICHOLINERGICS

[Atropine](#) (D, C, B, H, Po, Fer, Sw, Sh, A, R)  
[Glycopyrrolate](#) (D, C, Fer, Po, H, R)  
[Hyoscyamine](#) (D)

##### ACE INHIBITORS

[Benazepril](#) (D, C)  
[Captopril](#) (D, C)  
[Enalapril](#) (D, C, Fer, A)  
[Lisinopril](#) (D, C)  
[Ramipril](#) (D, C, H)

##### CALCIUM CHANNEL BLOCKING AGENTS

[Amlodipine](#) (D, C)  
[Diltiazem](#) (D, C, Fer)  
[Verapamil](#) (D, C, H, Po)

##### VASODILATING AGENTS

[Hydralazine](#) (D, C, H)  
[Isosorbide](#) (D, C)  
[Isoxsuprine](#) (H, D)  
[Nitroglycerin](#) (D, C, Fer)  
[Nitroprusside](#) (D, C)  
[Sildenafil](#) (D, C)  
[Tadalafil](#) (D)

##### AGENTS USED IN TREATMENT OF SHOCK

[Dobutamine](#) (D, C, H)  
[Dopamine](#)  
[Epinephrine](#) (D, C, A, H, B, Sh, Sw)  
[Isoproterenol HCl](#) (D, C, H)  
[Phenylephrine](#) (D, C, H)

##### ALPHA-ADRENERGIC BLOCKING AGENTS

[Phenoxybenzamine](#) (D, C, H)  
[Prazosin](#) (D, C)

##### BETA-ADRENERGIC BLOCKING AGENTS

[Atenolol](#) (D, C, Fer)  
[Carvedilol](#) (D)  
[Esmolol](#) (D, C)  
[Metoprolol](#) (D, C)  
[Propranolol](#) (D, C, Fer, H)  
[Sotalol HCl](#) (D, C)

##### ANTIHYPERTENSIVE AGENTS

[Irbesartan](#) (D)  
[Nitroprusside](#) (D, C)

##### OTHER CARDIOVASCULAR AGENTS

[Carnitine](#) (D, C)  
[Taurine](#) (D, C)

#### Respiratory Drugs

##### SYMPATHOMIMETICS

[Albuterol](#) (D, C, H)  
[Clenbuterol](#) (H)  
[Ephedrine](#) (D, C)  
[Epinephrine](#) (D, C, A, H, B, Sh, Sw)  
[Isoproterenol HCl](#) (D, C, H)

[Pseudoephedrine HCl](#) (D, C, H)  
[Terbutaline](#) (D, C, H)

#### XANTHINES

[Aminophylline/Theophylline](#) (D, C, Fer, H)

#### ANTITUSSIVES

[Butorphanol](#) (D, C, Fer, Po, B, H, A, L, R, Z)  
[Codeine](#) (D, C, Po)  
[Hydrocodone](#) (D, C)

#### MUCOLYTICS

[Acetylcysteine](#) (D, C, H)

#### OTHER RESPIRATORY AGENTS

[Cromolyn Sodium](#) (H)  
[Ipratropium Br](#) (H, Po)  
[Montelukast](#) (C)  
[Zafirlukast](#) (D, C)

#### Renal & Urinary Tract Agents

#### DIURETICS, CARBONIC ANHYDRASE INHIBITORS

[Acetazolamide](#) (D, C, B, H, Sh, Sw)  
[Dichlorphenamide](#) (D, C)  
[Methazolamide](#) (D, C)

#### DIURETICS, THIAZIDES

[Chlorothiazide](#) (D, C, B)  
[Hydrochlorothiazide](#) (D, C, H)

#### DIURETICS, LOOP

[Furosemide](#) (D, C, Fer, Po, B, H, A, R)  
[Torsemide](#) (D, C)

#### DIURETICS, POTASSIUM SPARING

[Spironolactone](#) (D, C)  
[Triamterene](#) (D)

#### DIURETICS, OSMOTIC

[Glycerine, Oral](#) (D, C)  
[Mannitol](#) (D, C, B, Sw, Sh, H)

#### AGENTS FOR URINARY INCONTINENCE/RETENTION

[Baclofen](#) (D)  
[Bethanechol](#) (D, C, H, B)  
[Ephedrine](#) (D, C)  
[Flavoxate](#) (D)  
[Imipramine](#) (D, C, H)  
[Oxybutynin](#) (D, C)  
[Phenoxybenzamine](#) (D, C, H)  
[Phenylpropanolamine](#) (D, C)  
[Pseudoephedrine HCl](#) (D, C, H)

#### URINARY ALKALINIZERS

[Sodium Bicarbonate](#) (D, C, H, B, Sh, A)

#### URINARY ACIDIFIERS

[Ammonium Chloride](#) (D, C, H, B, Sh)  
[Methionine](#) (D, C, B, H)

#### AGENTS FOR UROLITHIASIS

[Acetohydroxamic Acid](#) (D)  
[Allopurinol](#) (D, A, R)  
[Ammonium Chloride](#) (D, C, H, B, Sh)  
[Citrate Salts](#) (D, C)  
[Methionine](#) (D, C, B, H)  
[Tiopronin](#) (D)

#### MISCELLANEOUS RENAL/URINARY AGENTS

[Amitriptyline](#) (D, C, A)  
[Pentosan](#) (D, C, H)  
[Probenecid](#) (R)

#### Gastrointestinal Agents

#### ANTIEMETIC AGENTS

[Chlorpromazine](#) (D, C, B, H, Sw, Sh)  
[Dimenhydrinate](#) (D, C)  
[Diphenhydramine](#) (D, C, Fer, Po, A, H, B)  
[Dolasetron](#) (D, C)  
[Granisetron](#) (D, C)  
[Maropitant](#) (D, C)  
[Meclizine](#) (D, C, Po)  
[Metoclopramide](#) (D, C, Po, H)  
[Mirtazapine](#) (D, C)  
[Ondansetron](#) (D, C)

[Phenacetone](#) (D, C)  
[Prochlorperazine](#) (D, C)  
[Promethazine](#) (D, C)

## ANTACIDS

[Aluminum Hydroxide](#) (D, C, Po, B, H)  
[Calcium Salts, Oral](#) (D, C, B, H, Sh, Sw, A, R)  
[Sodium Bicarbonate](#) (D, C, H, B, Sh, A)

## H-2 ANTAGONISTS

[Cimetidine](#) (D, C, Fer, Po, H, Sw, R)  
[Famotidine](#) (D, C, Fer, Po H)  
[Nizatidine](#) (D, C)  
[Ranitidine](#) (D, C, Fer, H, Po)

## GASTROMUCOSAL PROTECTANTS

[Sucralfate](#) (D, C, Fer, H, R)

## PROSTAGLANDIN E ANALOGS

[Misoprostol](#) (D, H)

## PROTON PUMP INHIBITORS

[Omeprazole](#) (D, C, Fer, H, Sw)  
[Pantoprazole](#) (D, C, H)

## APPETITE STIMULANTS

[Cyproheptadine](#) (D, C, H)  
[Diazepam](#) (D, C, Fer, Po, A, B, H, Sw, Sh, Z)  
[Mirtazapine](#) (D, C)  
[Oxazepam](#) (D, C)

## GI ANTISPASMODICS-ANTICHOLINERGICS

[Aminopentamide](#) (D, C)  
[Hyoscyamine](#) (D)  
[N-Butylscopolammonium Br](#) (H)  
[Propantheline](#) (D, C, H)

## GI STIMULANTS

[Cisapride](#) (D, C, Po, H)  
[Dexpanthenol](#) (D, C, H)  
[Domperidone](#) (D, C, H)  
[Metoclopramide](#) (D, C, Po, H)  
[Neostigmine](#) (D, C, B, H, Sw, Sh)

## DIGESTIVE ENZYMES

[Pancrelipase](#) (D, C, Po, A)

## LAXATIVES

[Bisacodyl](#) (D, C)  
[Docusate](#) (D, C, H)  
[Lactulose](#) (D, C, A, R)  
[Laxatives, Hyperosmotic](#) (D, C, H, B, Sh, Sw, A)  
[Magnesium Hydroxide \(D, C, B, H, Sh\)](#)  
[Mineral Oil](#) (D, C, Po, B, H, Sw, Sh, A)  
[Psyllium](#) (D, C, H)

## ANTIDIARRHEALS

[Bismuth Subsalicylate](#) (D, C, B, H, Fer, Sw)  
[Clonidine](#) (D, C)  
[Diphenoxylate/Atropine](#) (D, C)  
[Kaolin/Pectin](#) (D, C, Fer, Po, B, H, Sw, Sh, A)  
[Loperamide](#) (D, C, Po)  
[Paregoric](#) (D, C H, B)

## EMETICS

[Apomorphine](#) (D, C)  
[Hydrogen Peroxide %](#) (D, C, Fer, Sw)  
[Xylazine](#) (D, C, Po, Fer, A, B, H, Sh, L, Z)

## MISCELLANEOUS GI DRUGS

[Bismuth Subsalicylate](#) (D, C, Fer, B, H, Sw)  
[Budesonide](#) (D, C)  
[Dirlotapide](#) (D)  
[Glutamine](#) (D, C)  
Olsalazine Sodium (D) 1005  
[SAMe](#) (D, C)  
[Silymarin](#) (D, C)  
[Sulfasalazine](#) (D, C, Fer)  
[Ursodiol](#) (D, C, A)

## Hormones/Endocrine/Reproductive Agents

### SEX HORMONES, ESTROGENS

[Diethylstilbestrol](#) (DES) (D, C)  
[Estradiol](#) (D, C, B, H)

### SEX HORMONES, PROGESTINS

**SEX HORMONES, PROGESTINS**

[Altrenogest](#) (D, H, Sw)  
[Medroxyprogesterone](#) (D, C, H, A)  
[Megestrol Acetate](#) (D, C)

**SEX HORMONES, ANDROGENS**

[Danazol](#) (D, C)  
[Methyltestosterone](#) (D, C)  
[Mibolerone](#) (D, C)  
[Testosterone](#) (D, C, B)

**ANABOLIC STEROIDS**

[Boldenone](#) (H, C)  
[Nandrolone](#) (D, C, R)  
[Stanozolol](#) (D, C, Fer, Po, H, Sh, A, R)

**POSTERIOR PITUITARY HORMONES**

[Desmopressin](#) (D, C, H)  
[Vasopressin](#) (D, C)

**OXYTOCICS**

[Oxytocin](#) (D, C, Po, B, H, Sw, Sh, A, L, R)

**ADRENAL CORTICAL STEROIDS**

[Corticotropin-ACTH](#) (D, C, B, H, A)  
[Cortisone Acetate](#) (D)  
[Cosyntropin](#) (D, C, H)

**MINERALOCORTICIDS**

[Desoxycorticosterone Piv.](#) (D, C)  
[Fludrocortisone](#) (D, C, Fer)

**GLUCOCORTICIDS**

[Betamethasone](#) (D, H)  
[Dexamethasone](#) (D, C, Po, B, H, Sw, L, A, R)  
[Flumethasone](#) (D, C, H)  
[Fluticasone](#) (D, C, H)  
[Hydrocortisone](#) (D, C, B, H)  
[Isoflupredone](#) (B, H, Sw)  
[Methylprednisolone](#) (D, C, H)  
[Prednisolone](#) (D, C, Po, Fer, B, H, L, Sw, A, R)  
[Prednisone](#) (D, C, Po, Fer, B, H, L, Sw, A, R)  
[Triamcinolone](#) (D, C, B, H)

**ADRENAL STEROID INHIBITORS**

[Ketoconazole](#) (D, C, H, Po, A, R)  
[Metyrapone](#) (C)  
[Mitotane](#) (D, Fer)  
[Selegiline](#) (D, C)  
[Trilostane](#) (D, C, H)

**ANTIDIABETIC AGENTS**

[Acarbose](#) (D, C)  
[Chlorpropamide](#) (D, C)  
[Chromium](#) (C)  
[Glimepiride](#) (C)  
[Glipizide](#) (C)  
[Glyburide](#) (C)  
Insulin (D, C, Fer, B, H, A) 710  
[Metformin](#) (C, A)  
[Vanadium](#) (C)

**GLUCOSE ELEVATING AGENTS**

[Diazoxide, Oral](#) (D, C, Fer)  
[Glucagon](#) (D, C, B)  
[Octreotide Acetate](#) (D, C, Fer)

**THYROID HORMONES**

[Levothyroxine](#) (D, C, H, A, R)  
[Liothyronine](#) (D, C)  
[Thyrotropin](#) (D, A)

**ANTITHYROID DRUGS**

[Carbimazole](#) (C)  
[Iodate Sodium](#) (C)  
[Methimazole](#) (D, C)

**PROSTAGLANDINS**

[Cloprostenol](#) (D, B, H, Sw, Sh, L)  
[Dinoprost](#) (D, C, B, H, Sw, Sh)

**MISC. ENDOCRINE/REPRODUCTIVE DRUGS**

[Aglepristone](#) (D, C)  
[Bromocriptine](#) (D, C, H)  
[Cabergoline](#) (D, C, A)  
[Chorionic Gonadotropin HCG](#) (D, C, Fer, Po, A, B, H)

[Chromic Gonadotropin-Releasing Hormone](#) (D, C, Fer, Po, A, B, H)  
[Deslorelin](#) (D, H)  
[Finasteride](#) (D, Fer)  
[Gonadorelin](#) (D, C, Fer, B, Sh)  
[Leuprolide](#) (Fer, A)  
[Melatonin](#) (D, C, Fer)  
[Metergoline](#) (D, C)  
[Mibolerone](#) (D, C)  
[Octreotide Acetate](#) (D, C, Fer)  
[Pergolide](#) (H) 1079  
[Somatotropin](#) (D)

#### Anti-infective Drugs

#### ANTIPARASITICS

[Albendazole](#) (D, C, Po, B, Sw, Sh, A)  
[Atovaquone](#) (D, C)  
[Clorsulon](#) (B, Sh, L)  
[Dichlorvos](#) (Po, Sw)  
[Diclazuril](#) (D, C, H, B, Sh)  
[Diethylcarbamazine](#) (D, C, Fer, B)  
[Diminazene](#) (D, C, H, B, Sh)  
[Doramectin](#) (D, C, B, Sw, Po)  
[Emodepside + Praziquantel](#) (C, R)  
[Eprinomectin](#) (C, H)  
[Epsiprantel](#) (D, C)  
[Fenbendazole](#) (D, C, Po, B, H, Sw, Sh, L, A, R, Z)  
[Furazolidone](#) (D, C, H)  
[Imidocarb](#) (D, C, Sh, H)  
[Ivermectin](#) (D, C, B, Fer, Po, H, Sw, Sh, L, A, R)  
[Levamisole](#) (D, C, Po, H, B, L, Sw, Sh, A, R)  
[Lufenuron](#) (D, C, Po)  
[Meglumine Antimoniate](#) (D)  
[Melarsomine](#) (D)  
[Metronidazole](#) (D, C, Fer, Po, H, A, R)  
[Milbemycin Oxime](#) (D, C, R)  
[Miltfosine](#) (D)  
[Morantel](#) (B, Sh)  
[Moxidectin](#) (D, C, Sh, L, H, B)  
[Nitazoxanide](#) (C, H)  
[Nitenpyram](#) (D, C, R)  
[Oxfendazole](#) (D, H, B, Sw, Sh)  
[Oxibendazole](#) (H, B, Sw, Sh)  
[Paromomycin](#) (D, C, L, R)  
[Piperazine](#) (D, C, Po, H, B, Sh, Sw, A, R)  
[Ponazuril](#) (D, C, Po, H, L, A, R)  
[Praziquantel](#) (D, C, Po, Sh, L, A, R)  
[Primaquine](#) (C)  
[Pyrantel](#) (D, C, Po, H, Sw, B, L, A, Sh)  
[Prymethamine](#) (D, C, H, A)  
[Prymethamine + Sulfadiazine](#) (H)  
[Quinacrine](#) (D, C, R)  
[Ronidazole](#) (C)  
[Selamectin](#) (D, C, Fer, Po)  
[Sodium Stibogluconate](#) (D)  
[Spinosad](#) (D)  
[Tinidazole](#) (D, C, H)  
[Trypan Blue](#) (D)

#### ANTICOCCIDIAL AGENTS

[Amprolium](#) (D, C, Fer, Po, B, Sw, Sh, L, A)  
[Decoquinat](#) (D, B, Sh, L)  
[Diclazuril](#) (D, C, B, Sh)  
[Toltrazuril](#) (D, C, Sh, A, R)

#### ANTIBIOTICS, AMINOCYCLITOLS

[Amikacin](#) (D, C, B, Fer, Fi, Po, H, A, R)  
[Apramycin](#) (B, Sw, A)  
[Gentamicin](#) (D, C, Fer, Po, H, Sw, A, R)  
[Neomycin](#) (D, C, Po, Fer, B, H, Sw, Sh, A, R)  
[Spectinomycin](#) (D, C, B, H, Sw, A)  
[Tobramycin](#) (D, C, H, L, A, R)

#### ANTIBIOTICS, CARBAPENEMS

[Ertapenem](#) (D, C)  
[Imipenem-Cilastatin](#) (D, C, H)  
[Meropenem](#) (D, C)

#### ANTIBIOTICS, CEPHALOSPORINS

[Cefaclor](#) (D, C)  
[Cefadroxil](#) (D, C, Fer)  
[Cefazolin](#) (D, C, H, R)  
[Cefepime](#) (D, H)  
[Cefixime](#) (D, C)  
[Cefotaxime](#) (D, C, H, A, R)  
[Cefotetan Disodium](#) (D, C)  
[Cefovecin](#) (D, C)

[Cefoxitin](#) (D, C, H)  
[Cefpodoxime Proxetil](#) (D, C, H)  
[Ceftazidime](#) (D, C, R)  
[Ceftiofur](#) (D, C, A, B, Sw, Sh, H, R, Z)  
[Ceftriaxone](#) (D, C, H)  
[Cefuroxime](#) (D)  
[Cephalexin](#) (D, C, Po, Fer, H, A)  
[Cephapirin](#) (B)

#### ANTIBIOTICS, MACROLIDES

[Azithromycin](#) (D, C, H, Po, A)  
[Clarithromycin](#) (D, C, Fer, H)  
[Erythromycin](#) (D, C, Fer, A, B, H, Sw, Sh)  
[Tulathromycin](#) (B, Sw, H)  
[Tylosin](#) (D, C, Fer, Po, B, Sw, Sh, A, R)

#### ANTIBIOTICS, PENICILLINS

[Amoxicillin](#) (D, C, Po, Fer, B, H, A, R)  
[Amoxicillin/Clavulanate](#) (D, C, Fer, A)  
[Ampicillin](#) (D, C, B, H, Fer, Sw, Po, A, R)  
[Ampicillin/Sulbactam](#) (D, C)  
[Cloxacillin](#) (D, C, B)  
[Dicloxacillin](#) (D, C)  
[Oxacillin](#) (D, C, H)  
[Penicillin G](#) (D, C, Fer, Po, B, H, Sw, A)  
[Penicillin V](#) (D, C, H)  
[Piperacillin](#) (D, C, H, A, R)  
[Piperacillin/Tazobactam](#) (D, C, A)  
[Ticarcillin/Clavulanate](#) (D, C, H)

#### ANTIBIOTICS, TETRACYCLINES

[Chlortetracycline](#) (D, C, Po, A, B, Sw)  
[Doxycycline](#) (D, C, Po, H, A, R)  
[Minocycline HCl](#) (D, C)  
[Oxytetracycline](#) (D, C, B, Po, Sw, Sh, H, A, R)  
[Tetracycline](#) (D, C, Fer, Po, B, Sh, H, Sw, A)

#### ANTIBIOTICS, LINCOSAMIDES

[Clindamycin](#) (D, C, Fer, A, R)  
[Lincomycin](#) (D, C, Fer, Sw)  
[Pirlimycin](#) (B)  
[Tilmicosin](#) (B, Sh, Po)

#### ANTIBIOTICS, QUINOLONES

[Ciprofloxacin](#) (D, C, Fer, Po, A)  
[Danofloxacin](#) (B)  
[Difloxacin](#) (D, H)  
[Enrofloxacin](#) (D, C, H, B, Fer, Po, R, A, L)  
[Ibafloxacin](#) (D, C)  
[Marbofloxacin](#) (D, C, R)  
[Orbifloxacin](#) (D, C, H)

#### ANTIBIOTICS, SULFONAMIDES

[Sulfachlorpyridazine](#) (B, Sw, A)  
[Sulfadiazine/Trimethoprim](#) (D, C, Fer, Po, B, H, Sw, A, R)  
[Sulfamethoxazole/Trimethoprim](#) (D, C, Fer, Po, B, H, Sw, A, R)  
[Sulfadimethoxine](#) (D, C, Fer, Po, B, H, L, R)  
[Sulfadimethoxine/Ormetoprim](#) (D)

#### MISCELLANEOUS ANTIBIOTICS, ANTIBACTERIALS

[Aztreonam](#) (D, Fi)  
[Chloramphenicol](#) (D, C, Po, Fer, H, A, R)  
[Clofazimine](#) (D, C, A)  
[Dapsone](#) (D, C, H)  
[Ethambutol](#) (D, C, A)  
[Florfenicol](#) (D, C, B, Sh, Sw)  
[Fosfomycin](#) (D, H)  
[Isoniazid](#) (D, C)  
[Methenamine](#) (D, C)  
[Metronidazole](#) (D, C, Po, Fer, H, A, R)  
[Nitrofurantoin](#) (D, C, H)  
[Novobiocin](#) (D, B)  
[Rifampin](#) (D, H, A)  
[Sodium Iodide](#) (D, C, B, Sh, H)  
[Tiamulin](#) (Sw)  
[Tinidazole](#) (D, C, H)  
[Vancomycin](#) (D, C)

#### ANTIFUNGAL AGENTS

[Amphotericin B](#) (D, C, H, Po, L, A, R)  
[Caspofungin](#) (D, C)  
[Fluconazole](#) (D, C, H, Po, A)  
[Flucytosine](#) (D, C, A)  
[Griseofulvin](#) (D, C, Po, B, Sh, H, Sw, A)  
[Itraconazole](#) (D, C, Po, A, H)  
[Ketoconazole](#) (D, C, H, A, R)

[Ketocanazole](#) (D, C, Po, H, A, R)  
[Nystatin](#) (D, C, H, A, R)  
[Terbinafine HCl](#) (D, C, A)  
[Voriconazole](#) (D, C, H, A)

#### ANTIVIRAL AGENTS

[Acyclovir](#) (A, C, H)  
[Amantadine](#) (D, C, H)  
[Famciclovir](#) (C)  
[Interferon Alfa](#) (D, C)  
[Interferon Omega](#) (D, C)  
[Lysine](#) (C)  
[Oseltamivir](#) (D, H)  
[Zidovudine](#) (AZT) (C)

#### Blood Modifying Agents

#### ANTICOAGULANTS/ANTITHROMBOTICS

[Aspirin](#) (D, C, Fer, Po, B, H, Sw, A)  
[Clopidogrel](#) (D, C)  
[Dalteparin](#) (D, C, H)  
[Enoxaparin](#) (D, C, H)  
[Heparin](#) (D, C, H)  
[Warfarin](#) (D, C, H)

#### ERYTHROPOIETIC AGENTS

[Cyanocobalamin](#) (D, C, H, Sw, B, Sh) 345  
[Darbepoetin](#) (D, C)  
[Epoetin Alfa](#) (Erythropoietin) (D, C, Fer, Po)  
[Ferrous Sulfate](#) (D, C, B, H, Sw, Sh)  
[Folic Acid](#) (D, C, H)  
[Iron Dextran](#) (D, C, Fer, Sw, A)

#### MISC. BLOOD MODIFYING AGENTS

[Aminocaproic Acid](#) (D)  
[Filgrastim](#) (D, C)  
[Gemfibrozil](#) (D, C)  
[Hemoglobin Glutamer](#) (D, C)  
[Pentoxifylline](#) (D, H)  
[Phytonadione](#) (D, C, Po, H, B, Sw, Sh, A)  
[Protamine Sulfate](#) (D, C, B)

#### FLUID & ELECTROLYTE MODIFIERS

[Albumin](#) (D, C)  
[Aluminum Hydroxide](#) (D, C)  
[Butaphosphan](#) (H, B, Sw, A)  
[Calcitonin](#) (D, R)  
[Calcitriol](#) (D, C)  
[Calcium Acetate](#) (D, C)  
[Calcium Salts](#) (D, C, B, H, Sh, Sw, A, R)  
[Dextran](#) (D, C, B)  
[Dihydrotachysterol](#) (D, C)  
[Ergocalciferol](#) (D, C)  
[Etidronate](#) (D, C)  
[Glycerine, Oral](#) (D, C)  
[Hydroxyethyl Starch](#) (D, C, H, A, L)  
[Lanthanum Carbonate](#) (C)  
[Magnesium](#) (D, C, B, H, Sh, Sw)  
[Mannitol](#) (D, C, B, Sw, Sh, H)  
[Pamidronate](#) (D, C)  
[Phosphate](#) (D, C, B, Sh)  
[Potassium](#) (D, C, H, B, Sh)  
[Sevelamer HCl](#) (D, C)  
[Sodium Polystyrene Sulfonate](#) (D)

#### Antineoplastics

#### ANTINEOPLASTICS, ALKYLATING AGENTS

[Busulfan](#) (D, C)  
[Carboplatin](#) (D, C, Po)  
[Chlorambucil](#) (D, C, H)  
[Cisplatin](#) (D, H)  
[Cyclophosphamide](#) (D, C, H, Po)  
[Dacarbazine](#) (D)  
[Ifosfamide](#) (D, C)  
[Lomustine](#) (D, C)  
[Mechlorethamine](#) (D, C)  
[Melphalan](#) (D, C)  
[Procarbazine](#) (D, C)  
[Thiotepa](#) (D)

#### ANTINEOPLASTICS, ANTIMETABOLITES

[Cytarabine](#) (D, C, H)  
[Fluorouracil](#) (5-FU) (D, C, H)  
[Mercaptopurine](#) (D)  
[Methotrexate](#) (D, C)  
[Thioguanine](#) (D, C)

## ANTINEOPLASTICS, ANTIBIOTICS

[Bleomycin](#) (D, C)  
[Dactinomycin](#) (D)  
[Doxorubicin](#) (D, C, Fer)  
[Streptozocin](#) (D)

## ANTINEOPLASTICS, MITOTIC INHIBITORS

[Vinblastine](#) (D, C)  
[Vincristine](#) (D, C, H)

## ANTINEOPLASTICS, MISCELLANEOUS

[Asparaginase](#) (D, C)  
[Gemcitabine](#) (D, C)  
[Hydroxyurea](#) (D, C)  
[Mitoxantrone](#) (D, C)  
[Piroxicam](#) (D, C, H, Po)  
[Toceranib](#) (D)

## Immunomodulators

### IMMUNOSUPPRESSIVE DRUGS

[Azathioprine](#) (D, C, Fer, H)  
[Cyclophosphamide](#) (D, C, H, Po)  
[Cyclosporine](#) (D, C)  
[Dexamethasone](#) (D, C, Po, B, H, Sw, L, A, R)  
[Flumethasone](#) (D, C, H)  
[Immune Globulin \(Human\), Intravenous](#) (D)  
[Leflunomide](#) (D, C)  
[Mercaptopurine](#) (D)  
[Methotrexate](#) (D, C)  
[Methylprednisolone](#) (D, C, H)  
[Mycophenolate](#) (D, C)  
[Prednisolone](#) (D, C, Po, Fer, B, H, L, Sw, A, R)  
[Prednisone](#) (D, C, Po, Fer, B, H, L, Sw, A, R)  
[Triamcinolone](#) (D, C, B, H)

### GOLD COMPOUNDS

[Aurothioglucose](#) (D, C, H)  
[Auranofin](#) (D, C)  
[Gold Sodium Thiomalate](#) (D, C, H)

### IMMUNOSTIMULANTS

[Acemannan](#) (D, C)  
[Mycobacterial Cell Wall Fraction Immunomodulator](#) (D, H)  
[Parapox Ovis Virus Immunomodulator](#) (H)  
[Propionibacterium acnes Inj.](#) (D, C, H)  
[Staphylococcal Phage Lysate](#) (D)

### Antidotes

[Acetylcysteine](#) (D, C, H)  
[Ammonium Molybdate](#) (Sh)  
[Ammonium Tetrathiomolybdate](#) (Sh)  
[Antivenin Black Widow Spider](#) (D, C)  
[Antivenin Coral Snake](#) (D, C, H)  
[Antivenin Crotalidae](#) (D, C, H)  
[Atipamezole](#) (D, C, Po, B, Sh, A, R, Z)  
[Charcoal, Activated](#) (D, C, H, B, Sh)  
[Deferoxamine](#) (D, C)  
[Dexrazoxane](#) (D)  
[Dimercaprol](#) (D, C, H, B, Sh, Sw)  
[Edetate Calcium Disodium](#) (D, C, Po, H, A, B, Sw, Sh)  
[Ethanol](#) (D, C)  
[Fat Emulsion, Intravenous](#)  
[Fomepizole](#) (D, C)  
[Leucovorin Calcium](#) (D, C, H)  
[Methylene Blue](#) (D, C, B, Sh, H)  
[Naloxone](#) (D, C, Po, H)  
[Penicillamine](#) (D, C, B, Sh, A)  
[Physostigmine](#) (D, H, B)  
[Phytonadione](#) (D, C, Po, B, H, Sw, Sh, A)  
[Pralidoxime](#) (D, C, B, Sh, H, A)  
[Protamine Sulfate](#) (D, C, B)  
[Pyridoxine](#) (D, C)  
[S<sub>A</sub>Me](#) (D, C)  
[Silymarin](#) (D, C)  
[Sodium Polystyrene Sulfonate](#) (D)  
[Sodium Sulfate](#) (B, Sh, Sw)  
[Sodium Thiosulfate](#) (D, C, H, B, Sh)  
[Succimer](#) (D, C, A)  
[Thiamine](#) (D, C, B, H, Sw, Sh, L)  
[Trientine HCl](#) (D)  
[Zinc Acetate/Sulfate](#) (D, C)

### Bone/Joint Agents

[Alendronate Sodium](#) (D, C)  
[Allopurinol](#) (D, A, R)

[Glucosamine+Chondroitin](#) (D, C, H)  
[Hyaluronate](#) (D, H)  
[Etidronate](#) (D, C)  
[Pentosan](#) (D, C, H)  
[Polysulfated Glycosaminoglycan](#) (H, D, C, Po)  
[Tiludronate Disodium](#) (H)

#### **Dermatologic Agents (Systemic)**

[Acitretin](#) (D, C)  
[Fatty Acids, Essential](#) (D, C)  
[Isotretinoin](#) (D, C)  
[Pentoxifylline](#) (D, H)

#### **Vitamins & Minerals/Nutrients**

[Ascorbic Acid](#) (C, Po, H, B)  
[Carnitine](#) (D, C)  
[Cyanocobalamin](#) (D, C, H, Sw, B, Sh)  
[Fat Emulsion, Intravenous](#)  
[Fatty Acids, Essential](#) (D, C)  
[Folic Acid](#) (D, C, H)  
[Medium Chain Triglycerides](#) (D)  
[Niacinamide](#) (D)  
[Pyridoxine](#) (D, C)  
[Thiamine](#) (D, C, B, H, Sw, Sh, L)  
[Vitamin E/Selenium](#) (D, C, H)  
[Zinc](#) (D, C)

#### **Cholinergic Muscle Stimulants**

[Edrophonium Chloride](#) (D, C)  
[Pyridostigmine](#) (D, C)

#### **Systemic Acidifiers**

[Acetazolamide](#) (D, C, B, H, Sh, Sw)  
[Acetic Acid](#) (B, Sh, H)

#### **Systemic Alkalinizers**

[Sodium Bicarbonate](#) (D, C, H, B, Sh, A)

#### **Unclassified**

[Aminocaproic Acid](#) (D)  
[Colchicine](#) (D, A)  
[Iohexol](#) (D, C, A)

### **Index of Systemic Drug Common Trade Names & Synonyms**

[2-MPG](#)  
[2-PAM](#)
