A formula for calculating dobutamine or dopamine CRI’s has been published (Plunkett & McMichael 2008): 6 x body weight in kg = the number of mgs of dobutamine or dopamine added to a total volume of 100 mL 0.9% NaCl. When delivered at a rate of 1 mL/hour IV, 1 microgram/kg/min is administered.

Dopamine is reported to be physically compatible with the following IV fluids: D5 in LRS, D5 in half-normal saline, D5 in normal saline, D5W, mannitol 20% in water, lactated Ringer’s, normal saline, and 1/6M sodium lactate. Dopamine is reported to be physically compatible with the following drugs: aminophylline, bretylium tosylate, calcium chloride, carbencillin disodium, cephalothin sodium neutral, chloramphenicol sodium succinate, dobutamine HCl, gentamicin sulfate (gentamicin potency retained for only 6 hours), heparin sodium, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, methylprednisolone sodium succinate.
DORAMECTIN
(dor-a-mek-tin) Dectomax®

**AVERMECTIN ANTIPARASITIC AGENT**

**Prescriber Highlights**

- Injectable (cattle, swine) & topical (cattle only) avermectin antiparasiticide
- Potentially useful for generalized demodicosis in small animals
- Manufacturer warns about using in other species
- IM injections may cause muscle blemishes
- Not labeled for female dairy cattle (20 months or older)
- Relatively long slaughter withdrawal times

**Uses/Indications**

Doramectin injection is indicated for the treatment and control of the following endo- and ectoparasites in cattle: roundworms (adults and some fourth stage larvae) —*Ostertagia ostertagi* (including inhibited larvae), *O. lyrata*, *Haemonchus placei*, *Trichostrongylus axei*, *T. colubriformis*, *T. longispicularis*, *Cooperia oncophora*, *C. pectinata*, *C. punctata*, *C. surabada* (syn. *mcmasteri*), *Banostomum phlebotomum*, *Strongyloides papillosus*, *Oesophagostomum radiatum*, *Trichuris* spp.; lungworms (adults and fourth stage larvae) —*Dictyocaulus viviparus*; eyeworms (adults) —*Thelazia* spp.; grubs (parasitic stages) —*Hypoderma bovis*, *H. lineatum*; lice —*Haematopinus suis*, *Linognathus vituli*, *Solenopotes capillatus*; and mange mites —*Psoroptes bovis*, *Sarcoptes scabiei*.

In swine the injection is labeled for the treatment and control gastrointestinal roundworms (adults and 4th stage) *Ascaris suum*, adults and 4th stage *Oesophagostomum dentatum*, *Oesophagostomum quadrispinolatum* adults, *Strongyloides ransomi* adults, and *Hydrostrongylus rubidus* adults), lungworms (*Stephanurus dentatus* adults), mange mites (adults and immature stages *Sarcoptes scabei* var. *suis*), and sucking lice (adults and immature stages *Haematopinus suis*).

The manufacturer states the doramectin protects cattle against infection or reinfection with *Ostertagia ostertagi* for up to 21 days. Doramectin topical (pour-on) is FDA-approved for use in cattle and has a similar spectrum of action against a variety of endo- and ectoparasites, including biting lice.

Injectable doramectin has been used for treating a variety of nematode and arthropod parasites in companion animals, including generalized demodicosis in dogs and cats and spirocercosis in dogs.

**Pharmacology/Actions**

The primary mode of action of avermectins like doramectin is to affect chloride ion channel activity in the nervous system of nematodes and arthropods. Doramectin binds to receptors that increase membrane permeability to chloride ions. This inhibits the electrical activity of nerve cells in nematodes and muscle cells in arthropods and causes paralysis and death of the parasites. Avermectins also enhance the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. Avermectins are generally not toxic to mammals as they do not have glutamate-gated chloride channels and these compounds do not readily cross the blood-brain barrier where mammalian GABA receptors occur.

**Pharmacokinetics**

After subcutaneous injection, the time to peak plasma concentration in cattle is about 5 days. Bioavailability is, for practical purposes, equal with SC and IM injections in cattle.

**Contraindications/Precautions/Warnings**

Doramectin is reported to be physically **incompatible** with: amphotericin B, ampicillin sodium, iron salts, metronidazole with sodium bicarbonate, penicillin G potassium, and sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; it is suggested to consult specialized references for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

- Dopamine HCl for Intravenous Injection: 20 mg/mL (10 mg/mL) & 40 mg/mL (20 mg/mL); & 800 mg/250 mL (3.2 mg/mL) in 250 mL premixed single-use containers; generic; (Rx)
- Dopamine HCl in Dextrose 5% Injection Solution: 200 mg/250 mL (0.8 mg/mL); 400 mg/500 mL (0.8 mg/mL); 400 mg/250 mL (1.6 mg/mL); 800 mg/500 mL (1.6 mg/mL); & 800 mg/250 mL (3.2 mg/mL) in 250 mL premixed single-use containers; generic; (Rx)

**References**

Contraindications/Precautions/Warnings
The manufacturer warns to not use in other animal species as severe adverse reactions, including fatalities in dogs, may result.

It is recommended to use alternative treatments for demodicosis or spirocercosis in untested dogs of breeds susceptible to MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet) as they are at higher risk for toxicity.

Adverse Effects
No listed adverse effects. Intramuscular injections may have a higher incidence of injection site blemishes at slaughter than do subcutaneous injections.

When used for demodicosis in dogs, adverse effects are uncommon but may include pupil dilation, lethargy, blindness, or coma.

Reproductive/Nursing Safety
In studies performed in breeding animals (bulls and cows in early and late pregnancy), at a dose of 3X recommended had no effect on breeding performance.

Overdosage/Acute Toxicity
In field trials, no toxic signs were seen in cattle given up to 25X the recommended dose. In breeding animals (bulls, and cows in early and late pregnancy), a dose 3 times the recommended dose had no effect on breeding performance.

Drug Interactions
- None noted

Doses

DOGS:
For treatment of generalized demodicosis:
  a) 600 micrograms/kg PO once daily has been utilized with success in some cases of canine generalized demodicosis. Once weekly subcutaneous injections at 600 micrograms/kg can also be used. If improvement is not seen after 60 days, an alternative therapy should be used. (Merchant 2009)
  b) Get informed consent from owner for extra-label treatment. Give 600 micrograms/kg (0.6 mg/kg) SC once per week. (Hillier 2006)

For treatment of benign nodules secondary to S. lupi:
  a) 400 micrograms/kg SC at two week intervals once; may use milbemycin in MDR-1 sensitive breeds. (Dvir & Clift 2009)

CATS:
For feline demodicosis (D. cati, D. gatoi):
  a) Get informed consent from owner for extra-label treatment. Give 600 micrograms/kg (0.6 mg/kg) SC once per week. Alternative treatments include Lime sulfur dips or amitraz. (Hillier 2006)

CATTLE:
  a) For labeled indications (Injectable): 200 micrograms/kg (1 mL per 110 lb. body weight) SC or IM. Injections should be made using 16 to 18 gauge needles. Subcutaneous injections should be administered under the loose skin in front of or behind the shoulder. Intramuscular injections should be administered into the muscular region of the neck. Beef Quality Assurance guidelines recommend subcutaneous administration as the preferred route. (Label Directions; Dectomax®—Pfizer)
  b) For labeled indications (Pour-on): Topically at a dosage of 500 micrograms/kg (1 mL per 22 lb. body weight). Administer topically along the mid-line of the back in a narrow strip between the withers and tailhead. (Label Directions; Dectomax® Pour-On—Pfizer)

SWINE:
  a) For labeled indications: 300 micrograms/kg (1 mL per 75 lb. body weight) IM. Injections should be made using 16 g x 1.5 inch needles for sows and boars and 18 g x 1 inch needle for young animals. Use a tuberculin syringe and a 20 g x 1 inch needle for piglets. Intramuscular injections should be administered into the muscular region of the neck. See the label for recommended treatment program for sows, gilts, boars, feeder pigs, weaners, growers and finishers. (Label Directions; Dectomax®—Pfizer)

RABBITS:
  a) For P. cuniculi infestations: 200 micrograms/kg IM once. (Kanbur et al. 2008)

Monitoring
- Efficacy

Client Information
- Read and follow all labeled instructions carefully.
- Cattle must not be slaughtered for human consumption within 35 days of treatment.
- Not for use in female dairy cattle 20 months of age or older.
- A withdrawal period has not been established for this product in pre-ruminating calves.
- Should not be used in calves to be processed for veal.
- Swine should not be slaughtered for human consumption within 24 days of treatment.

Chemistry/Synonyms
An avermectin antiparasitic compound, doramectin is isolated from fermentations from the soil organism Streptomyces avermitilis. Doramectin may also be known as UK-67994, or Dectomax®.

Storage/Stability
The commercially available injectable solution is a colorless to pale yellow, sterile solution. The injectable solution should be stored below 86°F (30°C). The topical pour on solution should be stored below 30°C (86°F) and protected from light.
VETERINARY-LABELED PRODUCTS:

Doramectin Injectable Solution: 10 mg/mL in 100 mL, 250 mL, and 500 mL multi-dose vials; Doramectin® Pour-On (Pfizer); (OTC). FDA-approved for use in cattle and swine. When used at labeled doses: Slaughter Withdrawal: cattle = 45 days, swine = 24 days. Do not use in female dairy cattle 20 months of age or older or in calves to be used for veal. A withdrawal period has not been established in preruminating calves.

Doramectin Pour-On Solution: 5 mg/mL in 250 mL, 1 L, 2.5 L and 5 L multi-dose containers; Doramectin® Pour-On (Pfizer); (OTC). FDA-approved for use in cattle. Slaughter withdrawal = 45 days. Not for use in female dairy cattle 20 months of age or older. A withdrawal period has not been established in preruminating calves. Doxapram should not be used as a substitute for aggressive artificial (mechanical) respiratory support in instances of severe respiratory depression.

HUMAN-LABELED PRODUCTS: None

References

DOXAPRAM HCL
(docks-a-pram) Doprarn-V®
CNS/RESPIRATORY STIMULANT
Prescriber Highlights

• CNS stimulant usually used to stimulate respirations in newborns or after anesthesia; also used for assessment of laryngeal function in small animals; use in small animal neonates is controversial

• Not a substitute for aggressive artificial (mechanical) respiratory support when required

• Possible contraindications: Receiving mechanical ventilation, hypersensitivity, seizure disorders, head trauma/CVA, uncompensated heart failure, severe hypertension, respiratory failure secondary to neuromuscular disorders, airway obstruction, pulmonary embolism, pneumothorax, acute asthma, dyspnea, or whenever hypoxia is not associated with hypercapnia.

• Caution: History of asthma, arrhythmias, or tachycardias. Use extreme caution in patients with cerebral edema or increased CSF pressure, pheochromocytoma, or hyperthyroidism.

• Avoid IV extravasation or using a single injection site for a prolonged period

• Adverse Effects: Hypertension, arrhythmias, seizures, & hyperventilation leading to respiratory alkalosis

Uses/Indications

The manufacturer of Doxapram®-V lists the following indications: For Dogs, Cats, and Horses: To stimulate respiration during and after general anesthesia and/or to speed awakening and reflexes after anesthesia. For Neonatal Dogs and Cats: stimulate respirations following dystocia or cesarean section. It is reported that in small animals, doxapram is most likely to be beneficial in increasing respiratory efforts in neonates with low-frequency, gasping, erratic pattern of breathing after receiving oxygen therapy (Traas 2009).

Doxapram has been used for treatment of CNS depression in food animals (not FDA-approved) and has been suggested as a treatment of respiratory depression in small animals caused by reactions to radiopaque contrast media or for barbiturate overdose (see precautions below).

The use of doxapram to initiate and stimulate respirations in newborns is somewhat controversial as the drug has been shown in experimental animals to increase myocardial oxygen demand and reduce cerebral blood flow.

Doxapram has been shown to be useful to offset suppression of general anesthetic agents when laryngeal function is being assessed.

Pharmacology/Actions

Doxapram is a general CNS stimulant, with all levels of the CNS affected. The effects of respiratory stimulation are a result of direct stimulation of the medullary respiratory centers and, possibly, through the reflex activation of carotid and aortic chemoreceptors. Transient increases in respiratory rate and volume occur, but increases in arterial oxygenation usually do not ensue. This is because doxapram usually increases the work associated with respirations with resultant increased oxygen consumption and carbon dioxide production.

Pharmacokinetics

Little published pharmacokinetic data appears for domestic animals. Onset of effect in humans and animals after IV injection usually occurs within 2 minutes. The drug is well distributed into tissues. In dogs, doxapram is rapidly metabolized and most is excreted as metabolites in the urine within 24–48 hours after administration. Small quantities of metabolites may be excreted up to 120 hours after dosing.

Contraindications/Precautions/Warnings

Doxapram should not be used as a substitute for aggressive artificial (mechanical) respiratory support in instances of severe respiratory depression. In calves, doxapram has been reported as contraindicative in premature calves or other patients with clinical signs indicative of lung immaturity as effects are only minimal and use could lead to increased pulmonary blood pressure with fetal circulation persisting resulting from a right-to-left shunt via the patent ductus and foramen ovale. (Bleut et al. 2010)
Contraindications from the human literature include: seizure disorders, head trauma, uncompensated heart failure, severe hypertension, cardiovascular accidents, respiratory failure secondary to neuromuscular disorders, airway obstruction, pulmonary embolism, pneumothorax, acute asthma, dyspnea, or whenever hypoxia is not associated with hypercapnia. Doxapram should be used with caution in patients with a history of asthma, arrhythmias, or tachycardias. It should be used with extreme caution in patients with cerebral edema or increased CSF pressure, pheochromocytoma or hyperthyroidism. Patients with a history of hypersensitivity to the drug or are receiving mechanical ventilation should not receive doxapram. The above contraindications/precautions are not listed in the veterinary product literature provided by the manufacturer.

Avoid the use of a single injection site for a prolonged period of time or extravasation when administering intravenously. Subcutaneous injection has been recommended however for use in neonatal feline and canine patients.

Repeated IV doses in neonates should be done with caution as the product contains benzyl alcohol.

**Adverse Effects**

Hypertension, arrhythmias, seizures, and hyperventilation leading to respiratory alkalosis has been reported. These effects appear most probable with repeated or high doses. The drug reportedly has a narrow margin of safety when used in humans.

Doxapram has been shown in experimental animals to increase myocardial oxygen demand and reduce cerebral blood flow.

**Reproductive/Nursing Safety**

Safety of doxapram has not been established in pregnant animals. The potential risks versus benefits should be weighed before using. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known whether this drug is excreted in milk.

**Overdose/Acute Toxicity**

Reported LD50 for IV administration in neonatal dogs and cats is approximately 75 mg/kg. Clinical signs of overdosage include: respiratory alkalosis, hypertension, skeletal muscle hyperactivity, tachycardia, and generalized CNS excitation including seizures. Treatment is supportive. Drugs such as short acting IV barbiturates may be used to help decrease CNS hyperactivity. Oxygen therapy may be necessary.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving doxapram and may be of significance in veterinary patients:

**ANESTHETICS, GENERAL:** Doxapram may increase epinephrine release; therefore, use should be delayed for approximately 10 minutes after discontinuation of anesthetic agents (e.g., halothane, enflurane) that have been demonstrated to sensitize the myocardium to catecholamines

**MUSCLE RELAXANTS:** Doxapram may mask the effects of muscle relaxant drugs

**SYMPATHOMIMETIC AGENTS:** Additive pressor effects may occur with sympathomimetic agents

**Doses**

**DOGS:**

a) 1.1 mg/kg (for gas anesthesia) or 5.5–11 mg/kg (for barbiturate anesthesia) IV; adjust dosage for depth of anesthesia, respiratory volume and rate. Dosage may be repeated in 15–20 minutes if necessary.

   To initiate or stimulate respirations in neonates after caesarian section or dystocia: May be administered either SC, sublingually, or via the umbilical vein in doses of 1–5 drops (1–5 mg) depending on size of neonate and degree of respiratory crisis. (Package Insert; Dopram®-V—Fort Dodge)

b) To stimulate respiratory function in neonates: 0.1 mL (2 mg) IV (IM or SL also possible); most likely to be beneficial to increase efforts in neonates with low-frequency, gasping, erratic pattern of breathing after receiving oxygen therapy (Traas 2009)

c) To assess laryngeal function: 2.2 mg/kg IV to stimulate respiration and increase intrinsic laryngeal motion. Onset of effect occurs within 15–30 seconds and persists for approximately 2 minutes. Anesthetic depth may lighten substantially. Prepare for immediate intubation should airway obstruction or laryngeal paralysis occur. (McKiernan 2007)

**CATS:**

a) 1.1 mg/kg (for gas anesthesia) or 5.5–11 mg/kg (for barbiturate anesthesia) IV; adjust dosage for depth of anesthesia, respiratory volume and rate. Dosage may be repeated in 15–20 minutes if necessary.

   To initiate or stimulate respirations in neonates after caesarian section or dystocia: May be administered either SC, sublingually, or via the umbilical vein in doses of 1–2 drops (1–2 mg) depending on severity of respiratory crisis. (Package Insert; Dopram®-V—Fort Dodge)

b) To stimulate respiratory function in neonates: 0.1 mL (2 mg) IV (IM or SL also possible); most likely to be beneficial to increase efforts in neonates with low-frequency, gasping, erratic pattern of breathing after receiving oxygen therapy. (Traas 2009)

**RABBITS/RODENTS/SMALL MAMMALS:**

For respiratory depression:

a) Rabbits: 2–5 mg/kg SC or IV q15 minute

b) Rodents: 2–5 mg/kg S C q15 minutes (Huerkamp 1995)

c) Mice, Rats, Gerbils, Hamsters: 5–10 mg/kg IV; Guinea pigs: 5 mg/kg IV; Chinchillas: 2–5 mg/kg IV (Adamcak & Otten 2000)

**BIRDS:**

a) For respiratory depression: 5–10 mg/kg IM or IV (Harris 2003)

**REPTILES:**

a) To stimulate respiration after general anesthesia: 5 mg/kg IV (Wilson 2002)

**CATTLE & SWINE:**

a) For respiratory depression: 2–5 mg/kg SC or IV q15 minute or 5–10 mg/kg IV q20 minute (Wilson 2002)
a) For primary apnea in asphyxic calves when intubation and mechanical ventilation are not feasible: 2 mg/kg IV. Contraindicated in premature calves or other patients with clinical signs indicative of lung immaturity. (Bleul et al. 2010)
b) For primary apnea in newborn calves: 2 mg/kg IV (Constable 2006)

**HORSES:** (Note: ARCI UCGFS Class 2 Drug)
a) 0.44 mg/kg (for halothane, methoxyflurane anesthesia) or 0.55 mg/kg (for chloral hydrate ± magnesium sulfate anesthesia) IV; adjust dosage for depth of anesthesia, respiratory volume and rate. Dosage may be repeated in 15–20 minutes if necessary. (Package Insert; Dopram®-V—Fort Dodge)
b) For adjunctive treatment to stimulate respirations in foals with sepsis or hypoxic-ischemic encephalopathy: 0.02–0.05 mg/kg/hr IV CRI; foals with significant hypercapnia and hypoxia despite O2 tx require positive pressure ventilation (Giguere et al. 2008), (McKenzie 2009).

**Monitoring**
- Respiratory rate
- Cardiac rate and rhythm
- Blood gases if available and indicated
- CNS level of excitation; reflexes
- Blood pressure if indicated

**Client Information**
- This agent should be used in an inpatient setting or with direct professional supervision.

**Chemistry/Synonyms**
Doxapram HCl is a white to off-white, odorless, crystalline powder that is stable in light and air. It is soluble in water, sparingly soluble in alcohol and practically insoluble in ether. Injectable products have a pH from 3.5–5. Benzy1 alcohol or chlorobutanol is added as a preservative agent in the commercially available injections. Doxapram HCl may also be known as: AHR-619, doxaprami hydrochloridum, Docatone®, Dopram®, Doxapril®, or Respiram®.

**Storage/Stability**
Store at room temperature and avoid freezing solution. Do not mix with alkaline solutions (e.g., thiopental, aminophylline, sodium bicarbonate). Doxapram is physically compatible with D5W or normal saline.

**Dosage Forms/Regulatory Status**
**VETERINARY-LABELED PRODUCTS:**
Doxapram HCl for Injection: 20 mg/mL; 20 mL multi-dose vial; Dopram-V® (BIVI); Respiram® (MVT); (Rx). FDA-approved for use in dogs, cats and horses.
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
Doxapram HCl for Injection: 20 mg/mL in 20 mL multi-dose vials; Dopram® (Baxter Healthcare Corp); generic; (Bedford); (Rx)

**References**

**DOXEPIN HCL**
(dox-e-pin) Sinequan®
**TRICYCLIC ANTIDEPRESSANT/ANTIHISTAMINE**

**Prescriber Highlights**
- Tricyclic antidepressant used primarily in small animals for adjunctive therapy of psychogenic dermatoses, particularly those that have an anxiety component; also has antihistaminic (H-1) properties
- Contraindications: Prior sensitivity to tricyclics; concomitant use with MAOIs (selegiline?); probably contraindicated in dogs with urinary retention or glaucoma
- Most likely adverse effects: Hyperexcitability, GI distress, or lethargy; ventricular arrhythmias after overdoses possible

**Uses/Indications**
The primary use for doxepin in veterinary medicine is the adjunctive therapy of psychogenic dermatoses, particularly those that have an anxiety component. Its efficacy as an antihistamine for atopic dermatoses is in question.

**Pharmacology/Actions**

Doxepin is a tricyclic agent that has antihistaminic, anticholinergic, and alpha1-adrenergic blocking activity. In the CNS, doxepin inhibits the reuptake of norepinephrine and serotonin (5-HT) by the presynaptic neuronal membrane, thereby increasing their synaptic concentrations. Doxepin is considered a moderate inhibitor of norepinephrine and weak inhibitor of serotonin.

**Pharmacokinetics**
Doxepin appears to be well absorbed after oral administration. The drug is extensively metabolized in the liver.

**Contraindications/Precautions/Warnings**
These agents are contraindicated if prior sensitivity has been noted with any other tricyclic. Concomitant use with monoamine oxidase inhibitors is generally contraindicated. Doxepin is probably contraindicated in dogs with urinary retention or glaucoma.

**Adverse Effects**
While doxepin has less potential for cardiac adverse effects than many other tricyclics, it can cause ventricular arrhythmias, particularly after overdoses. In dogs, it may also cause hyperexcitability, GI distress, or lethargy. However, potential adverse effects can run the entire gamut of systems. Refer to other human drug references for additional information.

**Reproductive/Nursing Safety**
Rodent studies have demonstrated no teratogenic effects, but safety during pregnancy has not been established. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Doxepin and its N-demethylated active metabolite are distributed into milk. One case report of sedation and respiratory depression in a human infant has been reported. Exercise caution when using in a nursing patient.

**Overdosage/Acute Toxicity**
Overdosage with tricyclics can be life-threatening (arrhythmias, cardiorespiratory collapse). Because the toxicities and therapies for treatment are complicated and controversial, it is recommended to contact an animal poison control center for further information in any potential overdose situation.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving doxepin and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS**: Because of additive effects, use with doxepin cautiously
- **CIMETIDINE**: May inhibit tricyclic antidepressant metabolism and increase the risk of toxicity
- **CNS DEPRESSANTS**: Because of additive effects, use with doxepin cautiously
- **MEPERIDINE, PENTAZOCINE, DEXTROMETHORPHAN**: Increased risk for serotonin syndrome
- **MONOAMINE OXIDASE INHIBITORS (including amitraz, and possibly selegiline)**: Concomitant use (within 14 days) of tricyclics with monoamine oxidase inhibitors is generally contraindicated (serotonin syndrome)
- **QUINIDINE**: Increased risk for QTc interval prolongation and tricyclic adverse effects
- **SSRIs** (*e.g.*, fluoxetine, paroxetine, sertraline, etc.): Increased risk for serotonin syndrome
- **SYMPATHOMIMETIC AGENTS**: Use in combination with tricyclic agents may increase the risk of cardiac effects (arrhythmias, hypertension, hyperpyrexia)

**Laboratory Considerations**
- Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG.
- Tricyclics may alter (increase or decrease) blood glucose levels.

**Doses**

**DOGS:**
For treatment of psychogenic dermatoses:
- a) 3–5 mg/kg PO q12h; maximum dose is 150 mg (per dog) q12h (Shanley & Overall 1992)
- b) 3–5 mg/kg, PO q8–12h. Begin at 3 mg/kg PO q12h for 2 weeks, then increase by 1 mg/kg PO q12h for 2 weeks up to the maximum dosage as needed; if no clinical response after at least 3–4 weeks of therapy, decrease dosage by 1 mg/kg PO q12h for 2 weeks until at the initial dosage (Virga 2003), (Virga 2005)
For antihistaminic effects in treatment of atopy:
- a) 2.2 mg/kg PO three times daily (White 2007)
- b) 3–5 mg/kg twice daily; used especially if dog has anxiety or other behavioral condition (Peikes 2003)
- c) 0.5–2 mg/kg PO q12h; may be best in nervous or highly strung dogs (Hillier 2006)
- d) 1–2 mg/kg PO q12h (Thomas 2005)
For treatment of behavior problems where tricyclics may be of benefit (*e.g.*, obsessive/compulsive disorders, acral lick granulomas):
- a) For OCD: 0.5–1 mg/kg PO twice daily; for acral lick granulomas: doses as above for psychogenic dermatoses. (Seksel 2008)

**CATS:**
For treatment of psychogenic dermatoses:
- a) 0.5–1 mg/kg PO q12–24h. Up to 25–50 mg (total dose) per cat. Allow 3–4 weeks for initial trial. (Virga 2003), (Virga 2005)
- b) For excessive grooming: 0.5–1 mg/kg PO q12h. (Siebert 2003a)
- c) For treatment of behavior problems where tricyclics may be of benefit (*e.g.*, overgrooming, intercat aggression, etc.): 0.5–1 mg/kg PO once to twice daily. (Seksel 2008)

**Laboratory Considerations**
- Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG.
- Tricyclics may alter (increase or decrease) blood glucose levels.

**Doses**

**DOGS:**
For treatment of psychogenic dermatoses:
- a) 3–5 mg/kg PO q12h; maximum dose is 150 mg (per dog) q12h (Shanley & Overall 1992)
- b) 3–5 mg/kg, PO q8–12h. Begin at 3 mg/kg PO q12h for 2 weeks, then increase by 1 mg/kg PO q12h for 2 weeks up to the maximum dosage as needed; if no clinical response after at least 3–4 weeks of therapy, decrease dosage by 1 mg/kg PO q12h for 2 weeks until at the initial dosage (Virga 2003), (Virga 2005)
For antihistaminic effects in treatment of atopy:
- a) 2.2 mg/kg PO three times daily (White 2007)

For treatment of anxiety, pruritus caused feather plucking in psittacines:
   a) 1–2 mg/kg PO q12h (Siebert 2003b)
   b) 0.5–1 mg/kg PO twice daily (Rich 2005)

**Chemistry/Synonyms**
A dibenzoxazepine derivative tricyclic antidepressant, doxepin HCl occurs as a white powder that is freely soluble in alcohol.
Doxepin may also be known as: doxepini hydrochloridum, NSC-108160, P-3693A, Adapin®, Anten®, Aponal®, Deptran®, Desdoxepin®, Doneurin®, Doxal®, Deroxip®, Gilex®, Mareen®, Quitaxon®, Sinequan®, Triadapin®, Xepin®, and Zonalon®.

**Storage/Stability**
Store hydroxyzine products protected from direct sunlight in tight, light-resistant containers at room temperature.

**References**

**DOXORUBICIN HCL**
(dox-oh-roo-bi-sin) Adriamycin®, Doxil®

**ANTINEOPLASTIC**

**Prescriber Highlights**

- Injectable antibiotic antineoplastic widely used alone or in combination protocols for small animals
- Relatively contraindicated in patients with myelosuppression, impaired cardiac function, or who have reached the total cumulative dose level of doxorubicin &/or daunorubicin
- Caution: Patients with hyperuricemia/hyperuricuria, or impaired hepatic function (dosage adjustments necessary)
- Breeds predisposed to developing cardiomyopathy (Doberman pinchers, Great Danes, Rottweilers, Boxers); monitor carefully
- Handle very carefully
- Teratogenic & embryotoxic
- Adverse Effects include bone marrow suppression, cardiac toxicity, nephrotoxicity (esp. cats), alopecia, gastroenteritis (vomiting, diarrhea), & stomatitis
- Immediate-hypersensitivity reported (primarily in dogs); potentially brand specific
- Extravasation injuries can be serious

**Uses/Indications**
Doxorubicin is perhaps the most widely used antineoplastic agent at present in small animal medicine. It may be useful in the treatment of a variety of lymphomas,
Pharmacology/Actions

Although possessing antimicrobial properties, doxorubicin’s cytotoxic effects preclude its use as an anti-infective agent. The drug causes inhibition of DNA synthesis, DNA-dependent RNA synthesis and protein synthesis, but the precise mechanisms for these effects are not well understood. The drug acts throughout the cell cycle and also possesses some immunosuppressant activity.

Doxorubicin is most cytotoxic to cardiac cells, followed by melanoma, sarcoma cells, and normal muscle and skin fibroblasts. Other rapidly proliferating “normal” cells, (such as bone marrow, hair follicles, GI mucosa), may also be affected by the drug.

Pharmacokinetics

Doxorubicin must be administered IV as it is not absorbed from the GI tract and is extremely irritating to tissues if administered SC or IM. After IV injection, the drug is rapidly and widely distributed, but does not appreciably enter the CSF. It is highly bound to tissue and plasma proteins, probably crosses the placenta and is distributed into milk.

Doxorubicin is metabolized extensively by the liver and other tissues via aldo-keto reductase primarily to doxorubicinol, which is active; other inactive metabolites are also formed. Doxorubicin and its metabolites are primarily excreted in the bile and feces. Only about 5% of the drug is excreted in the urine within 5 days of dosing. Doxorubicin is eliminated in a triphasic manner. During the first phase (t½ 0.6 hours) doxorubicin is rapidly metabolized, via the “first pass” effect followed by a second phase (t½ 3.3 hours). The third phase has a much slower elimination half-life (17 hours for doxorubicin; 32 hours for metabolites), presumably due to the slow release of the drug from tissue proteins.

Contraindications/Precautions/Warnings

Doxorubicin is contraindicated or relatively contraindicated (measure risk vs. benefit) in patients with myelosuppression, impaired cardiac function, have reached the total cumulative dose level of doxorubicin and/or daunorubicin. It is also contraindicated in cats with preexisting renal insufficiency. It should be used with caution in patients with hyperuricemia/hyperuricuria, or impaired hepatic function. Dosage adjustments are necessary in patients with hepatic impairment. Breeds predisposed to developing cardiomyopathy (Doberman pinchers, Great Danes, Rottweilers, Boxers) should be monitored carefully while receiving doxorubicin therapy.

Doxorubicin is actively transported by the p-glycoprotein pump and certain breeds susceptible to MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet) may be at higher risk for toxicity. Bone marrow suppression (decreased blood cell counts, particularly neutrophils) and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the ABCB1 mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25–30% and carefully monitoring these patients (WSU-VetClinPharmLab 2009).

Because doxorubicin can be very irritating to skin, gloves should be worn when administering or preparing the drug. Ideally, doxorubicin injection should be prepared in a biological safety cabinet. Should accidental skin or mucous membrane contact occur, wash the area immediately using soap and copious amounts of water.

Adverse Effects

Doxorubicin may cause several adverse effects including bone marrow suppression, cardiac toxicity, alopecia, gastroenteritis (vomiting, diarrhea), and stomatitis.

Myelosuppression nadirs are generally 5–10 days after treatment.

An immediate hypersensitivity reaction may be seen (particularly in dogs) characterized by urticaria, facial swelling, vomiting, arrhythmias (see below), and/or hypotension. The rate of infusion can have a direct impact on this effect. Pretreatment with a histamine1 blocker such as diphenhydramine (IV prior to treatment at 10 mg for dogs up to 9 kg; 20 mg for dogs 9–27 kg; and 30 mg for dogs over 27 kg) or alternatively, dexamethasone (0.55 mg/kg IV), is often recommended to reduce or eliminate these effects. There is some evidence to suggest that a given brand of doxorubicin may be more allergenic than another. Patients that have developed hypersensitive reactions to one brand, may not react, if switched to another.

Cardiac toxicity of doxorubicin falls into two categories, acute and cumulative. Acute cardiac toxicity may occur during IV administration or several hours subsequent, and is manifested by cardiac arrest preceded by ECG changes (T-wave flattening, S-T depression, voltage reduction, arrhythmias). Rarely, an acute hypertensive crisis has been observed after infusion. Acute cardiac toxicity does not preclude further use of the drug, but additional treatment should be delayed. The administration of diphenhydramine and/or glucocorticoids before doxorubicin administration may prevent these effects.

Cumulative cardiac toxicity requires halting any further therapy and can be extremely serious. Diffuse cardiomyopathy with severe congestive heart failure refractory to traditional therapies is generally noted. It is believed that the risk of cardiac toxicity is greatly increased in dogs when the cumulative dose exceeds 240 mg/m², but may be seen at doses as low as 90 mg/m². Therefore, it is not recommended to exceed 240 mg/m², total dose, in dogs. It is unknown what the incidence of cardiotoxicity or the dosage ceiling for doxorubicin is in cats, but most clinicians believe that 240 mg/m² should also be used as the upper limit cumulative dose in cats.

In cats, doxorubicin is a potential nephrotoxin and they should have renal function monitored both before and during therapy.

Doxorubicin should be administered IV slowly, over at least 10 minutes, in a free flowing line.

Extravasation injuries secondary to perivascular administration of doxorubicin can be quite serious, with severe tissue ulceration and necrosis possible. Prevention of extravasation should be a priority and animals should be frequently checked during the infusion. Should extravasation occur, it is suggested to treat as per the human recommendations. There are currently two treatments recommended for doxorubicin extravasation injuries. Both have been shown to be effective, but no comparative trials have been published. 1) Apply dimethyl sulfoxide (DMSO) 99% by saturating a gauze pad and painting on an area twice the size of the extravasation. Allow the site to air dry and repeat the application every 6 hours for 14 days. Do not cover the area with dressing. 2) Dexrazoxane is FDA-approved for the treatment of extravasation resulting from anthracycline IV therapy, refer to the dexrazoxane monograph for more information. Additionally, ice compresses applied to the affected area for 15 minutes every 6 hours for 48 hours may be useful.

Reproductive/Nursing Safety

Doxorubicin is teratogenic and embryotoxic in laboratory animals. It is unknown if it affects male fertility. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Doxorubicin is excreted in milk in concentrations that may exceed those found in plasma. Because of risks to nursing offspring, consider using milk replacer if the dam is receiving doxorubicin.
Overdosage/Acute Toxicity

Inadvertent acute overdosage may be manifested by exacerbations of the adverse effects outlined above. A lethal dose for dogs has been reported as 72 mg/m² (O’Keefe and Harris 1990). Supportive and symptomatic therapy is suggested should an overdose occur. Dexrazoxane may be useful to help prevent cardiac toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving doxorubicin and may be of significance in veterinary patients:

- **ANTINEOPLASTIC AGENTS, OTHER**: May potentiate the toxic effects of doxorubicin
- **CALCIUM-CHANNEL BLOCKERS**: Potentially could increase risk for cardiotoxicity associated with doxorubicin
- **CARBAMAZEPINE**: Decreased carbamazepine levels
- **CISPLATIN**: Increased risk of toxicity for both agents; carefully weigh risks versus benefits
- **CYCLOPHOSPHAMIDE**: May increase doxorubicin blood levels (AUC); doxorubicin may potentiate and prolong hematologic toxicity; coma and seizures have been reported in human patients
- **CYCLOSPORINE**: Cyclosporine can increase doxorubicin and doxorubicinol (active metabolite) levels
- **GLUCOSAMINE**: May reduce doxorubicin effectiveness; use together not recommended in humans
- **PHENYTOIN**: Doxorubicin may decrease phenytoin levels
- **PHENOBARBITAL**: May increase elimination and reduce blood levels of doxorubicin
- **STREPTOZOCIN**: May inhibit doxorubicin metabolism
- **VERAPAMIL**: May increase doxorubicin levels
- **WARFARIN**: Increased risk for bleeding
- **ZIDOVUDINE**: Increased risk for neutropenia

Laboratory Considerations

- Doxorubicin may significantly increase both blood and urine concentrations of uric acid

Doses

**Note**: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS:**

Depending on the protocol used, doxorubicin is usually dosed at 30 mg/m² (NOT mg/kg) IV every 2-3 weeks. Maximum cumulative dose = 240 mg/m².

**CATS:**

Depending on the protocol used, doxorubicin is usually dosed at 20–30 mg/m² (NOT mg/kg) IV every 2-4 weeks. Maximum cumulative dose is usually 240 mg/m².

**FERRETS:**

Depending on the protocol used, doxorubicin is usually dosed at 30 mg/m² (NOT mg/kg) IV every 3 weeks.

Monitoring

- **Efficacy**
- **Toxicity:**
  a) CBC with platelets
  b) Dogs with pre-existing heart disease should be monitored with regular ECG’s (insensitive to early toxic changes caused doxorubicin) and/or echocardiogram
  c) Evaluate hepatic function prior to therapy
  d) Urinalyses and serum creatinine/BUN in cats

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality. Clients should contact the veterinarian should the animal exhibit any clinical signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising.
- Doxorubicin may cause urine to be colored orange to red for 1–2 days after dosing; although uncommon in veterinary patients, it is not harmful should it occur.
- Mild anorexia and occasional vomiting are commonly seen 2–5 days post-therapy.
- Avoid skin contact with urine or feces of treated animals. After treatment, doxorubicin drug residues may be found in treated dog’s urine up to 21 days and in feces for several days. (Knobloch et al. 2010)
- Although it is unknown how much drug is found in the saliva of treated animals, do not allow treated animals to lick human skin while receiving chemotherapy treatment.

Chemistry/Synonyms

An anthracycline glycoside antibiotic antineoplastic, doxorubicin HCl occurs as a lyophilized, red-orange powder that is freely soluble in water, slightly soluble in normal saline, and very slightly soluble in alcohol. The commercially available powder for injection also contains lactose and methylparaben to aid dissolution. After
Storage/Stability

Lyophilized powder for injection should be stored away from direct sunlight in a dry place. After reconstituting with sodium chloride 0.9%, the single-use lyophilized powder product is reportedly stable for 24 hours at room temperature and 48 hours when refrigerated. The manufacturer recommends protecting from sunlight, not freezing the product and discarding any unused portion. However, one study found that powder reconstituted with sterile water to a concentration of 2 mg/mL lost only about 1.5% of its potency per month over 6 months when stored in the refrigerator. When frozen at -20°C, no potency loss after 30 days was detected and sterility was maintained by filtering the drug through a 0.22-micron filter before injection.

The commercially available solution for injection is stable for 18 months when stored in the refrigerator (2–8°C) and protected from light. The manufacturer states that after reconstitution, the multi-dose vials may be stored for up to 7 days at room temperature in normal room light, and for up to 15 days in the refrigerator.

Compatibility/Compounding Considerations

Doxorubicin HCl is reportedly physically compatible with the following intravenous solutions and drugs: dextrose 3.3% in sodium chloride 3%, D5W, Normosol R (pH 7.4), lactated Ringer’s injection, and sodium chloride 0.9%. In syringes with: bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin hydrochloride, vinorelbine, mitomycin, fluorouracil, leucovorin calcium, metothexate sodium, metoplopramide HCl, mitomycin, and vincristine sulfate. The drug is physically compatible during Y-site injection with bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin hydrochloride, leucovorin calcium, metothexate sodium, metoplopramide HCl, mitomycin, vinblastine sulfate and vincristine sulfate.

Doxorubicin HCl compatibility information conflicts or is dependent on diluent or concentration factors with the following drugs or solutions: vinblastine sulfate (in syringes and as an IV additive). Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Doxorubicin HCl is reportedly physically incompatible with the following solutions or drugs: aminophylline, cephalothin sodium, dexamethasone sodium phosphate, diazepam, fluorouracil (as an IV additive only), furosemide, heparin sodium, and hydrocortisone sodium succinate.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Doxorubicin HCl (Conventional) Lyophilized Powder for Injection, (conventional): 10 mg, 20 mg, 50 mg, and 150 mg vials;
Doxorubicin HCl (Conventional) Injection (aqueous): 2 mg/mL in 5 mL, 10 mL, 25 mL, and 100 mL;
Doxorubicin HCl (Conventional) Lyophilized Powder for Injection, (conventional): 10 mg, 20 mg, 50 mg, and 150 mg vials;

References

TETRACYCLINE ANTIBIOTIC

DOXYCYCLINE CALCIUM
DOXYCYCLINE HCLATE
DOXYCYCLINE MONOHYDRATE

(dox-i-sycl-klem) Vibramycin®

TETRACYCLINE ANTIBIOTIC

Prescriber Highlights

- Oral & parenteral tetracycline antibiotic
- Bone & teeth abnormalities are less likely to be caused than with other tetracyclines, but use with caution in pregnant & young animals
- May be used in patients with renal insufficiency
- Not for IV injection in horses; do not give IM or SC to any species
- Most common adverse effects are GI, but increased liver enzymes can occur
- Esophagitis and strictures possible; must follow oral doses with sufficient fluid to get medication into stomach
- Drug Interactions
**Uses/Indications**

Although there are no veterinary FDA-approved doxycycline products available, its favorable pharmacokinetic parameters (longer half-life, higher CNS penetration) when compared to either tetracycline HCl or oxytetracycline HCl make it a reasonable choice to use in small animals when a tetracycline is indicated, particularly when a tetracycline is indicated in an azotemic patient. It commonly used in small animals to treat a variety of infections caused by several different microorganisms that include Borrelia, Leptospira, Rickettsiae, Chlamydia, Mycoplasma, Bartonella, and Bordetella.

At the time of writing (2010) there is considerable interest in using ivermectin or another macrocyclic lactone with doxycycline for several months prior to melarsomine adulticide therapy in dogs. Ivermectin can kill *D. immitis* larval stages 3 & 4, kill microfilaria, and reduce lifespan of adult heartworms. Doxycycline treatment can potentially reduce adult worm populations by eliminating *Wolbachia*, a bacterium associated with *D. immitis*. The American Heartworm Society has stated, “... it is beneficial to administer a macrocyclic lactone for up to three months prior to administration of melarsomine, when the clinical presentation does not demand immediate intervention” and “Doxycycline administered at 10 mg/kg twice daily for four weeks has been shown to eliminate over 90% of the *Wolbachia* organisms and the levels remain low for three to four months.” (American-Heartworm-Society 2010)

In avian species, some clinicians feel that doxycycline is the drug of choice in the oral treatment of chlamydiosis, particularly when treating only a few birds.

**Pharmacology/Actions**

Tetracyclines generally act as bacteriostatic antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminoacyl-transfer-RNA. Tetracyclines also are believed to reversibly bind to 50S ribosomes and, additionally, alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can also inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococcus and streptococci, but resistance by these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines include: *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and *tetani*, *Listeria monocytogenes* and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity against, include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasteurella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, Klebsiella, Bacteroides, Enterobacter, Proteus and *Pseudomonas aeruginosa* are resistant to the tetracyclines.

Doxycycline generally has very similar activity as other tetracyclines against susceptible organisms, but some strains of bacteria may be more susceptible to doxycycline or minocycline and additional *in vitro* testing may be required.

**Pharmacokinetics**

Doxycycline is well absorbed after oral administration. Bioavailability is 90–100% in humans and it is thought that the drug is also readily absorbed in most monogastric animals. Unlike tetracycline HCl or doxycycline, tetracycline absorption in humans may only be reduced by 20% by either food or dairy products in the gut. But in horses, giving orally in fed state may reduce bioavailability to less than 5%. This may be due to the high fiber content in most equine diets.

Tetracyclines, as a class, are widely distributed to the heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, synovial fluid, ascitic fluid, and aqueous and vitreous humor. When doxycycline was dosed to horses at 10 mg/kg PO q12h, it did not yield appreciable levels in the aqueous or vitreous humor (Gilmour et al. 2005). In horses, doxycycline has been shown to penetrate into the synovial fluid with an AUC synovial fluid:plasma factor of 4.6 and is eliminated from synovial fluid more slowly than plasma (Schnabel et al. 2010).

Doxycycline is more lipid-soluble and penetrates body tissues and fluids better than tetracycline HCl or oxytetracycline, including into the CSF, prostate, and eye. While CSF levels are generally insufficient to treat most bacterial infections, doxycycline has been shown to be efficacious in the treatment of the CNS effects associated with Lyme disease in humans. The volume of distribution at steady-state in dogs is approximately 1.5 L/kg. Doxycycline is bound to plasma proteins in varying amounts dependent upon species. The drug is approximately 25–93% bound to plasma proteins in humans, 75–86% in dogs, 82% in horses, and about 93% in cattle and pigs. Cats have higher binding to plasma proteins than dogs. Doxycycline accumulates intracellularly and concentrates in equine PMNs (Davis et al. 2006).

Doxycycline’s elimination from the body is relatively unique. The drug is primarily excreted into the feces via non-biliary routes in an inactive form. It is thought that the drug is partially inactivated in the intestine by chelate formation and then excreted into the intestinal lumen. In dogs, about 75% of a given dose is handled in this manner. Renal excretion of doxycycline can only account for about 25% of a dose in dogs, and biliary excretion less than 5%. The serum half-life of doxycycline in dogs is approximately 10–12 hours and clearance is approximately 0.7 mL/kg/min. In calves, the drug has similar pharmacokinetic values. In horses, elimination half-life is about 12 hours and clearance is approximately 0.7 mL/kg/min. Doxycycline does not accumulate in patients with renal dysfunction.

**Contraindications/Precautions/Warnings**

Doxycycline is contraindicated in patients hypersensitive to the drug. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Doxycycline is considered to be less likely to cause these abnormalities than other more water-soluble tetracyclines (e.g., tetracycline, oxytetracycline). Unlike either oxytetracycline or tetracycline, doxycycline can be used in patients with renal insufficiency. As increases in hepatic enzymes have been documented in some dogs after doxycycline treatment, use with caution in dogs with significant liver dysfunction.

Until further studies documenting the safety of intravenous doxycycline in horses are done, the parenteral route of administering this drug in horses should be considered contraindicated.

Doxycycline is pumped by P-glycoprotein, but the Washington State University Clinical Pharmacology Lab reports that it has not seen any increased sensitivity to doxycycline and does not recommend any dose alterations in dogs with MDR1 mutations. (WSU-VetClinPharmLab 2009)

**Adverse Effects**

The most commonly reported side effects of oral doxycycline therapy in dogs and cats are vomiting, diarrhea and anorexia. Giving the drug with food may help alleviate these GI effects without significantly reducing drug absorption. Increased liver enzymes (ALT, ALP) have been reported in up to 40% of dogs treated. The clinical significance of increased liver enzymes has not been determined.

Oral doxycycline has been implicated in causing esophageal strictures in cats. If using oral tablets, be sure that “pilling” is followed by at least 6 mL of water. Do not dry pill.

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

In humans, doxycycline (or other tetracyclines) has also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

Intravenous injection of even relatively low doses of doxycycline has been associated with cardiac arrhythmias, collapse, and death in horses.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category D for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich et al. 2006), doxycycline received a category C rating, because of the potential for adverse effects on the fetus and/or impaired fertility, although data are seemingly inconclusive.

In general, doxycycline should not be used in pregnant or lactating women to avoid any potential harm to the fetus or the nursing infant. However, if the mother is at risk of acquiring a zoonotic disease, such as Lyme disease or Rocky Mountain spotted fever, the potential benefits from the use of the drug may be acceptable despite its potential risks.
Laboratory Considerations

Overdosage/Acute Toxicity
With the exception of intravenous dosing in horses (see above), doxycycline is apparently quite safe in most mild overdose situations. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Although doxycycline is less vulnerable to chelation with cations than other tetracyclines, oral administration of divalent or trivalent cation antacids may bind some of the drug and reduce GI distress. Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary.

Rapid intravenous injection of doxycycline has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. If overdose quantities are inadvertently administered, these effects may be more pronounced.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving doxycycline and may be of significance in veterinary patients:

Antacids, Oral: When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations. Oral antacids, saline cathartics, or other GI products containing aluminum, calcium, magnesium, zinc, or bismuth cations are most commonly associated with this interaction. Doxycycline has a relatively low affinity for calcium ions, but it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing product.

Bismuth Subsalicylate, Kaolin, Pectin: May reduce absorption

Iron, Oral: Oral iron products are associated with decreased tetracycline absorption, and administration of iron salts should preferably be given 3 hours before or 2 hours after the tetracycline dose.

Penicillins: Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides. There is a fair amount of controversy regarding the actual clinical significance of this interaction, however.

Phenobarbital: May decrease doxycycline half-life and reduce levels

Warfarin: Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant (e.g., warfarin) therapy may need dosage adjustment.

Doses

**DOGS:**

For susceptible infections:

a) General use for infection: 3–5 mg/kg PO q12h for 7–14 days;
   For soft tissue, urinary tract: 4.4–11 mg/kg PO or IV q12h for 7–14 days;
   For acute *E. canis* infection: 5 mg/kg PO q12h or 10 mg/kg PO q24h for 14–16 days;
   For chronic *E. canis* infection: 10 mg/kg PO q24h for 30–42 days. (Greene et al. 2006)

b) For canine granulocytic anaplasmosis (*Anaplasma phagocytophilum*): 5 mg/kg PO q12h for 14 days; most dogs show clinical improvement in 24–48 hours. (Carrade et al. 2009)

c) For Lyme disease: 10 mg/kg PO q24h for 21–28 days (Appel & Jacobson 1995)

d) For *Ehrlichiosis* (*E. canis*) in dogs with a positive test result and clinical signs consistent with the infection: 10 mg/kg PO (rarely IV) q12-24h for 28 days. (Ford 2009b)

e) For leptospirosis: 5–10 mg/kg PO twice daily for 2 weeks. Management of underlying renal disease is a must. Regardless 10-30% of patients die. (Ford 2009a)

f) For *Toxoplasma gondii*: 5–10 mg/kg PO q12h for 4 weeks (Lappin 2000a)

g) For Rocky Mountain Spotted Fever (*Rickettsia rickettsii*): 5 mg/kg PO q12h (Breitschwerdt 2000)

h) For idiopathic lymphoplasmacytic (chronic) rhinitis: Long term administration of antibiotics having immunomodulatory effects combined with nonsteroidal antiinflammatory agents can be helpful in some dogs. Doxycycline 3–5 mg/kg PO q12h, or azithromycin 5 mg/kg PO q24h in combination with piroxicam 0.3 mg/kg PO q24h. (Kuehn 2010)

i) For uncomplicated infectious tracheobronchitis (*B. bronchiseptica*): 5–10 mg/kg PO once daily for a minimum of 2 weeks; treatment for up to 3 months should be considered, particularly when managing simultaneous infections in multiple dogs in the same environment. (Ford 2009a)

j) In combination with ivermectin as an adulticide for *D. immitis*: In this study doxycycline was administered at 10 mg/kg PO once daily for 30 days along with ivermectin/pyrantel pamoate with the ivermectin dose at 6–14 micrograms/kg PO once every 15 days for 6 months. 100% (total of 11 dogs) were negative for circulating microfilaria by day 90. 74% of dogs were negative for circulating antigens at day 300 (4-months post ivermectin). (Grandi et al. 2010)

k) For salmon poisoning (*Neorickettsia helmintheca*): 10 mg/kg IV twice a day for at least 7 days (Rikihisa & Zimmerman 1995)

For its antiarthritic effect:

a) 3–4 mg/kg PO once daily for 7–10 days. (Greene et al. 2006)

**CATS:**

Do not dry pill cats with oral doxycycline; follow with at least 6 mL of water or use a compounded slurry (“triple fish” or similar) to administer.

For susceptible infections:
Doxycycline hyclate may also be known as doxycycline monohydrate, doxycyclinum, and GS-3065; many trade names are available.

**Chemistry/Synonyms**

A semi-synthetic tetracycline that is derived from oxytetracycline, doxycycline is available as hyclate, calcium and monohydrate salts. The hyclate salt is used in the injectable dosage form and in oral tablets and capsules. It occurs as a yellow, crystalline powder that is soluble in water and slightly soluble in alcohol. After reconstitution with sterile water, the hyclate injection has a pH of 1.8–3.3. Doxycycline hyclate may also be known as doxycycline hydrochloride.

**STORAGE**

Store in a cool, dry place. Do not expose to light. Keep out of reach of children. Store away from contaminants.

**MONITORING**

**Clinical efficacy**

**Adverse effects**

**Client Information**

Do not “dry pill” as esophageal damage can occur; if using oral tablets or capsules, especially in cats, give medication followed by at least one 6 mL (a little more than a teaspoonful) of liquid. In cats, buttering the lips after administration to induce salivation and reduce esophageal transit time has been suggested.

Oral doxycycline products may be administered without regard to feeding, but giving with some food may reduce gastrointestinal effects. Milk or other dairy products do not significantly alter the amount of doxycycline absorbed.

**ADVERSE EFFECTS**

**Mice, Rats:**

For mycoplasmal pneumonia: 5 mg/kg PO twice daily with enrofloxacin (10 mg/kg PO twice daily) (Burke 1999)

**Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats:** 2.5–5 mg/kg PO q12h. Do not use in young or pregnant animals. (Adamcak & Otten 2000)

**BIRDS:**

For Psittacosis (Chlamydiosis):

a) Study done in experimentally infected cockatiels: Doxycycline 35 mg/kg PO once daily for 21 days. Birds were dosed via metallic feeding tube into crop using the commercially available (Vibramycin®) human oral suspension. (Guzman et al. 2010)

b) Routes of treatment include intramuscular injections, oral dosage with a suspension, medicated mash (approximately 1000 mg per kg of feed), and water-soluble approaches.

   IM: 75–100 mg/kg IM every 5–7 days for the first 4 weeks and subsequently every 5 days for the duration of a 45 day treatment.

   PO: 40–50 mg/kg PO once daily for cockatiels, Senegal parrots, Blue fronted and Orange winged amazons, 25 mg/kg PO once daily for African Grey parrots, Goffin’s cockatoos, Blue and gold macaws and Green winged macaws. Empirically: 25–50 mg/kg PO once a day is the recommended starting dosage for unstudied avian species. (Speer 1999)

   c) Using the oral liquid/suspension: 50 mg/kg PO every 24 hours, or divided every 12 hours (use less for macaws). Using the hyclate salt on corn, beans, rice and oatmeal: 1 gram per kg of feed. Using the injectable product (Vibaravenos®—may not be available commercially in the USA): 100 mg/kg IM once weekly in macaws and lovebirds) (Bauck & Hoefer 1993)

   d) Ratites: 2–3.5 mg/kg PO twice daily (Jenson 1998)

**REPTILES:**

For susceptible infections:

a) For chelonians: 10 mg/kg PO once daily for 4 weeks. Useful for bacterial respiratory infections in tortoises having suspected Mycoplasma infections.

b) In most species: 10 mg/kg PO once daily for 10–45 days (Gauvin 1993)

**Warning:** Doxycycline intravenously in horses has been associated with fatalities. Until further work is done demonstrating the safety of this drug, it cannot be recommended for parenteral use in this species.

a) For Lyme disease: 10 mg/kg PO once to twice daily for up to 30 days (Divers 1999)

b) For equine granulocytic ehrlichiosis (anaplasmosis; EGE) as an alternative to oxytetracycline: 10 mg/kg PO q12h for 10–14 days. (Lewis et al. 2009)

c) For organisms with an MIC ≤ 0.25 micrograms/mL (including many susceptible Streptococcus spp, Staphylococcus spp, Pasteurella spp, Rhodococcus equi, Actinobacillus equuli, and most ehrlichial organisms), a dose of 20 mg/kg PO q24h; preferably food should be withheld for at least 8 hours before and 2 hours after dosing. For bacteria with an MIC of 0.5–1 micrograms/mL, 20 mg/kg PO q12h is necessary to maintain adequate trough levels. Feeding should ideally be withheld as above, but may not be practically possible. One horse in the study developed a severe, acute colitis and the authors recommended that further clinical and safety studies be performed before using this regimen. (Davis et al. 2006)

d) For susceptible mycobacterial, L-Forms, or mycoplasma infections: 5–10 mg/kg PO q12h. (Bonenberger 2009)

e) For treatment of Nocardia (N. nova) infections: Combination therapy with: amoxicillin 20 mg/kg PO twice daily with clarithromycin 62.5–125 mg (total dose per cat) PO twice daily and/or doxycycline 5 mg/kg or higher PO twice daily. (Malik 2006)

f) For feline chlamydial infections (C. felis): 10 mg/kg PO once daily for a minimum of 3–4 weeks; additional topical ocular treatment may reduce ocular discomfort. (Gruffyd-Jones 2009)

**HORSES:**

**Warning:** Doxycycline intravenously in horses has been associated with fatalities. Until further work is done demonstrating the safety of this drug, it cannot be recommended for parenteral use in this species.

a) For Hemotropic mycoplasmosis: 5–10 mg/kg PO once daily for 14 days; round dose to nearest whole tablet or capsule;

   For Bartonellosis: 50 mg (total dose) PO q12h for 14–28 days;

   For systemic infections, bacteremia: 5–11 mg/kg PO or IV q12h as long as necessary;

   For Ehrlichiosis or Anaplasmosis: 5–10 mg/kg PO q12h for 21 days. (Greene et al. 2006)

b) For clinical hemoplasmosis or bartonellosis: 10 mg/kg PO q12–24h (Lappin 2006)

c) For Toxoplasma gondii: 5–10 mg/kg PO q12h for 4 weeks (Lappin 2000b)

d) For susceptible mycobacterial, L-Forms, or mycoplasma infections: 5–10 mg/kg PO q12h. (Bonenberger 2009)

e) For treatment of Nocardia (N. nova) infections: Combination therapy with: amoxicillin 20 mg/kg PO twice daily with clarithromycin 62.5–125 mg (total dose per cat) PO twice daily and/or doxycycline 5 mg/kg or higher PO twice daily. (Malik 2006)

f) For feline chlamydial infections (C. felis): 10 mg/kg PO once daily for a minimum of 3–4 weeks; additional topical ocular treatment may reduce ocular discomfort. (Gruffyd-Jones 2009)

**MICE, RATS:**

For mycoplasmal pneumonia: 5 mg/kg PO twice daily with enrofloxacin (10 mg/kg PO twice daily) (Burke 1999)

**Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats:** 2.5–5 mg/kg PO q12h. Do not use in young or pregnant animals. (Adamcak & Otten 2000)

**BIRDS:**

For Psittacosis (Chlamydiosis):

a) Study done in experimentally infected cockatiels: Doxycycline 35 mg/kg PO once daily for 21 days. Birds were dosed via metallic feeding tube into crop using the commercially available (Vibramycin®) human oral suspension. (Guzman et al. 2010)

b) Routes of treatment include intramuscular injections, oral dosage with a suspension, medicated mash (approximately 1000 mg per kg of feed), and water-soluble approaches.

   IM: 75–100 mg/kg IM every 5–7 days for the first 4 weeks and subsequently every 5 days for the duration of a 45 day treatment.

   PO: 40–50 mg/kg PO once daily for cockatiels, Senegal parrots, Blue fronted and Orange winged amazons, 25 mg/kg PO once daily for African Grey parrots, Goffin’s cockatoos, Blue and gold macaws and Green winged macaws. Empirically: 25–50 mg/kg PO once a day is the recommended starting dosage for unstudied avian species. (Speer 1999)

c) Using the oral liquid/suspension: 50 mg/kg PO every 24 hours, or divided every 12 hours (use less for macaws). Using the hyclate salt on corn, beans, rice and oatmeal: 1 gram per kg of feed. Using the injectable product (Vibaravenos®—may not be available commercially in the USA): 100 mg/kg IM once weekly in macaws and lovebirds) (Bauck & Hoefer 1993)

   d) Ratites: 2–3.5 mg/kg PO twice daily (Jenson 1998)

**REPTILES:**

For susceptible infections:

a) For chelonians: 10 mg/kg PO once daily for 4 weeks. Useful for bacterial respiratory infections in tortoises having suspected Mycoplasma infections.

b) In most species: 10 mg/kg PO once daily for 10–45 days (Gauvin 1993)
Doxycycline hyalinate tablets and capsules should be stored in tight, light resistant containers at temperatures less than 30°C, and preferably at room temperature (15–30°C). After reconstituting with water, the monohydrate oral suspension is stable for 14 days when stored at room temperature. The hyalinate injection when reconstituted with a suitable diluent (e.g., D5W, Ringer’s injection, Sodium Chloride 0.9%, or Plasma-Lyte 56 in D5W) to a concentration of 0.1 to 1 mg/mL may be stored for 72 hours if refrigerated. Frozen reconstituted solutions (10 mg/mL in sterile water) are stable for at least 8 weeks if kept at -20°C, but should not be refrozen once thawed. If solutions are stored at room temperature, different manufacturers give different recommendations regarding stability, ranging from 12 to 24 hours. Infusions should generally be completed within 12 hours of administration.

Compatibility/Compounding Considerations
Doxycycline hyalinate for injection is reportedly physically compatible with the following IV infusion solutions and drugs: D5W, Ringer’s injection, sodium chloride 0.9%, or Plasma-Lyte 56 in D5W; to a concentration of 0.1 to 1 mg/mL may be stored for 72 hours if refrigerated. Frozen reconstituted solutions (10 mg/mL in sterile water) are stable for at least 8 weeks if kept at -20°C, but should not be refrozen once thawed. If solutions are stored at room temperature, different manufacturers give different recommendations regarding stability, ranging from 12 to 24 hours. Infusions should generally be completed within 12 hours of administration.

VETERINARY-LABELED PRODUCTS:

**Doxycycline (as the hyalinate) Tablets & Capsules:** 20 mg, 50 mg, & 100 mg; Periostar® (CollaGenex), Alvadox Convenience Kit® (OCuSOFT, Inc); Vibramycin® & Vibra-Tabs® (Pfizer); Oraxy® (E5 Pharma); generic (Rx)

**Doxycycline (as the hyalinate) Delayed-Release Tablets & Capsules:** 75 mg, 100 mg & 150 mg, & 40 mg (30 mg immediate release & 10 mg delayed release); Doryx® (Warner Chilcott); Oracea® (CollaGenex); (Rx)

**Doxycycline (as monohydrate) Tablets and Capsules:** 50 mg, 75 mg, 100 mg & 150 mg; Monodox® (Ocllassen); Adoxa® (Doak); generic; (Rx)

**Doxycycline Capsules (coated-pellets) (as hyalinate):** 75 mg & 100 mg; Doryx® (Warner Chilcott); generic (Eon); (Rx)

**Doxycycline (as the monohydrate) Powder for Oral Suspension:** 5 mg/mL after reconstitution in 60 mL; Vibramycin® (Pfizer); Doxycycline (Teva); (Rx)

**Doxycycline (as the calcium salt) Oral Syrup:** 10 mg/mL in 473 mL; Vibramycin® (Pfizer); (Rx)

**Doxycycline Injection:** 42.5 mg (as hyalinate, 10%) in vials; Atridox® (CollaGenex); (Rx)

**Doxycycline (as the hyalinate) Lyophilized Powder for Injection:** 100 mg & 200 mg with 300 mg & 600 mg manitol respectively in vials; Doxy®-100 & -200 (AAP); generic; (Rx)

**References**

Heavy metal chelator used primarily for lead or zinc toxicity

Contraindications: Patients with anuria; Extreme Caution: Patients with decreased renal function

Recommend using SC route when treating small animals; do not give PO

Adverse Effects: Renal toxicity (renal tubular necrosis); may cause depression & GI clinical signs in dogs

CaEDTA is used as a chelating agent in the treatment of lead poisoning. Succimer is more commonly recommended today for treating lead poisoning in dogs and cats. CaEDTA may be used in combination with dimercaprol treatment.

The calcium in CaEDTA can be displaced by divalent or trivalent metals to form a stable water-soluble complex that can be excreted in the urine. One gram of CaEDTA can theoretically bind 620 mg of lead, but in reality only about 5 mg per gram is actually excreted into the urine in lead-poisoned patients. In addition to chelating lead, CaEDTA chelates and eliminates zinc from the body. CaEDTA also binds cadmium, copper, iron, and manganese, but to a much lesser extent than either lead or zinc. CaEDTA is relatively ineffective for use in treating mercury, gold, or arsenic poisoning.

There is some evidence that thiamine supplementation may increase the clinical efficacy of CaEDTA in treating acute lead poisoning in cattle.

CaEDTA is well absorbed after either IM or SC administration. It is distributed primarily in the extracellular fluid. Unlike dimercaprol, CaEDTA does not penetrate erythrocytes or enter the CNS in appreciable amounts. The drug is rapidly excreted renally, either as unchanged drug or chelated with metals. Changes in urine pH or urine flow do not significantly alter the rate of excretion. Decreased renal function can cause accumulation of the drug and can increase its nephrotoxic potential. In humans with normal renal function, the average elimination half-life of CaEDTA is 20–60 minutes after IV administration, and 1.5 hours after IM administration.

CaEDTA is contraindicated in patients with anuria. It should be used with extreme caution and with dosage adjustment in patients with diminished renal function. Most small animal clinicians recommend using the SC route when treating small animals, as IV administration of CaEDTA has been associated with abrupt increases in CSF pressure and death in children with lead-induced cerebral edema.

Lead should be removed from the GI tract before using CaEDTA. Do not administer CaEDTA orally as it may increase the amount of lead absorbed from the GI tract.

Animals with clinical signs of cerebral edema should not be overhydrated.

The most serious adverse effect associated with this compound is renal toxicity (renal tubular necrosis), but in dogs, CaEDTA can cause depression, vomiting, and diarrhea. GI clinical signs may be alleviated by zinc supplementation.

Chronic therapy may lead to zinc deficiency; zinc supplementation should be considered in these animals.

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters).

It is not known whether this drug is excreted in milk.

Doses greater than 12 g/kg are lethal in dogs; refer to Adverse Effects for more information.

The following drug interactions have either been reported or are theoretical in humans or animals receiving CaEDTA and may be of significance in veterinary patients:

GLUCOCORTICOIDS: The renal toxicity of CaEDTA may be enhanced by the concomitant administration of glucocorticoids

INSULIN (NPH, PZI): Concurrent administration of CaEDTA with zinc insulin preparations (NPH, PZI) will decrease the sustained action of the insulin preparation

NEPHROTOXIC DRUGS, OTHER: Use with caution with other nephrotoxic compounds (e.g., aminoglycosides, amphotericin B)

Laboratory Considerations

CaEDTA may cause increased urine glucose values and/or cause inverted T-waves on ECG

The manufacturer of the injectable (human) product recommends diluting the injection to a concentration of 2–4 mg/mL with either normal saline or 5% dextrose when used for intravenous use. Because the injection is painful when given IM, it is recommended to add 1 mL of procaine HCl 1% to each mL of injection before administering IM.

DOGS & CATS:

For lead poisoning:

1. Be sure there is no lead in GI tract before using. Give 100 mg/kg SC divided into 4 daily doses in 5% dextrose 3 to 5 days. May require second course of therapy in 5 days.

2. For zinc poisoning: Give 500 mg/kg/day divided into 4 daily doses in 5% dextrose for 5 days.

3. For mercury, gold, or arsenic poisoning: Give 1 g/kg/day divided into 4 daily doses for 3 to 5 days.
a) Be sure there is no lead in GI tract before using. Give 100 mg/kg SC divided into 4 daily doses in 5% dextrose for 5 days. May require second course of treatment, particularly if blood lead levels >0.10 ppm. Do not exceed 2 g/day and do not treat for more than 5 consecutive days. (Grauer & Hjelle 1988)
b) 25 mg/kg SC four times daily for 5 days. Give as 1% solution in D5W. Provide a 5–7 day rest period between courses of treatment to minimize potential for nephrotoxicity. Succimer is now the treatment of choice for lead in small animals. (Poppenga 2002)
c) Cats: 27.5 mg/kg in 15 mL D5W SC four times daily for 5 days. Recheck blood lead 2–3 weeks later and repeat therapy (with either CaEDTA or penicillamine) if greater than 0.2 ppm. (Reid & Oehme 1989)

For zinc toxicity:

a) 100 mg/kg divided into four SC doses per day. Dilute in D5W to reduce local irritation at site of injection. Exact dosage is not known nor how long therapy should continue. If possible, monitor serum zinc concentrations and maintain animal’s hydration status. (Meurs & Breitschwerdt 1995)

RABBITS/RODENTS/SMALL MAMMALS:

a) Chinchillas: 30 mg/kg SC q12h (Adamcak & Otten 2000)

HORSES:

For lead poisoning:

a) Remove animal from source of lead. If severely affected give CaEDTA at 75 mg/kg IV slowly in D5W or saline daily for 4–5 days (may divide daily dose into 2–3 administrations per day). Stop therapy for 2 days and repeat for another 4–5 days. Give adequate supportive and nutritional therapy. (Oehme 1987)

FOOD ANIMALS:

Note: FARAD recommends a 2 day meat and milk withdrawal time after use in food animals. (Haskell et al. 2005)

For lead poisoning:

a) 110 mg/kg per day in 3–4 divided doses; dilute to 1 gram/mL in D5W; first dose IV, then subcutaneously (Post & Keller 2000)
b) Cattle: 67 mg/kg slow IV twice daily for 2 days; withhold dose for 2 days and then give again for 2 days. Cattle may require 10–14 days to recover and may require several series of treatments. (Bailey 1986)
c) Cattle: 73.3 mg/kg/day slow IV divided 2–3 times a day for 3–5 days. If additional therapy is required, a 2-day rest period followed by another 5-day treatment regimen is recommended. (Sexton & Buck 1986)

BIRDS:

For lead poisoning:

a) In psittacines: 35 mg/kg IM twice daily for 5–7 days. After initial therapy, may give orally until all lead fragments are dissolved and/or passed from GI tract. (McDonald 1989)
b) In raptors (falcons): In this study, 25% CaEDTA was given undiluted IM at a dose of 100 mg/kg q12h for 5–25 consecutive days. Falcons were treated if blood lead was >65 micrograms/dL for 5 day courses, until blood lead was <20 micrograms/dL. No evidence of muscle damage, nephrotoxicity or hepatotoxicity seen. (Samour & Naldo 2004)
c) For lead or zinc poisoning: 30–35 mg/kg IM q12h x 3-5 days, off 3-5 days, may repeat and/or use another chelator. Maintain hydration. Do not give orally or may increase lead absorption from GI tract. Can be used IV short term (48 hrs) at 20–35 mg/kg diluted in saline. Many published regimens. (Johnson-Delaney & Reavill 2009)

Monitoring

- Blood lead or zinc (serial), and/or urine d-ALA
- Renal function tests, urinalyses, hydration status
- Serum phosphorus and calcium values
- Periodic cardiac rate/rhythm monitoring may be warranted during administration

Client Information

- Because of the potential toxicity of this agent and the seriousness of most heavy metal intoxications, this drug should be used with close professional supervision only.

Chemistry/Synonyms

A heavy metal chelating agent, edetate calcium disodium (CaEDTA) occurs as an odorless, white, crystalline powder or granules and is a mixture of dihydrate and trihydrate forms. It has a slight saline taste and is slightly hygroscopic. CaEDTA is freely soluble in water and very slightly soluble in alcohol. The commercially available injection (human) has a pH of 6.5–8 and has approximately 5.3 mEq of sodium per gram of CaEDTA.

Edetate calcium disodium may also be known as: sodium calcium edetate, calcium disodium edathamil, calcium disodium edetate, calcium disodium ethylenediaminetetra-acetate, calcium disodium versenate, calcium EDTA, disodium calcium tetracemate, E385, natrii caclii edetas, sodium calciumedetate, Calcium Disodium Versenate®, Calcium Vitis®, Calciumedetat-Heyl®, Chelante®, Chelintox®, or Ledclair®.

Storage/Stability

CaEDTA should be stored at temperatures less than 40°, and preferably at room temperature (15–30°C). The injection can be diluted with either normal saline or 5% dextrose.

Dosage Forms/Regulatory Status

Note: Do not confuse with Edetate Disodium which should not be used for lead poisoning as it may cause severe hypocalcemia.

VETERINARY-LABELED PRODUCTS:

None in the USA; may be available from compounding pharmacies.

HUMAN-LABELED PRODUCTS:
**Uses/Indications**
The primary use for edrophonium is in the presumptive diagnosis of myasthenia gravis (MG). The so-called “Tensilon Test” for MG has a fair percentage of false-positives and false-negatives associated with it and is probably best to use while awaiting results from a more specific and sensitive test such as the acetylcholine receptor antibody test.

Edrophonium can also be used for the reversal of nondepolarizing agents (e.g., vecuronium, pancuronium, metocurine, atracurium, gallamine or tubocurarine). Because of its short duration of action, its clinical usefulness for this indication is questionable as longer acting drugs such as neostigmine or pyridostigmine may be more useful. Edrophonium, in a controlled intensive care-type setting, may also be useful in the diagnosis and treatment of some supraventricular arrhythmias, particularly when other more traditional treatments are ineffective.

**Pharmacology/Actions**
Edrophonium is an anticholinesterase agent that is very short acting. It briefly attaches to acetylcholinesterase thereby inhibiting its hydrolytic activity on acetylcholine. As acetylcholine accumulates, the following clinical signs may be noted: miosis, increased skeletal and intestinal muscle tone, bronchoconstriction, ureter constriction, diaphoresis, vomiting, defecation, bradycardia, atropine) can help

**Pharmacokinetics**
Edrophonium is an anticholinesterase agent that is very short acting. It briefly attaches to acetylcholinesterase thereby inhibiting its hydrolytic activity on acetylcholine. As acetylcholine accumulates, the following clinical signs may be noted: miosis, increased skeletal and intestinal muscle tone, bronchoconstriction, ureter constriction, diaphoresis, vomiting, defecation, bradycardia. Although usually mild and easily treated with a “tincture of time”, pre-treatment or treatment with an anticholinergic drug (e.g., atropine) can help prevent or alleviate these effects. Severe adverse effects are possible with large overdoses (see below).

**Contraindications/Precautions/Warnings**
Edrophonium is considered relatively contraindicated in patients with bronchial asthma, or mechanical urinary or intestinal tract obstruction. It should be used with caution (with adequate monitoring and treatment available) in patients with bradycardias or atrioventricular block. Some human patients are documented to be hypersensitive to the drug and exhibit severe cholinergic reactions.

It is recommended to have IV atropine and an endotracheal tube readily available before using edrophonium.

**Adverse Effects**
Adverse effects associated with edrophonium are generally dose related and cholinergic in nature (urination, lacrimation, vomiting, defecation, bradycardia, bronchospasm). Although usually mild and easily treated with a “tincture of time”, pre-treatment or treatment with an anticholinergic drug (e.g., atropine) can help prevent or alleviate these effects. Severe adverse effects are possible with large overdoses (see below).

**Reproductive/Nursing Safety**
Edrophonium’s safety profile during pregnancy is not established; use only when necessary. While no problems have been documented in nursing humans or animals, its safety has not been established. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown whether edrophonium enters maternal milk.

**Overdosage/Acute Toxicity**
Overdosage of edrophonium may induce a cholinergic crisis. Clinical signs of cholinergic toxicity can include: GI effects (nausea, vomiting, diarrhea), salivation, sweating (in animals able to do so), respiratory effects (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects (miosis, blurred vision, lacrimation), cardiovascular effects (bradycardia or tachycardia, cardiospasm, hypotension, cardiac arrest), muscle cramps and weakness.

**Sweating (in animals able to do so), respiratory effects (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects**
Edrophonium chloride injection should be stored at room temperature.

Storage/Stability
Edrophonium chloride injection should be stored at room temperature.

It is reportedly physically compatible at Y-site injections with heparin sodium, hydrocortisone sodium succinate, potassium chloride and vitamin B complex with C.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more information on its use for cholinergic toxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving edrophonium and may be of significance in veterinary patients:

- **ATROPINE:** Atropine will antagonize the muscarinic effects of edrophonium and some clinicians routinely use the two together, but concurrent use should be used cautiously as atropine can mask the early clinical signs of cholinergic crisis
- **DEXPANTHENOL:** Theoretically, dexpantenol may have additive effects when used with edrophonium
- **DIGOXIN:** Edrophonium’s cardiac effects may be increased in patients receiving digoxin; excessive slowing of heart rate may occur
- **MUSCLE RELAXANTS:** Edrophonium may prolong the Phase I block of depolarizing muscle relaxants (e.g., succinylcholine, decamethonium) and edrophonium antagonizes the actions of non-depolarizing neuromuscular blocking agents (e.g., pancuronium, tubocurarine, gallamine, vecuronium, atracurium, etc.)

**Doses**

**DOGS:**

For presumptive diagnosis of myasthenia gravis (MG):

a) This test is easiest to assess in patients with the generalized form of MG, those who tire with exercise. The patient is gently exercised until fatigued. Place indwelling catheter. Edrophonium dose is 0.1–0.2 mg/kg IV. (Have atropine drawn up so that if cholinergic signs (SLUD) develop, it can be given at 0.02–0.04 mg/kg IV). The catheter is flushed with sterile saline, and then the patient is immediately lightly exercised, or if non-ambulatory, encouraged to rise. In patients with focal MG such as facial muscle weakness, the palpebral reflex may be assessed after IV edrophonium. Patients are assessed as having a positive or negative “Tensilon Test”. (Vernau 2009)

b) 1–10 mg (total dose) IV; presumptive positive test results in transient improvement in clinical weakness; sometimes objective criteria for this test are difficult to establish. (LeCouteur 2005)

c) 0.1–0.2 mg/kg IV; have atropine and endotracheal tube readily available in case of overdose. (Abramson 2005)

d) Pre-treat with atropine (0.02–0.04 mg/kg IM or SC); then give edrophonium at 0.1 mg/kg IV. In affected animals, paresis should resolve within one minute and effects should last for up to 15 minutes. (Kornegay 2006)

**CATS:**

For presumptive diagnosis of myasthenia gravis (MG):

a) This test is easiest to assess in patients with the generalized form of MG, who tire with exercise. The patient is gently exercised until fatigued. Place indwelling catheter. Edrophonium dose is 0.25 to 0.5 mg (total dose) IV. (Have atropine drawn up so that if cholinergic signs (SLUD) develop, it can be given at 0.02–0.04 mg/kg IV). The catheter is flushed with sterile saline and then the patient is immediately lightly exercised, or if non-ambulatory, encouraged to rise. In patients with focal MG such as facial muscle weakness, the palpebral reflex may be assessed after IV edrophonium. Patients are assessed as having a positive or negative “Tensilon Test”. (Vernau 2009)

b) Pre-treat with atropine (0.02–0.04 mg/kg IM or SC); then give edrophonium at 0.1 mg/kg IV. In affected animals, paresis should resolve within one minute and effects should last for up to 15 minutes. (Kornegay 2006)

Monitoring

- Cholinergic adverse effects
- Improvement (for 1–15 minutes) of paresis for presumptive diagnosis of MG

Client Information

- Edrophonium is a drug that should be used in a controlled clinical setting
- Clients should be briefed on the side effects that can occur with its use

Chemistry/Synonyms

A synthetic quaternary ammonium cholinergic (parasympathomimetic) agent, edrophonium chloride occurs as a white crystalline powder having a bitter taste. Approximately 2 grams are soluble in 1 mL of water. The injection has a pH of approximately 5.4.

Edrophonium chloride may also be known as: edrophonii chloridum, Anticude®, Camsilon®, Enlon®, Reversol®, or Tensilon®.

Storage/Stability

Edrophonium chloride injection should be stored at room temperature.

It is reportedly physically compatible at Y-site injections with heparin sodium, hydrocortisone sodium succinate, potassium chloride and vitamin B complex with C.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Edrophonium Chloride Solution for Injection: 10 mg/mL in 10 mL & 15 mL vials; Enlon® (Bioniche); Reversol® (Organon); (Rx)

Edrophonium Chloride/Atropine Sulfate for Injection: 10 mg/mL with 0.14 mg/mL atropine sulfate in 5 mL single-dose amps & 15 mL multi-dose vials; Enlon-Plus®
EMODEPSIDE + PRAZIQUANTEL
(ee-moe-dep-side + pra-dee-kuh-tel) Profender®
TOPICAL ANTIPARASITIC (NEMATOCIDE; CESTOCIDE)

Prescriber Highlights

- Topical cestocide & nematocide labeled for cats
- Appears safe in cats >1 kg & at least 8 weeks old
- Applied to back of cat’s neck; do not allow patient or other cats to lick area of application for at least one hour

Uses/Indications
Emodepside/Praziquantel topical solution (Profender®) is indicated for the treatment and control of hookworm infections caused by *Ancylostoma tubaeforme* (adults, immature adults, and fourth stage larvae), roundworm infections caused by *Toxocara cati* (adults and fourth stage larvae), and tapeworm infections caused by *Dipylidium caninum* (adults) and *Taenia taeniaeformis* (adults) in cats.

Topical Profender® may also be of use in treating other species (e.g., reptiles) where oral dosing may be overly stressful.

There are also oral products available (not in USA) for use in dogs.

Pharmacology/Actions
Emodepside has a unique mode of action in comparison to other antiparasitic compounds. The drug attaches pre-synaptically at the neuromuscular junction to a latrophilin-like receptor, resulting in an increase in intracellular calcium and diacylglycerol levels. At the end of the signal transduction cascade, vesicles containing inhibitory neuropetide fuse with pre-synaptic membranes. Inhibitory neuropeptides such as PF1- and/or PF2-like receptor are then released into the synaptic cleft, stimulating postsynaptic receptors and resulting in an inhibition of pharyngeal pumping and locomotion of the nematode. The end result is flaccid paralysis and death of the parasite.

Praziquantel’s exact mechanism of action against cestodes has not been determined, but it may be the result of interacting with phospholipids in the integument causing ion fluxes of sodium, potassium and calcium. At low concentrations in *vivo*, the drug appears to impair the function of their suckers and stimulates the worm’s motility. At higher concentrations in *vivo*, praziquantel increases the contraction (irreversibly at very high concentrations) of the worm’s strobila (chain of proglottids). In addition, praziquantel causes irreversible focal vacuolization with subsequent cestodal disintegration at specific sites of the cestodal integument.

Pharmacokinetics
Following dermal application of the product (Profender®) to cats, emodepside and praziquantel are absorbed through the skin and into the systemic circulation. Absorption of both active ingredients through the skin is relatively rapid, with serum concentrations detectable within 2 hours for emodepside and within 1 hour for praziquantel. Peak concentrations occur within 6 hours for praziquantel and 2 days for emodepside. After a single application, both emodepside and praziquantel were detectable for up to 28 days following treatment were noted.

A study looking at topical absorption in a variety of reptiles found variability in blood levels that was associated with skin thickness (Schilliger *et al.* 2009).

Contraindications/Precautions/Warnings
There are no absolute contraindications for use of this product on cats noted on the label. However, safe use has not been evaluated in cats: less than 8 weeks of age or weighing less than 2.2 lb (1 kg), used for breeding, during pregnancy, or in lactating queens. Use with caution in sick or debilitated, or heartworm positive cats.

Adverse Effects
In pre-approval efficacy studies, the most common side effects observed were dermal- and gastrointestinal-related. In a field study, adverse reactions reported by cat owners included licking/excessive grooming (3%), scratching treatment site (2.5%), salivation (1.7%), lethargy (1.7%), alopecia (1.3%), agitation/nervousness (1.2%), vomiting (1%), diarrhea (0.5%), eye irritation in 3 cats (0.5%), respiratory irritation (0.2%) and shaking/tremors (0.2%). All adverse reactions were self-limiting. The following adverse events were reported voluntarily during post-approval use of the product in foreign markets: application site reaction (hair loss, dermatitis, pyoderma, edema, and erythema), salivation, pruritus, lethargy, vomiting, diarrhea, dehydration, ataxia, loss of appetite, facial swelling, rear leg paralysis, seizures, hyperesthesia, twitching, and death. A case report of one cat developing a morphea-like (scleroderma) lesion after application has been reported (Seixas & Taboada 2009).

Reproductive/Nursing Safety
Safe use has not been evaluated in cats used for breeding, during pregnancy, or in lactating queens. Studies performed in laboratory animals (rats, rabbits suggest that emodepside may interfere with fetal development in those species.

Overdosage/Acute Toxicity
Oral doses of emodepside of 200 mg/kg were tolerated by rats without mortalities. The oral LD50 in rats is >500 mg/kg; in mice >2,500 mg/kg. The acute dermal toxicity dose of emodepside in rats is high; a dose of 2,000 mg/kg was tolerated without mortality.

Praziquantel has a wide margin of safety. In rats and mice, the oral LD50 is at least 2 g/kg. An oral LD50 could not be determined in dogs, as at doses greater than...
Praziquantel has a wide margin of safety. In rats and mice, the oral LD50 is at least 2 g/kg. An oral LD50 could not be determined in dogs, as at doses greater than 200 mg/kg, the drug induced vomiting. Parenteral doses of 50–100 mg/kg in cats caused salivation, vomiting, anorexia, tremors, abnormal respirations, and ataxia. Adverse effects in all animals treated in these studies resolved without treatment.

**Drug Interactions**

No drug interactions have been documented for this product, but emodepside is reportedly a substrate for P-glycoprotein. Use with other drugs that are P-glycoprotein substrates or inhibitors (e.g., ivermectin, erythromycin, prednisolone, cyclosporine) could cause pharmacokinetic drug interactions.

**Doses**

**CATS:**

For labeled indications:

a) Minimum dose is 3 mg/kg emodepside & 12 mg/kg praziquantel applied to the skin on the back of the neck as a single topical dose. A second treatment should not be necessary. If re-infection occurs, the product can be re-applied after 30 days. (Label information; *Profender®*—Bayer)

**REPTILES:**

a) Serum levels vary between species, but a dose of 4 drops/100 g body weight appears to be effective. Aquatic species must be kept in a dry place for 48 hours after treatment. Caution is advised until further studies verify safety and efficacy, particularly in sick animals. (Schilliger et al. 2009)

**Monitoring**

- Clinical efficacy

**Client Information**

- Do not apply to broken skin or if hair coat is wet.
- Do not get in the cat’s mouth or eyes or allow the cat to lick the application site for one hour. Oral exposure can cause salivation and vomiting; treatment at the base of the head will minimize the opportunity for ingestion while grooming.
- In households with multiple pets, keep animals separated to prevent licking of the application site.
- Not for human use. Keep out of reach of children. To prevent accidental ingestion of the product, children should not come in contact with the application site for 24 hours while the product is being absorbed. Pregnant women, or women who may become pregnant, should avoid direct contact with, or wear disposable gloves when applying, this product.

**Chemistry/Synonyms**

Emodepside is an N-methylated 24-membered cyclooctadepsipeptide, consisting of four alternating residues of N-methyl-L-leucine, two residues of D-lactate, and two residues of D-phenylacetate.

Praziquantel occurs as a white to practically white, hygroscopic, bitter tasting, crystalline powder, either odorless or having a faint odor. It is very slightly soluble in water and freely soluble in alcohol.

Praziquantel may also be known as: EMBAY-8440, or praziquantelum.

**Storage/Stability**

Store product at or below 25°C (77°F); do not allow to freeze.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Emodepside (1.98% w/w; 21.4 mg/mL) and Praziquantel (7.94% w/w; 85.8 mg/mL) Topical Solution in 0.35 mL (cats 2.2–5.5 lb.), 0.7 mL (cats >5.5–11 lb.) & 1.12 mL (cats >11–17.6 lb.) tubes: *Profender®* (Bayer); (Rx). FDA-approved for use on cats.

An oral product for dogs, *Profender® for Dogs* is available in many countries, but is not currently FDA-approved in the USA.

**HUMAN-LABELED PRODUCTS:** None

**References**

**ENALAPRIL MALEATE**

**ENALAPRILAT** *(e-nal-a-pril) Enacard®, Vasotec® ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR**

**Prescriber Highlights**

- Veterinary & human ACE inhibitor used primarily as a vasodilator in the treatment of heart failure or hypertension; may also be of benefit in the treatment of chronic renal failure or protein losing nephropathies
Uses/Indications
The principle use of enalapril/enalaprilat in veterinary medicine at present is as a vasodilator in the treatment of heart failure. Recent studies have demonstrated that enalapril, particularly when used in conjunction with furosemide, does improve the quality of life in dogs with heart failure. There is now reasonable evidence that ACE inhibitors can modestly increase survival times in dogs with Class II-IV heart failure, but further studies are required to clarify any benefits. Enalapril may also be of benefit in treating the effects associated with valvular heart disease (mitral regurgitation) and left to right shunts.

Enalapril and ACE inhibitors decrease efferent glomerular resistance and may reduce proteinuria and have renoprotective effects; they are being explored for adjunctive treatment in idiopathic glomerulonephritis, chronic renal failure and protein losing nephropathies in small animals.

ACE inhibitors are used in treating feline hypertrophic cardiomyopathy and may be of benefit, but at present there is not good evidence that they prolong survival times.

While ACE inhibitors are a mainstay for treating hypertension in humans, they have not been particularly useful when used alone in treating hypertension in dogs or cats.

Pharmacology/Actions
Enalapril is converted in the liver to the active compound enalaprilat. Enalaprilat prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for enalaprilat than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased.

The cardiovascular effects of enalaprilat in patients with CHF include: decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure, no change or decrease in heart rate, and increased cardiac index and output, stroke volume, and exercise tolerance.

ACE inhibitors increase renal blood flow and decrease glomerular efferent arteriole resistance. In animals with glomerular disease, ACE inhibitors decrease proteinuria and may help to preserve renal function. Enalapril, at least partially blocks amlodipine’s activation of the renin-angiotensin-aldosterone system (RAAS) in dogs (Atkins et al. 2007).

Pharmacokinetics
Enalapril/enalaprilat has different pharmacokinetic properties than captopril in dogs. It has a slower onset of action (4–6 hours) but a longer duration of action (12–14 hours). In dogs, approximately 95% of enalaprilat is cleared via renal routes and reduced renal function can impact elimination rates.

In humans, enalapril is well absorbed after oral administration, but enalaprilat is not. Approximately 60% of an oral dose is bioavailable. Both enalapril and enalaprilat are distributed poorly into the CNS and are distributed into milk in trace amounts. Enalaprilat crosses the placenta. In humans, the half-life of enalaprilat is about 2 hours; enalaprilat about 11 hours. Half-lives are increased in patients with renal failure or severe CHF.

Contraindications/Precautions/Warnings
Enalaprilat is contraindicated in patients who have demonstrated hypersensitivity to the ACE inhibitors. It should be used with caution and close supervision in patients with renal insufficiency and doses may need to be reduced.

Enalaprilat should also be used with caution in patients with hyponatremia or sodium depletion, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE). Patients with severe CHF should be monitored very closely upon initiation of therapy.

Adverse Effects
Enalapril/enalaprilat’s adverse effect profile in dogs is principally GI distress (anorexia, vomiting, diarrhea). Potentially, weakness, hypotension, renal dysfunction and hyperkalemia could occur. Because it lacks a sulfhydryl group (unlike captopril), there is less likelihood that immune-mediated reactions will occur, but rashes, neutropenia, and agranulocytosis have been reported in humans. In humans, ACE inhibitors commonly cause coughs, but this occurs rarely in dogs or cats.

Adverse effects associated with enalapril in cats include lethargy and inappetence.

Reproductive/Nursing Safety
Enalapril crosses the placenta. High doses in rodents have caused decreased fetal weights and increases in fetal and maternal death rates; teratogenic effects have not been reported. In humans, the FDA categorizes this drug as category C for use during pregnancy in the first trimester (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In humans, the FDA categorizes this drug as category D for use during pregnancy in second and third trimesters (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) as ACE inhibitors may cause abnormal fetal and postnatal kidney development.

Enalapril/enalaprilat is excreted into milk. Safe use during nursing cannot be assumed.

Overdosage/Acute Toxicity
In dogs, a dose of 200 mg/kg was lethal, but 100 mg/kg was not. In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug’s long duration of action, prolonged monitoring and treatment may be required. Recent overdoses should be managed by using gut emptying protocols when warranted.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving enalaprilat and may be of significance in veterinary patients:

- **DIURETICS (e.g., furosemide, hydrochlorothiazide):** Potential for increased hypotensive effects; some veterinary clinicians recommend reducing furosemide doses (by 25-50%) when adding enalapril or benazepril to therapy in CHF.

- **ANTIDIABETIC AGENTS (insulin, oral agents):** Possible increased risk for hypoglycemia; enhanced monitoring recommended

- **Antihypertensives:** Potential for additive hypotensive effect

- **Antibiotics, particularly beta-lactams:** Potential for nephrotoxicity due to decreased glomerular filtration rate

- **CYP enzyme inhibitors:** Potential for increased blood levels of enalaprilat

- **CYP enzyme inducers:** Potential for decreased blood levels of enalaprilat

- **Anticoagulants, particularly heparin and warfarin:** Potential for increased anticoagulant effect

- **Antiviral agents, particularly zidovudine:** Potential for increased immunosuppression

- **ALCOHOL:** Potential for increased sedation

- **RAAS blockers:** Potential for additive hypotensive effect

- **Alcohol:*** Potential for increased sedation

- **Additional notes:** Enalaprilat is excreted primarily by the kidney. It should be used with caution in patients with renal disease. Prolonged monitoring and treatment may be required. Recent overdoses should be managed by using gut emptying protocols when warranted.
doses (by 25–50%) when adding enalapril or benazepril to therapy in CHF.

**DIURETICS, POTASSIUM-SPARING (e.g., spironolactone, triamterene):** Increased hyperkalemic effects, enhanced monitoring of serum potassium recommended.

**HYPOTENSIVE AGENTS, OTHER:** Potential for increased hypotensive effect

**LITHIUM:** Increased serum lithium levels possible; increased monitoring required

**NSAIDS:** May reduce the anti-hypertensive or positive hemodynamic effects of enalapril; may increase risk for reduced renal function, but clinical significance has not been demonstrated in dogs receiving enalapril and an NSAID.

**POTASSIUM SUPPLEMENTS:** Increased risk for hyperkalemia

**Laboratory Considerations**

When using iodohippurate sodium $^{123}$I/$^{131}$I or Technetium Tc $^{99}$m pententate renal imaging in patients with renal artery stenosis, ACE inhibitors may cause a reversible decrease in localization and excretion of these agents in the affected kidney which may lead to confusion in test interpretation.

**Doses**

**DOGS:**

a) As a vasodilator in heart failure: 0.5 mg/kg PO twice daily (Kittleson 2000)

b) For adjunctive treatment of heart failure: 0.5 mg/kg once daily initially with or without food. If response is inadequate increase to 0.5 mg/kg twice daily (Package Insert; Enacard®—Merial)

For adjunctive treatment of glomerular disease:

a) 0.5 mg/kg PO q12–24h (Grauer & DiBartola 2000)

b) 0.5 mg/kg PO once daily. If no reduction in proteinuria after 2–4 weeks, increase to twice daily. (Vaden 2003)

c) 0.25–1 mg/kg PO q12–24h. (Bartges 2009)

As an adjunctive treatment for ureteroliths:

a) 0.25–0.5 mg/kg PO q12–24h; may potentially reduce interstitial expansion and fibrosis. (Lulich 2006)

For systemic hypertension:

a) As a first step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after 1) enalapril/benazepril (0.5 mg/kg q12h); 2) amlodipine (0.1 mg/kg q24h); 3) amlodipine (0.2 mg/kg q24h); 4) spironolactone (1–2 mg/kg twice daily); 5) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

**CATS:**

For adjunctive treatment of heart failure due to hypertrophic cardiomyopathy:

a) 1.25–2.5 mg (total dose) PO once daily (q24h). (Kittleson 2009)

b) 0.25–0.5 mg/kg (roughly 1.25–2.5 mg per cat) PO once a day (q24h) (Meurs 2006)

c) 0.5 mg/kg PO once daily, twice daily if necessary (Ware & Keene 2000)

For proteinuria, hypertension in chronic kidney disease:

a) 0.25 mg/kg PO once daily to 0.5 mg/kg PO twice daily; rarely higher (Polzin 2006)

For systemic hypertension:

a) As a 2nd step drug when systolic BP >160 mmHg, diastolic >120 mmHg: 1) amlodipine (0.625 mg per cat q24h, if cat greater then 6 kg, 1.25 mg/cat q24h), add ACE inhibitor if proteinuric; 2) ACE inhibitor (benazepril/enalapril 0.5 mg/kg q12h); 3) spironolactone (1–2 mg/kg twice daily); 4) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

**FERRETS:**

For adjunctive therapy for heart failure:

a) 0.5 mg/kg PO once every other day (q48h) initially and may be increased to once a day if tolerated. Dissolve tablet(s) in distilled water and add a methylcellulose suspending agent (e.g., Ora-Plus® and cherry syrup for flavor. (Hoeffer 2000)

b) For dilative cardiomyopathy: 0.25–0.5 mg/kg PO once a day to every other day (Williams 2000)

**BIRDS:**

For adjunctive therapy for heart failure:

a) 1.25 mg/kg PO two to three times daily (Pees et al. 2006)

b) 0.25–0.5 mg/kg PO q24-48h with furosemide. (Oglesbee 2009)

**Monitoring**

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential, periodic
- Blood pressure (if treating hypertension or clinical signs associated with hypotension arise)

**Client Information**

- May be given with or without food
- Do not abruptly stop or reduce therapy without veterinarian’s approval
Chemistry/Synonyms
Angiotensin-converting enzyme (ACE) inhibitors, enalapril maleate and enalaprilat are structurally related to captopril. Enalapril is a prodrug and is converted in vivo by the liver to enalaprilat. Enalapril maleate occurs as a white to off white crystalline powder. 25 mg are soluble in one mL of water. Enalaprilat occurs as a white to off white crystalline powder and is slightly soluble in water.

Enalapril maleate may also be known as: enalapril maleus, and MK-421; many trade names are available. Enalaprilat may also be known as: enalaprilic acid, MK-422, Enacard®, Glotron®, Lotrilat®, Pres®, Renitec®, Reniten®, Vasotec®, and Xaneff®.

Storage/Stability
The commercially available tablets should be stored at temperatures less than 30°C in tight containers. When stored properly, the tablets have an expiration date of 30 months after manufacture.

Enalaprilat injection should be stored at temperatures less than 30°C. After dilution with D5W, normal saline, or D5 in lactated Ringer’s it is stable for up to 24 hours at room temperature.

Compatibility/Compounding Considerations
Enalapril has been documented to be physically incompatible with amphotericin B or phenytoin sodium. Many other medications have been noted to be compatible with enalaprilat at various concentrations. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Compound preparation stability: Enalapril oral suspension compounded from commercially available tablets has been published (Allen & Erickson 1998). Triturating six (6) enalapril 20 mg tablets with 60 mL of Ora-Plus® and as ad to 120 mL with Ora-Sweet® (or Ora-Sweet® SF) yields a 1 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Degradation of enalapril is pH dependent with maximum stability at pH 3 and increased decomposition above pH 5. Compounded preparations of enalapril should be protected from light.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
Enalapril Maleate Tablets: 1 mg, 2.5 mg, 5 mg, 10 mg & 20 mg; Enacard® (Merial); (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Enalapril Maleate Tablets: 2.5 mg, 5 mg, 10 mg & 20 mg; Vasotec® (Biovail); generic (Rx).
Enalaprilat Injection: (for IV use) equivalent to 1.25 mg/mL in 1 mL & 2 mL vials; generic; (Rx)

References

Enoxaparin Sodium
(en-oxa-par-in) Lovenox®
ANTICOAGULANT
Prescriber Highlights

- Low molecular weight (fractionated) heparin that may be useful for treatment or prophylaxis of thromboembolic disease
- Preferentially inhibits factor Xa & only minimally impacts thrombin & clotting time (TT or aPTT)
- Hemorrhage unlikely, but possible
- Must be given subcutaneously, potentially every 6 hours; fair amount of uncertainty about effective dosing requirements for dogs or cats
- Expense may be an issue, particularly in large dogs or horses

Uses/Indications
Enoxaparin may be useful for prophylaxis or treatment of deep vein thrombosis or pulmonary embolus. Recent pharmacokinetic work in dogs and cats, raises questions whether the drug can be effectively and practically administered long-term. In humans, it is also indicated for prevention of ischemic complications associated with unstable angina/non Q-wave MI.

Pharmacology/Actions

By binding to and accelerating antithrombin III, low molecular weight heparins (LMWHs) enhance the inhibition of factor Xa and thrombin. The potential advantage of using these products over standard (unfractionated) heparin is that they preferentially inhibit factor Xa; only minimally impacting thrombin and clotting times (TT or aPTT). Recent work in cats (Van De Wiele et al. 2010), has suggested that anti-Xa activity may not be an accurate determinant for predicting antithrombotic activity.

**Pharmacokinetics**

In dogs after SC administration, enoxaparin has a shorter duration of anti-Xa activity than in humans and probably must be dosed more frequently. A study examining enoxaparin dose response (anti-Xa activity) in dogs, showed that an enoxaparin dose of 0.8 mg/kg SC q6h would be required to effectively and consistently inhibit factor Xa activity in dogs (Lunsford, K.V. et al. 2009).

Cats appear to have a much shorter duration of activity (anti-Xa) associated with LMWHs than do humans and to maintain a therapeutic target of anti-XA activity of 0.5–1 IU/mL requires 1.5 mg/kg SC q6h dosing of enoxaparin (Alwood, A. et al. 2007). However, a recently published study (Van De Wiele et al. 2010) has suggested that anti-Xa activity may not be an accurate determinant for antithrombotic activity of enoxaparin in cats. In their venous stasis model, antithrombotic activity persisted well beyond the time after anti-Xa levels were below what are thought to be therapeutic.

After subcutaneous injection in humans, enoxaparin is absorbed rapidly, with a bioavailability of about 92%; peak plasma levels (activity) occur in 3–5 hours. Anti-factor Xa activity persists for up to 24 hours; doses are usually given once to twice a day. Enoxaparin is metabolized in the liver and excreted in the urine as both unchanged drug and metabolites; elimination half-life is about 4–5 hours.

**Contraindications/Precautions/Warnings**

Enoxaparin is contraindicated in patients who are hypersensitive to it, other LMWHs, heparin, or porcine products. Use enoxaparin cautiously in patients with significant renal dysfunction as drug accumulation could result.

Do not administer via IM or IV routes; enoxaparin must be given via deep subcutaneous injection only. Enoxaparin cannot be used interchangeably with other LMWHs or heparin sodium because the dosages differ for each.

**Adverse Effects**

In humans, adverse effects do not routinely occur; hemorrhage is a possibility and has been reported in up to 13% of patients in one study. Injection site hematoma, anemia, thrombocytopenia, nausea, and fever have also been reported.

**Reproductive/Nursing Safety**

In humans, enoxaparin is designated by the FDA as a category B drug. *Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*

**Overdosage/Acute Toxicity**

Overdosage may lead to hemorrhagic complications. If treatment is necessary, protamine sulfate may be administered via slow IV. One mg of protamine sulfate can inhibit the effects of one mg of enoxaparin.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving enoxaparin and may be of significance in veterinary patients:

- **ANTI-OAGULANTS, ORAL (warfarin):** Increased risk for hemorrhage
- **PLATELET-AGGREGATION INHIBITORS (aspirin, clopidogrel):** Increased risk for hemorrhage
- **THROMBOLYTIC AGENTS:** Increased risk for hemorrhage

**Laboratory Considerations**

- Low molecular weight heparins may cause asymptomatic, fully reversible increases in AST or ALT; bilirubin is only rarely increased in these patients. Therefore, interpret these tests with caution; increases do not necessarily indicate hepatic damage or dysfunction.

**Doses**

- **DOGS:**
  a) 0.8 mg/kg SC q6h appears to effectively and consistently maintain therapeutic levels of anti-Xa in normal dogs. (Lunsford, K. et al. 2005), (Lunsford, K.V. et al. 2009)
  b) 0.8–1 mg/kg SC q6-8h. (Alwood, A.J. 2008)

- **CATS:**
  a) From a study done in healthy cats: Doses of 1 mg/kg SC q12h results in a measurable antithrombotic effect. (Van De Wiele et al. 2010)
  b) Cats appear to have a much shorter duration of activity (anti-Xa) associated with LMWHs than do humans; to maintain a therapeutic target of anti-XA activity of 0.5–1 IU/mL requires 1.5 mg/kg SC q6h dosing of enoxaparin. Based on this research in healthy cats, current recommendations are to dose at 1.25 mg/kg SC q6h (Alwood, A. et al. 2007), (Alwood, A.J. 2008)

- **HORSES:**
  a) No published dosage recommendation at the time of writing. A study (Schwarzwald et al. 2002) investigating the pharmacokinetic variables of enoxaparin in horses demonstrated that the drug has similar activity (effect, duration) as in humans and the once daily SC injections may be useful for anticoagulant therapy.

**Monitoring**

- CBC (with platelet count); baseline and ongoing during therapy
- Urinalysis
- Stool occult blood test
- Routine coagulation tests (aPTT, PT) are usually insensitive measures of activity and usually not warranted
Routine coagulation tests (aPTT, PT) are usually insensitive measures of activity and usually not warranted. Factor Xa activity (available at Cornell Coagulation Laboratory) may be useful, particularly if bleeding occurs or patient has renal dysfunction.

Client Information
- If this drug is to be used on an outpatient basis, clients must be instructed in proper injection technique for subcutaneous injection. If not using the pre-filled syringes, use a very small gauge insulin or tuberculin syringe and needle (e.g., 27 g).
- Clients should immediately report any signs associated with bleeding or pulmonary thrombosis.
- Clients should understand that if they do not use the drug regularly (as prescribed), clots may form.

Chemistry/Synonyms
A low molecular weight heparin (LMWH), enoxaparin sodium is obtained by alkaline depolymerization of heparin derived from pork intestinal mucosa. The average molecular weight is about 4500 and ranges from 3500–5500 (heparin sodium has a molecular weight around 12000). 1 mg of enoxaparin is equivalent to 100 Units of anti-factor Xa.

Enoxaparin sodium may also be known as: Enoxaparinux natricum, PK-10169, RP-54563, Clexane®, Deciper®, Kleexane®, Lovenox®, Plaucina®, and Trombenox®.

Storage/Stability
The commercially available injection should be stored at room temperature (25°C, 77°F); excursions permitted to 15–30°C (59–86°F).

One study showed that diluting 100 mg/mL commercially available solution with sterile water to 20 mg/mL was stable for 4 weeks when stored in a glass vial or in plastic syringes at room temperature or refrigerated. (Dager et al. 2004)

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Enoxaparin Sodium for Injection: 30 mg/0.3 mL, 40 mg/0.4 mL, 60 mg/0.6 mL, 80 mg/0.8 mL, 100 mg/1 mL, 120 mg/0.8 mL, & 150 mg/1 mL preservative free in single-dose prefilled syringes; 300 mg/3 mL containing 15 mg/mL benzyl alcohol in 3 mL multidose vials; Lovenox® (Sanofi-Aventis); (Rx)

References

**ENROFLOXACIN**
(en-roe-fllox-a-sin) Baytril®
**FLUOROQUINOLONE ANTIBIOTIC**

Prescriber Highlights
- Veterinary oral & injectable fluoroquinolone antibiotic effective against a variety of pathogens; not effective against anaerobes
- In dogs, oral bioavailability is better than ciprofloxacin
- Relatively contraindicated for young, growing animals due to cartilage abnormalities
- FDA prohibits extra-label use in food animals
- Caution: Hepatic or renal insufficiency, dehydration
- Higher doses (>5 mg/kg/day) not recommended in cats; may cause blindness
- Adverse Effects: GI distress, CNS stimulation, crystalluria, or hypersensitivity; IV administration can potentially be very risky in small animals
- Administer PO (to dogs/cats) preferably on an empty stomach (unless vomiting occurs)
- Drug interactions
- Should not be used in humans (CNS effects)

Uses/Indications
Enrofloxacin is FDA-approved for use in dogs and cats (oral only) for the management of diseases associated with bacteria susceptible to enrofloxacin. Because of the dosage restriction (5 mg/kg) for cats, enrofloxacin is generally used in this species only for the most susceptible bacterial infections. It is also FDA-approved for use in cattle (not dairy cattle or veal calves), but extra-label use is prohibited.

Pharmacology/Actions
Enrofloxacin is a bactericidal agent. The bactericidal activity of enrofloxacin is concentration dependent, with susceptible bacteria cell death occurring within 20–30 minutes of exposure. Enrofloxacin has demonstrated a significant post-antibiotic effect for both gram-negative and -positive bacteria and is active in both stationary and growing bacterial cultures. It inhibits DNA gyrase and topoisomerase IV, which are responsible for replication and recombination of DNA. It is not a competitive inhibitor of mammalian DNA gyrase and topoisomerase IV. Enrofloxacin is rapidly absorbed after oral administration, and peak concentrations are reached within 1–2 hours. It is well distributed in most tissues, with tissue levels usually exceeding the MIC of susceptible bacteria. Enrofloxacin is primarily excreted unchanged in the urine, with a small fraction excreted in the feces. Its elimination half-life is approximately 4–6 hours in dogs and 9–12 hours in cats.
Both enrofloxacin and ciprofloxacin have similar spectrums of activity. These agents have good activity against many gram-negative bacilli and cocci, including most species and strains of *Pseudomonas aeruginosa*, *Klebsiella* spp., *E. coli*, Enterobacter, Campylobacter, Shigella, Salmonella, Aero monas, Haemophilus, Proteus, Yersinia, Serratia, and Vibrio species. Of the currently commercially available quinolones, ciprofloxacin and enrofloxacin have the lowest MIC values for the majority of these pathogens treated. Other organisms that are generally susceptible include *Brucella* spp., *Chlamydia trachomatis*, Staphylococci (including penicillinase-producing and methicillin-resistant strains), Mycoplasma, and *Mycoplasma* spp. (not the etiologic agent for John’s Disease).

The fluoroquinolones have variable activity against most streptococci and are not usually recommended for use in these infections. These drugs have weak activity against most anaerobes and are ineffective in treating anaerobic infections.

Bacterial resistance development is an ongoing concern, as many isolates of *Pseudomonas aeruginosa* are now resistant to enrofloxacin. Resistance occurs by mutation, particularly with *Pseudomonas aeruginosa*, *Klebsiella pneumonia*, Acinetobacter and enterococci, but plasmid-mediated resistance is not thought to commonly occur.

**Pharmacokinetics**

Enrofloxacin is well absorbed after oral administration in most species. In dogs, enrofloxacin’s bioavailability (approximately 80%) is about twice that of ciprofloxacin after oral dosing. Oral bioavailability in horses is between 60-80%. 50% of Cmax is reportedly attained within 15 minutes of dosing and peak levels (Cmax) occur within one hour of dosing. The presence of food in the stomach may delay the rate, but not the extent of absorption. In sheep, enrofloxacin administered orally is about 65–75% bioavailable.

Enrofloxacin is distributed throughout the body. Volume of distribution in dogs is approximately 3–4 L/kg. Only about 27% is bound to canine plasma proteins. Highest concentrations are found in the bile, kidney, liver, lungs, and reproductive system (including prostatic fluid and tissue). Enrofloxacin reportedly concentrates in macrophages. Therapeutic levels are also attained in bone, synovial fluid, skin, muscle, aqueous humor and pleural fluid. In hospitalized horses, volume of distribution was about 1.25 L/kg. After mechanical disruption of the blood-aqueous humor barrier (BAAB) in horses, 7.5 mg/kg IV produced levels in the aqueous humor sufficient to treat *Leptospira pomona* (Diers et al. 2008). Low concentrations are found in the CSF; levels may only reach 6–10% of those found in the serum. In cattle, the volume of distribution is about 1.5 L/kg and in sheep, 0.4 L/kg.

Enrofloxacin is eliminated via both renal and non-renal mechanisms. Approximately 15–50% of the drug is eliminated unchanged into the urine, by both tubular secretion and glomerular filtration. Enrofloxacin is metabolized to various metabolites, most of which are less active than the parent compounds. Approximately 10–40% of circulating enrofloxacin is metabolized to ciprofloxacin in most species including humans, dogs, cats, adult horses, cattle, turtles, and snakes. Foals, pigs, and some lizards apparently do not convert much enrofloxacin, if any, to ciprofloxacin. These metabolites are eliminated both in the urine and feces. Because of the dual (renal and hepatic) means of elimination, patients with severely impaired renal function may have slightly prolonged half-lives and higher serum levels that may not require dosage adjustment. The approximate elimination half-lives in various species are: dogs 4–5 hours; cats 6 hours; sheep 1.5–4.5 hours; horses 5-10 hours, turtles 18 hours; and alligators 55 hours.

**Contraindications/Precautions/Warnings**

Enrofloxacin is labeled as contraindicated in small and medium breed dogs from 2 to 8 months of age. Bubble-like changes in articular cartilage have been noted when the drug was given at 2–5 times recommend doses for 30 days, although clinical signs have only been seen at the 5X dose. To avoid cartilage damage, large and giant breed dogs may need to wait longer than the recommended 8 months before treatment since they may be in the rapid-growth phase past 8 months of age. Quinolones are contraindicated in patients hypersensitive to them.

Because ciprofloxacin has occasionally been reported to cause crystalluria in humans, animals should not be allowed to become dehydrated during therapy with either ciprofloxacin or enrofloxacin. Enrofloxacin may cause CNS stimulation and should be used with caution in patients with seizure disorders. Patients with severe renal or hepatic impairment may require dosage adjustments to prevent drug accumulation.

Use of the canine or bovine injectable products in cats or administered to dogs via other non-FDA-approved parenteral routes (IV, SC) is controversial and may result in significant adverse effects. Parenteral administration in cats at doses less than 5 mg/kg have reportedly caused ophthalmic toxicity (blindness). Because of the high pH (approx. 11) of the solution, subcutaneous administration in any species may cause pain and tissue damage. If administered rapidly or undiluted IV to dogs, there is an increased risk for cardiac arrhythmias, hypotension, vomiting, and mast cell degranulation (histamine and other mediator release).

The extra-label use in dogs of the IM 22.7 mg/mL (2.27%) product diluted 1:1 to 1:10 with sodium chloride 0.9% for slow IV administration (over at least 10 minutes; some give over 30–45 minutes) has anecdotally been described. However, the rapid absorption of enrofloxacin after IM administration in dogs (peak levels in about 30 minutes) questions the necessity of using this non-approved route (IV) of administration. Injectable enrofloxacin must not be mixed with, or come into contact with any IV solution containing magnesium (e.g., *Normosol-R*, *Plasmalyte-R*, -A, or –56); morbidity and mortality secondary to micro-precipitants lodging in patient lungs have been reported. Dilution and extra-label use in small animals of the large animal product (100 mg/mL; 10%) via any route is discouraged.

Do not use in foals as they appear to be highly susceptible to the fluoroquinolone’s arthropathic effects. Do not give rapidly IV to horses as ataxia and other neurologic effects may occur. IM injections are not recommended in horses as localized tissue reactions can occur.

Extra-label use of fluoroquinolones is prohibited in animals to be used for food.

Enrofloxacin should not be used by humans; it may cause hallucinations, vivid dreams, and headache.

**Adverse Effects**

With the exception of potential cartilage abnormalities in young animals (see Contraindications above), the adverse effect profile of enrofloxacin is usually limited to GI distress (vomiting, anorexia). In dogs, rare incidences of elevated hepatic enzymes, ataxia, seizures, depression, lethargy, and nervousness have also been reported. Hypersensitivity reactions or crystalluria could potentially occur.

In cats, rare incidences of ocular toxicity have been reported characterized by mydriasis, retinal degeneration, and blindness. These effects were generally seen at higher dosage ranges (>15 mg/kg) and have necessitated a reduction in dosage recommendations in cats to a maximum of 5 mg/kg/day. Other rare adverse effects seen in cats may include: vomiting, anorexia, elevated hepatic enzymes, diarrhea, ataxia, seizures, depression/lethargy, vocalization, and aggression.

While enrofloxacin has been implicated in causing antibiotic-associated diarrhea/enterocolitis in horses, due its poor activity against anaerobes, oral or parenterally administered enrofloxacin appears to carry a low risk of causing antibiotic-associated diarrhea.

**Reproductive/Nursing Safety**

The safety of enrofloxacin in pregnant dogs has been investigated. Breeding, pregnant, and lactating dogs receiving up to 15 mg/kg day demonstrated no treatment related effects. However, because of the risks of cartilage abnormalities in young animals, the fluoroquinolones are not generally recommended for use during pregnancy unless the benefits of therapy clearly outweigh the risks. Limited studies in male dogs at various dosages have indicated no effects on male breeding performance.

Safeguards in breeder, pregnant, or lactating cats has not been established.

**Use**

Enrofloxacin is distributed by various animal health companies and is available in many species and formulations including injectable (IV, IM), oral, and topical preparations. It is used for the treatment of a wide variety of bacterial infections in both dogs and cats.
Doses

Laboratory Considerations

Drug Interactions

Overdosage/Acute Toxicity

Drugs Interactions

Veterinary patients:
The following drug interactions have either been reported or are theoretical in humans or animals receiving ciprofloxacin or enrofloxacin and may be of significance in veterinary patients:

- **Antacids/Dairy Products:** Containing cations (Mg++, Al++, Ca++) may bind to enrofloxacin and prevent its absorption; separate doses of these products by at least 2 hours.
- **Antibiotics, Other (aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum):** Synergy may occur, but is not predictable against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although enrofloxacin/ciprofloxacin has minimal activity against anaerobes, *in vitro* synergy has been reported when used with *clindamycin* against strains of *Peptostreptococcus*, *Lactobacillus* and *Bacteroides fragilis*.
- **Cyclosporine:** Fluoroquinolones may exacerbate the nephrotoxicity and reduce the metabolism of cyclosporine (used systemically).
- **Flunixin:** Has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown if other NSAIDs interact with enrofloxacin in dogs.
- **Glyburide:** Severe hypoglycemia possible.
- **Iron, Zinc (oral):** Decreased enrofloxacin/ciprofloxacin absorption; separate doses by at least 2 hours.
- **Methotrexate:** Increased MTX levels possible with resultant toxicity.
- **Nitrofurantoin:** May antagonize the antimicrobial activity of the fluoroquinolones and their concomitant use is not recommended.
- **Phenytoin:** Enrofloxacin/ciprofloxacin may alter phenytin levels.
- **Probenecid:** Blocks tubular secretion of ciprofloxacin and may increase its blood level and half-life.
- **Quinidine:** Increased risk for cardiotoxicity.
- **Sucralfate:** May inhibit absorption of enrofloxacin; separate doses of these drugs by at least 2 hours.
- **Theophylline:** Enrofloxacin/ciprofloxacin may increase theophylline blood levels; in dogs theophylline levels may be increased by about 30-50% (Trepanier 2008).
- **Warfarin:** Potential for increased warfarin effects.

Doses

**DOGS:**

For susceptible infections:

- a) 5–20 mg/kg per day PO, may be given once daily or divided and given twice daily (q12h). Treatment should continue for at least 2–3 days beyond cessation of clinical signs, to a maximum duration of therapy is 30 days. (Package insert; Baytril®—Bayer)
- b) For sepsis: 5–20 mg/kg IV q12h (Hardie 2000)
- c) For skin, urinary infections: 2.5–5 mg/kg PO q12h for 7–14 days;
  
  - For deep pyoderma, complicated urinary infections: 5 mg/kg PO once daily (q24h) for 7–14 days (treatment may be required for 10–12 weeks for deep pyoderma, especially in German shepherds);
  - For lower respiratory tract infections: 5–10 mg/kg PO once daily (q24h) for 7–84 days;
  - For prostate infections: 5 mg/kg PO twice daily (q12h) for 7–14 days;
  - For histiocytic ulcerative colitis: 5 mg/kg PO twice daily (q12h) for 21–90 days;
  - For hemotropic mycoplasmosis: 5 mg/kg PO, IM q12h for 7–14 days;
  - For systemic orthopedic infections: 5–11 mg/kg PO, IV, IM, SC q12h for 10 days;
  - For *Pseudomonas* infections in soft tissues: 11–20 mg/kg PO, IM, SC q12h for 7 days minimum, treat as long as necessary;
  - For bacteremia, sepsis: 11 mg/kg PO, IV, IM, SC q12h for as long as necessary (Greene et al. 2006)
- d) For histiocytic ulcerative colitis: 5–10 mg/kg PO once daily for at least 4–6 weeks. (Burgener 2010)

**CATS:**

b) For hemoplasmosis: 5–10 mg/kg PO q24h for 14 days. (Dowers 2009)

**HORSES:**

Note: Usage of enrofloxacin in horses remains somewhat controversial. While there has been much discussion regarding the potential for cartilage abnormalities or other arthropathies in horses, objective data are lacking. At present, however, enrofloxacin probably should only be used in adult horses when other antibiotics are inappropriate. If using Baytril® injection orally in horses, it can be very irritating to the mouth. This may be alleviated by coating the liquid with molasses or preparing a gel (see Compounding Considerations below) and rinsing the horse’s mouth with water after administration.

a) 5 mg/kg IV q24h; 5–7.5 mg/kg PO q24h. (Haggett & Wilson 2008)
b) 7.5 mg/kg PO or IV once daily for susceptible respiratory infections (Ainsworth & Hackett 2004)
c) Using the compounded gel as described below (Compatibility/Compounding Considerations): 7.5 mg/kg PO once daily. Horses should be fasted for 11–14 hours prior to dosing and for 1–2 hours after dosing, but should have access to water. Rinse horse’s mouth with water after dosing to reduce risks for oral ulceration. (Epstein *et al.* 2004)

**CATTLE:**
a) Enrofloxacin (Baytril® 100) is FDA-approved for the treatment of bovine respiratory disease associated with *Pasteurella haemolytica*, *Pasteurella multocida*, and *Haemophilus somnus*. It is administered by injection and is intended for the treatment of individual animals. The labeled dosage is: 2.5–5 mg/kg SC once daily for 3–5 days or 7.5–12.5 mg/kg SC once. The product is prescription only and is not for use in cattle intended for dairy production or in veal calves. Animals intended for human consumption must not be slaughtered within 28 days from the last treatment. Extralabel use of fluoroquinolones in food animals is prohibited by the FDA.

**FERRETS:**

For susceptible infections:
a) 10–20 mg/kg PO, IM, SC twice daily (Williams 2000)

**RABBITS/RODENTS/SMALL MAMMALS:**
a) For Pasteurella upper respiratory infections in rabbits: 15–20 mg/kg PO twice daily for a minimum of 14 days in mild cases and up to several months for chronic infections; first dose may be made by SC injection (do NOT give subsequent doses SC or severe tissue reactions can occur). (Antinoff 2008)
b) Rabbits: 5 mg/kg PO, SC, IM or IV q12h for 14 days. Drug of choice for Pasteurella. If giving SC, dilute or skin may slough. Do not give injectable product PO because it is very unpalatable (Ivey & Morrissey 2000)
c) Hedgehogs: 5–10 mg/kg PO or SC q12h (Smith 2000)
d) Chinchillas: 5–10 mg/kg PO, IM q12h (Hayes 2000)
e) For mycoplasmal pneumonia in mice and rats: 10 mg/kg PO twice daily with doxycycline (5 mg/kg PO twice daily) (Burke 1999)
f) Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 5–10 mg/kg PO or IM q12h or 5–20 mg/kg PO or SC q24h. In drinking water: 50–200 mg/liter for 14 days. Do not use in young animals. (Adamcak & Otten 2000)
g) Chronic respiratory disease in rats: 10–25 mg/kg PO twice daily. If using theophylline concurrently, reduce theophylline dose by 30%. (Monks & Cowan 2009)

**CAMELIDS:**

For susceptible infections in alpacas:
a) 5 mg/kg SC or 10 mg/kg PO once daily (Gandolf *et al.* 2005)

**BIRDS:**

For susceptible gram-negative infections:
a) For empirical treatment in Psittacines. For stable, immunocompetent birds: 20 mg/kg PO once daily with amoxicillin/clavulanate (125 mg/kg PO three times daily). For debilitated immunocompetent birds: 15–20 mg/kg SC in fluid pocket once daily. For debilitated, immunocompromised birds: 15–20 mg/kg SC in fluid pocket twice daily. When used orally, compounding the liver-flavored tablets grape syrup (Syrpalt@; Humco Labs) may improve acceptance. (Flammer 2006)
b) Ratites: 1.5–2.5 mg/kg PO or SC twice daily. Drinking water: 10% solution, 10 mg/kg for 3 days; 5 mg/kg IM (IM injections cause severe muscle necrosis) twice daily for 2 days (Jenson 1998)

**REPTILES:**

For susceptible respiratory infections for most species:
a) 5 mg/kg IM every 5 days for 25 days; For chronic respiratory infections in tortoises: 15 mg/kg IM every 72 hours for 5–7 treatments (Gauvin 1993)

**Monitoring**

- Clinical efficacy
- Adverse effects
- In cats, monitor for mydriasis and/or retinal changes.

**Client Information**

- Do not crush film-coated tablets, as drug is very bitter tasting
- Animals should have access to water at all times
- Do not exceed dosage recommendations in cats; blindness can occur

**Chemistry/Synonyms**

- A fluoroquinolone antibiotic, enrofloxacin occurs as a pale yellow, crystalline powder. It is slightly soluble in water. Enrofloxacin is related structurally to the human-
A fluoroquinolone antibiotic, enrofloxacin occurs as a pale yellow, crystalline powder. It is slightly soluble in water. Enrofloxacin is related structurally to the human-FDA-approved drug ciprofloxacin (enrofloxacin has an additional ethyl group on the piperazinyl ring).

Enrofloxacin may also be known as: Bay-Vp-2674 or Baytril®.

Storage/Stability

Unless otherwise directed by the manufacturer, enrofloxacin tablets should be stored in tight containers at temperatures less than 30°C. Protect from strong UV light.

Enrofloxacin has been reported to be soluble and stable in water, but solubility is pH dependent and altering the pH of the commercially available injections can cause precipitation.

The canine FDA-approved product (2.27%) for IM injection should be stored protected from light; do not freeze.

The cattle FDA-approved product (10%) injectable solution should be stored protected from sunlight. It should not be refrigerated, frozen or stored above 40°C (104°F). If exposed to cold temperatures, precipitation may occur; to redissolve, warm and then shake the vial.

Injectable enrofloxacin must not be mixed with, or come into contact with any IV solution containing magnesium (e.g., Normosol-R, Plasmalyte-R, -A, or -56); morbidity and mortality secondary to micro-puncturists lodging in patient lungs have been reported.

Compatibility/Compounding Considerations

For horses an oral gel formulated from the bovine injectable product has been described (Epstein et al. 2004). 100 mL of the 100 mg/mL bovine injection (Baytril®/100) is used. Stevia (0.35 g) is mixed with approximately 15 mL of liquid enrofloxacin until dissolved. Apple flavoring 0.6 mL is added until dissolved. Sodium carboxymethylcellulose (2 g) is sprinkled over the mixture and stirred until incorporated. Immediately begin gradually adding the remaining enrofloxacin (85 mL) before the mixture solidifies. Approximate concentration is 100 mg/mL. Stable for up to 84 days if kept in the refrigerator and protected from light.

Enrofloxacin Injection: 22.7 mg/mL (2.27%) in 20 mL vials; Baytril® (Bayer); (Rx)

A fluoroquinolone antibiotic, enrofloxacin occurs as a pale yellow, crystalline powder. It is slightly soluble in water. Enrofloxacin is related structurally to the human-FDA-approved drug ciprofloxacin (enrofloxacin has an additional ethyl group on the piperazinyl ring).

Excreted into milk, may affect neonates

Adverse Effects: CNS stimulation, tachycardia, hypertension, or anorexia

Contraindications: Severe CV disease, especially with arrhythmias

Caution: Patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders or hypertension

Adverse Effects: CNS stimulation, tachycardia, hypertension, or anorexia

Excreted into milk, may affect neonates

References

**Uses/Indications**

Ephedrine is used chiefly for the treatment of urethral sphincter hypotonus and resulting incontinence in dogs and cats. It has also been used in an attempt to treat nasal congestion and/or bronchoconstriction in small animals. It can also be used parenterally as a pressor agent in the treatment of shock or anesthesia-associated hypotension.

**Pharmacology/Actions**

While the exact mechanism of ephedrine’s actions are undetermined, it is believed that it indirectly stimulates both alpha-, beta1-, beta2-adrenergic receptors by causing the release of norepinephrine. Prolonged use or excessive dosing frequency can deplete norepinephrine from its storage sites and tachyphylaxis (decreased response) may ensue. Tachyphylaxis has not been documented in dogs or cats, however, when used for urethral sphincter hypotonus.

Pharmacologic effects of ephedrine include: increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased bronchoconstriction, nasal congestion and appetite. Ephedrine can also increase urethral sphincter tone and produce closure of the bladder neck; its principle veterinary indications are as a result of these effects.

**Pharmacokinetics**

Ephedrine is rapidly absorbed after oral or parenteral administration. Although not confirmed, ephedrine is thought to cross both the blood-brain barrier and the placenta. Ephedrine is metabolized in the liver and excreted unchanged in the urine. Urine pH may significantly alter excretion characteristics. In humans: at urine pH of 5, half-life is about 3 hours; at urine pH of 6.3, half-life is about 6 hours.

**Contraindications/Precautions/Warnings**

Ephedrine is contraindicated in patients with severe cardiovascular disease, particularly with arrhythmias. Ephedrine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders or hypertension.

When administered IV, administration rate should not exceed 10 mg/minute (in humans); it is suggested to scale the rate for veterinary patients.

**Adverse Effects**

Most likely side effects include restlessness, irritability, tachycardia, or hypertension. Anorexia may be a problem in some animals.

Tachyphylaxis (decreased response to subsequent doses) secondary to depleted stores of endogenous norepinephrine can occur with repeated doses.

**Reproductive/Nursing Safety**

Ephedrine’s effects on fertility, pregnancy or fetal safety are not known. Use with caution during pregnancy. The drug is excreted in milk and may have deleterious effects on nursing animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Ephedrine is excreted in milk. If ephedrine is absolutely necessary for the dam, consider using milk replacer.

**Overdosage/Acute Toxicity**

Clinical signs of overdosage may consist of an exacerbation of the adverse effects listed above or, if a very large overdose, severe cardiovascular (hypertension to rebound hypotension, bradycardias to tachycardias, and cardiovascular collapse) or CNS effects (stimulation to coma) can be seen.

If the overdose was recent, empty the stomach using the usual precautions and administer charcoal and a cathartic. Treat clinical signs supportively as they occur.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving ephedrine and may be of significance in veterinary patients:

- **ACEPROMAZINE** (and other PHENOThIAZINES): Phenothiazines block alpha-adrenergic receptors; concomitant epinephrine or ephedrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate.

- **ALPHA-BLOCKERS** (e.g., phentolamine, prazosin): May negate the therapeutic effects of ephedrine

- **ANESTHETICS, GENERAL**: An increased risk of arrhythmias developing can occur if ephedrine is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.

- **BETA-BLOCKERS**: Concomitant use of ephedrine with beta-blockers may diminish the effects of both drugs

- **DIGOXIN**: An increased risk of arrhythmias may occur if ephedrine is used concurrently with digitalis glycosides.

- **MONAMINE OXIDASE INHIBITORS** (including amitraz): Ephedrine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors; severe hypertension, hyperpyrexia possible

- **SYMPATHOMIMETIC AGENTS, OTHER**: Ephedrine should not be administered with other sympathomimetic agents (e.g., phenylpropanolamine) as increased toxicity may result

- **RESERPINE**: May reverse the pressor effects of ephedrine

- **THEOPHYLLINE**: Ephedrine may increase the risk for theophylline toxicity

- **TRICYCLIC ANTIDEPRESSANTS**: May decrease the pressor effects of ephedrine

- **URINARY ALKALINIZERS** (e.g., sodium bicarbonate, citrates, carbonic anhydrase inhibitors): May reduce the urinary excretion of ephedrine and prolong its duration of activity. Dosage adjustments may be required to avoid toxic clinical signs.

**Laboratory Considerations**

- Beta-adrenergic agonists may decrease serum potassium concentrations. Clinical relevance is unknown.

**Doses**

**DOGS:**
For treatment of bronchospasm:
- For maintenance therapy: 1–2 mg/kg PO q8–12h (McKiernan 1992)
- 2 mg/kg PO q8–12h (Bonagura 1994)

For treatment of urinary incontinence responsive to adrenergic drugs:
- 5–15 mg (total dose) PO q8h (Labato 1994)
- 1.2 mg/kg PO q6–12h or 5–15 mg (total dose) PO q8h (Bartges 2003)

For treatment of hypotension associated with anesthesia:
- 0.03–0.1 mg/kg IV bolus. Dilute 5 mg in 10 mL of saline and give the lower dosage first as sinus tachycardia may accompany the higher dose. May repeat in 5 minutes after first dose if hypotension does not improve. (Pablo 2003)
- 0.1–0.25 mg/kg IV bolus (Mazzaferro 2005)
- For relatively short procedures in ASA I or II patients when hypotension is not responsive to 1 or 2 crystalloid boluses: 0.1–0.2 mg/kg IV bolus; duration of action is approximately 15-60 minutes after a single bolus. (Teixereia Neto 2009)
- Can give 0.15–0.25 mg/kg diluted into 5 mL of a balanced electrolyte solution or saline and give small increment IV boluses until desirable blood pressure achieved. Can also give as a CRI at 5–10 micrograms/kg/minute. (Ko 2009)

**CATS:**

For treatment of bronchospasm:
- For emergency treatment 2–5 mg PO (McKiernan 1992)

For treatment of urinary incontinence responsive to adrenergic drugs:
- 2–4 mg (total dose) PO q8h (Labato 1994)
- 2–4 mg/kg PO q6–12h or 2–4 mg (total dose) PO q8h (Bartges 2003)
- 2–4 mg per cat PO q8–12h (Polzin 2005)

For treatment of hypotension associated with anesthesia:
- Can give 0.15–0.25 mg/kg diluted into 5 mL of a balanced electrolyte solution or saline and give small increment IV boluses until desirable blood pressure achieved. Can also give as a CRI at 5–10 micrograms/kg/minute. (Ko 2009)

**Monitoring**

- Clinical effectiveness
- Adverse effects (see above)

**Client Information**

In order for this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.

Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

**Chemistry/Synonyms**

A sympathomimetic alkaloid, ephedrine sulfate occurs as fine, odorless, white crystals or powder. Approximately 770 mg are soluble in one mL of water. The commercially available injection has a pH of 4.5–7.

Ephedrine sulfate may also be known as ephedrine sulphate.

**Storage/Stability**

Store ephedrine sulfate products in tight, light resistant containers at room temperature unless otherwise directed.

When used parenterally, ephedrine sulfate is usually administered directly and not diluted.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
- Ephedrine Sulfate Capsules: 25 mg; generic (West-Ward); (OTC)
- Ephedrine Sulfate Injection: 50 mg/mL in 1 mL single-dose vials & preservative free in 1 mL single-dose amps; generic; (Rx)

In the USA, ephedrine sulfate is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

**References**

Uses/Indications
Epinephrine is employed primarily in veterinary medicine as a treatment for anaphylaxis or cardiac resuscitation. Because of its vasoconstrictive properties, epinephrine is added to local anesthetics to retard systemic absorption and prolong effect.

Pharmacology/Actions
Epinephrine is an endogenous adrenergic agent that has both alpha and beta activity. It relaxes smooth muscle in the bronchi and the iris, antagonizes the effects of histamine, increases glycogenolysis, and raises blood sugar. If given by rapid IV injection it causes direct stimulation of the heart (increased heart rate and contractility), and increases systolic blood pressure. If given slowly IV, it usually produces a modest rise in systolic pressure and a decrease in diastolic blood pressure. Total peripheral resistance is decreased because of beta effects.

Pharmacokinetics
Epinephrine is well-absorbed following IM or SC administration. IM injections are slightly faster absorbed than SC administration; absorption can be expedited by massaging the injection site. Epinephrine is rapidly metabolized in the GI tract and liver after oral administration and is not effective via this route. Following SC injection, the onset of action is generally within 5–10 minutes. The onset of action following IV administration is immediate and intensified.

Contraindications/Precautions/Warnings
Epinephrine is contraindicated in patients with narrow-angle glaucoma, hypersensitivity to epinephrine, shock due to non-anaphylactoid causes, during general anesthesia with halogenated hydrocarbons, during labor (may delay the second stage), cardiac dilatation or coronary insufficiency; cases where vasopressor drugs are contraindicated (e.g., thyrotoxicosis, diabetes, hypertension, toxemia of pregnancy). Epinephrine should also not be used in cases where vasopressor drugs are contraindicated (e.g., thyrotoxicosis, diabetes, hypertension, toxemia of pregnancy). It should not be injected with local anesthetics into small appendages of the body (e.g., toes, ears, etc.) because of the chance of necrosis and sloughing.

Use extreme caution patients with a prefibrillatory cardiac rhythm
Caution: Hypovolemia (not a substitute for adequate volume replacement)
Do not inject with local anesthetics into small appendages of the body (e.g., toes, ears, etc.); may cause necrosis/sloughing
Adverse Effects: Anxiety, tremor, excitability, vomiting, hypertension (overdosage), arrhythmias, hyperuricemia, & lactic acidosis (prolonged use or overdosage)
Concentrations must not be confused
Drug interactions
Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving epinephrine and may be of significance in veterinary patients:

**ALPHA-BLOCKERS** (*e.g.*, phentolamine, phenoxybenzamine, prazosin): May negate the therapeutic effects of epinephrine

**ALPHA-2 AGONISTS** (*e.g.*, detomidine, dexmedetomidine, medetomidine, xylazine): As epinephrine possesses alpha agonist effects, do NOT use to treat cardiac effects caused by alpha2 agonists

**ANESTHETICS, GENERAL:** An increased risk of arrhythmias developing can occur if epinephrine is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.

**ANTIHISTAMINES:** Certain antihistamines (*diphenhydramine, chlorpheniramine, etc.*) may potentiate the effects of epinephrine

**BETA-BLOCKERS:** Propranolol (or other beta-blockers) may potentiate hypertension, and antagonize epinephrine’s cardiac and bronchodilating effects by blocking the beta effects of epinephrine

**DIGOXIN:** An increased risk of arrhythmias may occur if epinephrine is used concurrently with digitalis glycosides

**NITRATES:** May reverse the pressor effects of epinephrine

**LEVOTHYROXINE:** May potentiate the effects of epinephrine

**OXYTOCIC AGENTS:** Hypertension may result if epinephrine is used with oxytocic agents

**SYMPATHOMIMETIC AGENTS, OTHER:** Epinephrine should not be administered with other sympathomimetic agents (*e.g.*, isoproterenol) as increased toxicity may result

**PHENOTHIAZINES:** May reverse the pressor effects of epinephrine

**RESERPINE:** May potentiate the pressor effects of epinephrine

**TRICYCLIC ANTIDEPRESSANTS:** May potentiate the effects of epinephrine

### Doses

**Note:** Be certain when preparing injection that you do not confuse 1:1000 (1 mg/mL) with 1:10,000 (0.1 mg/mL) concentrations. To convert a 1:1000 solution to a 1:10,000 solution for IV or intratracheal use, dilute each mL with 9 mL of normal saline for injection. Epinephrine is only one aspect of treating cardiac arrest; refer to specialized references or protocols for more information.

**DOGS:**

Cardiac resuscitation (asystole):

a) Using the epinephrine first protocol: After the “ABC’s” (airway, breathing, compressions) give epinephrine 0.01 mg/kg IV, continue ABCs for 3–5 minutes. If no response (return to spontaneous circulation; ROSC), vasopressin at 0.2–0.8 Units/kg IV, continue ABC’s for 3–5 minutes. If no ROSC, epinephrine 0.01 mg/kg IV, continue ABC’s for 3–5 minutes.

   Using the vasopressin first protocol: After the “ABC’s” (airway, breathing, compressions) give vasopressin 0.2–0.8 Units/kg IV, continue ABCs for 3–5 minutes. If no response (return to spontaneous circulation; ROSC), epinephrine 0.01 mg/kg IV, continue ABC’s for 3–5 minutes. If no ROSC, repeat epinephrine 0.01 mg/kg IV, continue ABC’s for 3–5 minutes.

   For either protocol, the authors suggest trying atropine 0.04 mg/kg IV and/or naloxone 0.02–0.04 mg/kg IV. (Scroggin & Quandt 2009)

b) Both high dose (0.1–0.2 mg/kg) and low dose (0.01–0.02 mg/kg) IV or IO epinephrine have been advocated. In human medicine, generally the low dose is attempted first and if no response go to the high dose. In veterinary medicine (at present), either dose seems acceptable. Doses may be repeated at 3–5 minute intervals if there is no response. (Drobatz 2004)

c) 0.01–0.02 mg/kg IV every 3–5 minutes or 0.03–0.1 mg/kg IT (dilute in 5–10 mL of sterile water or normal saline). (Lopez Quintana 2009)

d) Neonates, when respiratory support and chest compression fails to elicit a heartbeat: Epinephrine at 0.1–0.3 mg/kg IV or IO. (Traas 2009)

For anaphylaxis:

a) 0.01–0.02 mg/kg IV; or the dosage may be doubled and given via the endotracheal tube if IV line is not yet established. In less severe cases, may be given IM or SC (Cohen 1995)

b) 0.2–0.5 mg (total dose) SC or IM (Wohl 2005)

c) For bronchoconstriction: 20 micrograms/kg (0.02 mg/kg) IV, IM, SC, or IT (Johnson 2000)

For treatment of hypotension associated with anesthesia:

a) As a last line of defense: 1–10 micrograms/kg/minute CRI. (Ko 2009)

b) 0.05–0.4 micrograms/kg/minute IV (Dodam 2005), (Mazzaferro 2005)

**CATS:**

For cardiopulmonary-cerebral resuscitation:

a) See the Dog dose (Scroggin & Quandt 2009) above.

b) Neonates, when respiratory support and chest compression fails to elicit a heartbeat: Epinephrine at 0.1–0.3 mg/kg IV or IO. (Traas 2009)

For bronchoconstriction/anaphylaxis:

a) 0.01–0.02 mg/kg IV; or the dosage may be doubled and given via the endotracheal tube if IV line is not yet established. In less severe cases, may be given IM or SC. (Cohen 1995)

b) 20 micrograms/kg (0.02 mg/kg) IV, IM, SC, or IT (Johnson 2000)

**BIRDS:**

a) 0.1 mg/kg IV or intracardiac (Harris 2003)

**HORSES:**

Note: ARCI UCGFS Class 2 Drug
Epinephrine bitartrate is available as a powder form (aerosol) for inhalation, topical solution and a solution for nebulization; ophthalmic preparations are available.

**Epinephrine HCl Solution for Injection:**
- **1:10,000 (0.1 mg/mL as hydrochloride & may contain sulfites in 10 mL syringes & vials; generic; (Rx)**
- **1:2,000 (0.15 mg/0.3 mL) with sodium metabisulfite in 0.3 mL single dose auto-injectors;**
- **1:1,000 (0.15 mg/0.15 mL) in dual-dose auto-injectors with chlorobutanol & sodium bisulfite;**
- **1:1,000 (0.3 mg/0.3 mL); in prefilled single-dose syringes (may contain sodium metabisulfite); 0.3 mL single-dose auto-injectors with sodium metabisulfite;**
- **1 mg/mL (1:1,000) in 1 mL amps & 30 mL vials (may contain sulfites); & 30 mL (with chlorobutanol & sodium bisulfite) vials;**
- **Adrenalin Chloride® (JHP); generic; (Abbott); (Rx)**
- **EpiPen® (Dey); (Rx)**

HORSES: (Note: ARCI UCGFS Class 2 Drug)

For anaphylaxis:
- a) 3–5 mL of 1:1,000 per 450 kg of body weight either IM or SC; For foal resuscitation: 0.1 mL/kg of 1:1,000 IV (preferably diluted with saline) (Robinson 1987)

For cardiopulmonary resuscitation of newborn foals:
- a) 0.01–0.02 mg/kg (0.5–1 mL of a 1:1000 solution for a 50 kg foal) IV every 3 minutes until return of spontaneous circulation. If given intratracheally (IT), dose is 0.1–0.2 mL/kg. (Corley 2003)

Ruminants, Swine:

For treatment of anaphylaxis:
- a) 0.5–1 mL/100 lbs. body weight of 1:1,000 SC or IM; dilute to 1:10,000 if using IV; may be repeated at 15 minute intervals Often used in conjunction with corticosteroids and diphenhydramine (Clark 1986)

**Monitoring**
- Cardiac rate/rhythm
- Respiratory rate/auscultation during anaphylaxis
- Urine flow, if possible
- Blood pressure and blood gases, if indicated and possible

**Client Information**

- Pre-loaded syringes containing an appropriate amount of epinephrine may be dispensed to clients for treatment of anaphylaxis in animals with known hypersensitivity.
- Anaphylactic clinical signs (depending on species) should be discussed.
- Clients should be instructed in proper injection technique (IM or SC) and storage conditions for epinephrine.
- Do not use epinephrine if it is outdated, discolored, or contains a precipitate.

**Chemistry/Synonyms**

An endogenous catecholamine, epinephrine occurs as white to nearly white, microcrystalline powder or granules. It is only very slightly soluble in water, but it readily forms water-soluble salts (e.g., HCl) when combined with acids. Both the commercial products and endogenous epinephrine are in the Levo form, which is about 15 times more active than the dextro-isomer. The pH’s of commercial injections are from 2.5–5.

Epinephrine is commonly called adrenalin.

**Storage/Stability**

Epinephrine HCl for injection should be stored in tight containers protected from light. Epinephrine will darken (oxidation) upon exposure to light and air. Do not use the injection if it is pink, brown, or contains a precipitate. The stability of the injection is dependent on the form and the preservatives present and may vary from one manufacturer to another. Epinephrine is rapidly destroyed by alkalies, or oxidizing agents.

**Compatibility/Compounding Considerations**

Epinephrine HCl is reported to be physically compatible with the following intravenous solutions and drugs: Dextran 6% in dextrose 5%, Dextran 6% in normal saline, dextrose-Ringer’s combinations, dextrose-lactated Ringer’s combinations, dextrose-saline combinations, dextrose 2.5%, dextrose 5% (becomes unstable at a pH >5.5), dextrose 10%, Ringer’s injection, lactated Ringer’s injection, normal saline, and sodium lactate 1/6 M, amikacin sulfate, cimetidine HCl, dobutamine HCl, metaraminol bitartrate, and verapamil HCl.

Epinephrine HCl is reported to be physically incompatible with the following intravenous solutions and drugs: Ionsol-D-CM, Ionsol-PSL (Darrow’s), Ionsol-T with dextrose 5% (Note: other Ionsol products are compatible), sodium chloride 5%, and sodium bicarbonate 5%, aminophylline, cephapirin sodium, hyaluronidase, mephentermine sulfate, sodium bicarbonate, and warfarin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Epinephrine HCl for Injection 1 mg/mL (1:1,000) in 1 mL amps and syringes and 10 mL, 30 mL and 100 mL vials; **Amtech® Epinephrine Injection USP (Phoenix Scientific); Am-Vet® Epinephrine 1:1000 (Neogen); Epinephrine (Vedco, Vet Tek); Epineject® (Vetus); Epinephrine 1/1000 (AgriPharm, Durvet, Bimeda, Butler, Phoenix Pharmaceutical); Epinephrine Injection (AgriLabs); (Rx). Labeled for dogs, cats, cattle, horses, sheep and swine.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Epinephrine HCl Solution for Injection: 1 mg/mL (1:1,000) in 1 mL amps & 30 mL vials (may contain sulfites)& 1 mL (with sodium bisulfite) & 30 mL (with chlorobutanol & sodium bisulfite) vials; **Adrenalin Chloride® (JHP); generic; (Abbott); (Rx)**

Epinephrine HCl Solution for Injection: 1:1,000 (0.3 mg/0.3 mL) in prefilled single-dose syringes (may contain sodium metabisulfite); 0.3 mL single-dose auto-injectors with sodium bisulfite; in dual-dose auto-injectors with chlorobutanol & sodium bisulfite; **EpiPen® (Dey); Twinject® (Sciele); generic; (Rx)**

Epinephrine HCl Solution for Injection: 1:1,000 (0.15 mg/0.15 mL) in dual-dose auto-injectors with chlorobutanol & sodium bisulfite; **Twinject® (Sciele); (Rx)**

Epinephrine HCl Solution for Injection: 1:2,000 (0.15 mg/0.3 mL) with sodium metabisulfite in 0.3 mL single dose auto-injectors; **EpiPen Jr® (Dey); (Rx)**

Epinephrine HCl Solution for Injection: 1:10,000 (0.1 mg/mL) as hydrochloride & may contain sulfites in 10 mL syringes & vials; **generic; (Rx)**

Epinephrine bitartrate is available as a powder form (aerosol) for inhalation, topical solution and a solution for nebulization; ophthalmic preparations are available.
EPOETIN ALFA
ERYTHROPOIETIN
(éh-throh-po-eet-in) EPO, rHuEPO, Epogen®, Procrit®
ERYTHROPOIETIC AGENT

Prescriber Highlights

- Hormone that regulates erythropoiesis; used for anemia associated with chronic renal failure
- Contraindications: Patients with uncontrolled hypertension or in those who are hypersensitive to it; formation of significant autoantibodies with prior treatment
- Adverse Effects: Autoantibodies with resultant resistance to treatment, vomiting, hypertension, seizures, uveitis, iron depletion (iron supplementation often used), local reactions at injection sites, fever, arthralgia, & mucocutaneous ulcers
- Adequate monitoring vital

Uses/Indications
rHuEPO (human recombinant erythropoietin) has been used to treat dogs and cats for anemia associated with chronic renal failure. Some clinicians state that because of the expense and potential risks (especially formation of antibodies to erythropoietin) associated with its use, it is more often now considered a “last ditch effort” and PCV’s should be in the “teens” before considering EPO therapy. It is hoped that canine and feline recombinant products will become available commercially in the future to reduce autoantibody formation concerns. Additionally, EPO may be demonstrated in the future to have benefits in reducing the number or volume of transfusions, or as a neuroprotective agent.

Pharmacology/Actions
Erythropoietin is a naturally occurring substance produced in the kidney and considered a hormone as it regulates erythropoiesis. It stimulates erythrocyte production by stimulating the differentiation and proliferation of committed red cell precursors. EPO also stimulates the release of erythrocytes.

Recombinant Human EPO alfa (r-HuEPO-alpha) serves as a substitute for endogenous EPO, primarily in patients with renal disease. Various uremic toxins may be responsible for the decreased production of EPO by the kidney.

Pharmacokinetics
EPO is only absorbed after parenteral administration. It is unclear whether the drug crosses the placenta or enters milk. The drug’s metabolic fate is unknown. In dogs and cats, the most troublesome aspect of EPO therapy is the development of autoantibodies (20–70% incidence) with resultant resistance to further treatment. Perhaps up to 30% of all patients will develop antibodies significant enough to cause profound anemia, arrestment of erythropoiesis, and transfusion dependency.

Contraindications/Precautions/Warnings
EPO is contraindicated in patients with uncontrolled hypertension or in those who are hypersensitive to it (see Adverse Effects below). EPO cannot be recommended for use in equines. In animals with moderate to severe hypertension or iron deficiency, therapy should be started with caution or withheld until corrected.

Patients receiving EPO, generally require exogenous administration of iron supplements.

Adverse Effects
In dogs and cats, the most troublesome aspect of EPO therapy is the development of autoantibodies (20–70% incidence) with resultant resistance to further treatment. Perhaps up to 30% of all patients will develop antibodies significant enough to cause profound anemia, arrestment of erythropoiesis, and transfusion dependency. Should a patient develop refractory anemia while receiving adequate EPO doses and have normal iron metabolism, a bone marrow aspiration should be considered. A myeloid/erythroid ratio of greater than 6 predicts significant autoantibody formation and contraindicates further EPO therapy. Some clinicians believe that the drug (EPO) should be withdrawn if PCV starts to drop while on therapy.

Other effects reported include: systemic hypertension, high blood viscosity, seizures, and iron depletion. Local reactions at injection sites (which may be a predictor of antibody formation), fever, arthralgia, and mucocutaneous ulcers are also possible. Other effects that have been noted that may be a result of the animal’s disease (or compounded by such), include cardiac disease (may be related to hypertension associated with chronic renal failure). In humans, hyperkalemia, seizures, and iron deficiency have been reported.

Therapy should be discontinued if any of the following are recognized: polycythemia, fever, anorexia, joint pain, cellulitis, cutaneous or mucosal ulceration (Cowgill 2002).

Reproductive/Nursing Safety
Some teratogenic effects (decrease in body weight gain, delayed ossification, etc.) have been noted in pregnant rats given high dosages. Rabbits receiving 500 mg/Kg during days 6–18 of gestation showed no untoward effects on offspring; however, use during pregnancy only when benefits outweigh the potential risks. In humans.
albumin (2.5 mg per vial) is also added to the solution.

Available as a sterile, preservative-free, colorless solution. Sodium chloride solution is added to adjust tonicity and is buffered with sodium citrate or citric acid. Human

A biosynthetic form of the glycoprotein human hormone erythropoietin, epoetin alfa (EPO) has a molecular weight of approximately 30,000. It is commercially

Chemistry/Synonyms

For outpatient administration, training in proper injection techniques, drug handling and storage should be performed.

Chemistry/Synonyms

A biosynthetic form of the glycoprotein human hormone erythropoietin, epoetin alfa (EPO) has a molecular weight of approximately 30,000. It is commercially

Overdosage/Acute Toxicity

Acute overdoses appear to be relatively free of adverse effects. Single doses of up to 1600 Units per kg in humans demonstrated no signs of toxicity. Chronic

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving EPO and may be of significance in veterinary patients:

Doses

RABBITS/RODENTS/SMALL MAMMALS:

CATS:

DOGS:

RABBITS/RODENTS/SMALL MAMMALS:

FERRETS:

No laboratory interactions of major clinical importance have been described.

Doses

DOGS:

As adjunctive therapy for the treatment of anemia associated with end-stage renal disease:

a) Initially, 100 Units/kg SC 3 times weekly, until the bottom of the target hematocrit range of 37–45% is attained. Once the lower range of the target hematocrit

Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.

It is not known whether epoetin alfa is excreted in milk, but it is unlikely to pose much risk to nursing offspring.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving EPO and may be of significance in veterinary patients:

ANDROGENS: May increase the sensitivity of erythroid progenitors; this interaction has been used for therapeutic effect; (Note: This effect has not been confirmed

in well-controlled studies nor has the safety of this combination been determined.)

DESMOPRESSIN: With EPO can decrease bleeding times

PROBENECID: Probenecid has been demonstrated to reduce the renal tubular excretion of EPO; clinical significance remains unclear at this time

Laboratory Considerations

No laboratory interactions of major clinical importance have been described.

Doses

As adjunctive therapy for the treatment of anemia associated with end-stage renal disease:

a) Initially, 100 Units/kg SC 3 times weekly, until the bottom of the target hematocrit range of 37–45% is attained. Once the lower range of the target hematocrit

is attained, the dosing interval is changed to twice weekly. As the hematocrit approaches the upper target value, reduce to once weekly. The dosage schedule is then

further modified as required and EPO administered between one and three times weekly to maintain hematocrit within the target range.

A lower initial dosage of 50–100 Units/kg 3 times weekly may be used if slower response is acceptable and appropriate for the patient. If adequate control is not

achieved within 8–12 weeks, then dose can be increased by an additional 25–50 Units/kg every 3–4 weeks while maintaining dosing interval at 3 times a week.

Withhold treatment temporarily if hematocrit exceeds target range. Once hematocrit is reestablished at the upper limit of the target range, re-institute treatment at a

lower dosing schedule. Do not adjust dosage or dosing interval more often than once every three weeks (due to the long lag time for a response). Generally, a

maintenance dose of 75–100 Units/kg SC 1–2 times weekly is sufficient (not less than once per week, and not more than 3 times a week). Iron supplementation

required. (Cowgill 2002)

b) Initially, 48.4–145 Units/kg SC three times a week. Most dogs and cats should be started at 97 Units/kg SC 3 times a week. Use high end dose initially when

anemia is severe (HCT less than 14%) and low end dose if hypertension is present or when anemia is not severe. Monitor hematocrit weekly until a target

hematocrit of 37–45% is reached. When hematocrit reaches low end of target decrease dosing to two times weekly. Continue monitoring and adjusting dose and

frequency as necessary, but take lag phase into account and do not adjust too rapidly. If animal requires >145 Units/kg three times a week, evaluate for epoetin

resistance. Oral iron supplements recommended for all patients on epoetin. (Polzin et al. 2000)

CATS:

As adjunctive therapy for the treatment of anemia associated with end-stage renal disease:

a) As above (for each specific author), but the target hematocrit is: 30–40%. (Cowgill 2002), (Polzin et al. 2000)

b) Consider using epoetin when PCV is <20%; dose at 75–100 Units/kg SC three times a week until PCV is in the low normal range (35%), then reduce dose

and frequency to 50–75 Units/kg two times per week. Monitor PCV and blood pressure. It is important to administer iron at start of regime and until appetite is

good. (Scherk 2003)

c) Cats with problematic clinical signs and PCV <20%: Initially, 100 Units/kg SC 3 times per week. Iron deficiency is avoided by monitoring serum iron and total

iron binding capacity and providing oral supplementation with ferrous sulfate (5–50 mg per cat per day). When lower end of the target PCV range (30-40%) is

reached, reduce to twice per week. Depending upon the severity of anemia, it may require 3-4 weeks for the PCV to enter the target range. Up to 50% of treated

dogs and cats develop antibodies after 1 to 3 months of treatment. (Chew 2009)

b) Initially, 48.4–145 Units/kg SC three times a week. Most dogs and cats should be started at 97 Units/kg SC 3 times a week. Use high end dose initially when

anemia is severe (HCT less than 14%) and low end dose if hypertension is present or when anemia is not severe. Monitor hematocrit weekly until a target

hematocrit of 37–45% is reached. When hematocrit reaches low end of target decrease dosing to two times weekly. Continue monitoring and adjusting dose and

frequency as necessary, but take lag phase into account and do not adjust too rapidly. If animal requires >145 Units/kg three times a week, evaluate for epoetin

resistance. Oral iron supplements recommended for all patients on epoetin. (Polzin et al. 2000)

FERRETS:

RABBITS/RODENTS/SMALL MAMMALS:

a) Rabbits: 50–150 Units/kg SC every 2–3 days until PVC is normal; then once weekly (q7 days) for at least 4 weeks (Ivey & Morrisey 2000)

Monitoring

Hematocrit; PCV; (Initially weekly to every other week for 2–4 months, then when dose and Hct are stable, at 1–2 month intervals)

Blood Pressure (initially, at least monthly then every 1–2 months thereafter)

Renal Function Status

Iron status (serum iron, TIBC), RBC indices (initially and regularly during therapy to insure adequate iron availability)

Client Information

For outpatient administration, training in proper injection techniques, drug handling and storage should be performed.
Eprinomectin binds selectively to glutamate-gated chloride ion channels that occur in invertebrate nerve and muscle cells. This leads to an increase in cell membrane permeability to chloride ions, leading to paralysis and death of the parasite. Like ivermectin, eprinomectin enhances the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. These compounds are generally not toxic to mammals as they do not have glutamate-gated chloride channels and do not readily cross the blood-brain barrier.

Pharmacokinetics

No information noted.

Contraindications/Precautions/Warnings

Do not give orally or intravenously.

Adverse Effects

No adverse reactions are listed on the product label. On the FDA’s Cumulative Adverse Drug Experience database for topical administration on cattle, the three most common adverse experiences reported are: Ineffectiveness for parasite control, anorexia, and udder hypogalactia (Anon 2009). It must be noted that incidence rates are not listed and causal effect is not established for listings on this database.
Overdosage/Acute Toxicity
Calves given up to 5X dosage showed no signs of adverse effects. One subject (of 6) showed signs of mydriasis when given a 10X dose.

Drug Interactions
- No interactions noted

Doses

**CATTLE:**
- For labeled indications:
  - a) 1 mL per 10 kg (22 lb) body weight applied topically along backline in a narrow strip from the withers to the tailhead (Package Insert; Ivomec® Eprinex®—Merial)

**HORSES:**
- For treatment of psoroptic (P. equi) mange:
  - a) 500 micrograms/kg (0.5 mg/kg) topically once weekly for 4 treatments. Author’s suggest getting informed consent before use. (Ural et al. 2008)

Client Information
- When used as labeled, there are no milk or meat withdrawal times required.
- Weather conditions (including rainfall) during administration do not affect efficacy.
- Do not apply to backline if covered with mud or manure.
- Dispose of containers in an approved landfill or by incineration; do not contaminate water as eprinomectin may adversely affect fish and aquatic organisms.

Chemistry/Synonyms
A member of the avermectin-class of antiparasitic agents, eprinomectin is also known as MK-397 or 4-epi-acetylamino-4-deoxy-avermectin B1.

Storage/Stability
The commercially available product should be stored protected from light and kept at 86°F (30°C) or less. Storage up to 104°F (40°C) is permitted for a short period.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Eprinomectin Topical (Pour-On) Solution: 5 mg/mL in 250 mL/8.5 fl oz and 1 L/33.8 fl oz bottle with a squeeze-measure-pour-system, or a 2.5 L/84.5 fl oz and 5 L/169 fl oz collapsible pack for use with appropriate automatic dosing equipment; Ivomec® Eprinex® (Merial); (OTC). FDA-approved for use in beef or dairy cattle.

**HUMAN-LABELED PRODUCTS:** None

References
- Epsom Salts—see Magnesium Sulfate

Epsiprantel—see Magnesium Sulfate

---

**EPSPRANTEL**
(ep-si-pran-tel) Cestex®
Cestocidal Antiparasitic Agent

Prescriber Highlights

- Oral cestocide for dogs & cats
- Not appreciably absorbed when given orally
- Not FDA-approved in puppies or kittens less than 7 weeks old
- Adverse Effects: GI (vomiting, diarrhea) possible

Uses/Indications
Epsiprantel is indicated for the treatment (removal) of *Dipylidium caninum* and *Taenia pisiformis* in dogs, and *Dipylidium caninum* and *Taenia taeniaeformis* in cats.

Pharmacology/Actions
Epsiprantel’s exact mechanism of action against cestodes has not been determined. The tapeworm’s ability to regulate calcium is apparently affected, causing tetany and disruption of attachment to the host. Alteration to the integument makes the worm vulnerable to digestion by the host animal.

Pharmacokinetics
Unlike praziquantel, epsiprantel is absorbed very poorly after oral administration and the bulk of the drug is eliminated in the feces. Less than 0.1% of the drug is
Unlike praziquantel, epsiprantel is absorbed very poorly after oral administration and the bulk of the drug is eliminated in the feces. Less than 0.1% of the drug is recovered in the urine after dosing. No metabolites have thus far been detected.

**Contraindications/Precautions/Warnings**
There are no labeled contraindications to this drug, but the manufacturer states not to use it in puppies or kittens less than 7 weeks of age.

**Adverse Effects**
Adverse effects would be unexpected with this agent, although vomiting and/or diarrhea could potentially occur.

**Reproductive/Nursing Safety**
Safety for use in pregnant or breeding animals has not been determined, but teratogenic effects would be highly unlikely since the drug is so poorly absorbed.

**Overdosage/Acute Toxicity**
Acute toxicity resulting from an inadvertent overdose is highly unlikely. Doses as high as 36X the recommended dose resulted in vomiting in some of the kittens tested. Single doses of 36X those recommended in dogs caused no adverse effects.

**Drug Interactions/Laboratory Considerations**
- None reported; theoretically, prokinetic agents or fast acting laxatives may reduce the drug’s efficacy

**Doses**

**DOGS:**
- 5.5 mg/kg (2.5 mg/lb) PO once; round up to the next larger tablet size (Package insert; Cestex®—Pfizer)

**CATS:**
- 2.75 mg/kg PO once. Cats up to 10 lb. should receive one 12.5 mg tablet; cats 11–20 lb. should receive one 25 mg tablet (Package insert; Cestex®—Pfizer)

**Monitoring**
- Clinical efficacy

**Client Information**
- Fasting is not required nor is it recommended before dosing
- Because the worm may be partially or completely digested, worm fragments may not be seen in the feces after treatment.
- A single dose is usually effective, but measures should be taken to prevent reinfection, particularly against *D. caninum*.

**Chemistry/Synonyms**
A pyrazino-benzazepine oral cesticide, epsiprantel occurs as a white powder that is sparingly soluble in water.
- Epsiprantel may also be known as BRL-38705 or Cestex®.

**Storage/Stability**
Tablets should be stored at room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
Epsiprantel Oral Tablets (Film-coated): 12.5 mg, 25 mg, 50 mg & 100 mg; Cestex® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

**HUMAN-APPROVED PRODUCTS:** None

---

**ERGOCALCIFEROL**

---

**VITAMIN D ANALOG**

**Prescriber Highlights**
- May be used to treat hypocalcemia associated with hypoparathyroidism, but DHT or calcitriol usually recommended first
- Less expensive than DHT or calcitriol, but takes large initial doses for effect, effects take longer to be seen, & if hypercalcemia develops, takes longer (up to 18 weeks) for toxicity relief

**Uses/Indications**
Ergocalciferol is sometimes used in dogs or cats to treat hypocalcemia secondary to parathyroid gland failure, particularly when dihydrotachysterol or calcitriol are too expensive for the owner. When compared to those agents, ergocalciferol takes longer to have a maximal effect on serum calcium. Additionally, if hypercalcemia should develop, ergocalciferol’s effects persist longer than either calcitriol or dihydrotachysterol.

**Pharmacology/Actions**
Pharmacology/Actions

Ergocalciferol is first hydroxylated in the liver to 25-hydroxyvitamin D (has some activity) and then activated in the kidneys to 1,25-dihydroxyvitamin D, the primary active form of the drug. Vitamin D is considered a hormone and, in conjunction with parathormone (PTH) and calcitonin, regulates calcium homeostasis in the body. Active analogues (or metabolites) of vitamin D enhance calcium and phosphate absorption from the GI tract, promote reabsorption of calcium by the renal tubules, and increase the rate of accretion and resorption of minerals in bone.

Pharmacokinetics

Specific pharmacokinetic values for dogs and cats were not located. But the following information (human-based) generally applies: In the presence of bile salts, ergocalciferol is absorbed from the small intestine; after conversion to its 25-hydroxylated form in the liver and kidneys, it is stored in the liver and fat. Cats do not appear to convert ergocalciferol to its 25-hydroxylate form as well as cholecalciferol. Several days of therapy may be required until distribution steady state is achieved. In dogs and cats, maximal effect on calcium homeostasis is usually noted from 5–21 days after treatment was begun; effects may persist for up to 18 weeks once treatment is discontinued (Feldman 2005).

Contraindications/Precautions/Warnings

Ergocalciferol, at therapeutic dosages, is contraindicated in patients with hypercalcemia, vitamin D toxicity, malabsorption syndrome, or abnormal sensitivity to the effects of vitamin D. It should be used with extreme caution in patients with hyperphosphatemia. As patients with kidney dysfunction may not convert ergocalciferol into the primary active metabolite, calcitriol or DHT would be preferred since they do not require activation by the kidney. Chronic therapy should not be initiated unless owners are willing to commit to ongoing patient monitoring.

Adverse Effects

The primary concern with using ergocalciferol is “overshooting” the dosage with resultant hypercalcemia and, potentially, hyperphosphatemia or nephrocalcinosis. Hypercalcemia can persist for weeks to months.

Reproductive/Nursing Safety

Hypervitaminosis D in pregnant females has been implicated in causing teratogenic effects in animals and infants. Potential benefits of therapy must be weighed against the risks if considering use in pregnant dogs or cats.

As large doses of vitamin D can be excreted into milk, consider using milk replacer in offspring of dams receiving therapeutic dosages of ergocalciferol.

Overdosage/Acute Toxicity

Because of the potential serious ramifications of overdoses, contacting an animal poison control center is strongly recommended. The toxic acute oral dose of ergocalciferol in dogs is reported as 4 mg/kg (160,000 Units/kg).

Acute ingestions should be managed using established protocols for removal or prevention of the drug being absorbed from the GI. Orally administered mineral oil may reduce absorption and enhance fecal elimination.

Hypercalcemia secondary to chronic dosing of the drug should be treated by first temporarily discontinuing it and exogenous calcium therapy. If the hypercalcemia is severe, furosemide, calcium-free IV fluids (e.g., normal saline), urine acidification, and corticosteroids may be employed. Because of the long duration of action of ergocalciferol (potentially up to 18 weeks), hypercalcemia may persist. Restart therapy (if desired) at a reduced dosage only when calcium serum levels return to the normal range. Diligent monitoring is required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ergocalciferol and may be of significance in veterinary patients:

- **CORTICOSTEROIDS:** Can reduce the effects of vitamin D analogs
- **DIGOXIN or VERAPAMIL:** Patients on these drugs are sensitive to the effects of hypercalcemia; intensified monitoring is required
- **MINERAL OIL:** May reduce the amount of ergocalciferol absorbed
- **THIAZIDE DIURETICS:** May cause hypercalcemia when given in conjunction with Vitamin D analogs

Laboratory Considerations

- **Serum cholesterol** levels may be falsely elevated by vitamin D analogs when using the Zlatkis-Zak reaction for determination.

Doses

**DOGS/CATS:**

For maintenance therapy of parathyroid failure after using parenteral calcium to control hypocalcemic tetany:

- a) Dihydrotachysterol or calcitriol are preferred, but ergocalciferol is less expensive. If using ergocalciferol, patient should be hospitalized. Initially give ergocalciferol at 4000–6000 Units/kg PO once daily. After 1–5 days, parenteral calcium can usually be discontinued. Patient should remain hospitalized until serum calcium concentration remains between 8–10 mg/dL without parenteral calcium support, then patient can be discharged. Continue ergocalciferol, but administer every other day. Weekly serum calcium concentrations should be performed and ergocalciferol dosage adjusted to maintain serum calcium concentrations between 8–9.5 mg/dL. Maintenance doses usually range from 1000–2000 Units/kg PO once daily to once weekly. Goal is to prevent hypocalcemic tetany, but not induce hypercalcemia. Once animal is stable, monthly rechecks for 6 months are strongly advised; then every 2–3 months thereafter. (Feldman 2005)

Monitoring

- See dosage information above

Client Information

- While ergocalciferol is less expensive than DHT or calcitriol, it is usually not recommended as it takes longer to have an effect and can persist in the body longer than DHT or calcitriol
- Using vitamin D products may require lifelong treatment and regular laboratory monitoring

Pharmacology/Actions

Ergocalciferol is first hydroxylated in the liver to 25-hydroxyvitamin D (has some activity) and then activated in the kidneys to 1,25-dihydroxyvitamin D, the primary active form of the drug. Vitamin D is considered a hormone and, in conjunction with parathormone (PTH) and calcitonin, regulates calcium homeostasis in the body. Active analogues (or metabolites) of vitamin D enhance calcium and phosphate absorption from the GI tract, promote reabsorption of calcium by the renal tubules, and increase the rate of accretion and resorption of minerals in bone.
Using vitamin D products may require lifelong treatment and regular laboratory monitoring. While this agent can treat low calcium, it can cause calcium levels in the blood to become too high; this effect can last for many weeks, even after the medication is discontinued.

Chemistry/Synonyms
Ergocalciferol is obtained by irradiating (with ultraviolet light) ergosterol, a sterol present in fungi and yeasts. It occurs as white or almost white crystals or yellowish crystalline powder and is practically insoluble in water, but is soluble in fatty oils. One mg of ergocalciferol provides 40,000 Units of vitamin D activity. Ergocalciferol may be known as calciferol, vitamin D2, viosterol, activated ergosterol, or irradiated ergosterol; there are many international trade names.

Storage/Stability
Ergosterol is sensitive to light, heat and air. Store capsules or liquid at room temperature (15–30°C) and protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

- Ergocalciferol Oral Liquid (Drops): 8,000 Units/mL (200 micrograms/mL) in 60 mL; Drisdol® Drops (Sanofi), Calciferol® Drops (Schwarz); generic; (OTC)
- Ergocalciferol Oral Capsules: 50,000 Units (1.25 mg); Drisdol® (Sanofi), generic; (Rx)

ERTAPENEM SODIUM
(er-ta-pen-um) Invanz®
CARBAPENEM ANTIBIOTIC

Prescriber Highlights

- Carbapenem antibiotic similar to imipenem & meropenem, but has narrower spectrum of activity
- Not effective against Pseudomonas or Acinetobacter
- May only need to be dosed once daily
- Very limited information available for use in dogs or cats; must be considered investigational

Uses/Indications
Ertapenem may be useful in treating resistant gram-negative bacterial infections, particularly when aminoglycoside use would be risky (i.e., renal failure) or not effective (i.e., resistance or CNS infections), and when meropenem is not available. While ertapenem has a broad spectrum, it is not active against Pseudomonas aeruginosa. It potentially could be useful against mixed anaerobic/gram-negative aerobic infections when Pseudomonas is not considered a likely pathogen.

Pharmacology/Actions
Ertapenem is a carbapenem antibiotic similar to imipenem and meropenem. Like other beta-lactams, it inhibits bacterial cell wall synthesis and is usually bactericidal.

Ertapenem has a broad antibacterial spectrum similar to that of imipenem, but it is more active against Enterobacteriaceae and anaerobes, has equivalent activity against gram-positive bacteria, and minimal activity against Pseudomonas aeruginosa and Acinetobacter. Methicillin-resistant Staphylococci and Enterococcus are usually resistant to ertapenem. Because ertapenem, like meropenem, is more stable than imipenem to renal dehydropeptidase I, it does not require the addition of cilastatin to inhibit that enzyme.

Pharmacokinetics
At the time of writing, no pharmacokinetic data was available for dogs or cats.

In humans, the drug must be administered parenterally as it is not appreciably absorbed after oral administration. Intramuscular bioavailability is about 90% and peak plasma levels occur in approximately 2.3 hours. Ertapenem exhibits concentration-dependent binding to human plasma proteins. At plasma concentrations of <100 micrograms/mL, it is 95% bound; at 300 micrograms/mL, 85% bound. Ertapenem biotransformation is not dependent on hepatic mechanisms as the major metabolite (inactive) is formed by hydrolysis of the beta-lactam ring. Approximately 80% of an IV dose is excreted in the urine, evenly split between inactive metabolites and unchanged drug. Approximately 10% is excreted in the feces. In young, healthy adults, elimination half-life is about 4 hours; about 2.5 hours in pediatric patients.

Contraindications/Precautions/Warnings
Ertapenem is contraindicated in patients hypersensitive to it or other carbapenems and those that have developed anaphylaxis after receiving any beta-lactam antibiotic. It is contraindicated in patients hypersensitive to lidocaine or other amide-type local anesthetics (if used IM with 1% lidocaine as the diluent).

As ertapenem has not been widely used clinically in veterinary medicine and little information for use in dogs or cats is published, consider its use investigational.

Adverse Effects
The adverse effect profile for ertapenem in dogs or cats is unknown. In humans, intravenous injection site reactions are the most common adverse reaction. Gastrointestinal effects (nausea, vomiting, diarrhea), headache, or tachycardia have occasionally been reported. Rarely, hypersensitivity or CNS effects (hallucinations, agitation, seizures, etc.) have been seen.
Reproductive/Nursing Safety
Ertapenem has been shown to cross the placenta in rats, but no teratogenic effects have been reported. In humans, ertapenem is designated by the FDA as a category \textit{B} drug (\textit{Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.})

Although risk cannot be ruled out, it is likely that ertapenem is safe to use while nursing.

Overdosage/Acute Toxicity
Inadvertent overdoses are unlikely. Humans receiving 3 grams intravenously had an increased incidence of nausea and diarrhea. Should an overdose occur and adverse effects noted, treat supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ertapenem and may be of significance in veterinary patients:

\textbf{PROBENECID:} In humans, coadministration of ertapenem with probenecid can increase ertapenem AUC by 25\% and elimination half-life by about 20\%. Because of these relatively small effects, the manufacturer does not recommend using probenecid to extend the half-life of ertapenem.

Laboratory Considerations
- No specific laboratory interactions or concerns were noted.

Doses
\textbf{DOGS/CATS:}

\textbf{Note:} There is very little information available regarding ertapenem use in dogs or cats and, therefore use must be considered investigational. If the drug is to be administered, it is suggested to use the human pediatric dose of 15 mg/kg IV or IM every 12 hours (not to exceed a daily dosage of 1 gram). Monitor the literature for additional data and recommendations.

Monitoring
- Clinical efficacy (WBC, fever, etc.)
- Adverse effects (potentially: GI, neurotoxicity, hypersensitivity); in humans receiving ertapenem for a prolonged period, hepatic, hematopoietic, and renal function are suggested for periodic assessment

Client Information
- Clients should understand the investigational nature of using this drug in animals and that it should be administered only by veterinary professionals

Chemistry/Synonyms
Ertapenem sodium is a synthetic 1-(beta) methyl carbapenem antibiotic that occurs as a white to off-white, hygroscopic, crystalline powder. It is soluble in water and normal saline.

Ertapenem may also be known as L-749345, ML-0826, ZD-4433, ertapenemum or \textit{Invanz\textsuperscript{\textregistered}}.

Storage/Stability
The 1 gram injectable product contains approximately 6 mEq of sodium and 175 mg of sodium bicarbonate (as an excipient). It should be stored at temperatures at, or below, 25\°C.

Compatibility/Compounding Considerations
For intravenous use, vial contents can be reconstituted with 10 mL of water for injection, bacteriostatic water for injection, or 0.9\% sodium chloride injection. After shaking to dissolve the powder, immediately transfer to a 50 mL bag of 0.9\% sodium chloride. Do not use diluents containing dextrose. Once reconstituted and diluted in normal saline for IV use, ertapenem is stable at room temperature for 6 hours. If refrigerated, it can be stored for 24 hours and used within 4 hours after removal from the refrigerator. Do not freeze reconstituted solutions.

If ertapenem is to be given IM, dilute the vial with 3.2 mL of 1\% lidocaine HCl injection (\textit{without epinephrine}). Use within one hour. Do not give IV.

Do not mix ertapenem with other medications or use IV solutions containing dextrose.

Dosage Forms/Regulatory Status
\textbf{VETERINARY-LABELLED PRODUCTS:} None

\textbf{HUMAN-LABELLED PRODUCTS:}
Ertapenem Sodium Lyophilized Powder for Injection: 1 g (as 1.045 g ertapenem) in single-dose vials; \textit{Invanz\textsuperscript{\textregistered}} (Merck); (Rx)

---

ERYTHROMYCIN
ERYTHROMYCIN ESTOLATE
ERYTHROMYCIN ETHYLSUCCINATE
ERYTHROMYCIN LACTOBIONATE
\textit{(er-throe-my-cin)} Gallimycin\textsuperscript{\textregistered}
MACROLIDE ANTIBIOTIC
Prescriber Highlights
Macrolide antibiotic; also used as a prokinetic agent

Contraindicated in rabbits, gerbils, guinea pigs, & hamsters; oral use in ruminants, adult horses (?), hypersensitivity

Adverse Effects: GI distress (oral), pain on IM injection; thrombophlebitis (IV), hyperthermia (foals). May cause neurological signs in dogs with MDR1 mutation.

Many drug interactions possible

**Uses/Indications**

Erythromycin is FDA-approved for use to treat infections caused by susceptible organisms in swine, sheep, and cattle. It is often employed when an animal is hypersensitive to penicillins or if other antibiotics are ineffective against a certain organism.

Erythromycin, is still one of the treatments (with rifampin) for the treatment of *C. (Rhodococcus) equi* infections in foals, but many now use other macrolides (clarithromycin, azithromycin ± rifampin/rifampicin). Erythromycin estolate and microencapsulated base appear to be the most efficacious forms of the drug in foals due to better absorption and less frequent adverse effects.

Erythromycin may be used as a prokinetic agent to increase gastric emptying in dogs and cats. It may also be beneficial in treating reflux esophagitis.

**Pharmacology/Actions**

Erythromycin is usually a bacteriostatic agent, but in high concentrations or against highly susceptible organisms it may be bactericidal. The macrolides (erythromycin and tylosin) are believed to act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation.

Erythromycin has *in vitro* activity against gram-positive cocci (staphylococci, streptococci), gram-positive bacilli (*Bacillus anthracis*, Corynebacterium, *Clostridium* spp.—not *C. difficile*, Listeria, Erysipelothrix), and some strains of gram-negative bacilli, including Haemophilus, Pasteurella, and Brucella. Some strains of Actinomyces, Mycoplasma, Chlamydia, Ureaplasma, and Rickettsia are also inhibited by erythromycin. Most strains of the family Enterobacteriaceae (Pseudomonas, *E. coli*, Klebsiella, etc.) are resistant to erythromycin.

Erythromycin is less active at low pHs and many clinicians suggest alkalining the urine if using the drug to treat UTI’s.

At sub-antimicrobial doses, erythromycin mimics the effects of motilin (cats, humans, rabbits) or 5-hydroxytryptophan3 (5-HT3) and stimulates migrating motility complexes and antegrade peristalsis. By inducing antral contractions, gastric emptying is enhanced. Erythromycin also increases lower esophageal pressure. Erythromycin is reported to stimulate colonic activity in dogs, but not in cats. Erythromycin’s prokinetic mechanism of action in dogs is not completely understood, but probably is via activation of 5-HT3 receptors. Prokinetic activity may diminish with chronic use (tachyphylaxis). It has been suggested that combining erythromycin with metoclopramide may be associated with less tachyphylaxis.

Erythromycin is reported to stimulate colonic activity in pigs, but not in cattle. Erythromycin’s prokinetic mechanism of action in sheep is not completely understood, but probably is via activation of 5-HT3 receptors. Prokinetic activity may diminish with chronic use (tachyphylaxis). It has been suggested that combining erythromycin with metoclopramide may be associated with less tachyphylaxis.

**Pharmacokinetics**

Erythromycin is absorbed after oral administration in the upper small intestine. Several factors can influence the bioavailability of erythromycin, including salt form, dosage form, GI acidity, food in the stomach, and stomach emptying time. Both erythromycin base and stearate are susceptible to acid degradation; enteric coatings are often used to alleviate this. Both the ethylsuccinate and estolate forms are dissociated in the upper small intestine and then absorbed. After IM or SC injection of the polyethylene-based veterinary product (*Erythro*-200; *Gallimycin*-200) in cattle, absorption is very slow. Bioavailabilities are only about 40% after SC injection and 65% after IM injection.

Erythromycin is distributed throughout the body into most fluids and tissues including the prostate, macrophages, and leukocytes. CSF levels are poor. In foals, erythromycin levels in bronchiolar lavage cells are equivalent to those found in the serum, but concentrations in pulmonary epithelial lining fluid are lower. Erythromycin may be 73–81% bound to serum proteins and the estolate salt, 96% bound. Erythromycin will cross the placenta; fetal serum levels are 5–20% of maternal levels. Erythromycin levels of about 50% of those found in the serum can be detected in milk. The volume of distribution for erythromycin in dogs is reportedly 2 L/kg; 3.7–7.2 L/kg in foals; 2.3 L/kg in mares; and 0.8–1.6 L/kg in cattle. In lactating dairy cattle, the milk to plasma ratio about 6–7.

Erythromycin is primarily excreted unchanged in the bile, but is also partly metabolized by the liver via N-demethylation to inactive metabolites. Some of the drug is reabsorbed after biliary excretion. Only about 2–5% of a dose is excreted unchanged in the urine.

The reported elimination half-life of erythromycin in various species is: 60–90 minutes in dogs and cats, 60–70 minutes in foals and mares, and 190 minutes in cattle.

**Contraindications/Precautions/Warnings**

Erythromycin is contraindicated in patients hypersensitive to it. In humans, the estolate form has been associated rarely with the development of cholestatic hepatitis. This effect has not apparently been reported in veterinary species, but the estolate should probably be avoided in patients with preexisting liver dysfunction.

As it may induce a toxic enterocolitis, erythromycin (and other macrolides) is contraindicated in rabbits, gerbils, guinea pigs, and hamsters.

Many clinicians believe that erythromycin is contraindicated in adult horses (see Adverse Effects below), and oral erythromycin should not be used in ruminants as severe diarrhea may result. Unless *R. equi* is confirmed, erythromycin should be used with caution in horses greater than 4 months old (Divers 2009).

Because erythromycin is implicated in causing hyperthermia/fatal respiratory distress in foals treated during hot weather, provision of shade and close observation is advised.

**Adverse Effects**

Adverse effects are relatively infrequent with erythromycin when used in small animals, swine, sheep, or cattle. When injected IM, local reactions and pain at the injection site may occur. Oral erythromycin may occasionally cause GI disturbances such as diarrhea, anorexia, and vomiting. Rectal edema and partial anal prolapse have been associated with erythromycin in swine. Intravenous injections must be given very slowly, as they can readily cause thrombophlebitis. Allergic reactions can occur but are thought to be rare.

A case of a dog with the *mdr1* mutation developing neurological signs after receiving erythromycin has been reported.

Oral erythromycin should not be used in ruminants as severe diarrhea may result.

In foals treated with erythromycin, a mild, self-limiting diarrhea can occur; however, severe enterocolitis is possible. Erythromycin may alter temperature homeostasis in foals. Foals between the ages of 2–4 months old have been reported to develop hyperthermia with associated respiratory distress and tachyphnea. Physically cooling off these animals has been successful in controlling this effect.
Adult horses may develop severe, sometimes fatal, diarrheas from erythromycin making the use of the drug in adults very controversial. Mares of foals treated with erythromycin have, on occasion, developed severe diarrhea/fatal colitis, possibly through contamination of feeders, water buckets, or via coprophagia. When used as a prokinetic agent, erythromycin may actually increase clinical signs of intestinal distress as it can stimulate emptying of larger food particles into the intestine than is normal.

**Reproductive/Nursing Safety**

While erythromycin has not demonstrated teratogenic effects in rats, and the drug is not thought to possess serious teratogenic potential, it should only be used during pregnancy when the benefits outweigh the risks. In humans, the FDA categorizes erythromycin and its salts, except ethylsuccinate, as category B for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

In humans, the FDA categorizes erythromycin ethylsuccinate as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Erythromycin is excreted in milk and may concentrate (observed milk:plasma ratio of 0.5). Erythromycin is considered compatible with breastfeeding by the American Academy of Pediatrics.

**Overdosage/Acute Toxicity**

With the exception of the adverse effects outlined above, erythromycin is relatively non-toxic; however, shock reactions have been reported in baby pigs receiving erythromycin overdosages.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving erythromycin and may be of significance in veterinary patients:

- **AZOLE ANTIFUNGALS (ketoconazole, fluconazole, itraconazole)**: Possible increased erythromycin levels
- **CISAPRIDE**: Erythromycin can inhibit the metabolism of cisapride and the manufacturer states that use of these drugs together (in humans) is contraindicated; however it has been reported that in one study in dogs, erythromycin did not alter the pharmacodynamics of cisapride (Trepanier 2008).
- **CHLORAMPHENICOL**: *in vitro* evidence of antagonism
- **CLINDAMYCIN, LINCOMYCIN**: *in vitro* evidence of antagonism
- **DIGOXIN**: Erythromycin may increase the serum level of digoxin
- **DILTIAZEM, VERAPAMIL**: May increase erythromycin levels
- **ERGOT ALKALOIDS**: Acute ergot toxicity possible
- **OMEPRAZOLE**: Erythromycin and omeprazole can increase the plasma levels of one another
- **SUCRALFATE**: May reduce the absorption of erythromycin; separate doses by two hours if possible
- **WARFARIN**: Erythromycin may potentiate the effects of oral anticoagulant drugs

Erythromycin can inhibit the metabolism of other drugs that use the CYP3A subfamily of the cytochrome P450 enzyme system. Depending on the therapeutic index of the drug(s) involved, therapeutic drug monitoring and/or dosage reduction may be required if the drugs must be used together. These drugs include:

- **ALFENTANIL**
- **BROMOCRIPTINE**
- **BUSPIRONE**
- **CARBAMAZEPINE**
- **CYCLOSPORINE**
- **DISOPYRAMIDE** (also risk of increased QT interval)
- **METHYLPREDNISOLONE**
- **MIDAZOLAM, ALPRAZOLAM, TRIAZOLAM**
- **QUINIDINE** (also risk of increased QT interval)
- **SILDENAFIL**
- **TACROLIMUS** (systemic)
- **THEOPHYLLINE**

**Laboratory Considerations**

- Erythromycin may cause falsely elevated values of AST (SGOT), and ALT (SGPT) when using colorimetric assays.
- Fluorometric determinations of urinary catecholamines can be altered by concomitant erythromycin administration.

**Doses**

**DOGS:**

- For susceptible infections:
  a) 10–20 mg/kg PO three times daily (Aucoin 2000)
  b) For localized, soft tissue infections: 10–15 mg/kg PO q8h or 15–25 mg/kg PO q12h for 7–10 days;
For systemic, bacteremia infections: 22 mg/kg PO or IV q8h for as long as necessary (Greene & Watson 1998)

As a prokinetic agent:

a) 0.5–1 mg/kg PO q8h (Hall & Washabau 2000), (Twedt 2008)

**CATS:**

For susceptible infections:

a) 10–20 mg/kg PO three times daily (Aucoin 2000)

b) For localized, soft tissue infections: 10–15 mg/kg PO q8h or 15–25 mg/kg PO q12h for 7–10 days;

For systemic, bacteremia infections: 22 mg/kg PO or IV q8h for as long as necessary (Greene & Watson 1998)

As a prokinetic agent:

a) 0.5–1 mg/kg PO q8h (Hall & Washabau 2000)

**FERRETS:**

For susceptible infections:

a) 10 mg/kg PO 4 times daily (Williams 2000)

**BIRDS:**

For susceptible infections:

a) Oral suspension: 60 mg/kg PO q12h (Hoeffer 1995)

b) Ratites: 5–10 mg/kg PO 3 times daily (Jenson 1998)

**CATTLE:**

For susceptible infections:

a) 4–8 mg/kg IM q12–24h (Jenkins 1987)

b) For bronchopneumonia and fibrinous pneumonia in cattle associated with bacteria sensitive to erythromycin and resistant to sulfas, penicillin G and tetracyclines: Using Erythro-200®: 44 mg/kg IM q24h usually for a maximum of 4 days. Inject no more than 10 mL at any one site. Do not inject at any site previously used. Severe local tissue reactions may occur. Recommend a 30-day slaughter withdrawal at this dosage. (Hjerpe 1986)

For mastitis:

a) Dry cow (using dry cow formula): Milk out affected quarter, clean and disinfect. Infuse contents of one syringe into each affected quarter at time of drying off. Close teat orifice with gentle pressure and massage udder.

b) Lactating cow (using lactating cow formula): As above, but repeat after each milking for 3 milkings (Label directions; Erythro®-Dry and Erythro®-36—Ceva)

**HORSES:**

For treatment of C. (Rhodococcus) equi infections in foals:

a) Erythromycin: 15–25 mg/kg PO q12–24h daily, with Rifampin (5 mg/kg, PO q12h). Treatment may be necessary for 1–3 months. (Chaffin 2006)

b) Erythromycin: 25 mg/kg PO q12h with rifampin: 3–5 mg/kg PO q12h. If rifampin use becomes cost prohibitive, use erythromycin alone. Treat for 4–6 weeks or until lungs are clear of abscesses on radiographs. (Foreman 1999)

c) 20–25 mg/kg PO q6–8h (estolate or microencapsulated base are preferred) (Haggett & Wilson 2008)

For treatment of proliferative enteropathy caused by L. intracellularis infections in foals:

a) Erythromycin estolate: 25 mg/kg PO q6–8h, with rifampin: 10 mg/kg PO q12h for a minimum of 21 days (Lavoie & Drolet 2003)

**SWINE:**

For susceptible infections:

a) For respiratory infections: 2.2–6.6 mg/kg IM once daily

b) For scours in young pigs: 22 mg/kg IM in one or more daily doses (Label directions; Erythro®-100 and Erythro®-200—Ceva)

**SHEEP:**

For susceptible infections:

a) For respiratory infections in older animals: 2.2 mg/kg IM once daily as indicated.

b) For prevention of "dysentery" in newborn lambs when the likely causative agent is susceptible to erythromycin: 123 mg/kg IM once soon after birth (Label directions; Erythro®-100 and Erythro®-200—Ceva)

**Monitoring**

- **Clinical efficacy**
- **Adverse effects** (periodic liver function tests if patient receiving erythromycin estolate long-term; may not be necessary for foals receiving erythromycin and rifampin for Rhodococcus infections)

**Client Information**

- The intramuscular 100 mg/mL (Erythro-100®) product (Erythro-200®) has quite specific instructions on where and how to inject the drug. Refer to the label directions or package insert for more information before using.

- When administering orally to small animals, give on an empty stomach unless gastrointestinal signs (vomiting, lack of appetite, diarrhea) occur, then give with food. The estolate, ethylsuccinate or enteric-coated forms of erythromycin may be given with or without food.

- If gastrointestinal adverse effects are severe or persist, contact veterinarian.
Chemistry/Synonyms
A macrolide antibiotic, produced from Streptomyces erythreus, erythromycin is a weak base that is available commercially in several salts and esters. It has a pKa of 8.9.

Erythromycin base occurs as a bitter tasting, odorless or practically odorless, white to slightly yellow, crystalline powder. Approximately 1 mg is soluble in 1 mL of water; it is soluble in alcohol.

Erythromycin estolate occurs as a practically tasteless and odorless, white, crystalline powder. It is practically insoluble in water and approximately 50 mg are soluble in 1 mL of alcohol. Erythromycin estolate may also be known as erythromycin propionate lauryl sulfate.

Erythromycin ethylsuccinate occurs as a practically tasteless and odorless, white to slightly yellow, crystalline powder. It is very slightly soluble in water and freely soluble in alcohol.

Erythromycin lactobionate occurs as white to slightly yellow crystals or powder. It may have a faint odor and is freely soluble in water and alcohol. Erythromycin may also be known as: eritromicina, and erythromycinum; many trade names are available.

Storage/Stability
Erythromycin (base) capsules and tablets should be stored in tight containers at room temperature (15–30°C). Erythromycin estolate preparations should be protected from light. To retain palatability, the oral suspensions should be refrigerated.

Erythromycin ethylsuccinate tablets and powder for oral suspension should be stored in tight containers at room temperature. The commercially available oral suspension should be stored in the refrigerator to preserve palatability. After dispensing, the oral suspensions are stable for at least 14 days at room temperature, but individual products may have longer labeled stabilities.

Erythromycin lactobionate powder for injection should be stored at room temperature. For initial reconstitution (vials), only sterile water for injection should be used. After reconstitution, the drug is stable for 24 hours at room temperature and 2 weeks if refrigerated. To prepare for administration via continuous or intermittent infusion, the drug is further diluted in 0.9% sodium chloride, Lactated Ringer’s, or Normosol-R. Other infusion solutions may be used, but first must be buffered with 4% sodium bicarbonate injection (1 mL per 100 mL of solution). At pH’s of <5.5, the drug is unstable and loses potency rapidly.

Compatibility/Compounding Considerations
Many drugs are physically **incompatible** with erythromycin lactobionate; it is suggested to consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Erythromycin 100 mg/mL for IM Injection (with 2% butyl aminobenzoate as a local anesthetic) in 100 mL vials; Gallimycin®-100 (Cross); (OTC). FDA-approved for use in cattle, sheep, and swine. Milk withdrawal (when used as labeled) = 72 hours. Slaughter withdrawal (when used as labeled) for cattle = 14 days, sheep = 3 days, swine = 7 days.

There may also be erythromycin premixes alone and in combination with other drugs for use in swine and/or poultry.

**HUMAN-LABELED PRODUCTS:**

Erythromycin Base Delayed-release Oral Tablets enteric-coated: 250 mg, 333 mg & 500 mg; Ery-Tab® (Abbott); (Rx)

Erythromycin Base Tablets Film-coated: 250 mg, & 500 mg; Erythromycin Filmtabs® (Abbott); (Rx)

Erythromycin Base Delayed-release Oral Capsules enteric-coated pellets: 250 mg: generic (Abbott); (Rx)

Erythromycin Stearate Film-coated tablets: 250 mg: generic (Abbott); (Rx)

Erythromycin Ethylsuccinate Tablets: 400 mg; E.E.S. 400® (Abbott); generic (Abbott); (Rx) Erythromycin Ethylsuccinate Powder for Oral Suspension: 200 mg/5 mL when reconstituted 100 mL & 200; EryPed® 200 (Abbott); (Rx)

Erythromycin Ethylsuccinate Granules for Oral Suspension: 200 mg/5 mL in 100 & 200 mL; E.E.S. Granules® (Abbott)

Erythromycin Ethylsuccinate Powder for Oral Suspension: 400 mg/5 mL in 100, 200, & UD 5 mL; EryPed 400® (Abbott); (Rx)

Erythromycin Ethylsuccinate Powder for Oral Suspension: 100 mg/2.5 mL in 50 mL EryPed Drops® (Abbott); (Rx) Erythromycin Lactobionate Lyopholized Powder for Injection Solution: 500 mg & 1 g (as lactobionate) in vials; Erythoric® (Hospira); (Rx)

Erythromycin & Sulfoisoxazole Granules for Oral Suspension: erythromycin ethylsuccinate (equivalent to 200 mg erythromycin activity) and sulfisoxazole acetyl (equivalent to 600 mg sulfisoxazole) per 5 mL when reconstituted in 100 mL, 150 mL & 200 mL; Eryzole® (Alra); Pedazole® (Ross); generic; (Rx)

Topical and ophthalmic preparations are also available.

**References**

Ultra-short acting beta1-blocker used IV for short-term treatment of SVT’s or to determine if beta-blockers are effective for controlling arrhythmias

Contraindications: Patients with overt cardiac failure, 2nd or 3rd degree AV block, sinus bradycardia, or in cardiogenic shock

Caution: Patients with CHF, bronchoconstrictive lung disease, or diabetes mellitus

Adverse Effects: Hypotension & bradycardia are the effects most likely seen

Uses/Indications

Esmolol may be used as test drug to indicate whether beta-blocker therapy is warranted as an antiarrhythmic agent, particularly in cats with hypertrophic cardiomyopathy, or as an infusion in the short-term treatment of supraventricular tachyarrhythmias (e.g., atrial fibrillation/flutter, sinus tachycardia).

Pharmacology/Actions

Esmolol primarily blocks both beta1-adrenergic receptors in the myocardium. At clinically used doses, esmolol does not have any intrinsic sympathomimetic activity (ISA) and unlike propranolol, does not possess membrane-stabilizing effects (quinidine-like) or bronchoconstrictive effects. Cardiovascular effects secondary to esmolol include negative inotropic and chronotropic activity that can lead to reduced myocardial oxygen demand. Systolic and diastolic blood pressures are reduced at rest and during exercise. Esmolol’s antiarrhythmic effect is thought to be due to its blockade of adrenergic stimulation of cardiac pacemaker potentials. Esmolol increases sinus cycle length, slows AV node conduction, and prolongs sinus node recovery time.

Pharmacokinetics

After IV injection esmolol is rapidly and widely distributed but not appreciably to the CNS, spleen or testes. The distribution half-life is about 2 minutes. Steady-state blood levels occur in about 5 minutes if a loading dose was given or about 30 minutes if no load was given. It is unknown whether the drug crosses the placenta or enters milk. Esmolol is rapidly metabolized in the blood by esterases to a practically inactive metabolite. Renal or hepatic dysfunction do not appreciably alter elimination characteristics. Terminal half-life is about 10 minutes and duration of action after discontinuing IV infusion is usually about 20 minutes post-infusion in dogs.

Contraindications/Precautions/Warnings

Esmolol is contraindicated in patients with overt cardiac failure, 2nd or 3rd degree AV block, sinus bradycardia, or in cardiogenic shock. It should be used with caution (weigh benefit vs. risk) in patients with CHF, bronchoconstrictive lung disease, or diabetes mellitus.

Adverse Effects

At usual doses adverse effects are uncommon and generally are an extension of the drug’s pharmacologic effects. Hypotension (with resultant clinical signs) and bradycardia are the most likely adverse effects seen. These usually prove mild and transient in nature. Esmolol may mask certain clinical signs of developing hypoglycemia (such as increased heart rate or blood pressure).

Reproductive/Nursing Safety

Studies done in rats and rabbits demonstrated no teratogenic effects at doses up to 3 times the maximum human maintenance dose (MHMD). Higher doses (8 times or more MHMD) demonstrated some maternal death and fetal resorption.

It is unknown if esmolol is excreted in milk.

Overdosage/Acute Toxicity

The IV LD50 in dogs is approximately 32 mg/kg. Dogs receiving 2 mg/kg per minute for one hour showed no adverse effects; doses of 3 mg/kg/minute for one hour produced ataxia and salivation and 4 mg/kg/minute for one hour caused muscular rigidity, tremors, seizures, ptosis, vomiting, hyperpnea, vocalizations, and prostration. These effects all resolved within 90 minutes of the end of infusion. Because of the short duration of action of the drug, discontinuation or dosage reduction may be all that is required; otherwise, symptomatic and supportive treatment may be initiated.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving esmolol and may be of significance in veterinary patients:

DIGOXIN: Esmolol may increase serum digoxin levels up to 20%, but these drugs have been used together safely and effectively

MONOAMINE OXIDASE INHIBITORS: Concurrent use of monoamine oxidase inhibitors with esmolol is not recommended due to potential risk of hypertension

MORPHINE: Titrated esmolol dosage carefully in patients also receiving morphine as it may increase steady-state esmolol serum concentrations up to 50%.

RESERPINE: May see additive effects (hypotension, bradycardia) if used with esmolol

VASOCONSTRICTORS/INOTROPES (e.g., dopamine, epinephrine, norepinephrine): If systemic vascular resistance is high, there is an increase risk for blocked cardiac contractility; esmolol is not recommended to control SVT’s in patients receiving these drugs

VERAPAMIL: In humans, particularly with severe cardiomyopathy, cardiac arrest has occurred (rarely)

Doses

For ultra-short acting beta blockade (for treating or assisting in treatment of ventricular arrhythmias):

a) Can be administered two ways: 1) An initial loading dose of 0.25–0.5 mg/kg (250–500 micrograms/kg) administered IV as slow bolus over 1–2 minutes, then followed by a constant rate infusion of 10–200 micrograms/kg/minute; or 2) Start CRI at 10–200 micrograms/kg/minute without the bolus loading dose. If no
followed by a constant rate infusion of 10–200 micrograms/kg/minute; or

2) Start CRI at 10–200 micrograms/kg/minute without the bolus loading dose. If no loading dose, maximal effect should occur in 10–20 minutes. (Kittleson 2006)

Use of a loading dose and the high end of the infusion rate dose should only be used in dogs with normal cardiac function. In dogs with severe dilated cardiomyopathy or severe mitral regurgitation do not give loading dose and start CRI at 10–20 micrograms/kg/min and titrate upward every 10 minutes to an effective endpoint. (Kittleson 2006)

b) Give in incremental IV bolus doses of 0.05–0.1 mg/kg every 5 minutes up to a maximum dose of 0.5 mg/kg. Because esmolol’s effects are short-lived, if arrhythmia conversion does not occur, other negative inotropes (e.g., diltiazem, or verapamil) can be safely used 30 minutes after esmolol. (Smith 2009)

cATS:

For ultra-short acting beta blockade for treating or assisting in treatment of ventricular arrhythmias, or in cats with HCM to determine if beta-blockers will reduce the dynamic left-ventricular outflow tract obstruction resulting from systolic anterior motion of the mitral valve:

a) In cats with HCM: An initial loading dose of 0.25–0.5 mg/kg (250–500 micrograms/kg) administered IV as slow bolus over 1–2 minutes, then followed by a constant rate infusion of 10–200 micrograms/kg/minute. (Kittleson 2006)

b) Loading dose of 200–500 micrograms/kg IV over 1 minute; followed by a constant rate IV infusion of 25–200 micrograms/kg/minute (Ware 2000)

Monitoring
■ Blood Pressure
■ ECG
■ Heart Rate

Client Information
■ Esmolol should only be used in an in-patient setting where appropriate monitoring is available.

Chemistry/Synonyms
A short acting beta-adrenergic blocker, esmolol occurs as white or off white crystalline powder. It is not as lipophilic as either labetolol or propranolol, but is comparable to acebutolol. 650 mg are soluble in one mL of water and 350 mg are soluble in one mL of alcohol.

Esmolol HCl may also be known as ASL-8052, Brevibloc® or Miniblock®.

Storage/Stability
The concentrate for injection should be stored at room temperature; do not freeze and protect from excessive heat. It is a clear, colorless to light yellow solution. Expiration dates of 3 years are assigned after manufacture.

After diluted to a concentration of 10 mg/mL esmolol HCl is stable (at refrigeration temperatures or room temperature) for at least 24 hours in commonly used IV solutions.

Compatibility/Compounding Considerations
Esmolol may be diluted in standard D5, LRS or saline (or combinations thereof) IV fluids. At this concentration it is reportedly physically compatible with digoxin, dopamine, fentanyl, lidocaine, morphine sulfate, nitroglycerin, and nitroprusside. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Esmolol HCl Injection: 10 mg/mL regular & preservative free in 10 mL vials; 20 mg/mL preservative free in 5 mL vials & 100 mL bags; and 250 mg/mL in 10 mL amps; Brevibloc® (Baxter); generic; (Rx)

References
Uses/Indications
For mares, indications for the use of estradiol include enhancing estrus behavior and receptivity in ovariectomized mares and to treat estrogen-responsive incontinence. Historically, estradiol cypionate has been used as an abortifacient agent in cattle, cats, and dogs, but estrogens are no longer recommended by most theriogenologists for use as an abortifacient in small animals and the FDA stated (April 5, 2006): “The use of ECP in food-producing animals is illegal, and manufacturing and compounding of ECP for such use is illegal.”

Pharmacology/Actions
The most active endogenous estrogen, estradiol possesses the pharmacologic profile expected of the estrogen class. Estrogens are necessary for the normal growth and development of the female sex organs and in some species contribute to the development and maintenance of secondary female sex characteristics. Estrogens cause increased cell height and secretions of the cervical mucosa, thickening of the vaginal mucosa, endometrial proliferation, and increased uterine tone.

Estrogens have effects on the skeletal system. They increase calcium deposition, accelerate epiphyseal closure, and increase bone formation. Estrogens have a slight anabolic effect and can increase sodium and water retention.

Estrogens affect the release of gonadotropins from the pituitary gland. This can cause inhibition of lactation, ovulation, and androgen secretion.

Pharmacokinetics
No specific information was located regarding the pharmacokinetics of estradiol in veterinary species. In humans, estrogen in oil solutions after IM administration are absorbed promptly and absorption continues over several days. Esterified estrogens (e.g., estradiol cypionate) have delayed absorption after IM administration. Estrogens are distributed throughout the body and accumulate in adipose tissue. Elimination of the steroidal estrogens occurs principally by hepatic metabolism. Estrogens and their metabolites are primarily excreted in the urine, but are also excreted into the bile where most is reabsorbed from the GI.

Contraindications/Precautions/Warnings
Estradiol is contraindicated during pregnancy as it can cause fetal malformations of the genitourinary system and induce bone marrow depression in the fetus.

Estradiol cypionate should not be used to treat estrogen-responsive incontinence in small animals; other estrogens (DES, conjugated estrogens) are less toxic.

In cases of prolonged corpus luteum in cows, a thorough uterine exam should be completed to determine if endometritis or a fetus is present.

Adverse Effects
Estrogens have been associated with severe adverse reactions in small animals. In cats and dogs, estrogens are considered toxic to the bone marrow and can cause blood dyscrasias. Blood dyscrasias are more prevalent in older animals and if higher dosages are used. Initially, a thrombocytopenia and/or leukocytosis may be noted, but thrombocytopenia/leukopenia will gradually develop. Changes in a peripheral blood smear may be apparent within two weeks after estrogen administration. Chronic estrogen toxicity may be characterized by a normochromic, normocytic anemia, thrombocytopenia, and neutropenia. Bone marrow depression may be transient and begin to resolve within 30–40 days or may persist or progress to a fatal aplastic anemia.

Estrogens may cause cystic endometrial hyperplasia and pyometra. After therapy is initiated, an open-cervix pyometra may be noted 1–6 weeks after therapy. Estradiol may induce mammary neoplasia.

When used chronically in male animals, feminization may occur. In females, signs of estrus may occur and persist for 7–10 days.

In cattle, prolonged estrus, genital irritation, decreased milk flow, precocious development, and follicular cysts may develop after estrogen therapy. These effects may be secondary to overdosage and dosage adjustment may reduce or eliminate them.

Reproductive/Nursing Safety
Estradiol is contraindicated during pregnancy. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

Estrogens have been shown to decrease the quantity and quality of maternal milk.

Overdosage/Acute Toxicity
No reports of inadvertent acute overdosage in veterinary patients were located; see Adverse Effects above.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving estradiol and may be of significance in veterinary patients:

- AZOLE ANTIFUNGALS (fluconazole, itraconazole, ketoconazole): May increase estrogen levels
- CORTICOSTEROIDS: Enhanced glucocorticoid effects may result if estrogens are used concomitantly with corticosteroid agents. It has been postulated that estrogens may either alter the protein binding of corticosteroids and/or decrease their metabolism; corticosteroid dosage adjustment may be necessary when estrogen therapy is either started or discontinued
- MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin): May increase estrogen levels
- PHENOBARBITAL: May decrease estrogen activity if administered concomitantly
- RIFAMPIN: May decrease estrogen activity if administered concomitantly
- ST. JOHN’S WORT: May decrease estrogen activity if administered concomitantly
- WARFARIN: Oral anticoagulant activity may be decreased if estrogens are administered concurrently; increases in anticoagulant dosage may be necessary if adding estrogens

Uses/Indications
The following drug interactions have either been reported or are theoretical in humans or animals receiving estradiol and may be of significance in veterinary patients:

- In male animals, feminization may occur; in females, signs of estrus may occur;
- In cattle: Prolonged estrus, genital irritation, decreased milk flow, precocious development, & follicular cysts may develop
- Drug Interactions
Laboratory Considerations

- Estrogens in combination with progestins (e.g., oral contraceptives) have been demonstrated in humans to increase thyroid-binding globulin (TBG) with resultant increases in total circulating thyroid hormone. Decreased T₃ resin uptake also occurs, but free T₄ levels are unaltered. It is unclear if estradiol affects these laboratory tests in veterinary patients.

Doses

**DOGS:**

For pregnancy avoidance after mismating:

**Note:** This drug is rarely used for this indication today as there are safer, more effective treatments.

- 44 micrograms/kg (0.044 mg/kg) IM once; during day 4 estrus to day 2 of diestrus, toxic at ≥100 micrograms/kg. (Wiebe & Howard 2009)

**CATS:**

For pregnancy avoidance after mismating:

**Note:** This drug is rarely used for this indication today as there are safer, more effective treatments.

- 250 micrograms/kg (0.25 mg/kg) IM once 6 days after coitus; or 0.25 mg/cat IM at 40 hours after coitus. (Wiebe & Howard 2009)

**CATTLE:**

The FDA has stated that the use of ECP in food-producing animals is illegal.

**HORSES:**

To enhance estrus behavior and receptivity in ovariectomized mares:

- 5–10 mg (total dose) IM once. (Dascanio 2009)

For treatment of mares with estrogen-responsive incontinence:

- 4–10 micrograms/kg estradiol cypionate IM daily for three days and then every other day. Some mares will improve, but does not “cure.” (Schott II & Carr 2003)

Monitoring

When therapy is either at high dosages or chronic, see adverse effects for more information. Done at least monthly:

- Packed Cell Volumes (PCV)
- White blood cell counts (CBC)
- Platelet counts; Baseline, one month after therapy, and repeated two months after cessation of therapy if abnormal
- Liver function tests

Chemistry/Synonyms

Estradiol is a naturally occurring steroidal estrogen. Estradiol cypionate is produced by esterifying estradiol with cyclopentanepropionic acid, and occurs as a white to practically white, crystalline powder. It is either odorless or may have a slight odor and has a melting range of 149–153°C. Less than 0.1 mg/mL is soluble in water and 25 mg/mL is soluble in alcohol. Estradiol cypionate is sparingly soluble in vegetable oils.

Estradiol may also be known as: beta-oestradiol, dihydrofolliculin, dihydrotheelin, dihydroxyoestrin, estradiolum, NSC-9895, NSC-20293 (alpha-estradiol), and oestradiol; many trade names are available.

Estradiol Cypionate may also be known as: oestradiol cyclopentylpropionate, oestradiol cypionate, Delestrogen®, Depo-Estradiol®, Depogen®, Dura-Estrin®, ECP®, E-Cypionate®, Estra-D®, Estrace®, Estr-O-Cyp®, Estroject®, depGynogen®, Femtrace®, or Gynodiol®.

Storage/Stability

Estradiol cypionate should be stored in light-resistant containers at temperatures of less than 40°C, preferably at room temperature (15–30°C); avoid freezing.

Commercially available injectable solutions of estradiol cypionate are sterile solutions in a vegetable oil (usually cottonseed oil); they may contain chlorobutanol as a preservative.

Compatibility/Compounding Considerations

It is not recommended to mix estradiol cypionate with other medications.

In the USA it is illegal to compound estradiol for use in food producing animals.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

There are several estradiol-containing implants for use in beef cattle.

**HUMAN-LABELED PRODUCTS:**

- Estradiol Cypionate in Oil for Injection: 5 mg/mL in 5 mL vials; Depo-Estradiol® (Pfizer); (Rx)
- Estradiol Valerate in Oil for Injection: 10 mg/mL, 20 mg/mL & 40 mg/mL in 5 mL multi-dose vials; Delestrogen® (JHP); generic; (Rx)
- Estradiol Tablets: 0.45 mg, 0.5 mg, 0.9 mg, 1 mg, 1.5 mg, 1.8 mg & 2 mg micronized estradiol; Estrace® (Warner Chilcott), Gynodiol® (Novavax), Femtrace® (Warner Chilcott); generic; (Rx)

References

ETHAMBUTOL HCL
(e-tham-byoo-tole) Myambutol®, Ethibid®
ORAL ANTIMYCOBACTERIAL ANTIBIOTIC

Prescriber Highlights

- Can be used as an ingredient in an antimycobacterial “cocktail” for dogs, cats, birds
- Treating these infections is controversial because of potential public health risks associated with the infections
- Optic or neuro toxicity greatest concern

Uses/Indications
In combination with other antimycobacterial drugs, ethambutol may be useful in treating mycobacterial infections caused by M. bovis, M. tuberculosis, M. genavense, M. avium-intracellulare complex (MAC) in dogs or cats, particularly when the organism is resistant to treatment with other drug combinations (rifampin, enrofloxacin, azithromycin). In birds, ethambutol has been used in combination with other agents for treating mycobacterial (e.g., M. avium) infections.

Because of public health risks, particularly in the face of increased populations of immunocompromised people, treatment of mycobacterial (M. bovis, M. tuberculosis, etc.) infections in domestic or captive animals is controversial.

Pharmacology/Actions
A synthetic, bacteriostatic, antimycobacterial agent, ethambutol is only active against actively dividing mycobacteria. It enters mycobacterial cells and interferes with RNA synthesis and appears to interfere with the incorporation of mycolic acid into cell walls, allowing other antimycobacterial agents to penetrate the cell wall. Ethambutol does not have appreciable activity against other bacteria or fungi. Resistance can occur and is thought to develop in a step-wise manner. Cross-resistance with other antimycobacterial agents has not been reported.

Pharmacokinetics
Pharmacokinetic values for cats or birds were not located. In dogs, ethambutol is reported to have a volume of distribution of 3.8 L/kg, a total body clearance of 13.2 mL/min/kg, and an elimination half-life of 4.1 hours. Nephrectomized dogs had an elimination half-life of 5 hours.

In humans, ethambutol is rapidly absorbed after PO administration and bioavailability is around 75%. The drug is distributed widely in the body, but CSF levels only range from 10–50% of those found in serum. Erythrocyte concentrations are about twice that of the serum and can serve as a depot for the drug. About 15% of absorbed drug is hepatically metabolized to inactive metabolites. The majority of the drug is eliminated both by tubular secretion and glomerular filtration as unchanged drug in the urine. Elimination half-life in humans with normal renal function is about 3–4 hours; up to 8 hours if renal function is impaired.

Contraindications/Precautions/Warnings
Ethambutol should not be used in patients with a history of prior hypersensitivity reactions to it.

Patients with markedly reduced renal function may need dosage adjustment.

Adverse Effects
Well-described adverse effect profiles for ethambutol in dogs, cats or birds are not available. Because ethambutol is used in combination with other medications, adverse effects associated with treatment may not be a result of ethambutol. In pre-clinical studies, some dogs receiving ethambutol over prolonged periods developed non-dose related degenerative changes in the central nervous system. In toxicity studies, dogs receiving large, prolonged doses developed signs of myocardial toxicity and depigmentation of the tapetum lucidum of the eyes. However, doses as large as 400 mg/kg/day for 4 weeks in dogs demonstrated no significant abnormalities in electroretinogram or visual evoked potential. In humans, optic neuritis (usually reversible after drug discontinuation) causing decreased visual acuity has been reported; routine ophthalmologic exams are recommended for humans taking this medication long-term.

Because antimycobacterial therapy involves multiple drugs for extended periods of time, bacterial or fungal overgrowth infections can occur. Antifungal medications may be required.

Reproductive/Nursing Safety
Ethambutol crosses the placenta; fetal levels are reported to range from 30–75% of that found in maternal serum. Teratogenic effects associated with ethambutol have not been reported in humans, but studies in mice, rats, and rabbits given high doses yielded a variety of abnormalities in offspring. Although risks exist, most believe that ethambutol is relatively safe to use during human pregnancy and untreated tuberculosis poses a much greater risk to the fetus.

Ethambutol is excreted into milk in levels approximating those found in maternal serum. While no problems have been documented and it is most likely safe, risk to offspring cannot be ruled out.

Overdosage/Acute Toxicity
Very limited information exists. Acute overdoses of greater than 10 grams in humans have caused optic neuritis. Other adverse effects noted with human overdoses can include: CNS effects (confusion, visual hallucinations), abdominal pain, nausea, fever and headache; treatment is supportive.

Drug Interactions
The following drug interactions may be either reported or are theoretical in humans or animals receiving ethambutol and may be of significance in veterinary patients:

**ALUMINUM-CONTAINING ANTACIDS:** In humans, it has been documented that co-administration can reduce oral absorption of ethambutol; it is suggested to separate dosing by at least 4 hours if both drugs are necessary.
Laboratory Considerations

- No specific concerns; in humans, increased serum uric acid levels have been noted.

Doses

**DOGS:**

a) For treatment of disseminated *M. tuberculosis*: Ethambutol: 10–25 mg/kg PO once daily, in combination with rifampin (5–10 mg/kg PO q12–24h; maximum of 600 mg/day) and isoniazid (10–20 mg/kg PO once daily; maximum of 300 mg/day). May also add pyrazinamide at 15–40 mg/kg PO once daily. **Note:** pyrazinamide is ineffective for *M. bovis*. Treatment must continue for more than 9 months. (Greene & Gunn-Moore 2006)

**CATS:**

a) For treatment of feline tuberculosis: Initial treatment phase with rifampin (10–20 mg/kg PO q12–24h); enrofloxacin (5 mg/kg PO q12–24h); azithromycin (5–10 mg/kg PO q12–24h) for the first two months, then continuation phase (for approximately another 4 months) with rifampin and either enrofloxacin or azithromycin. If resistance develops, rifampin, isoniazid (10–20 mg/kg PO once daily) and ethambutol (15 mg/kg PO once daily) may be considered. If only two drugs are required, suggest using only rifampin and isoniazid. (Hartmann & Greene 2005)

**BIRDS:**

a) For treatment of *M. avium* infections in caged birds: Several protocols have been used, but controlled trials have not been performed. Combination therapy and treatment for 6–12 months is required.

- **Protocol 1:** Ciprofloxacin 20 mg/kg PO q12h or Enrofloxacin 15 mg/kg PO or IM (Note: repeated IM injections can cause muscle necrosis) for 10 days; Clofazimine 1.5 mg/kg PO once daily; Cycloserine 5 mg/kg PO q12h; and Ethambutol 20 mg/kg PO q12h.
- **Protocol 2:** Clofazimine 6 mg/kg PO once daily; Ethambutol 30 mg/kg PO once daily; Rifampin 45 mg/kg PO once daily.
- **Protocol 3:** Ciprofloxacin 80 mg/kg PO once daily or Enrofloxacin 30 mg/kg PO once daily; Ethambutol 30 mg/kg PO once daily; Rifampin 45 mg/kg PO once daily or Rifabutin 15 mg/kg PO once daily. (Phalen 2006)

b) For Avian mycobacteriosis: All are dosed PO once daily for 9–12 months: Rifabutin 45–55 mg/kg; Clarithromycin 60–85 mg/kg; Ethambutol 30–85 mg/kg; Enrofloxacin 20 mg/kg. (Flammer 2006)

Monitoring

- Clinical efficacy
- With long-term therapy, consider periodic monitoring of visual, liver, and renal function; CBC
- Monitor for fungal or bacterial overgrowth infections

Client Information

- Clients must be informed of the potential public health issues associated with mycobacterium infections and should be encouraged to contact a physician, preferably an infectious disease specialist for guidance
- Treatment can be very prolonged (many months) and expensive
- May be administered with or without food
- Report any changes noted with patient’s eyes or vision to the veterinarian

Chemistry/Synonyms

Ethambutol HCl occurs as a white, crystalline powder that is freely soluble in water and soluble in alcohol. Ethambutol may also be known as: CL-40882, etambutol, or ethambutoli; there are many trade names for international products.

Storage/Stability

Ethambutol tablets should be stored below 40°C and preferably, between 15–30°C in well-closed containers.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Ethambutol HCl Tablets: 100 mg, & 400 mg (scored); Myambutol® (X-Gen); generic; (Rx)

**ETHANOL**

**ALCOHOL, ETHYL**

(eth-a-nil) Alcohol

**ANTIDOTE**

Prescriber Highlights

- Used for treatment of ethylene glycol or methanol toxicity
Uses/Indications
The principal use of ethanol in veterinary medicine is for the treatment of ethylene glycol or methanol toxicity. While fomepizole (4-methyl pyrazole) is now the treatment of choice for ethylene glycol poisoning, alcohol is a readily available and an economical alternative when patients present within a few hours after ingestion. Percutaneous injection of ethanol 95% has been used successfully to treat feline hyperthyroidism. Ethyl alcohol has also been used in aerosol form as a mucokinetic agent in horses.

Pharmacology/Actions
By competitively inhibiting alcohol dehydrogenase, alcohol can prevent the formation of ethylene glycol to its toxic metabolites (glycoaldehyde, glycolate, glyoxalate, and oxalic acid). This allows the ethylene glycol to be principally excreted in the urine unchanged. A similar scenario exists for the treatment of methanol poisoning. For alcohol to be effective, however, it must be given very early after ingestion; it is seldom useful if started 8 hours after a significant ingestion.

Pharmacokinetics
Alcohol is well absorbed orally, but is administered intravenously for toxicity treatment. It rapidly distributes throughout the body and crosses the blood-brain barrier. Alcohol crosses the placenta.

Contraindications/Precautions/Warnings
Because ethylene glycol and methanol intoxications are life threatening, there are no absolute contraindications to ethanol’s use for these indications. Use of ethanol with fomepizole is usually contraindicated; see drug interactions for more information.

Adverse Effects
The systemic adverse effects of alcohol are quite well known. The CNS depression and respiratory depression associated with the high levels used to treat ethylene glycol and methanol toxicity can confuse the clinical monitoring of these toxicities. Ethanol’s affects on antidiuretic hormone (vasopressin) may enhance diuresis. As both ethylene glycol and methanol may also cause diuresis, fluid and electrolyte therapy requirements need to be monitored and managed. Hypocalcemia and metabolic acidosis may be noted and pulmonary edema can occur. Other adverse affects include pain and infection at the injection site and phlebitis. Extravasation should be watched for and avoided. When aerosolized in horses, irritation and bronchoconstriction may result.

Reproductive/Nursing Safety
Alcohol’s safety during pregnancy has not been established for short-term use. Use only when necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) Alcohol passes freely into milk in levels that approximate maternal serum levels, but it is unlikely to have negative effects on nursing offspring.

Overdosage/Acute Toxicity
If clinical signs of overdosage occur (lateral nystagmus, respiratory depression, profound obtundation), either slow the infusion or discontinue temporarily. Alcohol blood levels may be used to monitor both efficacy and toxicity of alcohol.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ethanol and may be of significance in veterinary patients:

- **BROMOCRIPTINE:** Alcohol may increase the severity of side effects seen with bromocriptine
- **CHARCOAL, ACTIVATED:** Will inhibit absorption of orally administered ethanol; do not use activated charcoal if administering ethanol orally for methanol or ethylene glycol intoxication
- **CNS DEPRESSANT DRUGS (e.g., barbiturates, benzodiazepines, phenothiazines, etc.):** Alcohol may cause additive CNS depression when used with other CNS depressant drugs
- **FOMEPIZOLE (4-MP):** Inhibits alcohol dehydrogenase; ethanol metabolism is reduced significantly and alcohol poisoning (CNS depression, coma, death) can occur. Use together is generally not recommended, but if both drugs are used, monitoring of ethanol blood levels is mandatory.
- **INSULIN and other antidiabetic drugs:** Alcohol may affect glucose metabolism and the actions of insulin or oral antidiabetic agents
  - A disulfiram reaction (increased acetaldehyde with tachycardia, vomiting, weakness) may occur if alcohol is used concomitantly with the following drugs: chlorpropamide, furazolidone, metronidazole.

Laboratory Considerations
Ethylene Glycol Testing Kits: Ethanol may cause false positive reports on ethylene glycol screening tests. Refer to the product used, for more information.

Doses

- **DOGS:**
  - As a 20% solution, give 5.5 mL/kg IV q4h for 5 treatments, then q6h for four additional treatments; dosed as a CRI over 1 hour (Forrester & Lees 1994), (Hall 2009)
References

For information on obtaining tax-free alcohol for medicinal purposes, contact a regional office of the Bureau of Alcohol, Tobacco, and Firearms.

Alcohol (Ethanol) in Dextrose Infusions:

HUMAN-LABELED PRODUCTS:

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status

Example:

To make a 7% ethanol solution (see Compatibility/Compounding Considerations below) and give 8.6 mL/kg slowly IV followed by a CRI of 1.43 mL/kg/hr for at least 36 hours although 48 hours is probably better. If the EG test was positive initially, then check it before stopping treatment; discontinue treatment if it reverts to negative. (Shell 2006)

CATS:

For ethylene glycol poisoning:

a) As a 20% solution, give 5 mL/kg IV q6h for 5 treatments, then q8h for four additional treatments; dosed as a CRI over 1 hour (Forrester & Lees 1994), (Hull 2009)

b) Make a 7% ethanol solution (see Compatibility/Compounding Considerations below) and give 8.6 mL/kg slowly IV followed by a CRI of 1.43 mL/kg/hr for at least 36 hours although 48 hours is probably better. If the EG test was positive initially, then check it before stopping treatment; discontinue treatment if it reverts to negative. (Shell 2006)

Monitoring

- Alcohol blood levels (and ethylene glycol or methanol levels). Note: In humans, blood ethanol levels should be maintained at 100 to 130 mg/deciliter (21.7 to 28.2 milliMoles/liter). It is safer to maintain a blood ethanol concentration greater than 130 mg/deciliter than to have it fall below 100 mg/deciliter. (POISINDEX® Managements, Thompson; MICROMEDEX® Healthcare Series, 2007)
- Degree of CNS effect
- Fluid/electrolyte status

Client Information

- Systemically administered alcohol should be given in a controlled clinical environment.

Chemistry/Synonyms

A transparent, colorless, volatile liquid having a characteristic odor and a burning taste, ethyl alcohol is miscible with water and many other solvents.

“Proof” is considered 2X the percentage of ethanol. For example, a 100 proof vodka is 50% ethanol; an 80 proof vodka is 40% ethanol. In some states, pure grain alcohol (often called “Everclear”) can be purchased which is a 95% ethanol (190 proof) product.

Ethanol may also be known as aethanolum, alcool, grain alcohol, ethanolum, and ethyl alcohol.

Storage/Stability/Preparation

Alcohol should be protected from extreme heat or freezing. Do not use unless the solution is clear. Alcohol may precipitate many drugs; do not administer other medications in the alcohol infusion solution unless compatibility is documented (consult specialized references or a hospital pharmacist for more specific information).

Compatibility/Compounding Considerations

Note: Since alcohol infusions are generally only used in veterinary medicine for the treatment of ethylene glycol/methanol toxicity and obtaining medical or laboratory grade alcohol or pharmaceutical grade products can be very difficult in an emergency, veterinarians have often had to improvise. One method that has been successful, albeit not pharmaceutically elegant, is to use commercially available vodka (40%–80 proof; 50%-100 proof) or grain alcohol (“Everclear”; 95%-190 proof) diluted in an appropriate IV solution (e.g., LRS, D5W, etc).

- To make an ethanol solution of a lesser concentration than the stock solution:
  - Choose the percentage you want (5%–20%) to administer
  - Divide this number by the % (NOT proof) of ethanol of the stock solution
  - Multiply this amount by the total volume of the IV bag that will be used (250 mL–1000 mL) to determine the mLs of stock solution to use.
  - Remove this amount from the fluid bag and add the appropriate amount of alcohol solution to make a solution of the desired alcohol percentage

Examples:

- To make a 20% ethanol solution using 80 proof (40%) vodka in a one liter bag of fluids: 20% ÷ 40% = 0.5; multiply by 1000 = 500 mL. Remove 500 mL of fluids from the bag and add 500 mL of 80 proof vodka = 1000 mL of a 20% ethanol solution
- To make a 5% solution using 100 proof (50%) vodka in a 500 mL bag of fluids: 5% ÷ 50% = 0.1; multiply by 500 = 50 mL. Remove 50 mL of fluids from the bag and add 50 mL of 100 proof vodka = 500 mL of a 5% ethanol solution
- To make a 7% ethanol solution from 190 proof (95%) “Everclear” in a 250 mL bag of fluids: 7% ÷ 95% = 0.074; multiply by 250 = 18.5 mL. Remove 18.5 mL of fluids from the bag and add 18.5 mL of 190 proof (95%) grain alcohol = 250 mL of a 7% ethanol solution

Regardless of the product used, it is recommended that an in-line filter be used for the IV and the client give informed consent for the use of this non-pharmaceutical product.

ETIDRONATE DISODIUM
(e-di-dro-ne-a-tet Diadrone®)
ORAL BIPHOSPHONATE BONE RESOPRTION INHIBITOR

Prescriber Highlights

- Biphosphonate that reduces calcium resorption from bone; used primarily to treat hypercalcemia associated with malignancy
- Contraindications: Treatment of hypercalcemia in patients with severe renal function impairment
- Caution in patients with bone fractures, enterocolitis, cardiac failure, or moderate renal function impairment
- Adverse Effects: Potentially, diarrhea, nausea, or bone pain/tenderness
- Do not confuse etidronate with etretinate or etomidate
- Expense may be an issue

Uses/Indications
Etidronate is a first generation bisphosphonate that may be useful for the treatment of severe hypercalcemia associated with neoplastic disease. Its use in human medicine has been largely replaced with newer, more potent bisphosphonates that can be dosed less often or have fewer adverse effects. Etidronate is also indicated in humans for the treatment of Paget’s disease and heterotopic ossification (e.g., after total hip replacement).

Pharmacology/Actions
Etidronate’s primary site of action is bone. It reduces normal and abnormal bone resorption. This effect can reduce hypercalcemia associated with malignant neoplasms. Etidronate can also increase serum phosphate concentrations, presumably by increasing the renal tubular reabsorption of phosphate. Some early studies in lab animals suggest that etidronate may inhibit the formation of bone metastases with some tumor types.

Pharmacokinetics
Oral absorption is poor and dose dependent. As little as 1% of a dose (smaller doses) may be absorbed; with higher doses, up to 20% may be absorbed. Food substantially reduces the amount absorbed. After oral dosing, the drug is rapidly cleared from blood and 50% of the drug absorbed goes into bone. At usual doses, it appears that etidronate does not cross the placenta. Duration of effect may be very prolonged. In humans, effects have persisted for up to one year after discontinuation in patients with Paget’s disease. Effects for hypercalcemia may last for 11 days. Absorbed etidronate is excreted unchanged by the kidneys. Approximately 50% of the absorbed dose is excreted within 24 hours; the remainder is chemisorbed to bone and then slowly eliminated.

Contraindications/Precautions/Warnings
Etidronate is considered contraindicated for the treatment of hypercalcemia in patients with renal function impairment (serum creatinines >5 mg/dL). Risk vs. benefit should be carefully considered in patients with bone fractures (delays healing), enterocolitis (higher risk of diarrhea), cardiac failure (especially with parenteral etidronate as patients may not tolerate the extra fluid load), or those with renal function impairment (serum creatinines 2.5–5 mg/dL).

Adverse Effects
Adverse effects are not well described in small animals. In humans, diarrhea, nausea (with higher oral doses), and bone pain/tenderness are most the likely adverse effects reported. Increases in serum creatinine are possible.

A syndrome called “frozen bone” has been reported in dogs on moderately high doses of etidronate or other non-amino bisphosphonates (clodronate). Bone remodeling and repair are inhibited enough that bones can weaken and fracture. Newer bisphosphonates appear to be much safer with respect to this syndrome.

Reproductive/Nursing Safety
Etidronate’s safety during pregnancy has not been established. Rabbits given oral doses 5X those recommended in humans, demonstrated no overt problems with offspring. Rats, given very large doses IV, showed skeletal malformations. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown if the drug enters milk.

Overdosage/Acute Toxicity
Very little information is available at this time. Overdoses may result in hypocalcemia (ECG changes may occur), bleeding problems (secondary to rapid chelation of calcium) and proximal renal tubule damage.

Use standard gut emptying protocols after oral ingestion when warranted. IV calcium administration (e.g., calcium gluconate) may be used to reverse hypocalcemia. Intensive monitoring is suggested.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving etidronate and may be of significance in veterinary patients:

ANTACIDS, DIARY PRODUCTS, MINERAL SUPPLEMENTS, and medications containing iron, magnesium, calcium or aluminum: Absorption of oral etidronate may be inhibited; separate etidronate doses from these substances by at least two hours.
Laboratory Considerations

- Etidronate may interfere with bone uptake of technetium Tc 99m medronate or technetium Tc 99m oxidronate

Doses

**DOGS:**

For severe hypercalcemia associated with neoplastic disease:
- 5–15 mg/kg daily to twice daily PO; for moderate to severe hypercalcemia (Chew et al. 2003)

**CATS:**

For severe hypercalcemia associated with neoplastic disease:
- 5–20 mg/kg/day PO (Ward 1999)

Monitoring

- Serum calcium
- Serum protein

Client Information

- Recommended to give dose to animal that has an empty stomach.
- If anorexia or vomiting occur, notify veterinarian.

Chemistry/Synonyms

An analog of pyrophosphate, etidronate disodium (also known as EHDP, Na2EHDP, or sodium etidronate) is a biphosphonate agent that occurs as a white powder and is freely soluble in water. Unlike pyrophosphate, etidronate is resistant to enzymatic degradation in the gut.

Etidronate disodium may also be known as: EHDP, disodium etidronate, etidronate disodium, Anfozan®, Bonemass®, Didronate®, Didronel®, Difosfen®, Diphos®, Dralent®, Dronate-OS®, Etidrate®, Etiplus®, Feminoflex®, Ostedron®, Osteodidronel, Osteum®, Ostogene®, Ostopor®, Somaflex®, and Sviroxit®.

Storage/Stability

Store tablets in tight containers at room temperature.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Etidronate Disodium Tablets: 200 mg, & 400 mg; Didronel® (Procter & Gamble Pharm.); generic (Genpharm); (Rx)

ETODOLAC

(ee-toe-doe-lak) EtoGesic®, Lodine®

**NON-STEROIDAL ANTIINFLAMMATORY AGENT**

Prescriber Highlights

- NSAID (SC, oral) used in dogs, relatively few adverse effects & labeled for once daily
- Contraindications: Hypersensitivity
- Caution: Patients with preexisting or occult GI, hepatic, renal, cardiovascular, or hematologic abnormalities
- Safe use not established for dogs less than 12 months of age or in breeding, pregnant, or lactating dogs
- Adverse Effects: Vomiting, diarrhea, lethargy, hypoproteinemia; keratoconjunctivitis sicca possible; localized pain or tissue reactions at injection site
- Drug interactions

Uses/Indications

Etidolac is labeled for the management of pain and inflammation associated with osteoarthritis in dogs. It may find uses, however, for a variety of conditions where pain and/or inflammation should be treated.

Pharmacology/Actions

Like other NSAIDs, etodolac has analgesic, antiinflammatory, and antipyretic activity. Etodolac appears to be more selective for inhibition of cyclooxygenase-2 than cyclooxygenase-1, but studies conflict and a definitive answer is not presently agreed upon. It may be better to describe etodolac as a COX-1 sparing drug, rather than...
Etodolac is a COX-2 selective drug. In dogs, etodolac dose also affects whether the drug causes gastrointestinal adverse effects. Doses as little as 2.7X can produce gastrointestinal lesions. Etodolac is also thought to inhibit macrophage chemotaxis, which may explain some of its antiinflammatory activity.

In horses, etodolac does not exhibit much COX-2 selectivity.

Pharmacokinetics
The S(+) enantiomer is thought to provide the bulk of the pharmacologic activity, but the drug is supplied as a racemic mixture. Pharmacokinetic studies that measure both forms as one are not very relevant clinically. After oral administration to healthy dogs, etodolac is rapidly and nearly completely absorbed. The presence of food may alter the rate, but not the extent, of absorption. Peak serum levels occur about 2 hours post dosing. Etodolac is highly bound to serum proteins. The drug is primarily excreted via the bile into the feces. Glucuronide conjugates have been detected in the bile but not the urine. Elimination half-life in dogs varies depending whether food is present in the gut, which may affect the rate of enterohepatic circulation of the drug. These values range from about 8 hours (fasted) to 12 hours (non-fasted). Serum half-life is not necessarily a good predictor for duration of efficacy, possibly due the drug’s high protein binding.

In horses, etodolac has an oral bioavailability of about 77%. After IV dosing, volume of distribution was 0.29 L/kg and the clearance was 235 mL/hr/kg. Elimination half-life (after IV dosing) was approximately 2.5–3.0 hours.

Contraindications/Precautions/Warnings
Etodolac is contraindicated in dogs previously found to be hypersensitive to it. It should be used with caution in dogs with preexisting or occult GI, hepatic, cardiovascular, or hematologic abnormalities as NSAIDs may exacerbate these conditions. Patients may be more susceptible to renal injury from etodolac if they are dehydrated, on diuretics, or have preexisting renal, hepatic, or cardiovascular dysfunction.

Safety of etodolac has not been established in dogs less than 12 months of age.

Adverse Effects
In clinical field studies, etodolac’s primary adverse effect was vomiting/regurgitation, reported in about 5% of dogs tested. Diarrhea, lethargy, and hypoproteinemia have also been reported in dogs. Uterine, behavioral changes, and inappetence were reported in less than 1% of dogs treated. Potentially, hepatotoxicity and/or nephrotoxicity are possible, but are not well-documented problems in dogs.

Etodolac injection may cause localized pain or tissue reactions at injection site.

Etodolac may decrease total serum T4 in some dogs. Clinical significance is unclear.

Etodolac appears to have less impact on clotting times than other canine-FDA-approved NSAIDs.

Cases have been reported of dogs developing keratoconjunctivitis sicca (KCS) after receiving etodolac treatment. Incidence rate is unknown at this time.

The manufacturer warns to terminate therapy if inappetence, vomiting, fecal abnormalities, or anemia are observed.

Reproductive/Nursing Safety
Safe use has not been established in breeding, pregnant, or lactating dogs; use only when the benefits clearly outweigh the potential risks in these animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Most NSAIDs are excreted in milk; use with caution.

Overdosage/Acute Toxicity
Limited information is available, but in a safety study where dogs were given 40 mg/kg/day (2.7X) GI ulcers, weight loss, emesis and local occult blood were noted. Doses of 80 mg/kg/day (5.3X), caused 6 of 8 dogs to either die or become moribund secondary to GI ulceration. It should be noted that these were not single dose overdoses. However, they demonstrate that there is a relatively narrow therapeutic window for the drug in dogs and that doses should be carefully determined (i.e., do not confuse mg/kg dosages with mg/lb).

There were 39 exposures to etodolac reported to the ASPCA Animal Poison Control Center (APCC) during 2006-2009. In these cases 4 were cats with 2 showing clinical signs and the remaining 35 cases were dogs with 5 showing clinical signs. Common findings in these cases are recorded in decreasing frequency including cardiovascular, or hematologic abnormalities as NSAIDs may exacerbate these conditions. Patients may be more susceptible to renal injury from etodolac if they are dehydrated, on diuretics, or have preexisting renal, hepatic, or cardiovascular dysfunction.

Cases have been reported of dogs developing keratoconjunctivitis sicca (KCS) after receiving etodolac treatment. Incidence rate is unknown at this time.

The manufacturer warns to terminate therapy if inappetence, vomiting, fecal abnormalities, or anemia are observed.

Drug Interactions
Note: Although the manufacturer does not list any specific drug interactions in the package insert, it does caution to avoid or closely monitor etodolac’s use with other drugs, especially those that are also highly protein bound. It also recommends close monitoring, or to avoid using etodolac with any other ulcerogenic drugs (e.g., corticosteroids, other NSAIDs). While some advocate a multi-day washout period when switching from one NSAID to another (not aspirin—see below), there does not appear to be any credible evidence that this is required. Until so, consider starting the new NSAID when the next dose would be due for the old one.

The following drug interactions have either been reported or are theoretical in humans or animals receiving etodolac and may be of significance in veterinary patients:

- **ACE INHIBITORS (enalapril, benazepril, etc.):** Etodolac may reduce the antihypertensive effects of ACE inhibitors. Because ACE inhibitors potentially can reduce renal blood flow, use with NSAIDs could increase the risk for renal injury. However, one study in dogs receiving tepoxalin did not show any adverse effect. It is unknown what effects, if any, occur if other NSAIDs and ACE inhibitors are used together in dogs.

- **ASPIRIN:** When aspirin is used concurrently with etodolac, plasma levels of etodolac could decrease and an increased likelihood of GI adverse effects (bleeding) could occur; concomitant administration of aspirin with etodolac cannot be recommended. Washout periods of several days is probably warranted when switching from an NSAID to aspirin therapy in dogs.

- **CYCLOSPORINE:** Etodolac may increase cyclosporine blood levels and increase the risk for nephrotoxicity.

- **DIGOXIN:** Etodolac may increase serum levels of digoxin. Use with caution in patients with severe cardiac failure.

- **FUROSEMIDE & OTHER DIURETICS:** Etodolac may reduce the saluretic and diuretic effects of furosemide.

- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with caution.

- **NEPHROTOXIC AGENTS (e.g., amphotericin B, aminoglycosides, cisplatin, etc.):** Potential for increased risk of nephrotoxicity if used with NSAIDs.

- **PHENOBARBITAL**: May increase the metabolism of etodolac in dogs.
PROBENECID: May cause a significant increase in serum levels and half-life of etodolac

WARFARIN: Etodolac may increase the risk for bleeding

Laboratory Considerations

- Etodolac may cause false-positive determinations of urine bilirubin.
- Etodolac therapy may alter thyroid function tests and their interpretation; falsely low values may occur in dogs receiving etodolac.

Doses

- **DOGS:**
  
  a) For treatment of pain and inflammation associated with osteoarthritis: Oral Tablets: 10–15 mg/kg PO once daily. Dogs less than 5 kg cannot be accurately dosed with EtoGesic® tablets. Adjust dose to obtain satisfactory response, but do not exceed 15 mg/kg. For long-term therapy, reduce dose level to minimum effective dosage.

  Injection: 10–15 mg/kg as a dorsoscapular subcutaneous (SC) injection. If needed, daily doses of tablets may begin 24 hours after the last injectable treatment. Use alternate injection sites. The likelihood of injection site reactions increases when administered near previous injection sites. (Package Insert; EtoGesic® Tablets; Injection—BIVI)

Monitoring

- Baseline (especially in geriatric dogs or dogs with chronic diseases or those where prolonged treatment is likely): physical exam, CBC, Serum chemistry panel (including liver and renal function tests), UA. It is recommended to reassess liver enzymes at one week of therapy. Should elevation occur, recommend discontinuing the drug.
- Tear production prior to, and during therapy
- Clinical efficacy
- Signs of potential adverse reactions: inappetence, diarrhea, mucoid feces, vomiting, melena, polyuria/polydipsia, anemia, jaundice, lethargy, behavior changes, ataxia, or seizures
- Chronic therapy: Consider repeating CBC, UA, and serum chemistries on an ongoing basis.

Client information

- Give the client written information on the proper use and monitoring for etodolac

Chemistry/Synonyms

An indole acetic acid derivative non-steroidal antiinflammatory agent (NSAID), etodolac occurs as a white, crystalline compound that is insoluble in water, but soluble in alcohol or DMSO. Etodolac has a chirally active center with a corresponding S (+) enantiomer and an R (-) enantiomer. The commercially available product is supplied as a racemic mixture of the forms.

Etodolac may also be known as: AY-24236, etodolacum, etodolic acid, Acudor®, Articular®, Dualgan®, Eccoxolac®, Edolan®, Elderin®, EtoGesic®, Etonox®, Etopan®, Flancox®, Hypen®, Lodot®, Lonine®, Metazin®, Sodolac®, Todolac®, Ultradol®, and Zedolac®.

Storage/Stability

The commercially available veterinary tablets should be stored at controlled room temperature (15–30°C).

The commercially available injection should be stored at or below 77°F (25°C).

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Etodolac Scored Tablets: 150 mg & 300 mg in bottles of 30 & 90; EtoGesic® (BIVI); (Rx). FDA-approved for use in dogs. Do not use in cats.

Etodolac Injection 10% (100 mg/mL) in 50 mL vials; EtoGesic® Injectable (BIVI); (Rx). FDA-approved for use in dogs. The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Etodolac Tablets: 400 mg & 500 mg; Capsules: 200 mg & 300 mg; and 400 mg, 500 mg & 600 mg extended-release tablets; generic; (Rx)

---

**ETOMIDATE**

(ee-to-mi-date) Amidate®

INJECTABLE ANESTHETIC

Prescriber Highlights

- Injectable non-barbiturate anesthetic agent that may be useful as an alternative to thiopental or propofol for induction, particularly in patients with preexisting cardiac dysfunction, head trauma, or that are critically ill
- Can inhibit cortisol production; may need to supplement corticosteroids in critically ill patients
- Not a controlled substance
- Relatively expensive, especially in large dogs
Uses/Indications
Etomidate may be useful as an alternative to thiopental or propofol for anesthetic induction in small animals, particularly in patients with preexisting cardiac dysfunction, head trauma, or that are critically ill.

Pharmacology/Actions
The exact mechanism of action of etomidate is not well defined. Etomidate causes minimal hemodynamic changes and little effect on the cardiovascular system when compared to other injectable anesthetic agents. At usual doses, etomidate has little effect on respiratory rate or rhythm. Etomidate decreases cerebral blood flow and oxygen consumption. It usually lowers intraocular pressure and causes slight decreases in intracranial pressure. Etomidate reportedly does not induce malignant hyperthermia, but can speed its onset in susceptible patients secondary to a triggering agent.

The reported therapeutic index (toxic dose/therapeutic dose) for etomidate is 16. Therapeutic indexes for propofol and thiopental are 3 and 5 respectively. In comparing etomidate with propofol when used for inductions in dogs, patients receiving etomidate had higher systolic arterial pressures and mean arterial pressures, but it caused longer and poorer recoveries than propofol (Sams et al. 2008).

Pharmacokinetics
No specific information on the pharmacokinetics of etomidate in domesticated animals was located. In humans, after intravenous injection etomidate is rapidly distributed into the CNS and then rapidly cleared from the brain back into systemic tissues. Duration of hypnosis is short (3–5 minutes) and dependent upon dose. Recovery from anesthesia appears to be as fast as with thiopental, but slower than propofol. Etomidate is 75% bound to plasma proteins. The drug is rapidly metabolized in the liver primarily via hydrolysis or glucuronidation to inactive metabolites. The majority of the drug and metabolites are excreted into the urine with the remainder into the bile and feces. Elimination half-life ranges from 1.25–5 hours.

Contraindications/Precautions/Warnings
Etomidate is contraindicated in patients known to be hypersensitive to it.

Etomidate can inhibit adrenocortical function; it should not be used for purposes other than induction, and with caution in patients whose adrenocortical function is impaired. Exogenous glucocorticoid administration should be considered in severely compromised animals.

Etomidate does not provide significant analgesia.

Adverse Effects
Common adverse effects include pain at intravenous injection site, vomiting, skeletal muscle movements (myoclonus), eye movements, and post-operative retching. Preatheoretic medications and a benzodiazepine (diazepam, midazolam) just prior to etomidate can minimize these effects.

Some hemolysis may occur due to the propylene glycol content of the injection. Some anesthesiologists recommend injecting etomidate into a running IV line to decrease the pain associated with injection and, potentially, reduce hemolysis.

While etomidate causes minimal cardiopulmonary depression, a brief period of hypventilation and decreased arterial blood pressure can occur after administration.

Apnea, laryngospasm, hiccups, hyperventilation, hypoventilation, hypertension, hypotension, lactic acidosis, arrhythmias, and postoperative vomiting have all been reported in human patients that have received the drug. Seizures have been reported in a few human patients receiving etomidate; this adverse effect may be reduced if an opiate premed is first administered.

Reproductive/Nursing Safety
In humans, the FDA categorizes etomidate as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). Etomidate has caused embryocidal effects in rats and maternal toxicity in rabbits and rats.

Some etomidate is excreted into maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity
Acute overdoses would be expected to cause enhanced pharmacologic effects of the drug. Treatment would be supportive (i.e., mechanical ventilation), until the effects of the medication are diminished.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving etomidate and may be of significance in veterinary patients:

- **CNS/RESPIRATORY DEPRESSANTS (e.g., barbiturates, opiates, anesthetics, etc.):** Additive pharmacological effects can occur if etomidate is used concurrently with other drugs that can depress CNS or respiratory function

- **VERAPAMIL:** Has been associated with potentiating the anesthetic and respiratory depressant effects of etomidate

Laboratory Considerations
- Etomidate’s effects on inhibiting cortisol may invalidate ACTH stimulation and glucose tolerance tests. In dogs, cortisol function may be affected up to 3 hours after an etomidate dose.

Doses
- **DOGS & CATS:**
  a) As an induction agent: etomidate 1 mg/kg IV plus diazepam 0.5 mg/kg IV (Cornell 2004)
  b) As an induction agent: 1–2 mg/kg rapidly IV (Heath 2003)
  c) As an induction agent: 0.5–2 mg/kg IV. Pre-medication is highly recommended to reduce incidence of side effects (myoclonus, vomiting). Alternatively or additionally, etomidate may be given with a benzodiazepine. Because of its effects on cortisol, administration of a physiologic dose of dexamethasone or another
**FERRERS:**

a) As an induction agent in the cardiovascular unstable patient: etomidate 1–2 mg/kg IV after diazepam (0.5 mg/kg IV) (Lichtenberger 2006)

**SMALL MAMMALS:**

a) **Rabbits:** As an induction agent in the cardiovascular unstable patient: etomidate 1–2 mg/kg IV after diazepam (0.5 mg/kg IV) (Lichtenberger 2006)

**Monitoring**

As per any anesthetic agent:

- Level of consciousness
- Respiration rate and depth
- Cardiovascular function

**Client Information**

Etomidate is a potent sedative-hypnotic that should only be used by professionals in a setting where adequate patient monitoring is available.

**Chemistry/Synonyms**

An injectable, carboxylic imidazole anesthetic, etomidate occurs as a white or almost white powder. It is very slightly soluble in water and freely soluble in alcohol. The commercially available injection has a pH of 8.1, contains 35% propylene glycol, and is hyperosmolar (4640 mosm/l).

Etomidate may also be known as: R-16659, Amidate®, Hypnomidate®, Radenarcon®, or Sibul®.

**Storage/Stability**

Unless otherwise labeled, store etomidate injection at room temperature and protect from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Etomidate Injection: 2 mg/mL in 10 mL & 20 mL single-dose vials, 10 mL & 20 mL amps and 20 mL Abboject syringes; Amidate® (Hospira); generic; (Rx)

**References**

**EUTHANASIA AGENTS WITH PENTOBARBITAL**

(yoo-than-ayzheh; pen-toe-barb-ital)

For therapeutic uses (other than euthanasia) of pentobarbital, see the main pentobarbital monograph for this agent. The sections on chemistry, storage, pharmacokinetics, overdosage, drug interactions, and monitoring parameters can be found in the main pentobarbital monograph.

**Prescriber Highlights**

- Used for humane euthanasia for animals not to be used for food
- Store so that it will not be confused with therapeutic agents; keep out of reach of children
- Use care in handling filled syringes & dispose of used injection equipment properly
- Avoid any contact with open wounds or accidental injection
- Tranquilizing agent may be necessary when the animal is in pain or agitated
- Renderers may not accept carcasses euthanized with pentobarbital

**Uses/Indications**

For rapid, humane euthanasia in animals not intended for food purposes. Individual products may be approved for use in specific species.

“The advantages of using barbiturates for euthanasia in small animals far outweigh the disadvantages. Intravenous injection of a barbituric acid derivative is the preferred method for euthanasia of dogs, cats, other small animals, and horses. Intraperitoneal injection may be used in situations when an intravenous injection would be distressful or even dangerous. Intracardiac injection must only be used if the animal is heavily sedated, unconscious, or anesthetized.” (AVMA Guidelines on Euthanasia, 2007)

**Pharmacology/Actions**

Pentobarbital causes death by severely depressing the medullary respiratory and vasomotor centers when administered at high doses. Cardiac activity may persist for several minutes following administration.
Phenytoin is added to Beuthanasia®-D Special (Schering) for its added cardiac depressant effects and to denature the compounds from a Class-II controlled substance to Class-III drugs.

**Contraindications/Precautions/Warnings**

Must not be used in animals to be used for food purposes (human or animal consumption). Should be stored in such a manner that these products will not be confused with therapeutic agents. Extreme care in handling filled syringes and proper disposal of used injection equipment must be undertaken. Avoid any contact with open wounds or accidental injection. Keep out of reach of children.

Prior use of a tranquilizing agent may be necessary when the animal is in pain or agitated.

**Adverse Effects**

Minor muscle twitching may occur after injection. Death may be delayed or not accomplished if injection given perivascularly.

**Doses**

Because different products have different concentrations, please refer to the information provided with the product in use.

**DOGS:**

a) Pentobarbital sodium (as a single agent): Approximately 120 mg/kg for the first 4.5 kg of body weight, and 60 mg/kg for every 4.5 kg of body weight thereafter. Preferably administer IV.

b) Pentobarbital sodium with phenytoin (Beuthanasia®-D Special): 1 mL for each 4.5 kg of body weight.

**CATS:**

a) Pentobarbital sodium (as a single agent): Approximately 120 mg/kg for the first 4.5 kg of body weight, and 60 mg/kg for every 4.5 kg of body weight thereafter. Administer IV.

b) Pentobarbital sodium with phenytoin: (Beuthanasia®-D Special): 1 mL for each 4.5 kg of body weight (not FDA-approved for use in this species).

**LARGE ANIMALS:**

Note: Must not be used in animals to be consumed by either humans or other animals.

a) Depending on product concentration, most animals require 10–15 mL per 100 pounds of body weight.

**Monitoring**

- Respiratory rate
- Cardiac rate
- Corneal reflex

**Client Information**

- Must be administered by an individual familiar with its use.
- Animals must be restrained during administration.
- Inform clients observing euthanasia that animal may give a terminal gasp after becoming unconscious.

**Dosage Forms/Regulatory Status**

See other pentobarbital dosage forms under the main pentobarbital monograph for lower concentration products that are used therapeutically.

**VETERINARY-LABELED PRODUCTS:**

Pentobarbital Sodium 390 mg/mL & Phenytoin Sodium 50 mg/mL for Injection (Euthanasia) in 100 mL vials; Beuthanasia®-D Special (Schering-Plough); Euthasol® (Virbac); Euthanasia-III® Solution (Med-Pharmex); Somnasol® (Butler); (Rx, C-III). Approved for use in dogs.

**Pentobarbital Sodium Powder:**

392 mg/mL when constituted with 250 mL of water. Fatal-Plus® Powder (Vortech), Pentasol® Powder (Virbac); (Rx, C-II). Approved for use in animals regardless of species.

Pentobarbital Sodium for Injection (Euthanasia):

- 260 mg/mL: Sleepaway® (Pfizer) 26%: in 100 mL bottles; (Rx, C-II). Labeled for use in dogs and cats.
- 324 mg/mL: SP5® (Vedco) in 100 mL vials; (Rx, C-II). Labeled for use in dogs and cats.
- 389 mg/mL: Socumb-6gr® (ButlerSchein), Somlethol® (Webster), SP6® (Vedco); 100 mL & 250 mL vials; (Rx, C-II). Labeled for use in dogs and cats.
- 390 mg/mL: Fatal-Plus® Solution (Vortech); in 250 mL vials (Rx, C-II). Labeled for use in animals regardless of species.

**HUMAN-LABELED PRODUCTS:** None

---

**FAMCICLOVIR**

(fam-sye-klow-veer) Famvir®

**ANTIVIRAL (HERPES)**

**Prescriber Highlights**

- May be effective in treating feline herpes (FHV-1) infections
May be effective in treating feline herpes (FHV-1) infections

Appears to be well tolerated when used short-term (2–3 weeks)

Relatively expensive, but prices may decrease now that generics are available

Uses/Indications
Famciclovir may be of benefit in treating feline herpes infections.

Pharmacology/Actions
In most species, famciclovir is rapidly converted in vivo to penciclovir. In cells infected with susceptible Herpes virus or varicella zoster virus, viral thymidine kinase phosphorylates penciclovir to penciclovir monophosphate. Cellular kinases further convert this compound to penciclovir triphosphate which inhibits herpes virus DNA polymerase via competition with deoxyguanosine triphosphate, thereby selectively inhibiting herpes viral DNA synthesis.

Viral resistance can occur by mutation.

Pharmacokinetics
The pharmacokinetics of famciclovir in cats is complex and not well understood. After oral administration of famciclovir (62.5 mg), penciclovir peak levels were less than the in vitro inhibitory concentration 50 (IC-50) for FHV-1. In humans, conversion of famciclovir to penciclovir requires oxidation by hepatic aldehyde oxidase. As cats possess little hepatic aldehyde oxidase they may require higher dosages than are used in humans or other species. (Thomasy et al. 2006), (Maggs 2009)

In humans, famciclovir is well absorbed after oral administration, but undergoes extensive first pass metabolism (not by CYP enzymes). Food can decrease peak levels, but does not significantly impact clinical efficacy. Penciclovir (active metabolite) is only marginally bound to plasma proteins. In humans, penciclovir elimination half-life is about 2–3 hours; excretion is primarily via renal mechanisms. Intracellular half-lives of penciclovir in infected cells are significantly longer.

Contraindications/Precautions/Warnings
Famciclovir is contraindicated in patients known to be hypersensitive to it or penciclovir.

It should be used with caution (and dosage adjustment) in patients with renal dysfunction. In humans patients with CrCl <40 mL/min, dosage adjustments are recommended.

Adverse Effects
Adverse effects in cats are not well documented, but the drug appears to be tolerated quite well when used for up to 3 weeks. At doses of 90 mg/kg PO q8h, anorexia and polydipsia have been noted in some cats.

In humans, famciclovir can cause nausea, vomiting, diarrhea, and headache. Neutropenia has been reported and renal failure can occur, particularly when doses are not adjusted in patients with renal dysfunction.

Reproductive/Nursing Safety
In laboratory animals, doses of up to 1,000 mg/kg/day did not cause any observed effects on developing embryos or fetuses. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Famciclovir (as penciclovir) is excreted in the milk of rats. It is unclear if there is any clinical significance for nursing offspring.

Overdosage/Acute Toxicity
Little information is available. Supportive treatment has been recommended. Penciclovir can be removed by hemodialysis.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving famciclovir and may be of significance in veterinary patients:

PROBENECID: Can reduce the amount of penciclovir excreted by the kidneys, increase penciclovir plasma levels can occur

Laboratory Considerations
No concerns noted

Doses
CATS:

For feline herpes virus (FHV-1):

Note: There is a considerable amount of uncertainty at present how to dose cats with famciclovir, but because the drug looks promising, there will be more data forthcoming.

a) There is a wide range of doses used; author’s choice: 125 mg (total dose) PO 2-3 times a day. (Ketring 2009)

b) For adjunctive treatment of FHV-1 rhinotracheitis: 31.25 mg (1/4 of one 125 mg tablet) PO q12h for 14 days. Has not been evaluated for long-term therapy. (Lappin 2007)

c) For chronic, recurrent and/or severe herpes viral infection: Dose range is variable! Kittens: ¼th of one 125 mg tablet PO once daily (q24h) for 2 weeks; adult cats: ¼ of one 250 mg tablet once daily (q24h) for 3 weeks. (Diehl 2007)

d) 1/4 of one 125 mg tablet PO twice daily (q12h) for 10–14 days; may continue once daily for up to 30 days. (Ramsey 2006)

e) For adjunctive treatment (with interferon and lysine) of herpes virus-associated ulcerative facial dermatitis & stomatitis: 125 mg PO q12h. (Hillier 2006)
Monitoring

- Clinical efficacy
- Adverse effects (most likely GI)
- Consider occasional CBC’s and creatinine to monitor for neutropenia or renal dysfunction if using the drug chronically

Client Information

- May be administered with food
- There is limited experience with this drug in cats, report any unusual effects to the veterinarian
- FHV-1 infections are controlled, not cured, and recurrence may occur even if the cat is treated life-long

Chemistry/Synonyms

A prodrug, famciclovir is a purine-derived, synthetic, acyclic purine nucleoside analog.

Famciclovir may also be known as AV 42810, BRL 42810, famciclovirum, or by the trade name *Famvir*.

Storage/Stability

Famiclovir tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Famiclovir Oral Tablets (film-coated) 125 mg, 250 mg, & 500 mg: *Famvir*® (Novartis); generic; (Rx)

**FAMOTIDINE**

(“fa-moe-tideen”) *Pepcid®*

**H2-RECEPTOR ANTAGONIST**

Prescriber Highlights

- H2-receptor antagonist used to reduce GI acid production
- Longer duration of action & fewer drug interactions than cimetidine
- Contraindications: Hypersensitivity to H2 blockers
- Caution: Patients with cardiac disease, significantly impaired hepatic or renal function; (consider dosage reduction)
- Adverse Effects: Too rapid IV infusion may cause bradycardia. Potentially: GI effects, headache, or dry mouth or skin; rarely, intravascular hemolysis anecdotally reported when given IV to cats

Uses/Indications

In veterinary medicine, famotidine may be useful for the treatment and/or prophylaxis of gastric, abomasal and duodenal ulcers, uremic gastritis, stress-related or drug-induced erosive gastritis, esophagitis, duodenal gastric reflux, and esophageal reflux. It has been recommended in dogs as an “… excellent drug for routine prophylaxis where cost is a concern and where an injectable drug is preferred or … in dogs requiring extended therapy (a minimum of one week), since its effects will improve with time and become comparable to the more expensive PPIs” (Bersenas 2007).

Famotidine has significantly fewer drug interactions than cimetidine and activity may persist longer.

In dogs, famotidine did not improve outcomes (eradication) of Helicobacter infections when added to triple antibiotic therapy (Leib *et al.* 2007). Omeprazole was superior to famotidine when used to prevent exercise-induced gastritis in racing Alaskan sled dogs (Williamson *et al.* 2010).

Pharmacology/Actions

At the H2 receptors of the parietal cells, famotidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, pentagastrin, histamine or insulin. Gastric emptying time, pancreatic or biliary secretion, and lower esophageal pressures are not altered by famotidine. By decreasing the amount of gastric juice produced, H2-blockers also decreases the amount of pepsin secreted.

Pharmacokinetics

Famotidine is not completely absorbed after oral administration, but undergoes only minimal first-pass metabolism. In humans, systemic bioavailability is about 40–50%. Distribution characteristics are not well described. In rats, the drug concentrates in the liver, pancreas, kidney and submandibular gland. Only about 15–20% is bound to plasma proteins. In rats, the drug does not cross the blood brain barrier or the placenta. It is distributed into milk. When the drug is administered orally, about 1/3 is excreted unchanged in the urine and the remainder primarily metabolized in the liver and then excreted in the urine. After intravenous dosing, about 2/3’s of a

Contraindications/Precautions/Warnings

Drug Interactions

Doses

CATS:

Note: See the warning (in the adverse effects section) about IV use in cats.

To reduce gastric acid production:

To reduce gastric acid production:

dogs:

24 hours before performing either of these tests.

Because of this wide margin of safety associated with the drug, most overdoses should require only monitoring. In massive oral overdoses, gut-emptying protocols should be considered and supportive therapy initiated when warranted.

Famotidine is contraindicated in patients with known hypersensitivity to the drug.

Famotidine may decrease the absorption of oral iron; administer iron at least one hour prior to famotidine

The pharmacokinetics of famotidine, ranitidine, and cimetidine have been investigated in horses. (Duran and Ravis 1993) After a single IV dosage, elimination half-lives of cimetidine, ranitidine, and famotidine all were in the 2–3 hour range and were not significantly different. Of the three drugs tested, famotidine had a larger volume of distribution (4.28 L/kg) than either cimetidine (1.14 L/kg) or ranitidine (2.04 L/kg). Bioavailability of each of the drugs was low; famotidine (13%), ranitidine (13.5%) and cimetidine (30%).

The following drug interactions have either been reported or are theoretical in humans or animals receiving famotidine and may be of significance in veterinary patients:

The minimum acute lethal dose in dogs is reported to be >2 grams/kg for oral doses and approximately 300 mg/kg for intravenous doses. IV doses in dogs ranging from 5–200 mg/kg IV caused: vomiting, restlessness, mucous membrane pallor and redness of the mouth and ears. Higher doses caused hypotension, tachycardia and collapse.

A retrospective study evaluating IV famotidine in 56 hospitalized cats did not show any evidence of hemolysis. The authors concluded that the IV route appeared safe in cats when famotidine was administered over 5 minutes (Galvao & Trepanier 2008).

To reduce gastric acid production:

Famotidine is excreted unchanged in the urine and the remainder primarily metabolized in the liver and then excreted in the urine. After intravenous dosing, about 2/3’s of a dose is excreted unchanged.

To reduce gastric acid production:

Histamine2-blockers may antagonize the effects of histamine and pentagastrin in the evaluation gastric acid secretion.

Overdosage/Acute Toxicity

Adverse Effects

Too rapid IV infusion may cause bradycardia. Other H2-blockers have been demonstrated to be relatively safe and exhibit minimal adverse effects. Potential adverse effects (documented in humans) that could be seen include GI effects (anorexia, vomiting, diarrhea), headache, or dry mouth or skin. Rarely, agranulocytosis may develop particularly when used concomitantly with other drugs that can cause bone marrow depression.

There are rare anecdotal reports of famotidine causing intravascular hemolysis when given intravenously to cats. It is believed this is probably an idiosyncratic reaction that occurs in a small percentage of cats treated. A retrospective study evaluating IV famotidine in 56 hospitalized cats did not show any evidence of hemolysis. The authors concluded that the IV route appeared safe in cats when famotidine was administered over 5 minutes (Galvao & Trepanier 2008).

Reproductive/Nursing Safety

In lab animal studies, famotidine demonstrated no detectable harm to offspring. Large doses could affect the mother’s food intake and weight gain during pregnancy that could indirectly be harmful. Use in pregnancy when potential benefits outweigh the risks. In rats, nursing from mothers receiving very high doses of famotidine, transient decreases in weight gain occurred. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Famotidine is excreted in the milk of rats. It is unclear if there is any clinical significance for nursing offspring with H2-blockers in milk.

The following drug interactions have either been reported or are theoretical in humans or animals receiving famotidine and may be of significance in veterinary patients:

• AZOLE ANTIFUNGALS (ketoconazole, itraconazole, fluconazole): By raising gastric pH, famotidine may decrease the absorption of these agents; if both drugs are required, administer the azole one hour prior to famotidine

• CEFPODOXIME, CEFUROXIME: Famotidine may decrease the absorption of these cephalosporins; taking with food may alleviate this effect

• IRON SALTS (ORAL): Famotidine may decrease the absorption of oral iron; administer iron at least one hour prior to famotidine

Unlike cimetidine or ranitidine, famotidine does not appear to inhibit hepatic cytochrome P-450 enzyme systems and dosage adjustments of other drugs (e.g., warfarin, theophylline, diazepam, procainamide, phenytoin) that are metabolized by this metabolic pathway should usually not be required.

Laboratory Considerations

• Histamine2-blockers may antagonize the effects of histamine and pentagastrin in the evaluation gastric acid secretion.

• After using allergen extract skin tests, histamine2 antagonists may inhibit histamine responses. It is recommended that histamine2 blockers be discontinued at least 24 hours before performing either of these tests.

Doses

While the use of H2 blockers in cats is unusual, the following dosages are based on human and canine usage:

To reduce gastric acid production:

To reduce gastric acid production:

DOSING:

a) 0.2 mg/kg PO, SC, IM, IV q24h (Marks, 2008)

b) 0.5 mg/kg PO, SC, IM, IV q12–24 hours (Matz 1995)

c) For esophagitis: 0.5–1 mg/kg PO q12h (Glazer & Walters 2008)

d) 0.55–1.1 mg/kg PO q24h (or every 12 hours if there is severe esophagitis) for 2–3 weeks in dogs with acute reflex esophagitis (Tams 2003)

e) For adjunctive treatment (to prevent/treat gastric ulcers) of mast cell tumors: 0.5 mg/kg once daily (route not specified). (Garrett 2006)

f) For adjunctive treatment of GI effects (anorexia, nausea, vomiting) associated with chronic kidney disease: 0.5 mg/kg PO once daily (q24h) Effective evidence grade: 3. (Polzin 2005)

FAT EMULSION, INTRAVENOUS

Intralipid®, Liposyn®, Intravenous Lipid

Emulsion

Prescriber Highlights

- Parenteral calorie and fatty acid source;
- Potentially useful in overdose situations to reduce free-drug blood levels of fat-soluble drugs; may be particularly useful in veterinary medicine for toxicities associated with high morbidity or mortality, particularly when traditional therapies have failed or are cost-prohibitive.
- When used for parenteral nutrition, use is controversial in critically ill patients.

Monograph reviewed by Justine Lee, DVM, DACVECC

Uses/Indications

Intravenous fat emulsions (IFE; intravenous lipid emulsion; ILE) can be used as a source of calories or essential fatty acids when parenteral feeding is required. IFE can be considered as a rescue treatment for intoxications caused by fat-soluble drugs/toxins when traditional treatments are not effective (Fernandez et al. 2011).

At present, this use is extra-label and good evidence is scant in veterinary medicine supporting this use clinically, but research is ongoing and some evidence-exists that IFE is, or theoretically could be useful for reducing free-drug levels for drugs or drug classes such as local anesthetics (bupivacaine, mepivacaine, ropivacaine, lidocaine) (O’Brien et al. 2010), macrocyclic lactones (ivermectin, moxidectin) (Crandell & Weinberg 2009), calcium channel blockers (verapamil, amlodipine), beta-blockers (propranolol, carvedilol), antidepressants (bupropion, doxepin, sertraline, clomipramine), antipsychotics (chlorpromazine, quetiapine), antiepileptics (carbamazepine, lamotrigine), muscle relaxants (baclofen, cyclobenzaprine), and flecainide. As certain treatments available for humans (e.g., hemoperfusion, hemodialysis, long-term ventilator or intensive care) are either unavailable or cost prohibitive in veterinary medicine, early intervention with IFE in the poisoned patient with severe clinical signs may be a relatively low cost and safe method to effectively treat veterinary patients for fat-soluble intoxications.

Pharmacology/Actions

Intravenously administered lipid emulsions can provide an efficient method (1 mL of a 20% emulsion provides approximately 2 kCal) of providing calories, and serve as a source of essential fatty acids. In addition, intravenous lipids can have immunosuppressive effects, increase pro-inflammatory cytokines, and affect pulmonary function.

When used for toxicologic indications, IFE’s exact mechanism of action is unknown, but it may serve as a “lipid sink” for fat soluble compounds, reducing the amount of free drug in the circulation and thereby reducing the drug’s toxic effects. Other hypotheses include: improving cardiac performance/function by increasing intracellular calcium and/or providing myocytes an energy substrate, or increasing the pool of fatty acids thus overcoming the inhibition of mitochondrial fatty acid metabolism by drugs such as bupivacaine.

Pharmacokinetics

IFE appears to be removed from the blood stream about as rapidly as chylomicrons, but the rate of removal requires prior lipolysis of IFE into free fatty acids and seems to be increased with hepatic activated lipoprotein. In humans, elimination half-life is about 30 minutes.

Contraindications/Precautions/Warnings

Intravenous lipids are contraindicated in patients with severe egg yolk allergies or abnormal fat metabolism. Strict aseptic technique and good IV catheter care are imperative when using IFE with or without amino acids and dextrose. When used alone, IFE may be administered via a peripheral line, but when combined with amino acids/dextrose as total parenteral nutrition (TPN), a dedicated central line is required due to the solution’s hypertonicity.

Use of IFE in critically ill animals is somewhat controversial. While there are no studies specifically addressing the role or safety of lipids in critically ill animals, human data suggests that lipid administration may be associated with significant immunosuppression, exacerbation of pre-existing pulmonary pathology, and increasing infection rates. Data also supports that withholding lipids for moderate periods of time is not associated with an increase in morbidity or mortality administration (Crandell 2005). In humans, intravenous lipids are used with caution in premature and low-birth weight infants (Black Box Warning; lipemia), patients with blood coagulation disorders, pulmonary disease, renal impairment, severe liver damage, and those at risk for fat emboli.

Adverse Effects

While IFE’s adverse effect profile/incidence rates have not been reported in veterinary patients, they are likely similar to those seen in human patients.

In humans, adverse effects associated with IFE are infrequent and are primarily reported when intravenous lipids are used for nutritional support. Most common are sepsis or thrombophlebitis secondary to IV administration, but these can occur whether intravenous lipids are used or not in parenteral nutrition therapy. Fat overload syndrome (hyperlipidemia, hepatomegaly, icterus, splenomegaly, fat embolism, thrombocytopenia, hemolysis, and prolonged clotting times) can occur, particularly if doses are too high or administration is too fast. More rarely (<1%), IFE can cause pulmonary toxicity, GI effects, somnolence, headache, flushing, fat emboli, hyperlipemia, pancreatitis, hypercoagulability, and hypersensitivity. IFE effects on pulmonary function and oxygenation are temporary and resolve after discontinuation.
Monitoring

Doses

As a nutritional agent for parenteral nutrition (PN):

Note: If using IFE for parenteral nutrition, the reader is advised to consult with a veterinary nutritionist and refer to more detailed references on the subject including: (Thomovsky, Backus et al. 2007), (Thomovsky, Reniker et al. 2007), (Chandler et al. 2008), (Campbell et al. 2006), (Freeman & Chan 2006)

a) Most recommendations are to consider intravenous lipids as energy substrates, and to administer them at 30-40% of total calories. In veterinary medicine, lipid administration ranges from 25-60% of calories administered. (Crandell 2005). Traditionally, IFE administration is not recommended at > 2 g/kg/day for TPN therapy. (Lee 2011).

b) There are two strategies employed by nutritionists to supply calories. One approach is to provide daily resting energy requirements (RER) with a mixture of all three nutrients (protein, dextrose, lipids) starting with provision of adequate protein (4-6 grams/100 kcal). Other nutritionists advocate supplying the daily RER in dextrose and lipids and adding protein “on top.” This approach asserts that proteins not catabolized for energy can be used to maintain protein synthesis. Hyperalimentation may be more frequent with the second approach. Generally, either approach can be used for total parenteral nutrition (TPN), but with partial parenteral nutrition (PPN) care should be taken with the second approach to keep the solution below 600 mOsm/L. Some nutritionists will supplement lipids alone for up to 3 days at RER. For example, a 10 kg dog with RER of 370 kcal/day. Intralipid® 20% solution (2 kcal/mL) could supply RER peripherally at 8 mL/hr. The lipid component of PPN is controversial and some nutritionists do not include lipids in PPN for critically ill patients because of concerns of increases in infection complications, immunosuppression, free radical generation and inflammation. Author recommends using caution when using imbalanced strategies. (Waldrop 2009)

As a rescue agent for fat-soluble drug/toxin intoxication:

a) In a study evaluating the evidence for using IFE for treating intoxications in humans, the authors concluded: Pending new evidence, IFE should be used in local anesthetic toxicity at the onset of neurological or cardiovascular signs. Also reasonable to administer IFE in any other hemodynamically significant intoxication from fat-soluble drugs after general supportive measures and recognized antidotes have been attempted unsuccessfully. All efforts to maximize oxygenation and perfusion should be provided before administration of ILE. No optimal regimen has been established to this date, but until then: IFE 20% via a sterile, peripheral IV catheter as a 1.5 mL/kg bolus over 1–3 minutes, then 0.25–0.5 mL/kg/min for 30–60 min. The bolus could be repeated in case of cardiac arrest. Titrating the infusion rate to the clinical response and repeating IFE administration at the onset of any recurrent deterioration appear reasonable. (Jamaty et al. 2010)

b) Currently, dose recommendations for IFE 20% are extrapolated from human medicine as noted in dose “a” above with a goal not to exceed 8 mL/kg/day. However, this dose has been exceeded in clinical recommendations by Pet Poison Helpline without ill effect and the use of IFE in an acute setting for toxicosis likely can exceed the current human recommendations. In a patient that continues to be symptomatic after traditional dosing (listed in dose “a” above), consider additional doses of 1.5 mL/kg IV over 30 min q4-6h for 24-36 hours until clinical signs resolve (based on clinical judgment), or maintaining a CRI of 0.5 mL/kg/hour until clinical signs resolve. (Lee 2010)

Overdosage/Acute Toxicity

In the case of an inadvertent overdose, stop the infusion until the lipid has cleared. This can be evaluated in a gross manner by visually inspecting the plasma (hematocrit tubes), or by laboratory methods (triglyceride concentrations, plasma light-scattering activity by nephelometry). When using IFE for drug toxicity, heparin therapy (75–250 Units/kg SQ q6h) can be considered in cases where severe hyperlipidemia is present as it may increase lipid clearance. However, heparin’s direct effect on IFE clearance is not proven. Weigh the risks of treating with heparin versus the effects of the target toxin, as the use of heparin may potentially affect the mechanism of action of IFE with fat-soluble toxicosis. Although there is no direct proof that hyperlipidemia secondary to IFE increases the risk for pancreatitis, some advocate using heparin when hyperlipemia occurs in dog breeds susceptible to pancreatitis (e.g., Shetland sheepdog, miniature schnauzer, Yorkshire terrier, obesity, etc.). Otherwise, heparin therapy is not recommended unless clinical signs or advanced diagnostics indicate otherwise. Monitor partial thromboplastin time (PTT) prior to use of heparin to ensure the patient is not already coagulopathic. If PTT exceeds 2-2.5X normal, the use of heparin should be either lowered (75 Units/kg SQ q 6-8) or discontinued. (Lee 2010).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving IFE and may be of significance in veterinary patients:

LIPID SOLUBLE DRUGS: Intravenous lipids (IFE) may affect the pharmacokinetics of lipid soluble drugs by serving as a “lipid sink” for free drug in the circulation. At present, clinical significance is not clear. However, when IFE is used (as a nutritional agent) concurrently with a fat soluble drug, monitor for decreased efficacy of the drug.

Laboratory Considerations

- Blood samples for diagnostics should be collected prior to administration of IFE to minimize affects from hyperlipidemia.
- Falsely high hemoglobin, MCH and MCHC values can occur if samples are drawn during or shortly after fat emulsion infusion.
- Serum bilirubin values may be affected by IFE.

Reproductive/Nursing Safety

When used clearly needed, the benefits of using intravenous lipids during pregnancy would likely outweigh the risks. However, the FDA has placed them in category C (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.). No data regarding the safe use of IFE during lactation is available, but while likely safe, the risks of nursing in patients that require IFE may outweigh the benefits to offspring.

Monitoring

- When used for toxicology indications: drug levels (serum or plasma) to evaluate the response to IFE therapy. This will aid in data collection for future retrospective study analysis. General recommended time frames for drug levels include: time 0 (at the time of presentation to the health care facility), 30 minutes after administration of IFE, 1 hour post, 6, hours post, 12 hours post, and 24 hours post. (Lee 2010) However, this should be based on the pharmacokinetics of said drug. (Lee 2010)

- When used for nutrition support; monitoring can be very involved and can include: blood glucose, serum triglycerides/lipemia, PCV, total protein, catheter and catheter site status, hydration status, vital signs (temperature, respiration rate, cardiac rate), serum electrolytes (including phosphorous), renal and liver function tests.
Fat Emulsion, intravenous are emulsified soybean (Intralipid®, Liposyn® III), or soybean and safflower (Liposyn® II) oils that provide the fatty acids: linoleic, stearic, linolenic, oleic and palmitic acids. Egg yolk phospholipids serve as the primary emulsifying agent and glycerol is used to adjust tonicity. Osmolarity varies with product, but range from 200–293 mOsm/L. The pH of IFE is between 6 and 9. Initially the pH is around 9, but secondary to hydrolysis of triglycerides into free fatty acids (FFA), the pH decreases to 6 at the end of the product’s shelf-life.

Storage/Stability
Unopened IFE products should be stored at room temperature (not above 25°C, 77°F) and not allowed to freeze. If accidentally frozen, it should be discarded. If a partial amount of a bag or bottle is used, the remaining product should be stored protected in the refrigerator (2-8°C), and discarded 24 hours after opening. A new bag or vial must be used every 24 hours.

Compatibility/Compounding Considerations
IFE is compatible when mixed with the usual components used in parenteral nutrition (dextrose, amino acids, parenteral multivitamins and trace elements), but it is advisable to contact a hospital pharmacist or refer to a drug compatibility reference for more information, as concentrations and mixing order can affect compatibility. This is particularly important as the opaque nature of IFE makes detection of precipitates very difficult.

Admixtures must be prepared with strict aseptic technique. Do not add additives directly to IFE, and in no case add fat emulsion to the total parenteral nutrition container first. The proper order of mixing: 1) transfer dextrose to the admixture container; 2) transfer amino acid solution; then 3) transfer fat emulsion. Alternatively, amino acids, dextrose, and fat emulsion may be simultaneously transferred to the admixture container; gently agitate the mixture. Use these admixtures promptly; store under refrigeration (2° to 8°C; 36° to 46°F) for 24 hours or less and use within 24 hours after removal from refrigeration.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Fat Emulsion, Intravenous 10%, 20%, 30%; depending on product, in 50 mL, 100 mL, 200 mL, 250 mL, & 500 mL bottles or bags; Intralipid® (Baxter), Liposyn® II & Liposyn® III (Hospira); (Rx)

References

**FATTY ACIDS, ESSENTIAL/OMEGA FISH OIL/VEGETABLE OIL**

**NUTRITIONAL**

**Prescriber Highlights**

- Used for treatment of dogs with pruritus associated with atopy, idiopathic seborrhea; in cats for pruritus associated with millary dermatitis & eosinophilic granuloma complex; may be useful in cats with heart failure.
- May also be useful in other species & for other disease states
- Safety in pregnancy not established; use caution in patients with coagulopathies
- Adverse Effects: High doses may cause GI distress; rarely some dogs may become lethargic or more pruritic

**Uses/Indications**

These products are usually used for the treatment of pruritus associated with atopy, idiopathic seborrhea, millary dermatitis and eosinophilic granuloma complex. In cats, omega-3 fatty acids may be helpful to reduce cytokines, and improve appetite in cats with heart failure. Fatty acids may improve coat quality and be helpful for adjunctive therapy for arthropathies such as hip dysplasia. When used for pruritus, significant therapeutic effects may be noted in only 25–50% of patients treated and require 2–3 months of treatment before evaluating efficacy. Antihistamine and fatty acid therapy may be synergistic for treatment of pruritus. Omega-3 fatty acids (linolenic, oleic and palmitic acids) are particularly the omega-3’s may prove to be useful for a variety of conditions, including renal failure, arthritis (both degenerative and autoimmune), cardiovascular disease (hypercoagulable states, heart failure, dysrhythmias), and some neoplastic diseases. One study suggested that dogs with chronic osteoarthritis fed a diet supplemented with fish oil omega-3 fatty acids could allow reductions in carprofen dosage (Fritsch et al. 2010). In another, dogs with osteoarthritis fed a diet with a very high omega-3 to omega-6 ratio (compared with the control diet, omega-3 levels were 31X greater, and omega-6 levels were 34X lower) had significantly lower serum levels of arachidonic acid and owners reported subjective improvement in arthritic condition (Roush et al. 2010).

The ACVM consensus statement on proteinuria in dogs and cats (Lees et al. 2005), states: “The treatment strategies to be considered are to feed an appropriate diet (one with reduced quantity but high quality protein with omega-3 fatty acid supplementation) to administer an angiotensin-converting enzyme inhibitor drug or both.”
There are many fish oil or flaxseed oil capsules available without prescription having various trade names. HUMAN-LABELED PRODUCTS: VETERINARY-LABELED PRODUCTS: Dosage Forms/Regulatory Status linolenic acid) that serve as essential fatty acids. They may also contain vitamin E (d-alpha tocopherol) and vitamin A. The commercially available veterinary products generally contain a combination of fish oil (eicosapentanoic and docosahexanoic acids) and vegetable oil (gamma linolenic or linoleic acids may be used as essential fatty acid sources which are necessary for normal skin and haircoats.

Chemistry/Synonyms/Storage/Stability

Monitoring

Efficacy

Adverse effects

Chemistry/Synonyms/Storage/Stability

The commercially available veterinary products generally contain a combination of fish oil (eicosapentanoic and docosahexanoic acids) and vegetable oil (gamma linolenic acid) that serve as essential fatty acids. They may also contain vitamin E (d-alpha tocopherol) and vitamin A.

The oral capsules should be stored in tight containers and protected from heat (cool, dry place).

Pharmacology/Actions

The exact pharmacologic actions of these products are not well described; particularly in light of the combination nature of the commercial products being marketed, it is difficult to ascertain which compounds may be responsible for their proposed efficacy. The particular therapeutic benefits and ratios of omega-3 versus omega-6 fatty acids are still being debated.

Fish oils affect arachidonic acid levels in plasma lipids and platelet membranes. They may affect production of inflammatory prostaglandins in the body, thereby reducing inflammation and pruritus. Linolenic or linoleic acids may be used as essential fatty acid sources which are necessary for normal skin and haircoats.

Contraindications/Precautions/Warnings

Because of potential affects on bleeding times, use with caution in patients with coagulation disorders or those receiving anticoagulant medications. Use with caution in patients with non-insulin dependent diabetes as omega-3 fatty acids have impaired insulin secretion with resultant increased glucose levels in humans with type-2 diabetes. Fatty acids should be used with caution in dogs that have had previous bouts with pancreatitis or protracted diarrhea.

Adverse Effects

At high dosages, GI disturbances (e.g., vomiting, diarrhea) may be seen. Rarely, some dogs become lethargic or more pruritic. In human patients, increased bleeding times and decreased platelet aggregation have been noted with use of fish oils; use with caution in patients with coagulopathies.

Reproductive/Nursing Safety

Safe use in pregnancy has not been established; these products are not recommended for use in pregnant human patients. Use cautiously in veterinary patients.

Overdosage/Acute Toxicity

With products containing vitamin A, acute toxicosis may result after accidental overdoses. Contact a poison control center for additional information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fatty acids/fish oils and may be of significance in veterinary patients:

ANTICOAGULANTS: Because of potential affects on bleeding times, use with caution in patients receiving anticoagulant medications such as aspirin, warfarin, or heparin

Doses

Because of the unique nature of each commercially available product, see the actual label directions of that product for specific dosage recommendations.

DOGS:

a) A few published clinical articles suggest that (for pruritus in dogs) a beneficial dose for eicosapentanoic acid (EPA) is around 22 mg/kg/day. (White 2003)
b) For adjunctive treatment of heart failure (particularly in dogs with cachexia or anorexia): The recommended daily dosage for fish oil is 40 mg/kg of eicosapentanoic acid (EPA) or 25 mg/kg of docosahexaenoic acid (DHA). (Note: the “or” in the previous sentence may be a typo and perhaps should be an “and” as fish oil supplements generally contain both EPA and DHA—Plumb) The amount of these specific fatty acids vary with different fish oil supplements, so check the label for recommending how many capsules to take. (Smith, F. 2009)
c) In Boxers with arrhythmogenic right ventricular cardiomyopathy (ARVC): Fish oil capsules containing a total of 390 mg EPA and 248.5 mg DHA were used in the study and dosed at PO once daily over 6 weeks. (Smith, C.E. et al. 2007)

CATS:

a) For adjunctive treatment in cats with CHF: Optimal dose of omega-3 fatty acids for cats is not yet known, author currently recommends 40 mg/kg EPA and 25 mg/kg DHA in cats. Fish oil supplements vary widely in the amount of EPA and DHA they contain so know the exact amount in supplements recommended. Capsules that contain approximately 180 mg EPA and 120 mg DHA can be purchased OTC at human pharmacies and administered at a dose of 1 capsule per 10 pounds body weight. Fish oil should contain vitamin E as an antioxidant, but supplements that contain other nutrients are not recommended to avoid toxicities. Cod liver oil and flax oil should not be used. (Freeman 2010)

Felbamate—See the product Drontal® Plus listed in the Praziquantel and Pyrantel monographs

**FELBAMATE**
(fel-ba-mayte) Felbatol®

**ANTICONVULSANT**

**Prescriber Highlights**

- 2nd or 3rd line antiseizure medication for dogs
- Appears relatively safe to use in dogs, but because of limited use, adverse effect profile may be incomplete
- Cost & accessibility may be issues

**Uses/Indications**
Felbamate is an anticonvulsant agent that may be useful for treating seizure disorders (generalized seizures, but especially complex partial seizures) in dogs. A potential advantage of felbamate therapy is that when used alone or in combination with phenobarbital and/or bromides, it does not appear to cause additive sedation.

**Pharmacology/Actions**
Felbamate’s anticonvulsant activity is thought to be due its ability to reduce excitatory neurotransmission; its exact mechanism is unknown, but it is believed to increase activation of sodium channels thereby decreasing sustained high-frequency firing of action potentials.

**Pharmacokinetics**
Felbamate is well absorbed after oral administration in dogs. Felbamate is both excreted unchanged and as metabolites in the urine (about 50:50). The half-life in dogs may range from 5–14 hours, but averages around 6 hours. Because the drug can induce liver enzyme induction, half-lives may decrease with time and dosages may need adjustment.

**Contraindications/Precautions/Warnings**
Felbamate is contraindicated in patients hypersensitive to it or other carbamates (meprobamate). In humans, felbamate should not be used in patients with a history of blood dyscrasias or hepatic dysfunction. In dogs, however, these are probably only cautions since dogs who require felbamate are often close to euthanasia due to the refractoriness of their conditions and a lack of evidence that felbamate causes liver toxicity in dogs.

**Adverse Effects**
Adverse reactions in the dog include KCS, liver enzyme induction, tremor, limb rigidity, salivation, restlessness and agitation (at high doses). In humans, aplastic anemia and hepatic necrosis have been noted and could be a factor in canine medicine. There apparently have not been any case reports yet of aplastic anemia in dogs, but blood dyscrasias (thrombocytopenia, lymphopenia, and leukopenia) have been reported. Additionally, sedation, and vomiting/nausea have been reported in dogs, but usually in those receiving other anticonvulsants as well.

**Reproductive/Nursing Safety**
Although no overt teratogenicity has been documented, felbamate should only be used during pregnancy when its potential benefits outweigh its potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

The drug is excreted into maternal milk, but adverse consequences to nursing puppies appear remote.

**Overdosage/Acute Toxicity**
Limited information is available. One human subject taking 12 grams over 12 hours only developed mild gastric distress and a slightly increased heart rate.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving felbamate and may be of significance in veterinary patients:

- **PHENOBARBITAL**: When felbamate is added to patients taking phenobarbital it may cause increases in phenobarbital levels. When phenobarbital is added to patients taking felbamate, felbamate levels may decrease. The same effect can occur with phenytoin.
- **VALPROATE**: Felbamate can cause increases in valproic acid levels

**Doses**

**DOGS:**

For seizures:

- a) As either add-on therapy or monotherapy: Starting dose is 15 mg/kg PO q8h. Dose can be increased in 15 mg/kg increments every 2 weeks until seizures are controlled. Doses as high as 70 mg/kg q8h are required and tolerated in some dogs. (Thomas 2010)
- b) As a third choice antiepileptic agent: 15–65 mg/kg PO q8h. Steady state reached after 4th oral dose. Monitor CBC and liver function tests as you would for phenobarbital. Therapeutic serum concentration reported to be 15–100 micrograms/mL. (Quesnel 2000)
phenobarbital. Therapeutic serum concentration reported to be 15–100 micrograms/mL. (Quesnel 2000)

c) For patients on phenobar and bromides (both in therapeutic range) and seizure activity unchanged or having intolerable side effects with this combination: If intolerable side effects, do levels and decrease the dose of the one that is in the high end of the range. Then add felbamate at 5–20 mg/kg PO three times daily. (Neer 2000)

Monitoring

- There is some controversy about monitoring felbamate use in dogs, probably since there is such limited experience with its use. Some clinicians state that liver function tests and CBC’s should be regularly assessed (q2–3 months). Others state that the drug is very safe in dogs and that monitoring does not appear to be necessary. Clearly, if the dog is receiving other drugs (especially phenobarbital), monitoring is essential.
- Therapeutic drug levels for felbamate in dogs are not truly known, but appear to be in the 25–100 micrograms/mL range. The usefulness of monitoring serum levels is questionable at this point.

Client Information

- Clients must understand the importance of giving doses as prescribed. Because of its short half-life, three times daily administration is routinely administered to adequately judge the efficacy of this drug.
- Because felbamate use in dogs has been limited, the adverse effect profile and possible incidence of serious effects (liver, blood) is not truly known.

Chemistry/Synonyms

Felbamate is a unique dicarbamate anticonvulsant agent, that is slightly soluble in water.

Felbamate may also be known by as: AD-03055, W-554, Felbamyl®, Felbatol®, Taloxa®, and Taloxa®.

Storage/Stability

Felbamate preparations should be stored at room temperature. The suspension should be shaken well before use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

- Felbamate Tablets: 400 mg, & 600 mg; Felbatol® (Wallace Labs); (Rx)
- Felbamate Suspension: 120 mg/mL in 240 & 960 mL; Felbatol® (Wallace Labs); (Rx)

FENBENDAZOLE
(Fen-ben-daz-ole) Panacur®, Safe-Guard®

ANTIPARASITIC AGENT

Prescriber Highlights

- Anthelmintic useful for a variety of parasites in dogs, cats, cattle, horses, swine, etc
- Adverse Effects: Antigen release by dying parasites may occur; particularly at high dosages; vomiting may occur infrequently in dogs or cats
- In dogs, give with food

Uses/Indications

Fenbendazole is indicated (labeled) for the removal of the following parasites in dogs: ascarids (*Toxocara canis, T. leonina*), Hookworms (*Ancylostoma caninum, Uncinaria stenocephala*), whipworms (*Trichuris vulpis*), and tapeworms (*Taenia pisiformis*). It is not effective against *Dipylidium caninum*. Fenbendazole has also been used clinically to treat *Capillaria aerophilica, Filaroides hirthi, and Paragonimus kellicotti* infections in dogs.

Fenbendazole is indicated (labeled) for the removal of the following parasites in cattle: Adult forms of: *Haemonchus contortus, Ostertagia ostertagi, Trichostrongylus axei, Bunostomum phlebotomum, Nematodirus helvetianus, Cooperia spp., Trichostrongylus colubriformis, Oesophagostomum radiatum, and Dictyocaulus vivaparus*. It is also effective against most immature stages of the above listed parasites. Although not FDA-approved, it has good activity against *Moniezia spp.*, and arrested 4th stage forms of *Ostertagia ostertagi*.

Fenbendazole is indicated (labeled) for the removal of the following parasites in horses: large strongyles (*S. edentatus, S. equinus, S. vulgaris*), small strongyles (*Cyathostomum spp., Cylicocyclus spp., Cylicostephanus spp., Triodontophorus spp.*), and pinworms (*Oxyuris equi*).

Fenbendazole is indicated (labeled) for the removal of the following parasites in swine: large roundworms (*Ascaris suum*), lungworms (*Metastrongyulus piarum*), nodular worms (*Oesophagostomum dentatum, O. quadrispinolatum*), small stomach worms (*Hyostrongylus rubidus*), whipworms (*Trichuris suis*), and kidney worms (*Stephanurus dentatus*; both mature and immature).

Although not FDA-approved, fenbendazole has been used in cats, sheep, goats, pet birds, and llamas. See Dosage section for more information.

Pharmacology/Actions

- Antihelmintic useful for a variety of parasites in dogs, cats, cattle, horses, swine, etc
- Adverse Effects: Antigen release by dying parasites may occur; particularly at high dosages; vomiting may occur infrequently in dogs or cats
- In dogs, give with food
Pharmacology/Actions
Fenbendazole is a methylcarbamate benzimidazole antiparasitic agent and has a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, benzimidazole mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase. Benzimidazoles may be considered time-dependent antiparasitic agents.

Pharmacokinetics
Fenbendazole is only marginally absorbed after oral administration. The amount absorbed from the gut is apparently more associated with the solubility of the drug and not the dose given. In dogs, when doses ranging from 25–100 mg/kg were administered, the area-under-the-curves were similar. Bioavailability is increased in dogs when fenbendazole is administered with food. Fat content of food does not significantly alter bioavailability (McKellar et al. 1993).

After oral dosing in calves and horses, peak blood levels of 0.11 micrograms/mL and 0.07 micrograms/mL, respectively, were measured. Absorbed fenbendazole is metabolized (and vice-versa) to the active compound, oxfendazole (sulfoxide) and the sulfone. In sheep, cattle, and pigs, 44–50% of a dose of fenbendazole is excreted unchanged in the feces, and <1% in the urine.

Contraindications/Precautions/Warnings
Fenbendazole is not FDA-approved for use in horses intended for food purposes.

Adverse Effects
At usual doses, fenbendazole generally does not cause any adverse effects. Hypersensitivity reactions secondary to antigen release by dying parasites may occur, particularly at high dosages. Salivation, vomiting, and diarrhea may infrequently occur in dogs or cats receiving fenbendazole. Pancytopenia has been reported in one dog (Gary et al. 2004).

Single doses (even at exaggerated doses) are not effective in dogs and cats; must treat for at least 3 days.

Reproductive/Nursing Safety
Fenbendazole is considered safe to use in pregnant bitches and is generally considered safe to use in pregnancy for all species. It is the drug of choice for treating giardia in pregnant animals (Tams 2007). In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Overdosage/Toxicity
Fenbendazole is apparently well tolerated at doses up to 100X recommended. The LD50 in laboratory animals exceeds 10 grams/kg when administered PO. It is unlikely an acute overdosage would lead to clinical signs.

Drug Interactions
**BROMSALAN FLUKICIDES** (dibromsalan, tribromsalan; not available in the USA): Oxfendazole or fenbendazole should not be given concurrently with the bromsalan flukicides; abortions in cattle and death in sheep have been reported after using these compounds together

Doses
**DOGS:**
For susceptible ascarids, hookworms, whipworms, and tapeworms (*Taenia* spp. only):
- a) 50 mg/kg, PO for 3 consecutive days (Package insert; Panacur®—Hoechst), (Cornelius & Roberson 1986)
- b) 55 mg/kg, PO for 3 days (5 days for *Taenia*) (Chiapella 1989), (Reinemeyer, C.R. 1985)

For *Giardia*:
- a) 50 mg/kg PO once daily for 3 consecutive days; if this does not clear the infection a longer course of therapy (5-7 days) is used (Tams 2007)
- b) To prevent transplacental and transmammary transmission of somatic *T. canis* and *A. caninum*:
  - a) 50 mg/kg PO once daily from the 40th day of gestation to the 14th day of lactation. (Kazacos 2002)
  - b) 50 mg/kg, PO once daily for 14 days. Symptoms may worsen during therapy, presumably due to a reaction when the worm dies. (Hawkins, E.C. et al. 1989)

For *Capillaria plica*:
- a) 50 mg/kg once daily for 3 days; repeat a single 50 mg/kg dose 3 weeks later (Todd et al. 1985)
- b) 50 mg/kg, PO daily for 3–10 days (Brown & Prestwood 1986)

For *Capillaria aerophilia*:
- a) 25–50 mg/kg q12h for 10–14 days (Hawkins, E.C. *et al*. 1989), (Hawkins, E. 2000)
- b) 50 mg/kg PO once daily for 10–14 days (Reinemeyer, C. 1995)

For *Filaroides hirthi*:
- a) 50 mg/kg, PO once daily for 14 days. Symptoms may worsen during therapy, presumably due to a reaction when the worm dies. (Hawkins, E.C. *et al*. 1989)
- b) 50 mg/kg PO once daily for 10–14 days (Reinemeyer, C. 1995)
- c) 50 mg/kg, PO once daily for 3 consecutive days; repeat in 2–3 weeks and again in 2 months (DeNovo 1988)

For *Paragonimus kellicotti*:
- a) 25–50 mg/kg PO twice daily for 10–14 days (Todd *et al*. 1985), (Hawkins, E. 2000)
- b) 50 mg/kg PO once daily for 10–14 days (Reinemeyer, C. 1995)
- c) 50 mg/kg, PO once daily for 3 consecutive days; repeat in 2–3 weeks and again in 2 months (DeNovo 1988)

For *Crenosoma vulpis*:
- a) 50 mg/kg PO once daily for 3 days (Reinemeyer, C. 1995); (Hawkins, E. 2000)

For *Eucoleus boehmi*:
- a) 50 mg/kg, PO once daily for 10–14 days; improvement may only be temporary (Reinemeyer, C. 1995)
**Cats, Domestic:**
For susceptible ascarids, hookworms, strongyloides, and tapeworms (*Taenia* spp. only):

- 50 mg/kg, PO for 5 days (Dimski 1989)

For Giardia:

- 50 mg/kg PO once daily for 3 consecutive days; if this does not clear the infection, a longer course of therapy (5-7 days) is used (Tams 2007)
- 25–50 mg/kg q12h for 10–14 days (Hawkins, E. C. et al. 1989); (Hawkins, E. 2000)
- 50 mg/kg, PO for 10 days (Pechman 1989)
- 20 mg/kg PO once daily for 5 days; repeat in 5 days (Reinemeyer, C. 1995)

For lungworms (*Aelurostrongylus abstrusus*):

- 25–50 mg/kg q12h for 10–14 days (Hawkins, E. C. et al. 1989); (Hawkins, E. 2000)
- 50 mg/kg, PO for 10 days (Pechman 1989)
- 20 mg/kg PO once daily for 5 days; repeat in 5 days (Reinemeyer, C. 1995)

For lungworms (*Capillaria aerophilia*):

- 50 mg/kg, PO for 10 days (Pechman 1989)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer, C. 1995)

For *Capillaria feliscati*:

- 25 mg/kg, twice daily PO for 3–10 days (Brown & Prestwood 1986)
- 25 mg/kg, PO q12h for 10 days (Brown & Barsanti 1989)

For *Capillaria feliscati*:

- 50 mg/kg, PO for 10 days (Pechman 1989)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer, C. 1995)

For *Paragonimus kellicotti*:

- 10 mg/kg PO once daily for 3 consecutive days. (Label information; *Panacur* 22.25 Granules—Intervet)

**Cats, Large (Exotic):**
For labeled parasites:

- 10 mg/kg PO once daily for 3 consecutive days. (Label information; *Panacur* 22.25 Granules—Intervet)

**Bears (Ursidae):**
For labeled parasites:

- 10 mg/kg PO once daily for 3 consecutive days. (Label information; *Panacur* 22.25 Granules—Intervet)

**Small Mammals/Rodents:**

- For pinworms in mice, rats, hamsters, gerbils and rabbits: 50 mg/kg PO once (Burke 1999)
- For Giardia in Chinchillas: 25 mg/kg PO once a day for 3 days (Hayes 2000)
- Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 20–50 mg/kg PO once daily for 5 days (Higher dose is for Giardia) (Adamcak & Otten 2000)

**Cattle:**
For removal/control of *Haemonchus contortus, Ostertagia ostertagi, Trichostrongylus axei, Bunostomum phlebotomum, Nematodirus helvetianus, Cooperia spp., Trichostrongylus colubriformis, Oesophagostomum radiatum, and Dictyocaulus viviparus*:

- 5 mg/kg, PO (Paul 1986)
- 7.5 mg/kg, PO (Roberson 1988)
- 4 mg/kg PO; under conditions of continuous exposure to parasites, animals may need to be retreated after 4–6 weeks, (Label information *Panacur* Paste—Intervet)

For *Moniezia* spp., and arrested 4th stage forms of *Ostertagia ostertagi*:

- 10 mg/kg, PO (Paul 1986), (Roberson 1988)

For giardiasis in calves:

- 15 mg/kg PO for 3 successive days and then moved to a pen that was thoroughly cleaned and disinfected with 10% ammonia. (Claerebout 2006)

**Horses:**
For susceptible parasites:

- For control of large and small strongyles, and pinworms in adult horses: 5 mg/kg PO;
  - For foals and weanlings (less than 18 months of age) where ascarids are a common problem: 10 mg/kg PO;
  - For control of encysted early 3rd stage, late 3rd stage and 4th stage cyathostome larvae and 4th stage *Strongylus vulgaris* larvae) 10 mg/kg PO for 5 consecutive days. (Label information *Panacur* Paste—Intervet)

For treatment of migrating large strongyles:

- 50 mg/kg PO for 3 consecutive days, or 10 mg/kg for 5 consecutive days (Herd 1987)

For mucosal stage of small strongyles:

- 7.5–10 mg/kg PO once daily for 5 days; a single dose of 30 mg/kg is effective against older encysted stages (Lyons & Drudge 2000)

**Swine:**
For susceptible parasites:

- 5 mg/kg PO; 3 mg/kg in feed for 3 days; 10 mg/kg for ascarids (Roberson 1988)
Fenbendazole 454 mg, Ivermectin 27 mcg, & Praziquantel 23 mg (2.16 g small chews) Chewable Tablets; Combination Products:

For susceptible parasites:
a) 5 mg/kg in feed for 3 days (Roberson 1988)  
b) For whipworms in pothellied pigs: 9 mg/kg PO for days (Braun 1995)

**SHEEP & GOATS:**

For susceptible parasites:
a) 5 mg/kg in feed for 3 days (Roberson 1988)

**CAMELIDS:**

For susceptible parasites in new world camelds:
a) 10–20 mg/kg PO for 3–5 days (Wolff 2009)  
b) For adjunctive treatment of meningeal worm infestation (*Parelaphostrongylus tenius*): Fenbendazole 50 mg/kg PO for 5 days with ivermectin 0.3 mg/kg SC for 5 days. Also use prophylactic treatment for stress ulcers (e.g., ranitidine, omeprazole), antiinflammatories (e.g., flunixin, dexamethasone, DMSO), fluids, nutritional support, etc. (Edmondson 2009)

**BIRDS:**

a) For Ascarids: 10–50 mg/kg PO once; repeat in 10 days. Do not use during molt (may cause stunted feathers) or while nesting.  
For flukes or microfilaria: 10–50 mg/kg PO once daily for 3 days  
For *Capillaria*: 10–50 mg/kg PO once daily for 5 days. Is not effective against gizzard worms in finches. (Clubb 1986)  
b) For nematodes, some trematodes: 10–50 mg/kg PO once daily for 3–5 days; 20–100 mg/kg oral single dose range; 125 mg/L of drinking water for 5 days (50 mg/L for 5 days in finches); or 100 mg/kg of feed for 5 days. Not recommended to be used in breeding season during molting. (Marshall 1993)  
c) *Ratites*: 15 mg/kg PO once daily for 3 days. Has efficacy against ostrich tapeworm. (*Houttuynia struthionus*) (Jenson 1998)

**REPTILES:**

For susceptible infections:
a) For most species: 50–100 mg/kg PO once; repeat in 2–3 weeks; very effective against Strongyloids. (Gauvin 1993)

**Chemistry/Synonyms**

A benzimidazole anthelmintic, fenbendazole occurs as a white, crystalline powder. It is only slightly soluble in water.  
Fenbendazole may also be known as: Hoe-881V, *Panacur®, and Safe-Guard®.*

**Storage/Stability**

Fenbendazole products should be stored at room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Fenbendazole Granules: 222 mg/gram (22.2%) in 0.18 oz and 1 g, 2 g, 4 g packets and 1 lb jars; *Panacur® Granules 22.2%* (Intervet); (Rx); *Safeguard® Canine Dewormer* (Intervet), (OTC), FDA-approved for use in dogs, large exotic cats (lions, etc.), and bears (black bears, polar bears, etc.)

Fenbendazole Granules: 222 mg/gram (22.2%); *Panacur® Granules 22.2%* (Intervet). (OTC). FDA-approved for use in horses not intended for food.

Fenbendazole Suspension: 100 mg/mL (10%); available in both equine and bovine labeled products; *Panacur® Suspension* (Intervet); (Rx). FDA-approved for use in horses (not intended for food) and cattle. Slaughter withdrawal = 8 days (cattle). *Safe-Guard® Suspension* (Intervet); (OTC). FDA-approved for use in beef and dairy cattle. Slaughter withdrawal at labeled doses = 8 days

Fenbendazole Paste: 100 mg/gm (10%); available in both equine and bovine labeled products and sizes. *Panacur® Paste* (Intervet); (OTC). FDA-approved for use in horses (not intended for food) and cattle. Slaughter withdrawal at labeled doses = 8 days (cattle). *Safe Guard® Paste* (Intervet); (OTC). FDA-approved for use in horses not intended for food and cattle. Slaughter withdrawal at labeled doses = 8 days; no milk withdrawal time at labeled doses.

**Fenbendazole Type B Medicated Feed**

Safe-Guard® EZ Scoop Swine Dewormer (Intervet) (OTC). 1.8% Fenbendazole No slaughter withdrawal time required at labeled doses

Safe-Guard® 0.96% Scoop Dewormer (Intervet); (OTC). FDA-approved for use in cattle. No milk withdrawal time; slaughter withdrawal time at labeled doses = 13 days

**Fenbendazole Type C Medicated Feed**

Safe-Guard® Free-choice Cattle Dewormer (Intervet); (OTC); 0.50% Fenbendazole (2.27 g/lb). FDA-approved for use in beef and dairy cattle. No milk withdrawal time.

Safe-Guard® 35% Salt Free-choice Cattle Dewormer (Intervet); (OTC); 1.9 g/lb Fenbendazole. FDA-approved for use in dairy and beef cattle. Slaughter withdrawal time at labeled doses = 13 days; no milk withdrawal time.

**Fenbendazole Pellets**

Safe-Guard® 0.5% Cattle Top Dress (Intervet); (OTC). At labeled dose, slaughter withdrawal time = 13 days; no milk withdrawal period at labeled doses

Safe-Guard® 1.96% Scoop Dewormer Mini Pellets (Intervet); (OTC). FDA-approved for use in beef and dairy cattle. No milk withdrawal time at labeled doses; slaughter withdrawal time at labeled doses = 13 days

**Fenbendazole Premix 20% Type A (200 mg/gram)**

Safe-Guard® Premix (Intervet); (OTC). FDA-approved for use in swine, growing turkeys, dairy and beef cattle, zoo and wildlife animals. Slaughter withdrawal for cattle = 13 days; no milk withdrawal time. Slaughter withdrawal for swine at labeled doses = none. Wildlife animal slaughter (hunting) withdrawal = 14 days at labeled doses.

**Combination Products:**

Fenbendazole 454 mg, Ivermectin 27 mcg, & Praziquantel 23 mg (2.16 g small chews) Chewable Tablets; *Panacur Plus® Soft Chews* (Intervet); (Rx). FDA-
Fentanyl is an opioid analgesic with a rapid onset of action and a relatively short duration of action. It is commonly used in veterinary medicine for the control of pain in small animals. Fentanyl injection and transdermal patches are used primarily in dogs and cats and have been shown to be useful for the adjunctive control of postoperative pain and in the control of severe pain associated with chronic pain, dull pain, and non-specific, widespread pain (e.g., associated with cancer, pancreatitis, aortic thromboemboli, peritonitis, etc.). Transdermal fentanyl may also reduce the requirements for inhalational anesthetics during surgery, which could be particularly advantageous in patients with compromised cardiac function. Because of its short duration of action, fentanyl CRI’s are particularly useful in critically ill or post-surgical patients as it can be adjusted to meet the analgesia needs of the patient, minimize adverse effects and temporarily halted to assess neurologic status. Injectable fentanyl may be particularly useful in cats, especially when higher analgesic doses are required, as it appears to have fewer adverse effects than either hydromorphone or morphine.

Pharmacology/Actions

Fentanyl is a mu opioid agonist that is very short acting and approximately 100 times more potent than morphine. Mu receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The pharmacology of the opiate agonists is discussed in more detail in the monograph, Narcotic (opiate) Agonist Analgesics. **Prescriber Highlights**

- Class-II opiate analgesic used parenterally & transdermally in small animals
- Contraindications: Use extreme caution when additional respiratory, or CNS depression would be deleterious
- Use caution in geriatric, very ill or debilitated patients & those with a preexisting respiratory problem
- Adverse Effects: Dose related respiratory, CNS & circulatory depression (bradycardia); also, rashes at the patch site, urine retention, constipation, dysphoria, or agitation
- Lag time before effective analgesia with patches; dispose of properly
- Lab values (amylase, lipase) may be altered

Uses/Indications

In veterinary medicine, fentanyl injection and transdermal patches are used primarily in dogs and cats and have been shown to be useful for the adjunctive control of postoperative pain and in the control of severe pain associated with chronic pain, dull pain, and non-specific, widespread pain (e.g., associated with cancer, pancreatitis, aortic thromboemboli, peritonitis, etc.). Transdermal fentanyl may also reduce the requirements for inhalational anesthetics during surgery, which could be particularly advantageous in patients with compromised cardiac function. Because of its short duration of action, fentanyl CRI’s are particularly useful in critically ill or post-surgical patients as it can be adjusted to meet the analgesia needs of the patient, minimize adverse effects and temporarily halted to assess neurologic status. Injectable fentanyl may be particularly useful in cats, especially when higher analgesic doses are required, as it appears to have fewer adverse effects than either hydromorphone or morphine.

Pharmacology/Actions

Fentanyl is a mu opioid agonist that is very short acting and approximately 100 times more potent than morphine. Mu receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The pharmacology of the opiate agonists is discussed in more detail in the monograph, Narcotic (opiate) Agonist Analgesics.
The following drug interactions have either been reported or are theoretical in humans or animals receiving fentanyl and may be of significance in veterinary patients:

### Contraindications/Precautions/Warnings

Fentanyl is contraindicated in patients with known hypersensitivity to it or any component of the product (including the adhesive for the patch). When transdermal patches are used, absorption and efficacy can be highly patient variable; injectable rescue analgesia should be available. Because of its potency, fentanyl injection should be used only by professionals familiar with its use in circumstances where patients can be adequately monitored and supported.

Use cautiously with other CNS depressants. Dosages of other opiates may need to be reduced when given with fentanyl transdermal, particularly several hours after application of the patch. Transderal fentanyl should be used cautiously in geriatric, very ill or debilitated patients and those with a preexisting respiratory problem. Febrile patients may have increased absorption of fentanyl and will require increased monitoring.

Because opioids may cause mydriasis in cats, approach slowly so as not to startle, and keep animal out of very bright light or sunlight while pupils are dilated. In the past, fentanyl patches were only available in a gel form that could not be cut. Now, other brands are available, but with the availability of 12 mg patches there is little therapeutic reason to do so. It is advised to obtain a pharmacist’s advice before cutting patches. Do not allow applied fentanyl patch to be exposed to exogenous heat sources (heating pads, etc.). Increased drug release and absorption have occurred with fatal results.

### Adverse Effects

Dose related respiratory, CNS and circulatory depression (bradycardia) are the primary adverse effects with fentanyl injection. Anticholinergic agents may be required to treat bradycardia, when fentanyl is used intraoperatively. Dogs and cats appear less prone, but not immune to opiate-induced respiratory depression, than are humans.

Respiratory depression and bradycardia associated with fentanyl patches are the most concerning adverse effects, but incidence of these effects have not been widespread thus far when used alone (without other opiates or other respiratory and cardio depressant medications). Rashes at the patch site have been reported and should they occur, the patch should be removed; if an additional patch is warranted, a different site should be chosen. Urine retention and constipation may occur. Consider removing patch in patients developing a fever after application, as fentanyl absorption may increase. Some patients exhibit dysphoria or agitation after application; acepromazine or other mild tranquilizer may alleviate dysphoria.

### Reproductive/Nursing Safety

Safe use in pregnancy has not been established. In humans, the FDA categorizes fentanyl as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Most narcotic agonist analgesics are excreted into milk, but effects on nursing offspring may not be significant.

### Overdose/Acute Toxicity

Overdose may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Other toxic effects may include cardiovascular collapse, tremors, neck rigidity, and seizures. There were 374 exposures to fentanyl reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 362 were dogs with 295 showing clinical signs, and 12 were cats with 5 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, hypersalivation, ataxia, bradycardia, hypothermia, depression, and diarrhea.

Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated; animals should be closely observed as naloxone’s effects sometimes diminish before sub-toxic levels of fentanyl are attained. Mechanical respiratory support should also be considered in cases of severe respiratory depression.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fentanyl and may be of significance in veterinary patients:

- **AZOLES ( ketoconazole, itraconazole, fluconazole):** May inhibit fentanyl metabolism
- **CNS DEPRESSANTS, OTHER:** Additive CNS effects possible
- **DIURETICS:** Opiates may decrease efficacy in CHF patients
- **MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin):** May inhibit fentanyl metabolism
- **MONOAmine OXIDASE INHIBITORS (e.g., amitraz, and possibly selegiline):** Severe and unpredictable opiate potentiation may be seen; not recommended (in humans) if MAO inhibitor has been used within 14 days
- **MUSCLE RELAXANTS, SKELETAL:** Fentanyl may enhance neuromuscular blockade
- **NITROUS OXIDE:** High fentanyl doses may cause cardiovascular depression
- **PHENOBARBITAL, PHENYTOIN:** May increase the metabolism of fentanyl
- **PHENOTHIAZINES:** May augment CNS depression
RIFAMPIN: May increase the metabolism of fentanyl

TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Fentanyl may exacerbate the effects of tricyclic antidepressants

WARFARIN: Opiates may potentiate anticoagulant activity

Laboratory Considerations

As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

WARNING: Do not confuse doses listed as micrograms/kg with those that are listed as mg/kg. Always double-check dosages and resulting volumes when using fentanyl.

**DOGS:**

Fentanyl Injectable:

a) For perioperative pain: The combination of a 10 micro-grams/kg loading dose IV followed by a CRI of 10 micrograms/kg/hour investigated in this study might be a guideline for a CRI dose of fentanyl during general anesthesia to provide analgesia in dogs. (Sano et al. 2006)
b) Loading dose: 2–5 micrograms/kg IV, followed by a CRI at 2–5 micrograms/kg/hr for pain management; CRI at 10–45 micrograms/kg/hr for surgical analgesia. (Wagner 2002)
c) For analgesia: 2–6 micrograms/kg/hour (Hansen 2008)
d) For induction: 0.001–0.005 mg/kg IV. For MAC reduction during general anesthesia: 10–45 micrograms/kg/hr CRI. (Mama 2002)
e) For severe to excruciating pain in the emergent patient: Fentanyl at 10–50 micrograms/kg, administered IV titrated to effect; use the effective dose as an hourly CRI. NSAIDs when not contraindicated. Ketamine at 4 mg/kg as a bolus, use with fentanyl. Lidocaine at 2–4 mg/kg bolus, followed by 2–4 mg/kg/hr CRI; caution with respect to overdose if local anesthetics have been administered by means of a different route. Tachycardia may persist and it may be impossible to control the pain. Consider combining these analgesics with epidurally placed analgesics or local blocks, or anesthetize the patient while attempting to find or treat the inciting cause. Remove the inciting cause immediately. This degree of pain can cause death. (Dyson 2008)
f) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted with 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)
g) For maintenance analgesia/heavy sedation in critically ill animals who become hypotensive animals when exposed to inhalant anesthetics: See cat dose “g” below. (Brainard 2009)

Fentanyl Transdermal:

**Note:** There is significant interpatient variability on the response of the transdermal product. When used as the primary analgesic for post-operative pain, application prior to surgery is advised as many hours may be required for “therapeutic” levels to be achieved. Generally in dogs = 12–24 hours may be necessary; cats = 6–24 hours; and horses = 6+ hours.

The following dosage regimen has been used at the University of Minnesota Veterinary Medical Center and is adapted from information provided by Dr. Lynelle Graham:

Choose your patient carefully, realizing that the fentanyl patch alone may not provide sufficient analgesia. Fentanyl patches are effective for relief of chronic pain, dull pain and non-specific, widespread pain (peritonitis, pancreatitis, cancer, aortic thromboemboli, declaws, etc.) In the face of acute surgical pain or severe traumatic pain (fractures, thoracotomies, HBC/traumatic injuries/head trauma), analgesia provided by a fentanyl patch tends to be inadequate. Therefore, the patch should be used as an adjunctive measure for pain relief in these patients. If the patient is febrile, do not use fentanyl patch.

Choose your Patch Size:

<table>
<thead>

</tbody>
</table>

**Note:** These patients can be dosed with 1/2 of a 25 mcg/hr patch, i.e., only half of the membrane is exposed to the patient’s skin (cover the other half with tape); depending on the brand used. DO NOT CUT the patch in half, as this will alter the drug releasing membrane and allow evaporation of the fentanyl-containing alcohol-cellulose gel. Obtain a pharmacist’s advice before cutting the patch. Current research suggests dosing with a whole 25 mcg/hr patch in otherwise healthy patients of this size (i.e., fractures, declaws). However, in order to avoid sedation, “half-patch” dosing may be desired for pediatric, geriatric, and systemically ill cats and very small dogs, but this is controversial.

Choose your location:

**Dog:** Thorax, inguinal area, metatarsal/carpal areas, base of tail (dorsal or lateral cervical area has been used, but leashes must not be placed around the neck if fentanyl patches are in place)

**Cat:** Lateral thorax, inguinal area, metatarsal/carpal areas; base of tail (the cervical area is NOT recommended, as the patch tends not to remain on)

**Horse:** Neck, antebrachium

**Pig:** Rabbit: Lateral thorax

**Sheep, Goat:** Abdomen, cervical area

**Note:** Direct patch contact with heating pads can significantly increase fentanyl absorption and risk toxicity. The patch should be kept dry; be aware of potential surgical clip sites.

Analgesic efficacy

**SHEEP, GOATS & SWINE:**

**HORSES:**

**RABBITS/RODENTS/SMALL MAMMALS:**

**CATS:**

- **Fentanyl Transdermal:**
  a) For perioperative pain: 5–20 micrograms/kg IV bolus (30–60 minute duration; causes sedation and respiratory depression) (Ivey & Morrisey 2000)
  b) Loading dose: 1–3 micrograms/kg IV, followed by a CRI at 1–4 micrograms/kg/hr for pain management; CRI at 10–30 micrograms/kg/hr for surgical analgesia. (Wagner 2002)
  c) For analgesia: 2–4 micrograms/kg/hour
  d) For induction: 0.001–0.002 mg/kg IV. For MAC reduction during general anesthesia: 10–20 micrograms/kg/hr CRI. (Mama 2002)
  e) For severe to excruciating pain in the emergent patient: Fentanyl at 10–50 micrograms/kg, administered IV titrated to effect; use the effective dose as an hourly CRI. NSAIDs when not contraindicated. Ketamine at 4 mg/kg, as a bolus (used with fentanyl). Lidocaine at 0.25–1 mg/kg bolus and then 0.5–2 mg/kg/hr CRI; caution with respect to overdose if local anesthetics have been administered by means of a different route. Tachycardia may persist and it may be impossible to control the pain. Consider combining these analgesics with epidurally placed analgesics or local blocks, or anesthetize the patient while attempting to find or treat the inciting cause. Remove the inciting cause immediately. This degree of pain can cause death. (Dyson 2008)
  f) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)
  g) For maintenance analgesia/heavy sedation in critically ill animals who become hypotensive animals when exposed to inhalant anesthetics: In addition to a local line block, fentanyl at 0.5–0.8 micrograms/kg/minute (equivalent to 30–50 micrograms/kg/hr). Intermittent IV bolus or a CRI of midazolam (0.1 mg/kg single bolus or given over an hour) will boost sedation to a neuroleptic state. 100% O2 provided via the anesthetic circuit. Monitor ventilation using end-tidal CO2 line block, fentanyl at 0.5–0.8 micrograms/kg/minute. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)

- **Fentanyl Injectable:**
  a) For perioperative pain: 2–3 micrograms/kg IV plus 2–3 micrograms/kg/hour IV infusion (Pascoe 2000)
  b) Loading dose: 1–3 micrograms/kg IV, followed by a CRI at 1–4 micrograms/kg/hr for pain management; CRI at 10–30 micrograms/kg/hr for surgical analgesia. (Pascoe 2000)
  c) Pre-op dose: 5–10 micrograms/kg IV plus 2–3 micrograms/kg/hour IV infusion (Pascoe 2000)
  d) See above in dog dose section (Graham)
  e) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)
  f) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)

- **RABBITS/RODENTS/SMALL MAMMALS:**

- **Fentanyl Transdermal:**
  a) For postoperative analgesia: 0.5–1 micrograms/kg IV bolus (30–60 minute duration; causes sedation and respiratory depression) (Ivey & Morrisey 2000)
  b) Rabbits: See above in dog dose section

  c) For analgesia: 2–4 micrograms/kg/hour
  d) For induction: 0.001–0.002 mg/kg IV. For MAC reduction during general anesthesia: 10–20 micrograms/kg/hr CRI. (Mama 2002)
  e) For severe to excruciating pain in the emergent patient: Fentanyl at 10–50 micrograms/kg, administered IV titrated to effect; use the effective dose as an hourly CRI. NSAIDs when not contraindicated. Ketamine at 4 mg/kg, as a bolus (used with fentanyl). Lidocaine at 0.25–1 mg/kg bolus and then 0.5–2 mg/kg/hr CRI; caution with respect to overdose if local anesthetics have been administered by means of a different route. Tachycardia may persist and it may be impossible to control the pain. Consider combining these analgesics with epidurally placed analgesics or local blocks, or anesthetize the patient while attempting to find or treat the inciting cause. Remove the inciting cause immediately. This degree of pain can cause death. (Dyson 2008)
  f) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)

- **Fentanyl Injectable:**
  a) Pre-op dose: 5–10 micrograms/kg IV plus 2–3 micrograms/kg/hour IV infusion (Pascoe 2000)
  b) Loading dose: 1–3 micrograms/kg IV, followed by a CRI at 1–4 micrograms/kg/hr for pain management; CRI at 10–30 micrograms/kg/hr for surgical analgesia. (Pascoe 2000)
  c) Pre-op dose: 5–10 micrograms/kg IV plus 2–3 micrograms/kg/hour IV infusion (Pascoe 2000)
  d) See above in dog dose section (Graham)
  e) As an epidural for pain control: 0.004 mg/kg (4 micrograms/kg), diluted 0.2 mL with preservative-free saline or local anesthetic. Has predominantly supraspinal effects. Onset in less than 10 minutes and duration of ½ hour. (Valverde 2008)

- **RABBITS/RODENTS/SMALL MAMMALS:**

- **Fentanyl Transdermal:**
  a) For postoperative analgesia: 0.5–1 micrograms/kg IV bolus (30–60 minute duration; causes sedation and respiratory depression) (Ivey & Morrisey 2000)
  b) Rabbits: See above in dog dose section

- **HORSES:**

- **Fentanyl Transdermal:** See above in dog dose section

- **SHEEP, GOATS & SWINE:**

- **Fentanyl Transdermal:** See above in dog dose section
Client Information

- Fentanyl injection should be used only by professionals familiar with its use in a setting where adequate monitoring can occur.
- Fentanyl Patches: Explain carefully to clients how to apply (if applicable), remove and dispose of patches. Consider making application, removal, and disposal an outpatient procedure, thereby bypassing concerns with clients.
- Should accidental human skin contact occur with the patch, wash with water only (no soap, etc.). Use cautiously in households where young children or animals could remove and ingest or be exposed to patches.

Chemistry/Synonyms

Fentanyl citrate, a very potent opiate agonist, occurs as a white, crystalline powder. It is sparingly soluble in water and soluble in alcohol. It is odorless and tasteless (not recommended for taste test because of extreme potency) with a pKa of 8.3 and a melting point between 147°–152°C.

Storage/Stability

Fentanyl transdermal patches should be stored at temperatures less than 25°C and applied immediately after removing from the individually sealed package. Do not cut patches.

The transmucosal (buccal) tablets should be stored at room temperature; do not refrigerate or freeze.

Fentanyl injection should be stored protected from light. It is hydrolyzed in an acidic solution.

Compatibility/Compounding Considerations

The injection is compatible with normal saline and D5W.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

**Fentanyl Buccal Tablets**: 100 mcg, 200 mcg, 400 mcg, 600 mcg, & 800 mcg with mannitol in color-coded blister packs; Fentora® (Cephalon); (Rx, C-II)

**Fentanyl Injectable**: 0.05 mg/mL (50 micrograms/mL) in 2 mL, 5 mL, 10 mL, & 20 mL amps; 30 mL and 50 mL vials; preservative free in 2 mL, 5 mL, 10 mL, & 20 mL amps; Sublimaze® (Akorn); generic; (Rx, C-II)

**Fentanyl Transdermal System**:

1.25 (5 cm²; 12 mcg/hr);
2.5 to 2.75 (6.25–10 cm²; 25 mcg/hr);
500 mcg/hr;
7.5 to 8.25 (18.75–30 cm²; 75 mcg/hr);
10 to 11 (25–40 cm²; 100 mcg/hr);

Duragesic®-12, -25, -50, -75 and -100 (Janssen); generic; (Rx, C-II)

**Fentanyl Iontophoretic Transdermal System**: 40 mcg/dose fentanyl hydrochloride (equivalent to 44.4 mcg of fentanyl) delivered over a 10-minute period upon each activation of the dose button; Each system contains fentanyl hydrochloride 10.8 mg; Ionsys® (Ortho-McNeil); (Rx; C-II)

**Fentanyl Transmucosal System**: Lozenges on a stick: 200 mcg, 400 mcg, 600 mcg, 800 mcg, 1200 mcg and 1600 mcg (as base); Actiq® (Cephalon); generic; (Rx, C-II)

All fentanyl products are Class-II controlled substances.

References

FERROUS SULFATE

(Fer as sul-faye) Fer-In-Soll®, Feosol®

NUTRITIONAL/HEMATINIC

Prescriber Highlights
Oral iron supplement for the treatment of iron-deficiency anemias

Contraindications: Patients with hemosiderosis, hemochromatosis, hemolytic anemias, or known hypersensitivity; some consider it contraindicated with GI ulcers

Adverse Effects: With non-toxic doses, mild gastrointestinal upset

May be very toxic (life threatening) if OD’d

Uses/Indications
While iron is a necessary trace element in all hemoglobin-utilizing animals, the use of therapeutic dosages of ferrous sulfate (or other oral iron) preparations in veterinary medicine is limited primarily to the treatment of iron-deficiency anemias in dogs (usually due to chronic blood loss), and as adjunctive therapy in cats when receiving epoetin (erythropoietin) therapy. Injectable iron products are usually used in the treatment of iron deficiency anemias associated with newborn animals.

Pharmacology/Actions
Iron is necessary for myoglobin and hemoglobin in the transport and utilization of oxygen. While neither stimulating erythropoiesis nor correcting hemoglobin abnormalities not caused by iron deficiency, iron administration does correct both physical signs and decreased hemoglobin levels secondary to iron deficiency.

Ionized iron is a component in the enzymes cytochrome oxidase, succinic dehydrogenase, and xanthine oxidase.

Pharmacokinetics
Oral absorption of iron salts is complex and determined by a variety of factors including diet, iron stores present, degree of erythropoiesis, and dose. Iron is thought to be absorbed throughout the GI tract, but is most absorbed in the duodenum and proximal jejunum. Food in the GI tract may reduce the amount absorbed.

After absorption, the ferrous iron is immediately bound to transferrin, transported to the bone marrow and eventually incorporated into hemoglobin. Iron metabolism occurs in a nearly closed system. Because iron liberated by the destruction of hemoglobin is reused by the body and only small amounts are lost by the body via hair and nail growth, normal skin desquamation and GI tract sloughing, normal dietary intake usually is sufficient to maintain iron homeostasis.

Contraindications/Precautions/Warnings
Ferrous sulfate (or other oral iron products) are considered contraindicated in patients with hemosiderosis, hemochromatosis, hemolytic anemias, or known hypersensitivity to any component of the product. Because of the GI irritating properties of the drugs, oral iron products are considered contraindicated by some clinicians in patients with GI ulcerative diseases.

Adverse Effects
Adverse effects associated with non-toxic doses are usually limited to mild gastrointestinal upset. Division of the daily dosage may reduce this effect, but dosage reduction may also be necessary in some animals.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category A for use during pregnancy (Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Overdosage/Acute Toxicity
Ingestion of iron containing products may result in serious toxicity. While lethal doses are not readily available in domestic species, as little as 400 mg (of elemental iron) is potentially fatal in a child. Initial clinical signs of acute iron poisoning usually present with an acute onset of gastrointestinal irritation and distress (vomiting—possibly hemorrhagic, abdominal pain, diarrhea). The onset of these effects may be seen within 30 minutes of ingestion, but can be delayed for several hours. Peripheral vascular collapse may rapidly follow with clinical signs of depression, weak and/or rapid pulse, hypotension, cyanosis, ataxia, and coma possible. Some patients do not exhibit this phase of toxicity and may be asymptomatic for 12–48 hours after ingestion, when another critical phase may occur. This phase may be exhibited by pulmonary edema, vasomotor collapse, cyanosis, pulmonary edema, fulminant hepatic failure, coma and death. Animals that survive this phase may exhibit long-term sequelae, including gastric scarring and contraction and have persistent digestive disturbances.

Because an acute onset of gastroenteritis may be associated with a multitude of causes, diagnosis of iron intoxication may be difficult unless the animal has been observed ingesting the product or physical evidence suggests ingestion. Ferrous sulfate (and gluconate) tablets are radiopaque and often can be observed on abdominal radiographs. Serum iron levels and total iron binding capacity (TIBC) may also be helpful in determining the diagnosis, but must be done on an emergency basis to have any clinical benefit.

Treatment of iron intoxication must be handled as an emergency. In humans who have ingested 10 mg/kg or more of elemental iron within 4 hours of presentation, the stomach is emptied, preferably using gastric lavage with a large bore tube to remove tablet fragments. It is generally recommended to avoid using emetics in patients who already have had episodes of hemorrhagic vomiting. These patients are lavaged using tepid water or 1–5% sodium bicarbonate solution.

In dogs, one author (Mount 1989), has recommended using oral milk of magnesia to help bind the drug, administering apomorphine if appropriate to help dislodge tablets, and to instill a gastric lavage slurry of 50% sodium bicarbonate with a portion left in the stomach. Deferoxamine is useful in chelating iron that has been absorbed. See that monograph for further information.

In addition to chelation therapy, other supportive measures may be necessary including treatment of acidosis, prophylactic antibiotics, oxygen, treatment for shock, coagulation abnormalities, seizures, and/or hyperthermia. After the acute phases have resolved, dietary evaluation and management may be required.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ferrous sulfate and may be of significance in veterinary patients:

ANTACIDS: May bind to iron and decrease oral absorption; administer at least two hours apart

CALCIUM (ORAL): May bind to iron and decrease oral absorption; administer at least two hours apart

CHLORAMPHENICOL: Because chloramphenicol may delay the response to iron administration, avoid using chloramphenicol in patients with iron deficiency anemia
FLUOROQUINOLONES (enrofloxacin, etc.): Iron may reduce the absorption of oral fluoroquinolones; administer at least two hours apart

H2-RECEPTOR ANTAGONISTS (e.g., ranitidine, famotidine, etc.): Increased gastric pH may decrease iron absorption

PENICILLAMINE: Iron can decrease the efficacy of penicillamine, probably by decreasing its absorption; if both drugs are required, space doses of the two drugs as far apart as possible

PROTON-PUMP INHIBITORS (e.g., omeprazole): Increased gastric pH may decrease iron absorption

TETRACYCLINES: Oral iron preparations can bind to orally administered tetracyclines, thereby decreasing the absorption of both compounds

THYROXINE: Iron may reduce the absorption of oral thyroxine; administer at least two hours apart

VITAMIN C: May enhance the absorption of iron

Laboratory Considerations
- Large doses of oral iron can color the feces black and cause false-positives with the guaiac test for occult blood in the feces.
- Iron does not usually affect the benzidine test for occult blood.

Doses
**Caution:** Unless otherwise noted, doses are for ferrous sulfate (regular—not dried). Dosing of oral iron products can be confusing; some authors state doses in terms of the iron salt and some state doses in terms of elemental iron. For the doses below, assume that the doses are for ferrous sulfate and not elemental iron, unless specified.

**DOGS:**
- For iron deficiency anemia:
  a) 100–300 mg (total dose) PO once a day. (Jutkowitz 2009)
  b) First correct underlying cause of blood loss, then give ferrous sulfate at 100–300 mg per day (total dose) PO. Absorption is enhanced if administered 1 hour before or several hours after feeding. Reduce dosage if GI side effects occur. (Harvey et al. 1982)
- For patients to be treated with epoetin (erythropoietin):
  a) 100–300 mg (total dose) PO per day (Cowgill 2002); (Vaden 2006)

**CATS:**
- For iron deficiency anemia:
  a) 50–100 mg (total dose) PO once daily (Macintire 2009), (Jutkowitz 2009)
  b) 30–200 mg (total dose) PO per day for 2 weeks or more (Adams 1988)
    - For patients to be treated with epoetin (erythropoietin):
      a) 50–100 mg (total dose) PO per day. Many cats do not tolerate oral iron therapy and are better treated with iron dextran at 50 mg IM q3–4 weeks. (Cowgill 2002)
      b) 5–50 mg per cat PO once daily (DiBartola & Chew 2006)
      c) 50–100 mg per cat PO once daily (Vaden 2006)
      d) 10 mg/kg PO once daily (Macintire 2009)

**CATTLE:**
- As a hematinic:
  a) 8–15 g PO per day for 2 weeks or more (Adams 1988)

**HORSES:**
- As a hematinic:
  a) 2–8 g PO per day for 2 weeks or more (Adams 1988)

**SWINE:**
- As a hematinic:
  a) 0.5–2 g PO per day for 2 weeks or more (Adams 1988)

**SHEEP:**
- As a hematinic:
  a) 0.5–2 g PO per day for 2 weeks or more (Adams 1988)

**Monitoring**
- Efficacy; adverse effects:
  a) Hemograms
  b) Serum iron and total iron binding capacity, if necessary. Normal serum iron values for dogs and cats are reported as 80–180 micrograms/dL and 70–140 micrograms/dL, respectively. Total iron binding for dogs and cats are reported as 280–340 micrograms/dL and 270–400 micrograms/dL, respectively. (Morgan 1988). Serum transferrin saturation can estimated by dividing serum iron by total iron binding capacity.

**Client Information**
- Because of the potential for serious toxicity when overdoses of oral iron-containing products are ingested by either children or animals, these products should be kept well out of reach of children and pets.
Filgrastim is a hematopoietic agent that primarily affects the bone marrow to increase the proliferation, differentiation, and activation of progenitor cells in the neutrophil-granulocyte line. While derived from human DNA, the product is not species specific and also affects canine and feline bone marrow.

**Chemistry/Synonyms**
An orally available iron supplement, ferrous sulfate occurs as odorless, pale-bluish-green, crystals or granules having a saline, styptic taste. In dry air the drug is efflorescent. If exposed to moisture or moist air, the drug is rapidly oxidized to a brownish-yellow ferric compound that should not be used medicinally. Exposure to light or an alkaline medium will enhance the conversion from the ferrous to ferric state.

Filgrastim is available commercially in two forms, a “regular” and a “dried” form. Regular ferrous sulfate contains 7 molecules of water of hydration and is freely soluble in water and insoluble in alcohol. Ferrous sulfate contains approximately 200 mg of elemental iron per gram. Dried ferrous sulfate consists primarily of the monohydrate with some tetrahydrate. It is slowly soluble in water and insoluble in water. Dried ferrous sulfate contains 300 mg of elemental iron per gram. Ferrous sulfate, dried may also be known as ferrous sulfate, effloresced.

Filgrastim may also be known as: eisen(II)-sulfate, ferreux (sulfate), ferrosi sulfas heptahydricus, ferrous sulphate, ferrum sulfuricum oxydulatum, iron (II) sulphate heptahydrate, iron sulphate; many trade names are available.

**Storage/Stability**
Unless otherwise instructed, store ferrous sulfate preparations in tight, light-resistant containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**
No veterinary-FDA-approved products containing only ferrous sulfate could be located, but there are many multivitamin with iron containing products available.

**HUMAN-LABELLED PRODUCTS:**

- Ferrous Sulfate Oral Tablets: 325 mg (65 mg iron); Feosol® (GlaxoSmithKline); FeroSul® (Major); generic; (OTC)
- Ferrous Sulfate Oral Elixir/Liquid: 220 mg/5mL (44 mg iron/5 mL) in 473 mL, 300 mg/5 mL (60 mg iron/5 mL) in 5 mL; generic; (OTC)
- Ferrous Sulfate Oral Drops: 15 mg iron/mL & 75 mg/0.6 mL (15 mg iron/0.6 mL) in 50 mL; Enfamil Fer-In-Sol® (Mead Johnson Nutritionals); Fer-Gen-Sol® (Goldline); generic; (OTC)

**References**

**Filgrastim (Granulocyte Colony Stimulating Factor; GCSF)**

- **fll-grass-stim)** Neupogen®
- **CYTOKINE HEMATOPOIETIC AGENT**

**Prescriber Highlights**

- Cytokine that in the bone marrow primarily increases the proliferation, differentiation, & activation of progenitor cells in the neutrophil-granulocyte line
- Human origin product; antibodies may form that can cause prolonged neutropenia
- Treatment is very expensive

**Uses/Indications**
Filgrastim may be of benefit in treating neutropenias in dogs or cats when the intrinsic response to endogenously produced cytokines is thought to be inadequate and there is evidence that there are precursors in the bone marrow available. Because of the drug’s cost, potential for antibody development and the lack of good evidence for its efficacy in reducing mortality versus using antibiotic therapy alone, its use in small animal medicine is controversial.

**Pharmacology/Actions**
Filgrastim is a hematopoietic agent that primarily affects the bone marrow to increase the proliferation, differentiation, and activation of progenitor cells in the neutrophil-granulocyte line. While derived from human DNA, the product is not species specific and also affects canine and feline bone marrow.

**Pharmacokinetics**
After subcutaneous injection, filgrastim is rapidly absorbed and distributed with highest concentrations found in the bone marrow, liver, kidneys and adrenal glands. It is unknown if it crosses the blood-brain barrier, placenta, or enters maternal milk. The elimination pathways of filgrastim are still under investigation.

**Contraindications/Precautions/Warnings**
Filgrastim is contraindicated in patients hypersensitive to it. Dogs or cats that have developed antibodies to filgrastim with resultant neutropenia should probably not receive it in the future.

**Adverse Effects**
Because the human DNA origin product can be immunogenic to dogs and cats, some patients may develop severe neutropenia by mounting an immune response against both endogenously produced and exogenously administered G-CSF. Studies in cats have demonstrated that short pulse doses of 3–5 days at the time of neutropenia induction and treatment are effective in some patients.

**Dose Form/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**
Filgrastim is contraindicated in patients hypersensitive to it. Dogs or cats that have developed antibodies to filgrastim with resultant neutropenia should probably not receive it in the future.

**HUMAN-LABELLED PRODUCTS:**
Filgrastim is contraindicated in patients hypersensitive to it. Dogs or cats that have developed antibodies to filgrastim with resultant neutropenia should probably not receive it in the future.
Filgrastim may also be known as: granulocyte colony-stimulating factor, G-CSF, recombinant methionyl human GCS-F, r-metHuG-CSF, Filgen®, Gran®, Granulokine®, Neulasta®, Neupogen®, and Neutromax®.

Chemistry/Synonyms
Prepared via recombinant DNA technology from human DNA, filgrastim is a single chain polypeptide containing 175 amino acids with a molecular weight of about 18,800 daltons. The commercially available injection occurs as a clear solution; buffered to a pH of 4.

Storage/Stability
Injection should be stored in the refrigerator (2–8°C). Do not freeze or shake contents of vial. The drug should never be diluted with saline as a precipitate may form. If necessary it may be diluted into 5% dextrose for injection, but if diluted to concentrations between 5 and 15 micrograms/mL, it is recommended that albumin be added within 24 hours of such antineoplastics

Doses
Note: To avoid the development of autoantibody formation, most clinicians using this agent recommend using filgrastim in dogs or cats using a “pulse” therapy of no more than 5 days in duration.

□DOGS:
  a) For adjunctive therapy of neutropenia (secondary to drug induced aplastic pancytopenia): 5 micrograms/kg SC daily (Ruiz de Gopegui & Feldman 2000)
  b) For neutropenia: 1–5 micrograms/kg SC daily (Ritt & Modiano 1999)

□CATS:
  a) For neutropenia secondary to drug toxicity, infectious diseases, FeLV-associated cyclic neutropenia or idiopathic causes: 5 micrograms/kg SC twice daily. Cost and/or development of antibodies usually limit usefulness to a few weeks, but often it is effective for acute or life-threatening neutropenia. (Levy, JK 2000)
  b) For neutropenia: 1–5 micrograms/kg SC daily (Ritt & Modiano 1999)
  c) For adjunctive therapy of neutropenia: 5 micrograms/kg SC daily until neutrophil count exceeds 3,000/mcl for 2 days (Levy, J 2002)

Monitoring
□ CBC with platelets, routinely

Client Information
□ Clients should be briefed on the cost of this agent as well as the possibility that it may cause antibodies to form against endogenously produced G-CSF, thereby causing a potentially life threatening neutropenia.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Filgrastim Injection: 300 micrograms/mL preservative free in 1 mL and 1.6 mL single dose vials; 300 micrograms/0.5 mL preservative free in 0.5 mL and 0.8 mL prefilled syringes; Neupogen® (Amgen); (Rx)

References
FINASTERIDE
(fin-ar-te-ride) Proscar®, Propecia®

5-ALPHA-REDUCTASE INHIBITOR

Prescriber Highlights

- 5-alpha-reductase inhibitor potentially useful for dogs with benign prostatic hypertrophy & ferrets with adrenal disease
- Contraindications: Hypersensitivity to finasteride; sexually developing animals
- Caution: Patients with significant hepatic impairment
- Adverse Effects: Potentially may cause some minor sexual side effects
- Expense may be an issue, but generics now available

Uses/Indications
Finasteride may be useful in treating the benign prostatic hypertrophy in canine patients, particularly those that are used for breeding. Because of the drug’s relative expense and the long duration of therapy required to see a response, its usefulness may be limited in veterinary medicine.

It may also be useful in the adjunctive treatment of adrenal disease in ferrets.

Pharmacology/Actions
Finasteride specifically and totally inhibits 5-alpha-reductase. This enzyme is responsible for metabolizing testosterone to dihydrotestosterone (DHT) in the prostate, liver and skin. DHT is a potent androgen and is the primary hormone responsible for the development of the prostate.

Pharmacokinetics
Finasteride is absorbed after oral administration and in humans about 65% is bioavailable. The presence of food does not affect absorption. It is distributed across the blood-brain barrier and is found in seminal fluid. In humans, about 90% is bound to plasma proteins. Finasteride is metabolized in the liver and the half-life is about 6 hours. Metabolites are excreted in the urine and feces. In humans, a single daily dose suppresses DHT concentrations for 24 hours.

Contraindications/Precautions/Warnings
Finasteride is contraindicated in patients hypersensitive to it. It should be used with caution in patients with significant hepatic impairment as metabolism of the drug may be reduced. Finasteride should be used in males only; do not use in sexually developing animals.

Adverse Effects
One study done in dogs reported no adverse effects or irreversibility of effects after treating for 21 weeks at 1 mg/kg. The adverse effects reported in humans have been very limited, mild and transient. Decreased libido, decreased ejaculate volume, and impotence have been reported.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

Finasteride is not indicated for use in females. It is not known whether finasteride is excreted in milk.

Overdosage/Acute Toxicity
Limited information is available; gastrointestinal effects may be noted.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving finasteride and may be of significance in veterinary patients:

ANTICHOLINERGIC DRUGS: May precipitate or aggravate urinary retention thereby negating the effects of the drug when used for BPH

Doses

- **DOGS:**
  - a) For benign prostatic hyperplasia: 0.1–0.5 mg/kg once daily PO; for a 10–50 kg dog, one 5 mg tablet daily (Sirinarumitr et al. 2001), (Bartges 2006)
  - b) For dogs <15 kg: 1.5 mg (approx. 1/3 of a 5 mg tablet); for dogs 15–30 kg = 2.5 mg (1/2 tablet); for dogs >30 kg = 5 mg (one tablet). Given PO daily. (Romagnoli 2006)

- **FERRETS:**
  - a) For adjunctive treatment of adrenal disease: 5 mg (total dose) tablet once daily (Johnson 2006a), (Johnson 2006b)

Monitoring

- Efficacy: Prostate exam

Client Information

- Clients should understand that therapy might be prolonged before efficacy can be determined and regular dosing compliance is mandatory. Once the drug is stopped, the prostate will start growing again.

- Pregnant women should be advised to guard against exposure to this drug as it may cause birth defects.

Firocoxib—See the listing in the Dermatological Agents, Topical Appendix
Doses

Higher doses (15–25 mg/kg; 3–5X) in this age range caused increased rates of hepatic fatty changes; some dogs died or were euthanized due to moribund conditions. The manufacturer states in the package insert: “Use of this product at doses above the recommended 5 mg/kg in puppies less than 7 months old has been associated with serious adverse reactions, including death” and “… this product cannot be accurately dosed in dogs weighing less than seven pounds in body weight.” The labeling in the UK states that it should not be used in dogs “less than 10 weeks of age.”

If changing from one NSAID to another in dogs for reasons of efficacy, consider a washout period between agents. While the actual length of time between agents is controversial and opinions vary widely, often a 24-hour washout period between COX-2 selective agents is recommended. Recommendations for washout periods before starting a COX-2 selective agent after using a non-selective agent or aspirin are usually much longer (72 hours–1 week).

Adverse Effects

Because firocoxib is a relatively new product, its adverse effect profile in dogs is yet to be fully determined. In pre-approval studies (128 dogs treated), vomiting and decreased appetite/anorexia were the most common adverse effects noted with an approximate incidence rate of 4% and 2%, respectively. The drug sponsor has a toll-free overdose hotline in the USA: 877-217-3543.

In the FDA’s CVM Cumulative Adverse Drug Experiences (ADE) Summaries Report (through 12/06/2006) for firocoxib in dogs, the most prevalent ADE reported was vomiting. On the list of 10 most reported ADE’s for firocoxib, the second most reported event was anorexia. Other effects on this list included: diarrhea, increases in BUN, creatinine, alkaline phosphatase and ALT, depression/lethargy, and ataxia. Melena, GI ulcers, bloody vomiting and GI perforation were included within the 25 most reported events listed. It should be noted that this data reflects voluntary reporting to the FDA and does not reflect actual incidence rates, nor is causation necessarily proven.

In pre-approval studies done in horses treated for 14 days, diarrhea/loose stools were seen in about 2%. Excitation was rarely (<1%) detected. In safety studies, oral lesions/ulcers were seen in some horses after dosages of 1–5X were given.

Reproductive/Nursing Safety

Information on the safety of firocoxib in breeding, pregnant or lactating dogs or horses is not available. Studies performed in pregnant rabbits at dosages approximating those given to dogs, demonstrated maternotoxic and fetotoxic effects.

Overdosage/Acute Toxicity

Limited information is available for acute overdoses in animals. The reported oral LD50 for rats is > 2 grams per kg. Should an overdose occur, contacting an animal poison control center or the manufacturer (1-877-217-3543) is highly recommended. Use of gut emptying protocols and supportive treatment (IV fluids, oral sucralfate, etc.) may be useful in managing the case.

Drug Interactions

In the package insert for Previcox, the manufacturer states the following (Note: bold mine—Plumb): “As a class, cyclooxygenase inhibitory NSAIDs may be associated with renal and gastrointestinal toxicity. Sensitivity to drug-associated adverse events varies with the individual patient. Patients at greatest risk for renal toxicity are those that are dehydrated, on concomitant diuretic therapy, or those with existing renal, cardiovascular, and/or hepatic dysfunction. Concurrent administration of potentially nephrotoxic drugs should be carefully approached. NSAIDs may inhibit the prostaglandins that maintain normal homeostatic function. Such antiprostaglandin effects may result in clinically significant disease in patients with underlying or pre-existing disease that has not been previously diagnosed. Since many NSAIDs possess the potential to produce gastrointestinal ulcerations, concomitant use with other antiinflammatory drugs, such as NSAIDs or corticosteroids, should be avoided or closely monitored. The concomitant use of protein bound drugs with Previcox® Chewable Tablets has not been studied in dogs. Commonly used protein-bound drugs include cardiac, anticonvulsant, and behavioral medications. The influence of concomitant drugs that may inhibit the metabolism of Previcox® Chewable Tablets has not been evaluated.”

Drug interactions reported in humans taking NSAIDS, that may be of significance in veterinary patients receiving firocoxib include:

- ACE INHIBITORS (e.g., enalapril, benazepril): Some NSAIDs can reduce effects on blood pressure
- ASPRIN: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- CORTICOSTEROIDS (e.g., prednisone): May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- DIGOXIN: NSAIDs may increase serum levels
- FLUCONAZOLE: Administration has increased plasma levels of celecoxib in humans and potentially could also affect firocoxib levels in dogs
- FUROSEMIDE: NSAIDs may reduce the saluretic and diuretic effects
- HIGHLY PROTEIN BINDING DRUGS (phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, sulfonylurea antidiabetic agents): As firocoxib is highly bound to plasma proteins (95–98%), it may displace other highly bound drugs or these agents could displace firocoxib. Increased serum levels, duration of toxicity and adverse effects may occur.
- METHOTREXATE: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- NEPHROTOXIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity development

Laboratory Considerations

- No specific laboratory concerns; see Monitoring

Doses

- DOGS:

  For the control of pain and inflammation associated with osteoarthritis (labeled indication):
  a) 5 mg/kg (2.27 mg/lb) PO once daily. Dosage should be calculated in half tablet increments and can be administered with or without food. (Package insert; Previcox®—Merial)

- CATS:
CATS:
Caution: While firocoxib may ultimately be shown to be safe for use in cats, supporting information (or FDA approval) is not currently available for it to be recommended.

HORSES:
For the control of pain and inflammation associated with osteoarthritis (labeled indication):
- 0.1 mg/kg (0.045 mg/lb) body weight PO daily for up to 14 days (Package insert; Equioxx®—Merial)

Monitoring
- Baseline and periodic physical exam including clinical efficacy and adverse effect queries
- Baseline and periodic: CBC, liver function, renal function, and electrolytes; urinalysis

Client Information
- The manufacturer provides a client hand-out that is recommended to be distributed each time the drug is dispensed
- May be administered with or without food
- Contact veterinarian if any of the following occur in dogs: vomiting, decreased appetite/weight loss, diarrhea or loose stools, changes in behavior or activity, changes in water consumption or urination, or yellowing of whites of eyes or mucous membranes
- For horses, contact veterinarian if patient develops ulcers or sores on tongue or in mouth, sores or lesions on facial skin or lips, diarrhea/loose stools, changes in behavior/activity, changes in feed or water consumption, or yellowing of whites of eyes or mucous membranes

Chemistry/Synonyms
Firocoxib occurs a white crystalline powder.
- Firocoxib may also be known as: 3-(cyclopropylmethoxy)-5,5-dimethyl-4-(4-methylsulfonyl) phenylfuran-2(5H)-on or ML-1,785,713, Equioxx®, and Previcox®

Storage/Stability
Commercially available tablets and oral paste should be stored at room temperature (15–30°C); brief excursions are permitted up to 40°C (104°F).

Dosage Forms/Regulatory Status
VETERINARY-LABELLED PRODUCTS:
- Firocoxib Chewable Tablets (scored): 57 mg, & 227 mg; Previcox® (Merial); (Rx). FDA-approved for use in dogs.
- Firocoxib Oral Paste: 0.82% w/w (8.2 mg firocoxib per gram of paste) in a 6.93 gram oral syringe (total of 56.8 mg of firocoxib per syringe); Equioxx® (Merial); (Rx).

HUMAN-LABELLED PRODUCTS: None

Fish Oil—See Fatty Acids

FLAVOXATE HCL
(flav'o-xate) Urispas®
PARASYMPATHETIC BLOCKER; URINARY ANTISPASMODIC

Prescriber Highlights
- Alternative medication to treat with detrusor hyperspasticity (hyperactive bladder; urge incontinence) in dogs
- Not commonly used; little information available on veterinary use
- Most likely adverse effect is weakness

Uses/Indications
Flavoxate may be considered for treating dogs with detrusor hyperspasticity (hyperactive bladder, urge incontinence). Flavoxate, propantheline or oxybutinyn can be particularly useful in dogs where phenylpropanolamine alone has not resulted in continence.

Pharmacology/Actions
Flavoxate has direct smooth muscle relaxing properties and antimuscarinic effects.

Pharmacokinetics
No information was located for dogs or cats. In humans, the drug’s onset of action is within an hour with peak effects at around 2 hours post dose. 57% of a dose is excreted in the urine within 24 hours.

Contraindications/Precautions/Warnings
Flavoxate is contraindicated in human patients with pyloric or duodenal obstruction, obstructive intestinal lesions or ileus, achalasia, GI hemorrhage or obstructive
Urinary tract uropathies of the lower urinary tract. It is to be given with caution in patients with suspected glaucoma.

Adverse Effects
Weakness is the most likely adverse effect seen in dogs treated with flavoxate.

Reproductive/Nursing Safety
In laboratory animals, doses of up to 34X (human dose) demonstrated no harm to fetuses or impaired fertility. In humans, flavoxate is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) It is not known whether this drug is excreted into milk. Use with caution in nursing mothers.

Overdosage/Acute Toxicity
The approximate oral LD-50 for rats and mice are 4300 mg/kg and 1800 mg/kg respectively.

Drug Interactions
- No significant drug interactions with flavoxate were located; however, concomitant use with other anticholinergic drugs may cause additive effects.

Laboratory Considerations
- No concerns noted

Doses
- DOGS:
  - To decrease urinary bladder contractility:
    - a) 100–200 mg (per dog) PO q6–8h (Bartges 2006)

Monitoring
- Clinical efficacy
- Adverse effects (most likely GI)
- Consider occasional CBC’s and creatinine to monitor for neutropenia or renal dysfunction if using the drug chronically

Client Information
- May cause weakness or changes in activity level in treated dogs; if these become a problem, contact veterinarian

Chemistry/Synonyms
Flavoxate HCl occurs as a white or almost white crystalline powder. It is slightly soluble in water or alcohol.
  - Flavoxate may also be known as flavoxato, AK 123, or Rec 7-0040. A common trade name is Urispas®.

Storage/Stability
Flavoxate tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
- Flavoxate HCl Oral Tablets (film-coated) 100 mg: Urispas® (Ortho-McNeil), generic (Global); (Rx)

References

FLORFENICOL
(flor-fen-i-col) NuFlor®
ANTIBIOTIC

Prescriber Highlights
- Broad spectrum antibiotic FDA-approved for use in cattle, swine, & fish, but may be useful in other species (e.g., dogs, cats)
- Contraindications: Do not give IV, to veal calves or cattle of breeding age (per manufacturer)
- Adverse Effects: Cattle: Anorexia, decreased water consumption, diarrhea, injection site reactions (may result in trim loss); IM injection may be painful in small animals
- Slaughter withdrawals depend upon route of administration (IM shorter than SC)
Uses/Indications
The drug is FDA-approved for use in cattle only (in the USA) for the treatment of bovine respiratory disease (BRD) associated with *Mannheimia haemolytica*, *Pasteurella multocida*, *Histophilus somni*, and *Mycoplasma bovis*.

Because florfenicol has activity against a wide range of microorganisms, it may be useful for treating other infections in cattle (or other species) as well, but specific data is limited.

The combination product containing florfenicol and flunixin (*Resflor Gold®*) is FDA-approved for SC use in beef and non-lactating dairy cattle (not veal calves) for treatment of BRD associated with *Mannheimia haemolytica*, *Pasteurella multocida*, *Histophilus somni*, *Mycoplasma bovis* and control BRD-associated pyrexia.

Pharmacology/Actions
Like chloramphenicol, florfenicol is a broad-spectrum antibiotic that has activity against many bacteria. It acts by binding to the 50S ribosome, thereby inhibiting bacterial protein synthesis.

Pharmacokinetics
After IM injection in cattle, approximately 79% of the dose is bioavailable. The drug appears to be well distributed throughout the body, including achievement of therapeutic levels in the CSF. In cattle, the volume of distribution is about 0.7 L/kg and only about 13% is bound to serum proteins. Mean serum half-life is 18 hours, but wide interpatient variation exists. When dosed at 40 mg/kg IM, serum levels are above the MIC90 (1 microgram/mL) for *M. haemolytica* for 72 hours and above MIC90 (0.5 micrograms/mL) for *P. multocida* and *H. somnis* for 96 hours.

In dogs, florfenicol is absorbed poorly after subcutaneous injection and has an elimination half-life of less than 5 hours. After IV administration, total body clearance is approximately 1 L/kg/hr. PO administration results in good bioavailability (95%), but the drug is eliminated rapidly (elimination half-life 1.25 hours) (Park et al. 2006).

Cats, however, have high absorption of a 100 mg/mL solution when either given IM or orally and have an elimination half-life of less than 5 hours. Times above an MIC of 2 mg/mL were 12 hours (IM) and 18 hours (PO); and an MIC of 8 mg/mL were 10 hours (IM) and 6 hours (PO), respectively, in cats.

Contraindications/Precautions/Warnings
Not for use in animals intended for breeding purposes. The effects of florfenicol on bovine reproductive performance, pregnancy, and lactation have not been determined. Also see the residue warnings (in Dosage Forms).

Caution: Do not give this drug IV.

Adverse Effects
Noted transient adverse reactions in cattle include anorexia, decreased water consumption, or diarrhea. Injection site reactions can occur that may result in trim loss. Reactions may be more severe if injected at sites other than the neck. Anaphylaxis and collapse have been reported in cattle.

When used in other species (mammals), gastrointestinal effects, including severe diarrheas are potentially possible.

Reproductive/Nursing Safety
Safety or effects when used in breeding cattle or swine, during pregnancy, or during lactation are unknown and the manufacturer states that the drug is not for use in cattle of breeding age or in swine intended for breeding.

Overdosage/Acute Toxicity
In toxicology studies where feeder calves were injected with up to 10X the recommended dosage, the adverse effects noted above were seen, plus increased serum enzymes. These effects were generally transient in nature. Long-term (43 day) standard dosage studies showed a transient decrease in feed consumption, but no long-term negative effects were noted.

Drug Interactions
No specific drug interactions for florfenicol were located, but the drug may behave similarly to chloramphenicol. If so, florfenicol could antagonize the bactericidal activity of the *penicillins* or *aminoglycosides*. This antagonism has not been demonstrated *in vivo*, and these drug combinations have been used successfully many times clinically. Other antibiotics that bind to the 50S ribosomal subunit of susceptible bacteria (*erythromycin, clindamycin, lincomycin, tylosin*, etc.) may potentially antagonize the activity of chloramphenicol or vice versa, but the clinical significance of this potential interaction has not been determined. For other drug interactions that florfenicol may share with chloramphenicol, see the monograph for chloramphenicol or refer to other drug information resources.

Doses
**CATTLE:**

a) For treatment of BRD: 20 mg/kg IM (in neck muscle only); repeat in 48 hours. Alternatively, a single 40 mg/kg SC dose (in neck) may be used. Note: 20 mg/kg equates to 3 mL of the injection per 100 lb. of body weight. Do not exceed 10 mL per injection site. (Package Insert; Nuflor® — Schering Plough)

b) For treatment of BRD: 40 mg/kg (6 mL/100 lb B.W.) administered once by subcutaneous injection. Do not administer more than 15 mL at each site. The injection should be given only in the neck. Injection sites other than the neck have not been evaluated. (Label Information; Nuflor Gold®—Intervet Schering)

c) Using the combination product containing florfenicol/flunixin (*Resflor Gold®*): 40 mg/kg florfenicol/2.2 mg/kg flunixin (6 mL/100 lb. B.W.) SC once. Do not administer more than 10 mL at each site. The injection should be given only in the neck. Injection sites other than the neck have not been evaluated. (Label Information—Resflor Gold®; Intervet Schering)

**DOGS:**

a) For susceptible systemic (bacterial or rickettsial) infections when myelotoxic potential (in humans or animals) of chloramphenicol is to be avoided: 20 mg/kg IM q8h for 3–5 days. (Greene et al. 2006)

**CATS:**

a) For susceptible systemic infections (bacterial or rickettsial) infections when myelotoxic potential (in humans or animals) of chloramphenicol is to be avoided: 22 mg/kg IM, PO q12h for 3–5 days (Note: Oral dosage form not available, but solution given orally to experimental cats was well absorbed) (Greene et al. 2006)
SHEEP & GOATS:

a) For respiratory disease complex in kids: 20 mg/kg a day (route not specified; assume IM) for 2 days (de la Concha 2002).

SWINE:

a) For swine respiratory disease: In water at a concentration of 400 mg/gallon (100 ppm). Use as only source of drinking water for 5 days. For bulk tank add one gallon concentrate to 128 gallons of water; for proportioner set to 1:128 (0.8%). (Label information; NuFlor® Concentrate Solution—Schering-Plough)

Monitoring

■ Clinical efficacy
■ Injection site reactions

Client Information

■ Residue Warnings: When administered as labeled, cattle slaughter withdrawal is 28 days post injection if using the IM route; 38 days after the SC route. Swine (in drinking water) = 16 days.
■ Not to be used in female dairy cattle 20 months of age or older.
■ A withdrawal period has not been established in preruminating calves. Do not use in calves to be processed for veal.
■ Do not give IV.

Chemistry/Synonyms

A fluorinated analog of thiamphenicol, florfenicol is commercially available as light yellow to straw-colored injectable solution also containing n-ethyl-2-pyrolidone, propylene glycol, and polyethylene glycol. The commercially available products range from a bright yellow to straw color. Color does not affect potency. Florfenicol may also be known as Sch-25298 and NuFlor®.

Storage/Stability

Florfenicol injection (Nuflor®, Nuflor Gold®) should be stored between 2°–30°C (36°–86°F). Use within 28 days of first use. The oral solution (swine) should be stored between 2°–26°C (36°–77°F). The combination product with flunixin (Resflor Gold®) should not be stored above 30°C (86°F) and used within 28 days. The 500 mL vial should not be punctured more than 10 times.

Dosage Forms/Regulatory Status/Withdrawal Times

VETERINARY-LABELED PRODUCTS:

Florfenicol Injection: 300 mg/mL in 100 mL, 250 mL and 500 mL multi-dose vials; NuFlor® (Intervet Schering); (Rx). FDA-approved for use in cattle; see residue warnings above. Slaughter withdrawal (at labeled dosages) = 28 days (IM treatment), 38 days (subcutaneous treatment). Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established in preruminating calves. Do not use in calves to be processed for veal.

Florfenicol Injection: 300 mg/mL (also contains 300 mg of 2-pyrrolidone, and triacetin) in 100 mL, 250 mL, & 500 mL vials; Nuflor Gold® (Intervet Schering); (Rx). FDA-approved for use in beef and non-lactating dairy cattle. Do not slaughter within 44 days of last treatment. Do not use in female dairy cattle 20 months of age or older. Use may cause milk residues. A withdrawal period has not been established in preruminating calves.

Florfenicol 2.3% (23 mg/mL) Concentrate Solution in 2.2 btls; NuFlor® Concentrate Solution (Schering-Plough); (Rx). FDA-approved for use in swine; Slaughter withdrawal (at labeled dosages) = 16 days.

There are florfenicol products for addition to catfish or salmonid feeds (Aquaflor®) and to feed for swine.

Florfenicol 300 mg/mL with Flunixin 16.5 mg/mL Injection in 100 mL, 250 mL and 500 mL vials; Resflor Gold® (Intervet Schering); (Rx). FDA-approved for use in beef and non-lactating dairy cattle. Do not slaughter within 38 days of last treatment. Not for use in female dairy cattle 20 months of age or older in calves to be processed for veal. Use may cause milk residues. A withdrawal period has not been established in preruminating calves.

HUMAN-LABELED PRODUCTS: None

FLUCONAZOLE

(floo-ko-naz-ole) Diflucan®

ANTIFUNGAL

Prescriber Highlights

- Oral or parenteral antifungal particularly useful for CNS infections
- Caution: Renal failure (dosage adjustment needed), pregnancy (safety not established), hepatic failure
- Adverse Effects: Occasional GI effects (inappetence) in cats or dogs; in humans: headache &, rarely, increased liver enzymes & hepatic toxicity
- Expensive, but price is decreasing now that it is available as a generic
- Drug Interactions
Uses/Indications
Fluconazole may have use in veterinary medicine in the treatment of systemic mycoses, including cryptococcal meningitis, blastomycosis, and histoplasmosis. It may also be useful for superficial candidiasis or dermatophytosis. Because of the drug’s unique pharmacokinetic qualities, it is probably more useful in treating CNS infections or fungal urinary tract infections than otherazole derivatives. Fluconazole does not have appreciable effects (unlike ketoconazole) on hormone synthesis and may have fewer side effects than ketoconazole in small animals.

Pharmacology/Actions
Fluconazole is a fungistatic triazole compound. Triazole-derivative agents, like the imidazoles (clotrimazole, ketoconazole, etc.), presumably act by altering the cellular membranes of susceptible fungi, thereby increasing membrane permeability and allowing leakage of cellular contents and impaired uptake of purine and pyrimidine precursors. Fluconazole has efficacy against a variety of pathogenic fungi including yeasts and dermatophytes. In vivo studies using laboratory models have shown that fluconazole has fungistatic activity against some strains of Candida, Cryptococcus, Histoplasma, and Blastomyces. In vivo studies of efficacy against Aspergillus strains have been conflicting.

Pharmacokinetics
Fluconazole is rapidly and nearly completely absorbed (90%) after oral administration. Gastric pH or the presence of food, do not appreciably alter fluconazole’s oral bioavailability. It has low protein binding and is widely distributed throughout the body and penetrates well into the CSF, eye, and peritoneal fluid. Fluconazole is eliminated primarily via the kidneys and achieves high concentrations in the urine. In humans, fluconazole’s serum half-life is about 30 hours in patients with normal renal function. Because of it’s long half-life, fluconazole does not reach steady state plasma levels for 6–14 days after beginning therapy, unless loading doses are given. Patients with impaired renal function may have half-lives extended significantly and dosage adjustment may be required.

Contraindications/Precautions/Warnings
Fluconazole should not be used in patients hypersensitive to it or otherazole antifungal agents. In patients with hepatic impairment it should be used only when the potential benefits outweigh the risks. Because fluconazole is eliminated primarily by the kidneys, fluconazole doses or dosing intervals may need to be adjusted in patients with renal impairment.

Adverse Effects
There is limited experience with this drug in domestic animals. Thus far, it appears to be safe to use in dogs and cats. Occasionally, inappetence, vomiting, or diarrhea may be reported. Hepatotoxicity is possible.

Reproductive/Nursing Safety
Safety during pregnancy has not been established and it is not recommended for use in pregnant animals unless the benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Overdose/Acute Toxicity
There is very limited information on the acute toxicity of fluconazole. Rats and mice survived doses of 1 g/kg, but died within several days after receiving 1–2 g/kg. Rats and mice receiving very high dosages demonstrated respiratory depression, salivation, lacrimation, urinary incontinence, and cyanosis. If a massive overdose occurs, consider gut emptying and give supportive therapy as required. Fluconazole may be removed by hemodialysis or peritoneal dialysis.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving fluconazole and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Lab animal studies have shown that fluconazole used concomitantly with amphotericin B may be antagonistic against Aspergillus or Candida; the clinical importance of these findings is not yet clear
- **BUSPIRONE**: Plasma concentrations may be elevated
- **CISAPRIDE**: Fluconazole may increase cisapride levels and the possibility for toxicity
- **CORTICOSTEROIDS**: Fluconazole may inhibit the metabolism of corticosteroid; potential for increased adverse effects
- **CYCLOPHOSPHAMIDE**: Fluconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity
- **CYCLOSPORINE**: Fluconazole increases cyclosporine levels. In normal dogs, fluconazole at 5 mg/kg once daily decreased cyclosporine dosages by 29%-51% to achieve similar therapeutic trough levels. In renal transplant dogs (also on mycophenolate), fluconazole decreased cyclosporine dose requirements 33% on average (Katayama et al. 2010).
- **DIURETICS, THIAZIDES**: Increased fluconazole concentrations
- **FENTANYL/ALFENTANIL**: Fluconazole may increase fentanyl levels
- **MIDAZOLAM**: Increased midazolam levels and effects
- **NSAIDS**: Fluconazole may increase plasma levels; increased risk for adverse effects
- **QUINIDINE**: Increased risk for cardiotoxicity
- **RIFAMPIN**: May decrease fluconazole efficacy; fluconazole may increase rifampin levels
- **THEOPHYLLINE/AMINOPHYLLINE**: Increased theophylline concentrations

THEOPHYLLINE/AMINOPHYLLINE: Increased risk of toxicity

RIFAMPIN: May decrease fluconazole efficacy; fluconazole may increase rifampin levels

NSAIDS: Fluconazole may increase plasma levels; increased risk for adverse effects

QUINIDINE: Increased risk for cardiotoxicity

RIFAMPIN: May decrease fluconazole efficacy; fluconazole may increase rifampin levels

THEOPHYLLINE/AMINOPHYLLINE: Increased theophylline concentrations
A synthetic triazole antifungal agent, fluconazole occurs as a white crystalline powder. It is slightly soluble (8 mg/mL) in water.

**Chemistry/Synonyms**

Fluconazole may be known as UK-49858; many trade names are available.

**Client Information**

- Have clients report any potential adverse effects.
- Compliance with treatment recommendations must be stressed.
- The cost of this drug may be an issue. Fluconazole therapy may be prolonged (several weeks to months) and an average dosage in a cat (50 mg twice a day) may be very expensive.
- With long-term therapy, occasional liver function tests are recommended.

**Doses**

**DOGS:**

a) General dosing guidelines: Give twice calculated daily dose for the first day of treatment; give for 2–3 days if rapidly advancing or severe disseminated mycosis. Give IV solution over 1–2 hours.

- For cryptococcosis, candidiasis, systemic mycoses, nasal aspergillosis: 2.5–5 mg/kg PO or IV q12–24h for 56–84 days. Often treat neurologic ocular cryptococcosis for at least 12 weeks or 2 weeks after CSF exam shows resolution of inflammation and antigen test results on serum and CSF are negative.
- For fungal meningitis: 5–8 mg/kg PO or IV q12h OR 8–12 mg/kg PO or IV once daily (q24h) for 56–84 days;
- For fungal candidiasis: 5–10 mg/kg PO q24h for 21–42 days;
- For urinary Candida glabrata infection: 12 mg/kg PO once daily for 21–42 days. (Greene et al. 2006)

b) For cryptococcosis: 5 mg/kg PO once or twice daily. Treatment should continue for at least 2 months beyond resolution of clinical signs. (Taboada 2000)

c) For blastomycosis: 5 mg/kg PO q12h for 60 days

- For cryptococcosis: 5–15 mg/kg PO q12–24h for 6–10 months (Lemarie 2003)

d) For treatment of Malassezia (may be safer than itraconazole or ketoconazole in dogs with hepatic disease): 5 mg/kg PO once daily. (Thomas 2005)

e) For systemic treatment of Malassezia dermatitis: 5 mg/kg PO once daily; for recurrent Malassezia dermatitis: 5 mg/kg PO 3 times per week. (Ihrke 2008)

f) For systemic treatment of Malassezia dermatitis: 2–5 mg/kg PO once daily (q24h). (Beale & Murphy 2006)

g) As an alternative to itraconazole or terbinafine for nasal aspergillosis (with topical agents when the cribiform plate is penetrated): 2.5–5 mg/kg PO q12h for 3–6 months. Cure rates up to 60%. (Kuehn 2010)

**CATS:**

a) General dosing guidelines: Give twice calculated daily dose for the first day of treatment; give for 2–3 days if rapidly advancing or severe disseminated mycosis. For cryptococcosis or other systemic infections, treatment should continue until antigen testing results of blood or CSF are negative, this is usually at least 2 months beyond clinical resolution (mean time of 8 months treatment).

- For nasal or dermal cryptococcosis: 5–10 mg/kg PO q12–24h, or 10 mg/kg PO q24h; for most infections, 50 mg/cat PO once daily achieves adequate therapeutic levels.
- For CNS, intraocular, or multisystemic cryptococcosis: 50–100 mg/cat PO or IV q12h. Often treat neurologic ocular cryptococcosis for at least 12 weeks or 2 weeks after CSF exam shows resolution of inflammation and antigen test results on serum and CSF are negative.

- For CNS, intraocular or multisystemic mycoses: 50 mg/cat PO once daily (q24h); (Greene et al. 2006)

b) For cryptococcosis: 50 mg (total dose) PO twice daily. Treatment should continue for 1 month beyond resolution of clinical signs. (Legendre 1995)

c) For cryptococcosis: 50 mg (total dose) PO twice daily. Treatment should continue for at least 2 months beyond resolution of clinical signs. (Taboada 2000)

**HORSES:**

a) For C. immitis infection or Candida bacteremia: Loading dose of 14 mg/kg followed by 5 mg/kg PO once daily. Anecdotal reports of successful treatment of fungal keratitis using 1 mg/kg PO q24h. (Stewart et al. 2008)

**RABBITS/RODENTS/SMALL MAMMALS:**

a) Rabbits: 25–43 mg/kg slow IV q12h (Ivey & Morrisey 2000)

**BIRDS:**

a) For treating candidiasis: A report where fluconazole pharmacokinetics were determined in Goffin’s cockatoos, Timneh African grey parrots, and orange-winged Amazon parrots showed that fluconazole dosed at 20 mg/kg PO q24-48h or 10 mg/kg PO q24h would likely be effective for treating C. albicans. C. galabrata and C. papasilsis may have MIC’s greater than this dose could effectively treat. (Flammer 2008)

b) For treating candidiasis in cockatiels: In this report, both a 10 mg/kg fluconazole PO suspension and 100 mg/mL fluconazole treated drinking water maintained plasma levels above the MIC for most strains of Candida albicans. (Ratzlaff & Flammer 2009)

c) As an alternate treatment of aspergillosis: 5–10 mg/kg PO once daily for up to 6 weeks, with or after amphotericin B. (Oglesbee & Bishop 1994)

**Monitoring**

- Clinical Efficacy
- With long-term therapy, occasional liver function tests are recommended

**Client Information**

- Cost of this drug may be an issue. Fluconazole therapy may be prolonged (several weeks to months) and an average dosage in a cat (50 mg twice a day) may be very expensive.
- Compliance with treatment recommendations must be stressed.
- Have clients report any potential adverse effects.

**Chemistry/Synonyms**

A synthetic triazole antifungal agent, fluconazole occurs as a white crystalline powder. It is slightly soluble (8 mg/mL) in water.

**Theophylline/Aminophylline:** Increased theophylline concentrations

**Tricyclic Antidepressants** (e.g., amitriptyline, clomipramine, etc.): Fluconazole may exacerbate the effects of tricyclic antidepressants

**Sulfonurea Antidiabetic Agents** (e.g., glipizide, glyburide): Fluconazole may increase levels; hypoglycemia possible

**Vincristine/Vinblastine:** Fluconazole may inhibit vinca alkaloid metabolism

**Warfarin:** Fluconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants
Flucytosine may also be known as UK-49858; many trade names are available.

Storage/Stability
Flucytosine tablets should be stored at temperatures less than 30°C in tight containers. Flucytosine injection should be stored at temperatures from 5–30°C (5–25°C for the Viaflex® bags); avoid freezing. Do not add additives to the injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None

HUMAN-LABELLED PRODUCTS:
Flucytosine Oral Tablets: 50 mg, 100 mg, 150 mg, & 200 mg; Diflucan® (Pfizer); generic; (Rx)
Flucytosine Powder for Oral Suspension: 10 mg/mL & 40 mg/mL (when reconstituted) in 35 mL; Diflucan® (Pfizer); generic; (Rx)
Flucytosine Injection: 2 mg/mL in 100 mL or 200 mL bottles or Viaflex Plus (available with sodium chloride or dextrose diluents); Diflucan® (Pfizer); generic; (Rx)

References

FLUCYTOSINE
(floo-sy-toe-seen) Anobon®
ANTIFUNGAL

Prescriber Highlights

- Infrequently used antifungal used in combination with other drugs (to reduce resistance development)
- Extreme Caution: Renal impairment, preexisting bone marrow depression, hematologic diseases, or receiving other bone marrow suppressant drugs
- Caution: Hepatic disease
- Adverse Effects: Most common: GI disturbances; Potentially: dose dependent bone marrow depression, cutaneous eruption & rash primarily seen on the scrotum & nasal planum (in dogs), oral ulceration, increased hepatic enzymes, CNS effects in cats
- Dogs may not tolerate therapy for more than 10–14 days
- Teratogenic in rats

Uses/Indications
Flucytosine is principally active against strains of Cryptococcus and Candida. When used alone, resistance can develop quite rapidly to flucytosine, particularly with Cryptococcus. Because it penetrates relatively well into the CNS, it has been used in combination for the treatment of CNS cryptococcosis. Some cases of subcutaneous and systemic chromoblastosis may also respond to flucytosine. The drug can have synergistic efficacy when used with amphotericin B. Clinically, it is used primarily with amphotericin B in the treatment of cryptococcosis.

Pharmacology/Actions
Flucytosine penetrates fungal cells where it is deaminated by cytosine deaminase to fluorouracil. Fluorouracil acts as an antimetabolite by competing with uracil, thereby interfering with pyrimidine metabolism and eventually RNA and protein synthesis. It is thought that flucytosine is converted to fluoroacycyuridylate that inhibits thymidylate synthase and ultimately DNA synthesis.

In human cells, cytosine deaminase is apparently not present or only has minimal activity. Rats apparently metabolize some of the drug to fluorouracil, which may explain the teratogenic effects seen in this species. It is unclear how much cytosine deaminase activity dog and cat cells possess.

Pharmacokinetics
Flucytosine is well absorbed after oral administration. The rate, but not extent, of absorption will be decreased if given with food.

Flucytosine is distributed widely throughout the body. CSF concentrations may be 60–100% of those found in the serum. In healthy humans, the volume of distribution is about 0.7 L/kg. Only about 2–4% of the drug is bound to plasma proteins. It is unknown if flucytosine is distributed into milk.

Absorbed flucytosine is excreted basically unchanged in the urine via glomerular filtration. In humans, the half-life is about 3–6 hours in patients with normal renal function, but may be significantly prolonged in patients with renal dysfunction.

Contraindications/Precautions/Warnings
Flucytosine is contraindicated in patients hypersensitive to it.

Flucytosine should be used with extreme caution in patients with renal impairment. Some clinicians recommend monitoring serum flucytosine levels in these patients and adjusting dosage (or dosing interval) to maintain serum levels at less than 100 micrograms/mL. One clinician (Macy, 1987) recommends dividing the flucytosine
Use fluocytosine with extreme caution in patients with preexisting bone marrow depression, hematologic diseases, or receiving other bone marrow suppressant drugs. Fluocytosine should also be used cautiously (with enhanced monitoring) in patients with hepatic disease.

Adverse Effects

Most common adverse effects seen with fluocytosine are GI disturbances (nausea, vomiting, diarrhea). Other potential adverse effects include a dose dependent bone marrow depression (anemia, leukopenia, thrombocytopenia), cutaneous eruption and rash primarily seen on the scrotum and nasal planum (occurring in dogs), oral ulceration and increased levels of hepatic enzymes. Dogs receiving fluocytosine often develop a severe drug reaction within 10–14 days of treatment. Reports of aberrant behavior and seizures in a cat without concurrent CNS infection have been noted after fluocytosine use. There are anecdotal reports of toxic epidermal necrolysis occurring in cats treated with fluocytosine.

Reproductive/Nursing Safety

Flucytosine has caused teratogenic effects in rats. It should be used in pregnant animals only when the benefits of therapy outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is not known whether this drug is excreted in milk. Because there are potential serious adverse reactions in nursing offspring, consider using milk replacer.

Overdosage/Acute Toxicity

No specifics regarding fluocytosine overdosage were located. It is suggested that a substantial overdose be handled with gut emptying, charcoal and cathartic administration unless contraindicated.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluocytosine and may be of significance in veterinary patients:

**AMPHOTERICIN B:** When used with amphotericin B, synergism against Cryptococcus and Candida has been demonstrated in vitro. However, if amphotericin B induces renal dysfunction, toxicity of fluocytosine may be enhanced if it accumulates. Should clinically significant renal toxicity develop, fluocytosine dosage may need to be adjusted.

Laboratory Considerations

When determining serum creatinine using the Ektachem® analyzer, false elevations in levels may be noted if patients are also taking fluocytosine.

Doses

**DOGS:**

For cryptococcosis:

a) 50–75 mg/kg PO q8h; treatment requires 1–12 months. Must be given with a polyene or azole antifungal agent. (Malik et al. 2006)

For candidiasis:

a) 25–50 mg/kg PO q6h or 50–65 mg/kg PO q8h for 42 days. Must be given with a polyene or azole antifungal agent. (Greene & Watson 1998)

**CATS:**

For cryptococcosis:

a) Fluocytosine at 30 mg/kg PO q6h or 50 mg/kg PO q8h or 75 mg/kg PO q12h). Cats 3.5 kg or greater should receive 250 mg (total) q6–8h. Must be given with a polyene (amphotericin B) or azole antifungal agent. Treatment requires 1–9 months. (Malik et al. 2006)

For candidiasis:

a) 25–50 mg/kg PO q6h or 50–65 mg/kg PO q8h for 42 days. Must be given with a polyene or azole antifungal agent (Greene & Watson 1998)

**BIRDS:**

For susceptible fungal infections:

a) In Psittacines: 250 mg/kg twice daily as a gavage. May be used for extended periods of time for aspergillosis. May cause bone marrow toxicity; periodic hematologic assessment is recommended.

   In raptors: 18–30 mg/kg q6h as a gavage

   In Psittacines and Mynahs: 100–250 mg/lb in feed for flock treatment of severe aspergillosis or Candida (especially respiratory Candida). Apply to favorite food mix or mixed with mash. (Clubb 1986)

b) Ratites: 80–100 mg/kg PO twice daily (Jenson 1998)

Monitoring

- Renal function (at least twice weekly if also receiving amphotericin B)
- CBC with platelets
- Hepatic enzymes at least monthly

Client Information

- Clients should report any clinical signs associated with hematologic toxicity (abnormal bleeding, bruising, etc.).
- Prolonged treatment times, as well as costs of medication and associated monitoring, require substantial client commitment.

Chemistry/Synonyms

A fluorinated pyrimidine antifungal agent, fluocytosine occurs as a white to off-white, crystalline powder that is odorless or has a slight odor with pKₐs of 2.9 and
A fluorinated pyrimidine antifungal agent, flucytosine occurs as a white to off-white, crystalline powder that is odorless or has a slight odor with pKₐs of 2.9 and 10.71. It is sparingly soluble in water and slightly soluble in alcohol.

Flucytosine may also be known as: 5-FC, 5-fluorocytosine, flucytosinum, Ro-2-9915, Alcobon®, and Ancotil®.

Storage/Stability
Store flucytosine capsules in tight, light-resistant containers at temperatures less than 40°C, and preferably at room temperature (15–30°C). The commercially available capsules are assigned an expiration date of 5 years from the date of manufacture.

Compatibility/Compounding Considerations
Compounded preparation stability: Flucytosine oral suspension compounded from commercially available capsules has been published (Allen & Erickson 1996). Triturating four (4) flucytosine 250 mg capsules with 50 mL of Ora-Plus® and qs ad to 100 mL with Ora-Sweet® (or Ora-Sweet® SF) yields a 10 mg/mL oral suspension that retains >95% potency for 60 days stored at both 5°C and 25°C.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Flucytosine Oral Capsules: 250 mg & 500 mg; Ancobon® (ICN); (Rx)

References

FLUDROCORTISONE ACETATE
(fluh-droy-kor-tis-one) Florinef®
MINERALOCORTICOID
Prescriber Highlights
• Oral mineralocorticoid alternative to DOCP used to treat adrenal insufficiency in small animals; may be useful to treat hyperkalemia as well
• Also has some glucocorticoid effect which may cause adverse effects
• Adverse Effects: Dosage related; PU/PD, hypertension, edema, & hypokalemia possible
• May be excreted in significant quantities in milk
• Patients may require supplemental glucocorticoids
• Expense may be an issue, especially in larger dogs

Uses/Indications
Fludrocortisone is used in small animal medicine for the treatment of adrenocortical insufficiency (Addison’s disease). It can also be used as adjunctive therapy in hyperkalemia.

Additionally, in humans, fludrocortisone has been used in salt-losing, congenital adrenogenital syndrome and in patients with severe postural hypotension.

Pharmacology/Actions
Fludrocortisone acetate is a potent corticosteroid that possesses both glucocorticoid and mineralocorticoid activity. It is approximately 10–15 times as potent a glucocorticoid agent as hydrocortisone, but is a much more potent mineralocorticoid (125 times that of hydrocortisone). It is only used clinically for its mineralocorticoid effects.

The site of action of mineralocorticoids is at the renal distal tubule where they increase the absorption of sodium. Mineralocorticoids also enhance potassium and hydrogen ion excretion.

Pharmacokinetics
In humans, fludrocortisone is well absorbed from the GI with peak levels occurring in approximately 1.7 hours; plasma half-life is about 3.5 hours, but biologic activity persists for 18–36 hours.

Contraindications/Precautions/Warnings
Fludrocortisone is contraindicated in patients known to be hypersensitive to it.

Some dogs or cats may require additional supplementation with a glucocorticoid agent on an ongoing basis. All animals with hypoadrenocorticism should receive additional glucocorticoids (2–10 times basal) during periods of stress or acute illness.

Adverse Effects
Adverse effects of fludrocortisone are generally a result of chronic, excessive dosage (see Overdosage below) or if withdrawal is too rapid. Since fludrocortisone also possesses glucocorticoid activity, it theoretically could cause the adverse effects associated with those compounds and polyuria/polydipsia may be a problem for some dogs. (See the section on the glucocorticoids for more information.)
Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)
Fludrocortisone may be excreted in clinically significant quantities in milk. Puppies or kittens of mothers receiving fludrocortisone should receive milk replacer after colostrum is consumed.

Overdose/Acute Toxicity
Overdosage may cause hypertension, edema, and hypokalemia. Electrolytes should be aggressively monitored and potassium may need to be supplemented. Patients should have the drug discontinued until clinical signs associated with overdosage have resolved; then restart the drug at a lower dosage.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving fludrocortisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Patients may develop hypokalemia if fludrocortisone is administered concomitantly with amphotericin B
- **ASPIRIN**: Fludrocortisone may reduce salicylate levels
- **DIURETICS, POTASSIUM-DEPLETING (e.g., thiazides, furosemide)**: Patients may develop hypokalemia if fludrocortisone is administered concomitantly with diuretics; diuretics can cause a loss of sodium, and may counteract the effects of fludrocortisone
- **INSULIN**: Potentially, fludrocortisone could increase the insulin requirements of diabetic patients

Doses

**DOGS:**
For hypoadrenocorticism:

a) Initial dose of 0.01 mg/kg PO twice daily. Adjust dose based on monitoring serum electrolyte concentrations every 1-2 weeks until stable. Once stable, recheck serum chemistry profile including electrolytes every 3-4 months. Many dogs do well on fludrocortisone alone, but some dogs require additional glucocorticoid treatment. Polyuria, polydipsia, and other signs of Cushing’s syndrome can be a problem in some dogs on fludrocortisone and can occur even when hyponatremia and, less frequently, hyperkalemia persist. Addition of NaCl (0.1 g/kg/day) can be useful in reducing the dose of fludrocortisone, maintaining a normal serum sodium, and possibly reduce the PU/PD. (Panciera 2009)

b) For maintenance: Initially, 0.01–0.02 mg/kg/day PO and adjusted by 0.05–0.1 mg (total dose) increments based on serial electrolyte determinations. Electrolytes are initially checked weekly until stabilized in normal range. In many dogs, dose requirements increase incrementally over the first 6–24 months. Most dogs will ultimately require 0.02–0.03 mg/kg/day. (Kintzer 2004)

c) 0.01 mg/kg PO twice daily. Titrate dose to effect; typically dose needs to be increased over time. For glucocorticoid replacement, starting dose of prednisone is 0.1–0.22 mg/kg initially, but then taper to lowest dose that will control clinical signs. Only 50% of dogs on fludrocortisone require supplemental prednisone. (Scott-Moncrieff 2010)

**CATS:**
For maintenance therapy of hypoadrenocorticism:

a) 0.02 mg/kg PO once daily. Prednisone or prednisolone (1.25 mg per cat PO once daily) can be used for glucocorticoid replacement. (Scott-Moncrieff 2010)

b) Maintenance therapy: 0.1 mg total dose/cat PO once daily with prednisolone (0.2 mg/kg PO once daily). (Caney 2009)

**FERRETS:**
For hypoadrenocorticism:

a) For those animals that still exhibit Addisonian signs even with prednisone therapy: 0.05–0.1 mg/kg PO q24h or divided q12h. (Johnson 2006)

Monitoring

- Serum electrolytes, BUN, creatinine; initially every 1–2 weeks, then every 3–4 months once stabilized
- Weight, PE for edema

Client Information

- Clients should be familiar with the signs associated with both hypoadrenocorticism (e.g., weakness, depression, anorexia, vomiting, diarrhea, etc.) and fludrocortisone overdosage (e.g., edema) and report these to the veterinarian immediately.

Chemistry/Synonyms
A synthetic glucocorticoid with significant mineralocorticoid activity, fludrocortisone acetate occurs as hygroscopic, fine, white to pale yellow powder or crystals. It is odorless or practically odorless and has a melting point of approximately 225°C. Fludrocortisone is insoluble in water and slightly soluble in alcohol.
Fludrocortisone acetate may also be known as: fluohydrosone acetate, fluohydrocortisone acetate, 9alpha-fluorohydrocortisone acetate, fludrocortisoni acetas, 9alpha-fluorohydrocortisone 21-acetate, Astonin®, Astonin H®, Florinef®, Florinefe®, and Lonikan®.

Storage/Stability
Fludrocortisone acetate tablets should be stored at room temperature (15–30°C) in well-closed containers; avoid excessive heat. The drug is relatively stable in light and air.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None
Fludrocortisone Acetate Tablets: 0.1 mg; Florinef® Acetate (Monarch); generic; (Rx)

References

FLUMAZENIL
(Floo-maz-e-nil) Romazicon®
BENZODIAZEPINE ANTAGONIST
Prescriber Highlights

- Benzodiazepine antagonist to reverse either OD’s or therapeutic effects
- Contraindications: Known hypersensitivity, when benzodiazepines are treating life-threatening conditions (e.g., status epilepticus, increased CSF pressure), during tricyclic antidepressant OD treatment
- Use extreme caution in mixed overdoses
- Adverse Effects: Potentially injection site reactions, vomiting, cutaneous vasodilatation, vertigo, ataxia, & blurred vision; seizures have been reported in humans
- Potentially teratogenic at high dosages

Uses/Indications
Flumazenil may be useful for the reversal of benzodiazepine effects after either therapeutic use or overdoses. Flumazenil may be of benefit in the treatment of encephalopathy in patients with severe hepatic failure or in treating overdoses with zolpidem (Ambien®) or other imidazopyridine hypnotic agents.

A report of using flumazenil to reverse the anesthetic effects of tiletamine-zolazepam in dogs, demonstrated that analgesia, posture, and auditory effects were reversed, but it had no effect on sedation or muscle relaxation. Recovery times (head up, sternal recumbency, standing, walking) from anesthesia were reduced in the flumazenil treated dogs. Heart rates, glucose levels, body temperature were significantly higher in the flumazenil treated group. (Kim et al. 2009).

Pharmacology/Actions
Flumazenil is a competitive blocker of benzodiazepines at benzodiazepine receptors in the CNS. It antagonizes the sedative and amnestic qualities of benzodiazepines.

Pharmacokinetics
Flumazenil is administered by rapid IV injection. Therapeutic effect may occur within 1–2 minutes of administration. It is rapidly distributed and metabolized in the liver. In humans, the average half-life is about one hour.

Contraindications/Precautions/Warnings
Flumazenil is contraindicated in patients hypersensitive to it or other benzodiazepines or in patients with where benzodiazepines are being used to treat a potentially life-threatening condition (e.g., status epilepticus, increased CSF pressure). It should not be used in patients with a serious tricyclic antidepressant overdose. Flumazenil should not be used, or used with extreme caution, in patients with mixed overdoses where benzodiazepine reversal may lead to seizures or other complications.

While flumazenil has been tried as treatment for overdoses of baclofen or carisoprodol, it may actually be contraindicated as it may cause worsening of clinical signs (Mazzaferro 2008). Flumazenil does not alter benzodiazepine pharmacokinetics. Effects of long-acting benzodiazepines may recur after flumazenil’s effects subside.

Adverse Effects
In some human patients, flumazenil use has been associated with seizures. These patients usually have a long history of benzodiazepine use or are showing signs of serious tricyclic antidepressant toxicity. Adverse effects reported in humans include injection site reactions, vomiting, cutaneous vasodilatation, vertigo, ataxia and blurred vision. Deaths have been associated with its use in humans having serious underlying diseases.

Overdosage/Acute Toxicity
Large IV overdoses have rarely caused symptoms in otherwise healthy humans. Seizures, if precipitated, have been treated with barbiturates, benzodiazepines and phenytoin, usually with prompt responses.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving flumazenil and may be of significance in veterinary patients:

- CYCLIC (tri-, tetra-) ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline, etc.): Increased risk for seizures; use contraindicated
- NEUROMUSCULAR BLOCKING AGENTS: Not recommended to use flumazenil until neuromuscular blockade has been fully reversed

Doses

**DOGS & CATS:**
As an antagonist for benzodiazepines:

a) Dogs: 0.01 mg/kg IV (Bunch 2003)
For adjunctive therapy to improve neurologic function in dogs with severe hepatic encephalopathy:

- **Dogs/Cats:** 0.01 mg/kg IV (one time) (Bunch 2003)
- **Dogs/Cats:** 0.01 mg/kg IV; may need to be repeated as half-life is only about an hour. May also be administered intratracheally in an emergency. (Wismer 2004)

### ZOO, EXOTIC, WILDLIFE SPECIES:

For use of flumazenil in zoo, exotic and wildlife medicine refer to specific references, including:

- **Exotic Animal Formulary, 3rd Ed.** Carpenter, J.W., Saunders. 2005
- **The 2009 American Association of Zoo Veterinarian Proceedings** by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

### Monitoring

- **Efficacy**
- **Monitor for seizures in susceptible patients**

### Client Information

- Flumazenil should only be used in a controlled environment by clinically experienced professionals.

### Chemistry/Synonyms

A benzodiazepine antagonist, flumazenil is a 1,4-imidazobenzodiazepine derivative.

Flumazenil may also be known as: flumazenilum, flumazepil, Ro-15-1788, Ro-15-1788/000, **Anexit®**, Flumage®, Flumanovag®, Flumazen®, Fluxifarm®, Lanexat® and Romazicon®.

### Storage/Stability

Store flumazenil at 25°C (77°F); excursions are permitted from 15° to 30°C (59° to 86°F). Once drawn into a syringe or mixed with the above solutions, discard after 24 hours.

### Compatibility/Compounding Considerations

Flumazenil is physically compatible with lactated Ringer’s, D5W, or normal saline solutions.

### References

### Uses/Indications

Flumethasone injection is available commercially as a free steroid alcohol solution. While it does not work quite as rapidly as the corticosteroid phosphate and succinate esters (methylprednisolone sodium succinate, prednisolone sodium succinate, or dexamethasone sodium phosphate), it can be given either IM or IV and is significantly less expensive than the esters. It is contraindicated in the presence of active infection, blood dyscrasias, diabetes mellitus, or myasthenia gravis. For a complete list of safety information, refer to the full prescribing information for Flumethasone.
The following drug interactions have either been reported or are theoretical in humans or animals receiving flumethasone and may be of significance in veterinary medicine.

Drug Interactions

- **Acute Overdose/Acute Toxicity:** Accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.
- **Glucocorticoids:** When given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after chronic glucocorticoid administration has been reported.
- **Reproductive/Nursing Safety:** Corticosteroid therapy may induce parturition in large animal species during the later stages of pregnancy.
MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin): May decrease the metabolism of glucocorticoids and increase flumethasone blood levels

MITOTANE: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency

NSAIDS: Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration

PHENYTOIN: May increase the metabolism of glucocorticoids and decrease flumethasone blood levels

RIFAMPIN: May increase the metabolism of glucocorticoids and decrease flumethasone blood levels

VACCINES: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations

- Glucocorticoids may increase serum cholesterol
- Glucocorticoids may increase urine glucose levels
- Glucocorticoids may decrease serum potassium
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce $T_3$ & $T_4$ values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of $^{131}$I by the thyroid may be decreased by glucocorticoids.
- Reactions to skin tests may be suppressed by glucocorticoids
- False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause neutrophilia within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause lymphopenia which can persist for weeks after drug discontinuation in dogs

Doses

**DOGS:**
For labeled indications (musculoskeletal conditions due to inflammation …, certain acute and chronic dermatoses … when given orally, and also for allergic states or shock when given intravenously). Treat and adjust dosage on an individual basis:

a) Orally: 0.0625–0.25 mg daily in divided doses. Dosage is dependent on size of animal, stage and severity of disease. **Note:** Tablets no longer marketed in the USA
   - Parenterally: 0.0625–0.25 mg IV, IM, SC daily; may repeat;
   - Intra-articularly: 0.166–1 mg;
   - Intra-lesionally: 0.125–1 mg (Package insert; Flucort®—Fort Dodge)

b) 0.06–0.25 mg IV, IM, SC, or PO once daily (Kirk 1989)

**CATS:**
For labeled indications (certain acute and chronic dermatoses …): Treat and adjust dosage on an individual basis:

a) Orally: 0.03125–0.125 mg daily in divided doses; **Note:** Tablets no longer marketed in the USA
   - Parenterally: 0.03125–0.125 mg IV, IM, or SC. If necessary, may repeat. (Package insert; Flucort®—Fort Dodge)

b) 0.03–0.125 mg IV, IM, SC, or PO once daily (Kirk 1989)

**HORSES:**  **(Note: ARCI UCGFS Class 4 Drug)**
For labeled indications (musculoskeletal conditions due to inflammation, where permanent changes do not exist; and also for allergic states such as hives, urticaria and insect bites):

a) 1.25–2.5 mg daily by IV, IM or intra-articular injection. If necessary, the dose may be repeated. (Package insert; Flucort®—Fort Dodge)

b) 1–2.5 mg/450 kg IV or IM (Robinson 1987)

Monitoring
Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.
FLUNIXIN MEGLUMINE
(Bloo-nix-in) Banamine®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- Veterinary-only non-steroidal antiinflammatory agent used in a variety of species
- Caution in patients with preexisting GI ulcers, renal, hepatic, or hematologic diseases; in horses with colic, flunixin may mask the behavioral & cardiopulmonary signs associated with endotoxemia or intestinal devitalization
- Use in small animals largely supplanted by FDA-approved agents or those with better adverse effect profile in target species
- If first dose is ineffective for pain control, subsequent doses unlikely to be of benefit
- Adverse Effects in Horses & Cattle: Rare anaphylaxis (especially after rapid IV administration); IM injections (extra-label in food animals) may cause pain/swelling

Uses/Indications

In the United States, flunixin meglumine is FDA-approved for use in horses, cattle and swine; however, it is approved for use in dogs in other countries. The FDA-approved indications for its use in the horse are for the alleviation of inflammation and pain associated with musculoskeletal disorders and alleviation of visceral pain associated with colic. In cattle it is FDA-approved for the control of pyrexia associated with bovine respiratory disease and endotoxemia, and control of inflammation in endotoxemia. In swine, flunixin is FDA-approved for use to control pyrexia associated with swine respiratory disease. In ruminants, there is some evidence that flunixin is a better analgesic for visceral pain rather than musculoskeletal pain.

Flunixin has been suggested for many other indications in various species, including: Horses: foal diarrheas, shock, colitis, respiratory disease, post-race treatment, and pre- and post ophthalmic and general surgery; Dogs: disk problems, arthritis, heat stroke, diarrhea, shock, ophthalmic inflammatory conditions, pre- and post ophthalmic and general surgery, and treatment of parvovirus infection; Cattle: acute respiratory disease, acute coliform mastitis with endotoxic shock, pain (downer cow), and calf diarrheas; Swine: agalactia/hypogalactia, lameness, and piglet diarrhea. It should be noted that the evidence supporting some of these indications is equivocal and flunixin may not be appropriate for every case.

The combination product containing florfenicol and flunixin (Resflor Gold®) is FDA-approved for SC use in beef and non-lactating dairy cattle (not veal calves) for treatment of BRD associated with Mannheimia haemolytica, Pasteurella multocida, Histophilus somni, Mycoplasma bovis and control BRD-associated pyrexia.

Pharmacology/Actions

Flunixin is a very potent inhibitor of cyclooxygenase and, like other NSAIDs, it exhibits analgesic, antiinflammatory, and antipyretic activity. Flunixin does not appreciably alter GI motility in horses and may improve hemodynamics in animals with septic shock.

Pharmacokinetics

In the horse, flunixin is rapidly absorbed following oral administration with an average bioavailability of 80% and peak serum levels in 30 minutes. Oral bioavailability is good when the injection is mixed with molasses and given orally. The onset of action is generally within 2 hours; peak response occurs between 12–16 hours and the duration of action lasts up to 30 hours. Flunixin is highly bound to plasma proteins (>99% cattle, 92% dogs, 87% horses). Volume of distributions ranges from approximately 0.15 L/kg in horses to 0.78 L/kg in cattle. Elimination is primarily via hepatic routes by biliary excretion. Serum half-lives have been determined in horses – 3.1–8.1 hours. Flunixin is detectable in equine urine for at least 48 hours after a dose.

Contraindications/Precautions/Warnings

The only contraindication the manufacturer lists for flunixin’s use in horses is for patients with a history of hypersensitivity reactions to it. It is suggested, however, that flunixin be used cautiously in animals with renal, hepatic, or hematologic diseases. When using to treat colic, flunixin may mask the behavioral and cardiopulmonary signs associated with endotoxemia or intestinal devitalization and must be used with caution.

Storage/Stability

Flunixin should be stored at room temperature; avoid freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Flunixin Injection: 0.5 mg/mL in 100 mL vials; Flucort® Solution (Pfizer); (Rx). FDA-approved for use in dogs, cats, and horses.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

References

Drug/Drug Interactions have not been appreciably studied for flunixin and the label does not mention any drug interactions. However, the following drug interactions should be considered:

**Overdosage/Acute Toxicity**

No clinical case reports of flunixin overdoses were discovered. It is suggested that acute overdosage be handled by using established protocols of emptying the gut (if oral ingestion and practical or possible) and treating the patient supportively.

**Reproductive/Nursing Safety**

Although reports of teratogenicity, effects on breeding performance, or gestation length have not been noted, flunixin should be used cautiously in pregnant animals. Flunixin is not recommended for use in breeding bulls (lack of reproductive safety data).

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

**Drug Interactions**

Drug/drug interactions have not been appreciably studied for flunixin and the label does not mention any drug interactions. However, the following drug interactions should be considered:

- **Aspirin**: When aspirin is used concurrently with NSAIDs, plasma levels of the NSAID could decrease and an increased likelihood of GI adverse effects (blood loss) could occur.
- **Cyclosporine**: NSAIDs may increase cyclosporine blood levels and increase the risk for nephrotoxicity.
- **Digoxin**: NSAIDs may increase serum levels of digoxin; use with caution in patients with severe cardiac failure.
- **Enrofloxacin**: Has been shown in dogs to increase the AUC and elimination half-life of flunixin and flunixin increases the AUC and elimination half-life of enrofloxacin; it is unknown if other NSAIDs interact with enrofloxacin in dogs. Enrofloxacin and flunixin did not interact in rabbits.
- **Furosemide & Other Diuretics**: NSAIDs may reduce the saluretic and diuretic effects of furosemide.
- **Methotrexate**: Serious toxicity has been observed when NSAIDs have been concomitantly used with methotrexate; use together with caution.
- **Nephrotoxic Agents** (e.g., amphotericin B, aminoglycosides, cisplatin, etc.): Potential for increased risk of nephrotoxicity if used with NSAIDs.
- **Probenecid**: May cause a significant increase in serum levels and half-life of some NSAIDs.
- **Warfarin**: Use with NSAIDs may increase the risk for bleeding.

**Doses**

- **Dogs**:
  
  **Note:** There are many canine doses published from a time when there were no FDA-approved NSAIDs for dogs; using FDA-approved drugs first is recommended.
  
  a) As an antidiarrheal/antipyretic: 1 mg/kg IV (do not administer more than once in an animal that has received corticosteroids (Tams 1999))
  
  b) For surgical pain: 1 mg/kg IV, SC or IM initially once; 1 mg/kg subsequent daily doses

    For pyrexia: 0.25 mg/kg IV, SC or IM once, may be repeated in 12–24 hours if needed

    For ophtho procedures: 0.25–1 mg/kg IV, IM or SC once; may be repeated in 12–24 hours if needed (Johnson 1996)

- **Ferrets**:
  
  a) 0.5–2 mg/kg PO or IM one time daily (Williams 2000)

- **Rabbits/Rodents/Small Mammals**:

  a) 0.01–0.02 mg/kg PO or IM once daily

  b) 0.5 mg/kg SC once daily

  c) 0.25 mg/kg SC or IM once daily (Herron 1995)
All flunixin products should be stored between 2–30°C (36–86°F). It has been recommended that flunixin meglumine injection not be mixed with other drugs because of potential for drug interactions.

**Flunixin**

- **Chemistry/Synonyms**: Flunixin meglumine, a nonsteroidal antiinflammatory agent is a highly substituted derivative of nicotinic acid, and is unique structurally when compared to other NSAIDs. It occurs as a white to off-white powder that is soluble in water and alcohol. The chemical name for flunixin is 3-pyridine-carboxylic acid.

**Client Information**

- Monitoring
  - Analgesic/antinflammatory/antipyretic effects
  - GI effects in dogs
  - CBC’s, occult blood in feces with chronic use in horses

- **Chemistry/Synonyms**
  - Flunixin meglumine, a nonsteroidal antiinflammatory agent is a highly substituted derivative of nicotinic acid, and is unique structurally when compared to other NSAIDs. It occurs as a white to off-white powder that is soluble in water and alcohol. The chemical name for flunixin is 3-pyridine-carboxylic acid.
  - Flunixin may also be known as 3-pyridine-carboxylic acid, flunixin meglumine, Sch-14714, Banamine®, Flume-glumine®, and Finadyne®, Flu-Nix®, Flunixamine®, Flunizicet®, Flunizine®, Preval®, Suppressor®, and Vedagesic®.

**Storage/Stability**

All flunixin products should be stored between 2–30°C (36–86°F). It has been recommended that flunixin meglumine injection not be mixed with other drugs because of potential for drug interactions.
Fluorouracil is converted via intracellular mechanisms to active metabolites (fluoruridine monophosphate—FUMP and fluoruridine triphosphate—FUTP). FUMP inhibits the synthesis of deoxythymidine triphosphate thereby interfering with DNA synthesis. FUTP incorporates into RNA and inhibits cell function.

Pharmacokinetics

inhibits the synthesis of deoxythymidine triphosphate thereby interfering with DNA synthesis. FUTP incorporates into RNA and inhibits cell function.
Fluorouracil is administered systemically via the IV route. It rapidly disappears from the systemic circulation (plasma half life is about 15 minutes in humans) and is primarily distributed into tumor cells, intestinal mucosa, liver, and bone marrow. While some of the drug is converted to active metabolites, (see Pharmacology above), the majority of it is metabolized by the liver. A small amount (about 15% of dose) is excreted unchanged into the urine.

**Contraindications/Precautions/Warnings**

Cats develop a severe, potentially fatal neurotoxicity when given fluorouracil. It is contraindicated in cats in any form (including topical).

- 5-FU is contraindicated in patients hypersensitive to it, in poor nutritional states, with depressed or reduced bone marrow function or concurrent serious infections.

**Adverse Effects**

In dogs, 5-FU causes a dose-dependent myelosuppression, GI toxicity (diarrhea, GI ulceration/sloughing, stomatitis), and neurotoxicity (seizures). Fluorouracil has a very narrow therapeutic index and should be used only by clinicians with experience using cancer chemotherapeutic agents.

**Reproductive/Nursing Safety**

The drug is a known teratogen and its use should be weighed against any risks to offspring. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

It is not known whether fluorouracil is excreted in milk. Because fluorouracil inhibits DNA, RNA and protein synthesis, milk replacer should be considered if the dam requires 5-FU.

**Overdosage/Acute Toxicity**

While overdoses are possible with IV use, careful checking of dosages and preparation should minimize the risks. Oral ingestions of topical products have occurred with dogs and cats and can be very serious. The lowest reported toxic dose at which dogs show adverse signs is 8.6 mg/kg. Signs at lower doses include mild GI irritation and vomiting. Seizures and death have been reported at doses as low as 10.3 mg/kg (APCC database) and survival in dogs may be as low as 25%. Very small ingestions can reportedly cause death in cats. Clinical signs may be seen within 30 minutes to 6 hours after ingestion; death has been reported in 7 hours. Clinical signs include acute nausea, vomiting, hemorrhagic diarrhea, abdominal pain, GI sloughing, ataxia, severe and non-responsive seizures, and severe dose-dependent myelosuppression affecting all cell lines. Severe metabolic acidosis and signs of multi-organ failure can be seen. (Lee 2010)

There were 90 exposures to fluorouracil reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 89 were dogs with 72 showing clinical signs and the remaining 1 case was a cat showing no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, seizures, ataxia, disorientation, euthanasia, lethargy, and death.

Should an oral ingestion occur, aggressive GI decontamination with GI protection should be done, especially if the ingestion was very recent. However, decontamination may not be effective due to the rapid onset of toxicity. Treatment is primarily supportive and can include antiemetics, anticonvulsants, fluid support, etc. Intensive monitoring is required. Seizure control with diazepam is often unrewarding and a barbiturate or general anesthesia is often required. Control of pain and body temperature are important. Use broad-spectrum antibiotics to prevent secondary bacterial infections. If bone marrow suppression develops, filgrastim (Neupogen®) can be considered to stimulate bone marrow stem cell proliferation in dogs. Complete blood counts should be routinely performed (every 3–4 days) for at least 18 days, as it may take up to 3 weeks before all cell lines return to normal (Lee 2010).

Patients given an accidental parenteral overdose should undergo intensive hematologic monitoring for at least 4 weeks and be supported as required.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluorouracil and may be of significance in veterinary patients:

- **LEUCOVORIN:** May increase the GI toxic effects of 5-FU

**Laboratory Considerations**

- Fluorouracil may cause increases in alkaline phosphatase, serum transaminase, serum bilirubin, and lactic dehydrogenase

**Doses**

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

- **DOGS:**

  a) For canine mammary carcinoma (in combination with doxorubicin and cyclophosphamide—FAC protocol), dermal squamous cell carcinoma and GI tract tumors: 150 mg/m2 IV weekly, or 5–10 mg/kg IV weekly (Kitchell & Dhaliwal 2000)

- **CATS:**

  5-FU is CONTRAINDICATED in cats in any form (including topical)

- **HORSES:**

  a) For intratumoral injection with epinephrine into certain skin neoplasms (squamous cell carcinoma, melanoma, sarcoma): 0.3 mL of 1:1000 epinephrine is added to each mL of 5-FU solution up to a maximum of 3 mL of epinephrine per total volume of 5-FU injected. Epinephrine may result in white hair growth and can cause transient excitation, tachycardia, and shaking if absorbed systemically in sufficient quantities. (Moll 2002)

**Monitoring**

- CBC’s (nadirs usually occur between days 9–14 with recovery by day 30; no dog info located)

- GI and CNS adverse effects

- Efficacy

**Client Information**

Clients should understand the serious potential effects of the drug (including death) and be committed for follow-up monitoring.
Chemistry/Synonyms
A pyrimidine antagonist antineoplastic agent, fluorouracil (5-FU) occurs as a white, practically odorless, crystalline powder. It is sparingly soluble in water and slightly soluble in alcohol. The commercially available injection has its pH adjusted to 8.6–9.4 and may be colorless or slightly yellow in color.
Fluorouracil may also be known as 5-fluorouracil, fluorouracilo, fluorouracileum, 5-FU, NSC-19893, Ro-2-9757, and WR-69596; many trade names are available.

Storage/Stability
The injection should be stored between 15–30°C; avoid freezing and exposure to light. Slight color changes in the solution can be ignored. If a precipitate forms, the solution can be heated to 60°C and shaken vigorously to redissolve the drug. Cool to body temperature before administering. If unsuccessful in redissolving the drug, it should not be used.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Fluorouracil Injection: 50 mg/mL in 10 mL, 20 mL, 50 mL, & 100 mL vials and 10 mL amps; Adrucil® (Gensia Sicor); generic; (Rx)

Also available in topical creams and solutions in concentrations ranging from 0.5% to 5%. These are indicated in humans for treating multiple actinic or solar keratoses, and superficial basal cell carcinomas (5%) when other treatments are impractical.

References

FLUOXETINE HCL
(floo-ox-e-teen) Prozac®, Reconcile®

SELECTIVE SEROTONIN-REUPTAKE INHIBITOR (SSRI)

Prescriber Highlights

- A selective-serotonin reuptake inhibitor antidepressant used in dogs & cats for a variety of behavior disorders
- Contraindications: Patients with known hypersensitivity or receiving monoamine oxidase inhibitors
- Caution: Patients with diabetes mellitus or seizure disorders; dosages may need to be reduced in patients with severe hepatic impairment
- Adverse Effects: Dogs: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting, & aggressive behavior in previously unaggressive dogs is possible; Cats: May exhibit behavior changes (anxiety, irritability, sleep disturbances), anorexia, & changes in elimination patterns
- Drug Interactions

Uses/Indications
Fluoxetine may be beneficial for the treatment of canine aggression, stereotypic behaviors (and other obsessive-compulsive behaviors), and anxiety. It may be useful in cats for the aforementioned behaviors and, additionally, for inappropriate elimination.

The veterinary FDA-approved product (Reconcile®) has a labeled indication for the treatment of canine separation anxiety in conjunction with a behavior modification plan.

Pharmacology/Actions
Fluoxetine is a highly selective inhibitor of the reuptake of serotonin in the CNS thereby potentiating the pharmacologic activity of serotonin. Fluoxetine apparently has little effect on other neurotransmitters (e.g., dopamine or norepinephrine). In dogs and cats, fluoxetine has anxiolytic and anticomulsive effects, and may also reduce aggressive behaviors.

Pharmacokinetics
Fluoxetine is apparently well absorbed after oral administration. In a study done in beagles, approximately 70% of an oral dose reached the systemic circulation. The presence of food altered the rate, but not the extent, of absorption. The oral capsules and oral liquid apparently are bioequivalent. When applied transdermally (15% in a PLO gel) to cats, bioavailability was approximately 10% of the oral route (Ciribassi et al. 2003).

Fluoxetine enters maternal milk in concentrations about 20–30% of those found in plasma.
The labeling for the veterinary (canine) FDA-approved drug states that fluoxetine should not be used in dogs with epilepsy or a history of seizures, and should not be given with drugs that lower the seizure threshold (e.g., acetazolamide, chlorpromazine). Fluoxetine is contraindicated in patients with known hypersensitivity to it, as well as those receiving monoamine oxidase inhibitors (see Drug Interactions below).

Fluoxetine should be used with caution in patients with diabetes mellitus as it may alter blood glucose. Dosages may need to be reduced in patients with severe hepatic impairment.

Because of the long half-life of norfluoxetine, tapering off the drug is probably only necessary when a patient has been on the drug long-term (>8 weeks) (Landsberg 2008).

**Adverse Effects**

In multi-site field trials in dogs, seizures were reported in some of the dogs treated with fluoxetine. Absolute causality and incidence rate has not been determined. Fluoxetine may cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side-effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously unaggressive dogs has been reported. Cats may exhibit behavior changes (anxiety, irritability, sleep disturbances), anorexia, and changes in elimination patterns.

In humans, potential adverse effects are extensive and diverse, but most those most commonly noted include anxiety, nervousness, insomnia, drowsiness, fatigue, dizziness, anorexia, nausea, rash, diarrhea, and sweating; seizures or hepatotoxicity are possible. About 15% of human patients discontinue treatment due to adverse effects.

**Reproductive/Nursing Safety**

Fluoxetine’s safety during pregnancy has not been established. The canine FDA-approved product states that studies to determine the effects of fluoxetine in breeding, pregnant, or lactating dogs or in patients less than 6 months of age have not been conducted. Preliminary studies done in rats demonstrated no overt teratogenic effects. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

The drug is excreted into milk (20–30% of plasma levels), so caution is advised in nursing patients. Clinical implications for nursing offspring are not clear.

**Overdose/Acute Toxicity**

The LD50 for rats is 452 mg/kg. Five of six dogs given an oral “toxic” dose developed seizures that immediately stopped after giving IV diazepam. The dog having the lowest plasma level of fluoxetine that developed seizures had a level twice that expected of a human taking 80 mg day (highest recommended dose).

There were 363 exposures to fluoxetine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 293 were dogs with 59 showing clinical signs, 68 were cats with 17 showing clinical signs. The remaining reported cases were 2 birds showing no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, mydriasis, lethargy, and hyperactivity. Common findings in cats recorded in decreasing frequency included hyperactivity, vomiting, mydriasis, and vocalization.

Treatment of fluoxetine overdoses consists of symptomatic and supportive therapy. Gut emptying techniques should be employed when warranted and otherwise not contraindicated. Diazepam should be considered to treat seizures. Cyproheptadine can be used as a serotonin antagonist.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluoxetine and may be of significance in veterinary patients:

- **BUPRIONE**: Increased risk for serotonin syndrome
- **CYPROHEPTADINE**: May decrease or reverse the effects of SSRIs
- **DIAZEPAM, ALPRAZOLAM**: Fluoxetine may increase diazepam levels
- **DIURETICS**: Increased risk for hyponatremia
- **INSULIN**: May alter insulin requirements
- **ISONIAZID**: Increased risk for serotonin syndrome
- **MAO INHIBITORS** (including amitraz and potentially, selegiline): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing fluoxetine and a 2 week washout period if first discontinuing the MAO inhibitor
- **PENTAZOCINE**: Serotonin syndrome-like adverse effects possible
- **PHENYTOIN**: Increased plasma levels of phenytoin possible
- **PROPRANOLOL, METOPROLOL**: Fluoxetine may increase these beta-blocker’s plasma levels; atenolol may be safer to use if fluoxetine required
- **TRAMADOL**: SSRI’s can inhibit the metabolism of tramadol to the active metabolites decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures).
- **TRICYCLIC ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline)**: Fluoxetine may increase TCA blood levels and may increase the risk for serotonin syndrome
- **TRAZODONE**: Increased plasma levels of trazodone possible
- **WARFARIN**: Fluoxetine may increase the risk for bleeding

**Doses**

For the adjunctive treatment of behavior disorders (see Indications above):

- **DOGS:**
  
  a) For the treatment of canine separation anxiety in conjunction with a behavior modification plan: 1–2 mg/kg PO once daily (Label Information; Reconcile®—Lily)
  
  b) For separation anxiety and noise aversions: 1–2 mg/kg PO once daily with behavioral therapy. May use long-term. Continue medication until 2 months after a
b) For separation anxiety and noise aversions: 1–2 mg/kg PO once daily with behavioral therapy. May use long-term. Continue medication until 2 months after a satisfactory response and then discontinue gradually if possible; behavioral management program should continue. Animals that relapse may resume therapy. Some dogs may require life-long treatment at the lowest effective dose. During seasonal noise fears, may add a benzodiazepine. (Sherman & Mills 2008)

c) For adjunctive pharmacological intervention for conflict-related aggression: 1–2 mg/kg PO once a day. May take up to 4 weeks for efficacy. (Luescher & Reisner 2008)

d) For compulsive disorders: 1–2 mg/kg PO once daily (Irinmajiri et al. 2009)

e) 1–1.5 mg/kg PO once daily (Seibert 2003)

f) 1 mg/kg PO once daily (up to 3 mg/kg PO once daily) (Landsberg 2004)

CATS:

a) For adjunctive treatment of aggression: 0.5–1.5 mg/kg PO once daily. (Curtis 2008)

b) To help control urine marking or separation anxiety: 0.5–1 mg/kg (2.5–5 mg per cat) PO once daily. (Levine 2008), (Neilson 2006b); (Neilson 2006a)

c) To control pruritus when other therapies have failed: 1–5 mg/cat PO once daily; advise obtaining baseline lab work. Assess therapy after 1–4 weeks. Taper off dose over 6–8 weeks. (Messinger 2000)

d) For generalized anxiety disorder: 0.5–1.5 mg/kg PO once daily (Crowell-Davis 2009), (Landsberg 2004)

Client Information

Efficacy

Adverse effects; including appetite (weight)

Chemistry/Synonyms

A member of the phenylpropylamine-derivative antidepressant group, fluoxetine differs both structurally and pharmacologically from either the tricyclic or monoamine oxidase inhibitor antidepressants. Fluoxetine HCl occurs as a white to off-white crystalline solid. Approximately 50 mg are soluble in 1 mL of water.

Fluoxetine may also be known as: fluoxetini hydrochloridum, and LY-110140; many trade names are available.

Storage/Stability

Capsules and tablets should be stored in well-closed containers at room temperature. The oral liquid should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Fluoxetine Chewable Tablets: 8 mg, 16 mg, 32 mg, & 64 mg; Reconcile® (Lilly); (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Fluoxetine HCl Oral Tablets: 10 mg, 15 mg & 20 mg; generic; (Rx)

Fluoxetine HCl Oral Capsules: 10 mg, 20 mg, 40 mg & 90 mg (delayed-release only);

Fluoxetine HCl Oral Solution 20 mg/5 mL (may contain alcohol, sucrose) in 120 mL & 473 mL; (Warner Chilcott); generic; (Rx)

References

Uses/Indications
While there are topical forms of fluticasone, most veterinary interests are in the inhaled versions of the drug. The aerosol for pulmonary inhalation appears to be effective in treating feline asthma, recurrent airway obstruction (RAO, heaves) or inflammatory airway disease (IAD) in horses, and dogs with chronic tracheobronchial disease. While the majority of small animal use has been with fluticasone, there are several other aerosol corticosteroids for inhalation (beclomethasone dipropionate, flunisolide, and triamcinolone acetonide) that theoretically could be used for the same purpose. The nasal inhalation corticosteroid products may be useful for allergy-related chronic rhinosinusitis in cats and dogs.

Pharmacology/Actions
Like other glucocorticoids, fluticasone has potent antiinflammatory activity. Fluticasone has an affinity 18X that of dexamethasone for human glucocorticoid receptors. For a more thorough discussion of glucocorticoid effects, refer to the Glucocorticoids, General Information monograph.

Pharmacokinetics
In humans, when fluticasone aerosol is administered via the lung, about 30% is absorbed into the systemic circulation. In humans, a dose of 880 micrograms (4 puffs of the 220 microgram aerosol) showed peak plasma concentrations of 0.1 to 1 ng/mL. Volume of distribution averages 4.2 L/kg and it is 91% bound to human plasma proteins. Fluticasone is metabolized via cytochrome P450 3A4 isoenzymes to a metabolite with negligible pharmacologic activity. Terminal elimination half-life is about 8 hours. Most of the drug is excreted in the feces as parent drug and metabolites.

Contraindications/Precautions/Warnings
Fluticasone is contraindicated when patients are hypersensitive to it or during acute bronchospasm (status asthmaticus).

Adverse Effects
In humans, the most likely adverse effects are pharyngitis and upper respiratory infections. While inhaled steroids generally cause significantly fewer adverse effects than injectable or oral therapy, suppression of the HPA axis can potentially occur. However, one study in cats using different concentrations of inhaled fluticasone, did not show any significant HPAA suppression at any of the doses used (Cohn et al. 2010). When transferring patients from systemic steroid therapy to inhaled steroids, wean slowly off systemic therapy to avoid acute adrenal insufficiency. Prepare to cover patients with additional steroid therapy during periods of acute stress, severe asthma attacks occurring during the withdrawal stage, or after transfer to inhaled steroids. Fluticasone is not useful for acute bronchospasm; cases of fluticasone-induced bronchospasm have been reported in humans.

Reproductive/Nursing Safety
In humans, the FDA categorizes inhaled fluticasone as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). When given subcutaneously to laboratory animals, fluticasone caused a variety of teratogenic effects, including growth retardation, cleft palate, omphalocele and retarded cranial ossification. It should be used during pregnancy only when the benefits clearly outweigh the risks of therapy.

It is not known if the drug enters maternal milk; use with caution in nursing dams.

Overdosage/Acute Toxicity
Acute overdoses of this medication are unlikely, but there have been reported cases of dogs puncturing canisters of albuterol and developing adverse effects. A similar occurrence with fluticasone would unlikely require treatment. Chronic overdoses could result in significant HPA axis suppression and cushinoid effects.

Drug Interactions
While the manufacturer states that due to the low systemic plasma levels associated with inhalational therapy clinically significant drug interactions are unlikely, use caution when used in conjunction with other drugs (such as ketoconazole) that can inhibit CYP 3A4 isoenzymes; theoretically, fluticasone levels could be increased.

Laboratory Considerations
No specific laboratory interactions or considerations were noted.

Doses
CATS:
For treatment of feline “asthma”:

a) Initially, try the 44 micrograms/puff MDI: one puff q12h. In the study, all three dosages (44 micrograms, 110 micrograms and 220 micrograms) significantly reduced the proportion of eosinophils in airway lavage fluid. (Cohn et al. 2010)

b) For cats with signs of bronchial disease that occur more than once per week:

Give prednisolone at 1–2 mg/kg PO twice daily for 5-7 days. Most newly diagnosed cats will have greatly diminished signs; then the dose is slowly tapered over at least 2-3 months. Some cats are effectively managed by low dose, alternate day corticosteroids, but most will continue to wheeze/cough. For those, encourage inhaled corticosteroids such as fluticasone.
Use a delivery device (e.g., *AeroKat®*) in combination with a spacer and 110 micrograms fluticasone metered dose inhaler (MDI) and administer one puff twice daily. Cats with more serious disease may require the 220 micrograms MDI. Author has not found the 44 microgram inhaler to provide consistent clinical results.

Attach MDI and the facemask to the spacer. Place facemask gently over cats mouth and nose and actuates the MDI to fill the spacer with medication. The cat breathes in and out for 7–10 times with the mask in place. (Padrid 2006), (Padrid 2008)

**DOGS:**

For adjunctive treatment of chronic tracheobronchial disease:

a) In dogs with excessive side effects associated with oral steroids therapy: Use a delivery device (e.g., *AeroDawg®*) in combination with either fluticasone 220 microgram or 110 microgram (1 puff) twice daily. Ensure a tightly fitting face mask and counting 7–10 respirations after actuating the MDI into the spacer is important for optimizing therapy. (Johnson 2007)

b) Using the 220 micrograms/puff MDI: 2 puffs q12h. (Hawkins 2009)

**HORSES:**

Use a delivery device (e.g., *Aeromask® or Equine-haler®*) in combination with a metered dose inhaler:

a) For the prototypical young racehorse with IAD: Weeks 1 and 2: Fluticasone 2200 micrograms (10 puffs) twice daily or beclomethasone HFA 1000 mg (5 puffs) twice daily with albuterol 450 micrograms (5 puffs) prior to steroid inhaler and at approximately 30 minutes before exercise. Weeks 3 and 4: Fluticasone 2200 micrograms (10 puffs) once daily or beclomethasone HFA 1000 mg (5 puffs) twice daily. Recheck in 4 weeks to determine further treatment.

For the typical horse with moderate RAO (heaves): Begin stringent control of environment and a course of systemic prednisone therapy. (Note: Reference does not state when oral prednisone should be discontinued.) At week 3 add fluticasone 2200 micrograms (10 puffs) twice daily with salmeterol 210 micrograms (10 puffs) twice daily. Week 4: fluticasone 2200 micrograms (10 puffs) once daily with salmeterol 210 micrograms (10 puffs) once daily. If lung function shows a good response at end of 4 weeks: fluticasone 2200 micrograms (10 puffs) once every other day with salmeterol 210 micrograms (10 puffs) once daily. (Mazan 2002); (Mazan 2003)

b) Using the EquineHaler: 6 mg q12h. In the study this dose was as effective as dexamethasone (0.1 mg/kg IV) for prevention of exacerbations, but not as effective as dexamethasone for short-term treatment. It is highly likely that a lower dose of fluticasone can be used. (Robinson *et al.* 2009)

**Efficacy**

**Client Information**

- Before using, shake well and, if possible, bring canister to room temperature. Do not puncture or incinerate can. Must be used with a spacer device appropriate for the species being treated.
- Allow animal to breath with the mask on for 7–10 times before removing
- One puff twice a day will last approximately 2 months

**Chemistry/Synonyms**

A trifluorinated glucocorticoid, fluticasone propionate occurs as a white to off-white powder that is practically insoluble in water and slightly soluble in ethanol.

Fluticasone may also be known as: CCI-18781, fluticasoni propionas, *Advair Diskus®, Cutoffate®, Flixotide®, Flixonase®, Flovent®, and Flutivate®*.

**Storage/Stability**

Fluticasone propionate aerosol for inhalation (*Flovent®*) should be stored between 2–30°C (36–86°F); protect from freezing and direct sunlight. Store canister with the mouthpiece down.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Fluticasone Propionate aerosol for inhalation: 44 micrograms per actuation, 110 micrograms per actuation, 220 micrograms per actuation in 10.6 g & 12 g canisters

Fluticasone is also available commercially in combination as:

- Fluticasone Propionate/Salmeterol Powder for Inhalation: 100 mcg fluticasone propionate, 50 mcg salmeterol; 250 mcg fluticasone propionate, 50 mcg salmeterol; & 500 mcg fluticasone propionate, 50 mcg salmeterol) in color-coded blisters; *Advair Diskus®* (GlaxoSmithKline); (Rx)

Fluticasone is also available commercially in combination as:

- Fluticasone Propionate/Salmeterol Aerosol for Inhalation: 45 mcg fluticasone propionate/salmeterol 21 mcg per actuation; 115 mcg fluticasone propionate/salmeterol 21 mcg per actuation & 230 mcg fluticasone propionate/salmeterol 21 mcg per actuation equiv. to salmeterol xinafoate 30.45 mcg in 12 g pressurized canisters containing 120 metered inhalations.

**Nasal solutions, topical creams and ointments containing fluticasone are also available.**

FLUVOXAMINE MALEATE
(floo-vox-a-meen) Luvox®
SELECTIVE SEROTONIN-REUPTAKE INHIBITOR (SSRI)

Prescriber Highlights

- A selective-serotonin reuptake inhibitor (SSRI) antidepressant similar to fluoxetine; used in dogs & cats for a variety of behavior disorders
- Not commonly used
- Contraindications: Patients with known hypersensitivity or receiving MAOIs
- Must treat for 6–8 weeks before evaluating efficacy
- Caution: Patients with severe cardiac, renal or hepatic disease; dosages may need to be reduced in patients with severe renal or hepatic impairment
- Adverse effect profile not well established: Potentially, Dogs: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting; aggressive behavior in previously non-aggressive dogs possible. Cats: May exhibit sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), & changes in elimination patterns
- Drug-drug interactions

Uses/Indications
Fluvoxamine may be considered for use in treating a variety of behavior-related diagnoses in dogs and cats, including aggression and stereotypic behaviors (and other obsessive-compulsive behaviors).

Pharmacology/Actions
Fluvoxamine is a highly selective inhibitor of the reuptake of serotonin in the CNS thereby potentiating the pharmacologic activity of serotonin. Fluvoxamine apparently has little effect on dopamine or norepinephrine, and apparently no effect on other neurotransmitters.

Pharmacokinetics
There is limited data on the pharmacokinetics of fluvoxamine in domestic animals. In dogs, fluvoxamine appears to be completely absorbed; only about 10% of a dose is excreted unchanged in the urine. Half-life appears to be similar to humans (15 hours).

In humans, fluvoxamine is absorbed after oral administration, but bioavailability is only around 50%. Peak plasma concentrations occur between 3–8 hours post-dose. Food does not appear to affect the absorptive characteristics of the drug. Fluvoxamine is widely distributed in the body and about 80% bound to plasma proteins. The drug is extensively metabolized in the liver to non-active metabolites and eliminated in the urine. Plasma half-life is about 15 hours.

Contraindications/Precautions/Warnings
Fluvoxamine is contraindicated in patients hypersensitive to it or any SSRI or if the patient is receiving a monoamine oxidase inhibitor (MAOI) or cisapride. Consider using a lower dosage in patients with hepatic impairment or in geriatric patients.

Adverse Effects
The adverse effect profile of fluvoxamine in dogs or cats has not been well established. In dogs, SSRIs can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously non-aggressive dogs has been reported. SSRIs in cats can cause sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), and changes in elimination patterns.

In humans, common adverse reactions (>10%) include sexual side effects (abnormal ejaculation, anorgasmia), agitation/nervousness, insomnia, nausea, dry mouth, constipation/diarrhea, dyspepsia, dizziness, headache, and somnolence

Reproductive/Nursing Safety
In humans, the FDA categorizes fluvoxamine as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). In rats, fluvoxamine reportedly increased pup mortality at birth and was associated with decreased birth weights.

Fluvoxamine enters maternal milk, although it appears unlikely to be of significant clinical concern.

Overdosage/Acute Toxicity
Limited data exists for animals. Reportedly, any dosage over 10 mg/kg can cause tremors and lethargy. Other signs associated with overdoses may include vomiting, somnolence/coma, tremors, diarrhea, hypotension, heart rate/rhythm disturbances (bradycardia/tachycardia, ECG changes), seizures, etc.

Cyproheptadine may be useful in the adjunctive treatment of serotonin syndrome.

Fatalities have been reported in human overdoses; the highest reported dose where the patient survived was 10,000 mg. Treatment recommendations include standard protocols for drug adsorption/removal from the GI for potentially dangerous overdoses and symptomatic and supportive therapy. Serotonin effects may be negated somewhat by administration (oral or rectal) with cyproheptadine at a dose of 1.1 mg/kg. Seizures or other neurologic signs may be treated with diazepam. The drug has an elimination half-life of approximately 15 hours in dogs.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving fluvoxamine and may be of significance in veterinary patients:

- BUSPIRONE: Fluvoxamine may paradoxically decrease the clinical efficacy of buspirone
CUSIPRIDE: Fluvoxamine may increase plasma levels of cisapride leading to toxicity

CYPROHEPTADINE: Fluvoxamine may reverse the effects of dilitiazem; bradycardia has been reported in humans taking this drug combination

DIAZEPAM, ALPRAZOLAM, MIDAZOLAM: Fluvoxamine may increase diazepam levels

DILTIAZEM: Fluvoxamine may increase the effects of diltiazem; bradycardia has been reported in humans taking this drug combination

MAO INHIBITORS (including amitraz and potentially, selegiline): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing fluvoxamine and a 2 week washout period if first discontinuing the MAO inhibitor

METHODONE: Fluvoxamine may increase plasma levels of methadone, leading to toxicity

PHENYTOIN: Increased plasma levels of phenytoin possible

PROPRANOLOL, METOPROLOL: Fluvoxamine may increase these beta-blocker’s plasma levels; atenolol may be safer to use if fluoxetine required

THEOPHYLLINE: Fluvoxamine may increase plasma levels of theophylline

TRAMADOL: SSRIs can inhibit the metabolism of tramadol to the active metabolites decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures)

TRICYCLIC ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline): Fluvoxamine may increase TCA blood levels and may increase the risk for serotonin syndrome

WARFARIN: Fluvoxamine may increase the risk for bleeding

Laboratory Considerations
No fluvoxamine-related laboratory interactions noted.

Doses

DOGS:

a) For treatment of compulsive disorders: 0.5–2 mg/kg PO twice daily (Landsberg 2004)
b) 1–3 mg/kg PO once daily (q24h); (allow 8 weeks for initial trial). (Virga 2007)
c) For treatment of behavioral diagnoses: 1 mg/kg PO q12–24h (once to twice a day); must treat for 3–5 weeks minimum to assess effects; then treat until “well” and either have no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Continue to treat for another 1–2 months (minimum) so that reliability of assessment is reasonably assured. If weaning off the drug, do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)

CATS:

a) For treatment of compulsive disorders: 0.25–0.5 mg/kg PO once daily (Landsberg 2004)
b) For treatment of behavioral diagnoses: 0.25–0.5 mg/kg PO q24h (once a day); must treat for 3–5 weeks minimum to assess effects; then treat until “well” and either have no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Continue to treat for another 1–2 months (minimum) so that reliability of assessment is reasonably assured. If weaning off the drug, do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)
c) For spraying: 0.25 mg/kg PO q12h; avoid use with benzodiazepines (Seksel 2006)
d) 0.5–1 mg/kg PO once daily (q24h); (allow 8 weeks for initial trial) (Virga 2007)

Monitoring

■ Efficacy
■ Adverse Effects; including appetite (weight)
■ Consider doing baseline liver function tests and ECG and re-test as needed

Client Information

■ This medication is most effective when used with a behavior modification program
■ Keep this medication away from children and other pets
■ Because there has not been widespread use of fluvoxamine in dogs or cats, its adverse effect and efficacy profiles have not been yet fully determined; clients should be briefed to report any significant abnormal findings to the veterinarian.
■ Clients must understand that this drug is unlikely to have effect immediately or even in the short term, and must commit to using the drug for months so that an adequate trial can occur.

Chemistry/Synonyms

A selective serotonin-reuptake inhibitor (SSRI), fluvoxamine maleate occurs as a white to almost white crystalline powder. It is freely soluble in alcohol and sparingly soluble in water.

Fluvoxamine may also be known as DU-23000, desifluvoxamin, Dumirox®, Dumyrox®, Faverin®, Favoxil®, Felixsan®, Fevarin®, Flox-ex®, Floxyfral®, Fluvoxhal®, Fluvosol®, Fluvoxadura®, Fluvoxin®, Luxox®, and Maveral®.

Storage/Stability

The commercially available tablets should be stored in tight containers at room temperatures of 15–30° C (59–86° F) and protected from high humidity.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Fluvoxamine Oral Tablets: 25 mg, 50 mg, & 100 mg; *Luvox®* (Jazz); generic; (Rx)

Fluvoxamine Oral Extended-release Capsules: 100 mg & 150 mg; *Luvox CR®* (Jazz); (Rx)

**References**

---

**FOLIC ACID**

*(foh-lik ass-id)* Folate, Folacin

**WATER-SOLUBLE “B” VITAMIN**

**Prescriber Highlights**

- “B” Vitamin necessary for nucleoprotein synthesis & normal erythropoiesis
- Injectable or oral dosage forms
- Folic acid deficiency may be seen in animals (especially cats) with proximal or diffuse small intestinal inflammatory disease
- May be used when dihydrofolate reductase inhibitor drugs (e.g., trimethoprim, ormetoprim, pyrimethamine) are used for a prolonged period
- Very safe

**Uses/Indications**

Folic acid is used to treat folic acid deficiency in dogs, cats, and horses (theoretically in other animal species as well) often due to small intestinal disease. Cats with exocrine pancreatic insufficiency appear to be most at risk for folate and cobalamin deficiencies secondary to malabsorption of folic acid in the diet. Dogs with exocrine pancreatic insufficiency often are noted to have increased folate levels secondary to overgrowths of folate-synthesizing bacteria in the proximal small intestine. Chronic administration of dihydrofolate reductase inhibiting drugs such as pyrimethamine, ormetoprim or trimethoprim can potentially lead to reduced activated folic acid (tetrahydrofolinic acid); folic acid supplementation is sometimes prescribed in an attempt to alleviate this situation.

**Pharmacology/Actions**

Folic acid is required for several metabolic processes. It is reduced via dihydrofolate reductase in the body to tetrahydrofolate (5-methyltetrahydrofolate) which acts as a coenzyme in the synthesis of purine and pyrimidine nucleotides that are necessary for DNA synthesis. Folic acid is also required for maintenance of normal erythropoiesis.

**Pharmacokinetics**

Therapeutically administered folic acid is primarily absorbed in the proximal small intestine via carrier-mediated diffusion. In humans, synthetic folic acid is nearly completely absorbed after oral administration while folate in foodstuffs is about 50% bioavailable. Folic acid is converted to its active form, tetrahydrofolic acid, principally in the liver and plasma. Folate is distributed widely throughout the body and is stored in the liver. Erythrocyte and CSF levels can be significantly higher than those found in serum. It can undergo enterohepatic recirculation and is excreted primarily in the urine either as metabolites or unchanged drug (when administered in excess of body requirements).

**Contraindications/Precautions/Warnings**

Folic acid treatment is contraindicated only when known intolerance to the drug is documented. In humans, cobalamin (B-12) levels may be reduced with megaloblastic anemias; folic acid therapy may mask the signs associated with it. Folic acid doses in people above 0.4 mg/day (except during pregnancy and lactation) are not to be used until pernicious anemia has been ruled out.

As dogs may have increased, normal, or decreased folate levels associated with enteropathies, do not administer therapeutic doses until folate and cobalamin levels have been determined.

**Adverse Effects**

Folic acid is quite non-toxic and should not cause significant adverse effects. Rarely in humans, folic acid tablets or injection have reportedly caused hypersensitivity reactions or gastrointestinal effects. Very high oral doses in humans (15 mg/day) have occasionally caused CNS effects (e.g., difficulty sleeping, excitement, confusion, etc.).

**Reproductive/Nursing Safety**

Folic acid is safe to use during pregnancy and in humans it is routinely prescribed as part of prenatal vitamin supplementation as folate deficiency can increase the risk for fetal neural tube defects. In humans, the FDA categorizes this drug as category A for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Folic acid is distributed into milk, but is safe. Folic acid requirements may be increased in lactating animals.

**Overdosage/Acute Toxicity**

Folic acid is relatively non-toxic and no treatment should be required if an inadvertent overdose occurs. Excess drug is metabolized or rapidly excreted unchanged in the urine.
Drug Interactions
The following drug interactions or have been reported in humans and may be of significant in veterinary patients receiving folic acid or may alter patient folic acid requirements:

- **CHLORAMPHENICOL**: May delay response to folic acid
- **METHOTREXATE, TRIMETHOPRIM, PYRIMETHAMINE** (drugs that inhibit dihydrofolate reductase): May interfere with folic acid utilization
- **PHENYTOIN**: May decrease serum folate levels, and phenytoin dosage may need to be increased; increased frequency in seizures can occur
- **SULFASALAZINE, BARBITURATES, NITROFURANTOIN, PRIMIDONE**: May increase risk for folate deficiency

Laboratory Considerations
- Serum samples to be analyzed for cobalamin and/or folate should be protected from bright light and excessive heat
- Hemolysis can cause falsely elevated serum concentrations of folate
- Potentially, decreased cobalamin serum levels (B-12) can occur in patients receiving prolonged folic acid supplementation

Doses

**DOGS/CATS:**

1. For severe folate deficiency: 0.5–2 mg (total dose) once daily for 1 month. (Williams 2000)
2. For cats with folate deficiency secondary to exocrine pancreatic insufficiency: 400 micrograms (0.4 mg) PO once daily. (Steiner & Williams 2005)
3. For cats on long-term use of high dose trimethoprim/sulfa (for treating *Nocardia*): 2 mg (total dose) PO once daily. (Wolf 2006)
4. For dogs with folate and cobalamin deficiency secondary to inflammatory bowel disease: folic acid at 5 mg (total dose) PO once daily for 1–6 months and cyanocobalamin 750 micrograms (total dose) parenterally once per month. (Hoskins 2005)
5. For adjunctive therapy in cats with inflammatory bowel disease: 0.5–1 mg PO q24h (once daily) with cobalamin at 125–250 micrograms (total dose) SC or IM once a week for 4–6 weeks. (Boothe 2009)

**HORSES:**

1. Prolonged therapy with antifolate medications (e.g., trimethoprim, pyrimethamine): Sometimes recommend folic acid at 20–40 mg (total dose) PO per day. Pregnant mares should routinely receive folic acid supplementation during treatment with antifolates. (Granstrom & Saville 1998)

Monitoring

- Small Animals: folate & cobalamin levels (serum); before and after treatment
- Clinical signs associated with deficiency
- CBC, baseline and ongoing if abnormal

Client Information

- When used to treat folate deficiency associated with small intestinal disease or pancreatic insufficiency, lifelong monitoring and periodic replacement therapy may be required

Chemistry/Synonyms

Folic acid occurs as a yellow, yellow-brownish, or yellowish-orange, odorless crystalline powder. It is very slightly soluble in water and insoluble in alcohol. Commercially available folic acid is obtained synthetically.

Folic acid may also be known as: folate, folacin, vitamin B9, acidum folicum, pteroylglutamic acid, pteroylmonoglutamic acid, Folvite® and vitamin B11.

Storage/Stability

Folic acid tablets should be stored in well-closed containers below 40°C (104°F), preferably between 15–30°C; protect from light and moisture. The injection should be stored protected from light below 40°C (104°F), preferably between 15–30°C. Do not allow to freeze.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

None as sole ingredient products. There are many products available that contain folic acid as one of the ingredients. If using one of these products, be certain it has enough folic acid to treat folate deficiency without overdosing fat soluble vitamins A or D.

**HUMAN-LABELED PRODUCTS:**

- Folic Acid Tablets: 0.4 mg, & 0.8 mg; generic (OTC); 1 mg, 7.5 mg, & 15 mg; Deplin® (Pamlab); generic; (Rx)
- Folic Acid Injection: 5 mg/mL in 10 mL vials; Folvite® (Lederle), generic (American Pharmaceutical Partners); (Rx)

References

Prescriber Highlights

- Synthetic alcohol dehydrogenase inhibitor used to treat dogs and cats for ethylene glycol poisoning
- May be efficacious in cats at high dosages, if given within 3 hours of ingestion
- Adverse Effects: Rapid IV infusion may cause vein irritation & phlebosclerosis; anaphylaxis is potentially possible
- Dilute as directed in the commercially available kit
- Monitor & treat acid/base, fluid, electrolyte imbalances
- May inhibit elimination of ethanol (& vice versa)
- Expense & rapid availability may be issues

Uses/Indications
Fomepizole is used for the treatment of known or suspected ethylene glycol toxicity in dogs (and humans). Fomepizole, at high doses, may be efficacious in treating recent (within 3 hours) ingestion of ethylene glycol in cats. Ethanol treatment has been recommended as the drug of choice for ethylene glycol toxicity in cats, but a recent study demonstrated that high dose fomepizole was more effective. (Connally, H.E. et al. 2010)

Pharmacology/Actions
Ethylene glycol itself is only mildly toxic in dogs, but when it is metabolized to glycoaldehyde, glycolate, glyoxalic acid, and oxalic acid, the resultant metabolic acidosis and renal tubular necrosis can be fatal. Fomepizole is a competitive inhibitor of alcohol dehydrogenase, the primary enzyme that converts ethylene glycol into glycoaldehyde and other toxic metabolites. This allows ethylene glycol to be excreted primarily unchanged in the urine decreasing the morbidity and mortality associated with ethylene glycol ingestion.

Pharmacokinetics
Fomepizole is excreted primarily by the kidneys and apparently exhibits a dose-dependent accumulation of the drug over time; therefore, a reduction in subsequent doses can safely occur.

Contraindications/Precautions/Warnings
There are no labeled contraindications to fomepizole’s use. In dogs, fomepizole treatment may be successful as late as 8 hours post-ingestion, but if azotemia is noted, treatment is less successful and the prognosis is poor. If so, treatment should still be considered up to 36 hours post-ingestion, as fomepizole can potentially prevent further renal damage and some dogs may survive with dialysis and supportive therapy.

Fomepizole has been shown to be effective in treating ethylene glycol in cats, but a high dosage is required and treatment should be started within 3 hours of ingestion.

Adverse Effects
Giving concentrated drug rapidly intravenously may cause vein irritation and phlebosclerosis. Dilute as directed in the commercially available kit.

- One dog during clinical trials was reported to develop anaphylaxis.
- Cats may develop mild sedation when receiving fomepizole.
- Use of fomepizole alone without adequate monitoring and adjunctive supportive care (e.g., correction of acid/base, fluid, electrolyte imbalances) may lead to therapeutic failure. If animal presents within 1–2 hours post ingestion, consider inducing vomiting and/or gastric lavage with activated charcoal to prevent further absorption.

Reproductive/Nursing Safety
Fomepizole’s safe use during pregnancy, lactation or in breeding animals has not been established. However, because of the morbidity and mortality associated with ethylene glycol toxicity, the benefits of fomepizole should generally outweigh its risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

- It is not known whether this drug is excreted in milk.

Overdosage/Acute Toxicity
Overdosage may cause significant CNS depression. No specific treatment is recommended.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving fomepizole and may be of significance in veterinary patients:

- ETHANOL: Fomepizole inhibits alcohol dehydrogenase; ethanol metabolism is reduced significantly and alcohol poisoning (CNS depression, coma, death) can occur. Use together is generally not recommended, but if both drugs are used, monitoring of ethanol blood levels is mandatory.

Laboratory Considerations
Ethylene Glycol Testing Kits: Fomepizole may cause false readings on ethylene glycol screening tests. Refer to the product used, for more information.
**DOGS:**

a) For treatment of ethylene glycol toxicity: Initially load at 20 mg/kg IV; at 12 hours post initial dose give 15 mg/kg IV; at 24 hours post initial dose give another 15 mg/kg IV and at 36 hours after initial dose give 5 mg/kg; may give additional 5 mg/kg doses as necessary (animal has not recovered or has additional ethylene glycol in blood). (Package Insert; Antizol-Vet®)

**CATS:**

a) For treatment of ethylene glycol toxicity: Initially, 125 mg/kg slow IV; at 12, 24, 36 hours give 31.25 mg/kg IV. In addition, treat supportively with supplemental fluids. Cats must be treated within 3 hours of ingestion. Cats whose treatment began 4 hours post ethylene glycol had 100% mortality with either fomepizole or ETOH therapy. (Connally, H. & Thrall 2002), (Connally, H.E. et al. 2010)

**Monitoring**

- Ethylene glycol blood levels (mostly important to document diagnosis if necessary and to determine if therapy can be discontinued after 36 hours of treatment.)
- Blood gases and serum electrolytes
- Hydration status
- Renal function tests (e.g., Urine output and urinalysis; BUN or serum creatinine)
- Cats: body temperature

**Client Information**

- Clients should be informed that treatment of serious ethylene glycol toxicity is an “intensive care” admission and that appropriate monitoring and therapy can be quite expensive, particularly when fomepizole is used in large dogs.
- Because time is of the essence in this therapy, clients will need to make an informed decision rapidly. Dogs treated within 8 hours post ingestion have a significantly better prognosis than those treated after 10–12 hours post ingestion. Cats must be treated within 3 hours of ingestion with high dosages.

**Chemistry/Synonyms**

A synthetic alcohol dehydrogenase inhibitor, fomepizole is commonly called 4-methylpyrazole (4-MP). Its chemical name is 4-methyl-1H-pyrazole. It has a molecular weight of 81; it is soluble in water and very soluble in ethanol.

Fomepizole may also be known as: 4-methylpyrazole, 4-MP, fomepisol, fomepizolum, and Antizol®.

**Storage/Stability**

Commercially available solutions should be stored at room temperature. The concentrate for injection may solidify at temperatures less than 25°C. Should this occur, resolubolize by running warm water over the vial. Solidification or resolubolization does not affect drug potency or stability. Store reconstituted vial at room temperature and discard after 72 hours.

**Compatibility/Compounding Considerations**

Preparation: If drug has solidified, run warm water over vial; Add entire contents to 30 mL vial of 0.9% NaCl (in kit), mix well. Resultant solution is: 50 mg/mL. Reconstituted solutions may be further diluted in D5W or normal saline for IV infusion.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Fomepizole 1.5 g Kit for Injection; Antizol-Vet® (Paladin); (Rx). FDA-approved for use in dogs. **Note:** At recommended doses 1 kit will treat a 26 kg dog (up to 58 lb.); larger dogs will require additional kits

**HUMAN-LABELED PRODUCTS:**

Fomepizole Injection Concentrate: 1 g/mL preservative free (must be diluted) in 1.5 mL vials; Antizol® (Paladin); generic (X-Gen Pharm.); (Rx)

**References**

---

**FOSFOMYCIN TROMETHAMINE**

(fos-foe-my-sin) Monurol®

**PHOSPHONIC ACID ANTIMICROBIAL**

**Prescriber Highlights**

- Human phosphonic acid derivative urinary antibiotic; only oral dose form (granules) available in USA
- Potentially could be useful in dogs for UTI, especially multi-drug resistant E.coli; may be useful for systemic infections, but data supporting clinical use is lacking
- Appears to be nephrotoxic in cats; use with extreme caution in this species
- Currently, very expensive
Pharmacology/Actions
Fosfomycin is a phosphonic acid derivative, synthetic, antibacterial agent. It irreversibly inhibits phosphoenolpyruvate transferase, an enzyme that catalyzes the formation of uridine diphosphate-N-acetylmuramic acid, which is the first step of microbial cell wall peptidoglycan synthesis. Additionally, it reduces adherence of bacteria to uroepithelial cells. Fosfomycin is primarily a time-dependent antibacterial, but it also exhibits some characteristics of a concentration–dependent agent. It is bactericidal in urine (at therapeutic doses) against susceptible bacteria. It has activity (in vitro) against a variety of gram-positive and gram-negative bacteria, including multi-drug resistant isolates of E. coli and enterococcus. Cross resistance apparently does not occur with beta-lactams or aminoglycosides. Resistance to fosfomycin, when it occurs, is via hydrolysis secondary to FosX or FosA enzymes that are chromosomally mediated.

Pharmacokinetics
Fosfomycin tromethamine is rapidly converted to the free acid fosfomycin after absorption. Fosfomycin is distributed into the kidneys, bladder wall, and prostate, and crosses the placenta. Primary route of elimination is as unchanged drug in urine (38% of an oral dose in humans). Renal dysfunction can substantially increase half-life and reduce urine levels.

In dogs, fosfomycin (disodium salt) is rapidly absorbed after oral administration; peak levels occur about 2 hours in dogs after oral dosing. Bioavailability in dogs is about 29% which is similar to the values reported for humans (tromethamine salt). Volume of distribution (steady-state) is about 0.7 L/kg and protein binding is very low; clearance is approximately 15 mL/kg/hour, and terminal half-life is approximately 2 hours (Gutierrez et al. 2008).

In horses (using fosfomycin disodium), SC bioavailability is about 85%. Peak levels occur about 3.25 hours after SC dosing. Mean volume of distribution (steady-state) is 0.21 L/kg; clearance 16-24 mL/kg/hour; and terminal half-life about 1.3 hours (Zozaya et al. 2008).

Contraindications/Precautions/Warnings
Because of concerns that fosfomycin may be nephrotoxic in cats, it presently should be considered contraindicated in young cats and used with caution in adult cats. In a study where cats where given 20 mg/kg of fosfomycin (as the calcium or sodium salt) once daily for 3 days, all young cats (actual age not noted) given the drug orally had significant increases in serum creatinine. Tubular necrosis, disappearance of tubular cells and rearrangement of eosinophilic non-structural material were observed in the kidneys of all the young and adult cats (Fukata et al. 2008).

In humans, this drug is used as a one-time dose; multiple doses do not enhance efficacy and increase incidence of adverse events.

Adverse Effects
There is very little information available on this drug’s adverse effect profile in animals. In humans, the most common adverse effect is diarrhea. In cats, renal tubular damage is possible (see contraindications above).

Reproductive/Nursing Safety
In humans, fosfomycin is listed as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is unknown if fosfomycin is distributed into milk; use with caution in nursing dams.

Overdosage/Acute Toxicity
No information was located. Single overdoses would most likely cause GI effects. Overdoses in cats may cause nephrotoxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving fosfomycin and may be of significance in veterinary patients:

- **METOCLOPRAMIDE:** Can decrease serum concentrations and reduce urine levels. Although no interactions have been reported, other drugs that increase GI motility (e.g., bethanechol, cisapride, domperidone, ranitidine, laxatives) may have a similar effect.

Laboratory Considerations
- No specific concerns noted

Doses

- **DOGS:**
  
  For UTI:
  
  a) Until scientific evidence defines the most appropriate dose, interval and duration, the use of fosfomycin might be prudently reserved for treatment of MDR- E. coli for which no other alternative exists and the risk of not treating the infection presents harm to the patient. Use of fosfomycin should be based on susceptibility testing only. If the decision is made to use fosfomycin, re-culture and supportive care are indicated. A single dose of 40 mg/kg (disodium salt) PO was well tolerated in dogs in a pharmacokinetic study. Future studies should determine pharmacokinetic data for the commercially available preparation (tromethamine salt), time or concentration dependency, and evidence of safety. These should be followed by multi-center randomized clinical trials involving dogs with spontaneous UTI associated with E. coli. (Boothe & Hubka 2010), (Hubka & Boothe 2010)

- **HORSES:**
  
  a) Based on their pharmacokinetic study, the authors concluded that clinically effective plasma concentrations might be obtained for up to 10 hours administering 20 mg/kg SC. (Zozaya et al. 2008) *(Note: In this study, fosfomycin disodium was used. This salt is not currently commercially available in the USA)*

Monitoring

- **Adverse Effects:** GI

Uses/Indications
Fosfomycin, an antibacterial agent that may be useful for treating multi-drug resistant urinary tract infections in dogs. Very little information has been published for this agent in veterinary medicine and its use must be considered as investigational for treating UTI's when other antibiotics are not effective.
**Chemistry/Synonyms**

Fosfomycin tromethamine (also known as fosfomycin trometamol) is an antibacterial isolated from Streptomyces fradiae. It occurs as a white or almost white, hygroscopic powder that is very soluble in water, slightly soluble in alcohol or methyl alcohol, and practically insoluble in acetone. A 5% solution in water has a pH of 3.5 to 5.5.

Fosfomycin may also be known as MK-955, phosphomycin, phosphonomycin, fosfomicina, fosfomycine, fosfomycinum, or fosfomysini. Its chemical name is cis-1, 2-epoxyphosphonic acid.

**Storage/Stability**

Fosfomycin tromethamine granules should be stored at room temperature (25°C).

**Compatibility/Compounding Considerations**

The product’s label (for human use) states: Pour the entire contents of a single-dose sachet of fosfomycin into 90 to 120 mL of water (1/2 cup) and stir to dissolve. Do not use hot water. Fosfomycin should be taken immediately after dissolving in water.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Fosfomycin Tromethamine 3 grams per packet (for dilution and oral use); Monurol® (Forest); (Rx)

**References**

---

**FURAZOLIDONE**

(fyouz-uh-zoe-ld-uhn) Furoxone®

**ANTIBACTERIAL/ANTIPROTOZOAL**

**Prescriber Highlights**

- Antibacterial/antiprotozoal nitrofuran that has been used in dogs & cats; availability is an issue
- Contraindications: Known hypersensitivity; food animals
- Adverse Effects: GI effects (anorexia, vomiting, cramping & diarrhea) possible
- May innocuously discolor urine to a dark yellow to brown color
- Drug Interactions

**Uses/Indications**

Furazolidone is usually a drug of second choice in small animals to treat enteric infections caused by the organisms listed below. Because it is no longer commercially available (in the USA), it may be difficult to locate.

**Pharmacology/Actions**

Furazolidone interferes with susceptible bacterial enzyme systems. Its mechanism against susceptible protozoa is not well determined. Furazolidone has activity against Giardia, *Vibrio cholerae*, Trichomonas, Coccidia, and many strains of *E. coli*, Enterobacter, Campylobacter, Salmonella, and Shigella. Not all strains are sensitive, but resistance is usually limited and develops slowly. Furazolidone also inhibits monoamine oxidase.

**Pharmacokinetics**

Conflicting information on furazolidone’s absorption characteristics are published. As colored metabolites are found in the urine, it is clearly absorbed to some extent. Because furazolidone is used to treat enteric infections, absorption becomes important only when discussing adverse reactions and drug interaction issues. Furazolidone reportedly distributes into the CSF. Absorbed furazolidone is rapidly metabolized in the liver and the majority of absorbed drug is eliminated in the urine.

**Contraindications/Precautions/Warnings**

Furazolidone is contraindicated in patients hypersensitive to it.
The FDA has prohibited the extralabel use of furazolidone in food animals.

**Adverse Effects**

Adverse effects noted with furazolidone are usually minimal. Anorexia, vomiting, cramping, and diarrhea may occasionally occur. Some human patients are reported to be hypersensitive to the drug. Because furazolidone also inhibits monoamine oxidase, it may, potentially, interact with several other drugs and foods (see Drug Interactions below). The clinical significance of these interactions remains unclear, particularly in light of the drug’s poor absorptive characteristics.

**Reproductive/Nursing Safety**

While the safe use of furazolidone during pregnancy has not been established, neither were there any teratogenic issues located for it. However, one reference (Tams 2003) states that furazolidone should not be used in pregnant queens. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

- It is unknown if furazolidone enters maternal milk.

**Overdosage/Acute Toxicity**

No information was located; but moderate overdoses are unlikely to cause significant toxicity. Gut emptying may be considered for large overdoses.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving furazolidone and may be of significance in veterinary patients:

- **ALCOHOL:** With furazolidone may cause a disulfiram-like reaction.
- Because furazolidone inhibits monoamine oxidase, its use concurrently with the following drugs is not recommended because dangerous hypertension could occur:
  - AMITRAZ
  - BUSPIRONE
  - SELEGILINE
  - SYMPATHOMIMETIC AMINES (phenylpropanolamine, ephedrine, etc.)
  - TRICYCLIC ANTIDEPRESSANTS
  - FISH OR POULTRY (high tyramine content)

**Laboratory Considerations**

- Furazolidone may cause a false-positive urine glucose determination when using the cupric sulfate solution test (*e.g.*, Clinitest®).

**Doses**

**DOGS:**

a) For *amebic colitis*: 2.2 mg/kg PO q8h for 7 days;
   - For coccidiosis: 8–20 mg/kg PO for one week (Sherding & Johnson 1994)

b) For treatment of Giardia: 4 mg/kg PO twice daily (q12h) for 7 days
   - For *Cystoisospora* spp.: 8–20 mg/kg PO q12–24h for 5 days (Lappin 2000)

c) For coccidiosis: 8–20 mg/kg PO once daily for 7 days
   - For *Entamebiasis*: 2.2 mg/kg PO q8h for 7 days (Greene & Watson 1998)

**CATS:**

a) For treatment of Giardia: 4 mg/kg PO twice daily (q12h) for 7–10 days; if re-treatment is required, elevated dosages or lengthened treatment regimens may provide better results. (Reinemeyer 1992)

b) For treatment of Giardia: 4 mg/kg, PO twice daily (q12h) for 7 days
   - For *Cystoisospora* spp.: 8–20 mg/kg PO q12–24h for 5 days (Lappin 2000)

c) For coccidiosis: 8–20 mg/kg PO once daily for 7 days
   - For giardiasis: 4 mg/kg PO q12h for 5–10 days
   - For amebiasis: 2.2 mg/kg PO q8h for 7 days (Greene & Watson 1998)

d) For *amebic colitis*: 2.2 mg/kg PO q8h for 7 days; For coccidiosis: 8–20 mg/kg PO for one week; for Giardia: 4 mg/kg PO q12h for 5 days (Sherding & Johnson 1994)

**HORSES:**

a) 4 mg/kg PO three times daily (Robinson 1992)

**Monitoring**

- Efficacy (stool exams for parasitic infections)

**Client Information**

- Furazolidone may discolor urine to a dark yellow to brown color; this is not significant.
- Have clients report prolonged or serious GI effects.

**Chemistry/Synonyms**

A synthetic nitrofuran derivative antibacterial/antiprotozoal, furazolidone occurs as a bitter-tasting, yellow, crystalline powder. It is practically insoluble in water.
A synthetic nitrofuran-derivative antibacterial/antiprotozoal, furazolidone occurs as a bitter-tasting, yellow, crystalline powder. It is practically insoluble in water.

Furazolidone may also be known as: nifurazolidon, Enterolidon®, Exofur®, Furasian®, Furion®, Furoxona®, Fuxol®, Giarcid®, Giarlam®, NeoFurasil®, Nifuran®, Novafur®, Salmocide®, and Seforman®.

Storage/Stability
Store protected from light in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS:
No systemic products are available; a 4% topical powder/spray is available. The FDA prohibits its use on food producing animals.

HUMAN-LABELLED PRODUCTS:
None; the human product Furoxone® has apparently been withdrawn from the USA market. Preparations may be available from compounding pharmacies.

FUROSEMIDE
(fur-oh-se-mide) Lasix®
LOOP DIURETIC

Prescriber Highlights

• A loop diuretic commonly used in many species for treatment of congestive cardiomyopathy, pulmonary edema, udder edema, hypercalcic nephropathy, uremia, as adjunctive therapy in hyperkalemia & occasionally, as an antihypertensive agent
• Used in racehorses to prevent/reduce EIPH
• Contraindications: Patients with anuria, hypersensitivity, or seriously depleted electrolytes
• Caution: Patients with pre-existing electrolyte or water balance abnormalities, impaired hepatic function, & diabetes mellitus
• Adverse Effects: Fluid & electrolyte (esp. hypotension, hypovolemia) abnormalities, others included: ototoxicity, GI distress, hematologic effects, ototoxicity, weakness, & restlessness
• Pre-renal azotemia if dehydration occurs
• Encourage normal food & water intake

Uses/Indications
Furosemide is used for its diuretic activity in all species. It is used in small animals for the treatment of congestive cardiomyopathy, pulmonary edema, hypercalcic nephropathy, uremia, as adjunctive therapy in hyperkalemia and, occasionally, as an antihypertensive agent. In cattle, it is FDA-approved for use for the treatment of post-parturient udder edema. It has been used to help prevent or reduce epistaxis (exercise-induced pulmonary hemorrhage; EIPH) in racehorses.

Pharmacology/Actions
Furosemide reduces the absorption of electrolytes in the ascending section of the loop of Henle, decreases the reabsorption of both sodium and chloride and increases the excretion of potassium in the distal renal tubule, and directly effects electrolyte transport in the proximal tubule. The exact mechanisms of furosemide’s effects have not been fully established. It has no effect on carbonic anhydrase nor does it antagonize aldosterone.

Furosemide increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate. In dogs, excretion of potassium is affected much less so than is sodium; hypernatremia may be more of a concern than hypokalemia. It causes some renal vasoconstriction and transiently increases glomerular filtration rates (GFR). Renal blood flow is increased and decreased peripheral resistance may occur. While furosemide increases renin secretion, due to its effects on the nephron, increases in sodium and water retention do not occur. Furosemide can cause hyperglycemia, but to a lesser extent than the thiazides. At high doses (10–12 mg/kg), thoracic duct lymph flow is increased in dogs. In horses, guinea pigs and humans, furosemide has some bronchodilative effects. Cats are reportedly more sensitive than other species to the diuretic effects of furosemide.

Pharmacokinetics
The pharmacokinetics of furosemide have been studied in a limited fashion in domestic animals. In dogs, the oral bioavailability is approximately 77% and the elimination half-life approximately 1–1.5 hours.

In humans, furosemide is 60–75% absorbed following oral administration. The diuretic effect takes place within 5 minutes after IV administration and within one hour after oral dosing. Peak effects occur approximately 30 minutes after IV dosing, and 1–2 hours after oral dosing. The drug is approximately 95% bound to plasma proteins in both azotemic and normal patients. The serum half-life is about 2 hours, but prolonged in patients with renal failure, uremia, CHF, and in neonates.

Contraindications/Precautions/Warnings
Furosemide is contraindicated in patients with anuria or who are hypersensitive to the drug. The manufacturer states that the drug should be discontinued in patients with history of gout, hyperuricemia, and uric acid nephropathy. It should not be used in animals with pre-existing electrolyte abnormalities and in those with impaired hepatic function.
Doses

Laboratory Considerations

Adverse Effects

Furosemide may induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium, magnesium and sodium). Prenatal azotemia may result if moderate to severe dehydration occurs. Hyponatremia is probably the greatest concern, but hypocalcemia, hypokalemia, and hypomagnesemia may all occur. Animals that have normal food and water intake are much less likely to develop water and electrolyte imbalances than those who do not.

Other potential adverse effects include ototoxicity, especially in cats with high dose IV therapy. Dogs reportedly require dosages greater than 22 mg/kg IV to cause hearing loss. Other effects include gastrointestinal disturbances, hematologic effects (anemia, leukopenia), weakness, and restlessness.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Furosemide appears in milk; clinical significance to nursing offspring is unknown.

Overdosage/Acute Toxicity

The LD₅₀ in dogs after oral administration is >1000 mg/kg; after IV injection >300 mg/kg. Chronic overdosing at 10 mg/kg for six months in dogs led to development of calcification and scarring of the renal parenchyma.

Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures) and cardiovascular collapse.

Treatment consists of emptying the gut after recent oral ingestion, using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that can occur. Aggressively monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and cardiovascular status. Treat supportively and symptomatically if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving furosemide and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., enalapril, benazepril): Increased risks for hypotension, particularly in patients who are volume or sodium depleted secondary to diuretics
- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc.): Increased risk for ototoxicity
- **AMPHOTERICIN B**: Loop diuretics may increase the risk for nephrotoxicity development; hypokalemia
- **CORTICOSTEROIDS**: Increased risk for GI ulceration; hypokalemia
- **DIGOXIN**: Furosemide-induced hypokalemia may increase the potential for digoxin toxicity
- **INSULIN**: Furosemide may alter insulin requirements
- **MUSCLE RELAXANTS, NON-DEPOLARIZING** (e.g., atracurium, tubocurarine): Furosemide may prolong neuromuscular blockade
- **PROBENECID**: Furosemide can reduce uricosuric effects
- **SALICYLATES**: Loop diuretics can reduce the excretion of salicylates
- **SUCCINYLCHOLINE**: Furosemide may potentiate
- **THEOPHYLLINE**: Pharmacologic effects of theophylline may be enhanced when used with furosemide

Laboratory Considerations

- **Free T4**: Furosemide can result in an increased free T4 fraction; furosemide inhibits T4 binding to canine serum in vitro

Doses

- **DOGS & CATS:**
  
  As a general diuretic:

  a) 2.5–5 mg/kg (lower dose suggested for cats) once or twice daily at 6–8 hour intervals PO, IV or IM (Package Insert; Salix®—Intervet)

  For cardiogenic or pulmonary edema:

  a) For severe acute pulmonary edema (parenteral dosing)

  **Dogs**: Up to 8 mg/kg IV or IM every 1–2 hours until respiratory rate and/or respiratory character improves; alternately a CRI of 0.66 mg/kg/hr may be used and potentially can produce greater diuresis, natriuresis and less kaliuresis.

  **Cats**: Initially 2-4 mg/kg IV or IM; cats that can tolerate an IV injection may benefit from a faster onset of action (5 minutes IV vs 30 minutes IM). The dose may be repeated within 1-2 hours. To avoid severe dehydration, dosing must be reduced sharply once respiratory rate starts to decrease.

  For heart failure (oral dosing; often in combination with an ACE inhibitor and digoxin):

  **Dogs**: Dosage ranges from 1 mg/kg PO every other day for very mild heart failure to 4 mg/kg PO q8h for severe heart failure;

  **Cats**: Currently, author still recommends using an ACE inhibitor with furosemide in cats with HCM. Maintenance dose of furosemide usually ranges from 6.25 mg once a day to 12.5 mg PO q8h (higher doses, up to 37.5 mg PO q12h have been used in some cats not responding to conventional treatment without severe consequences as long as they were eating and drinking.) Doses must be titrated carefully in each patient and the owner should be instructed how to count sleeping respiration rates at home and to do a daily log of respiratory rate (normal sleeping respiration rates are 15-30 per minute, but some cats...
Animals must drink adequate amounts of water or severe dehydration may result. (Kittleson 2000), (Kittleson 2006), (Kittleson 2009)

b) For chronic therapy: Most cardiologists now recommend using ACE inhibitors and diuretics in animals with CHF, but it is difficult to define the exact dose of furosemide required by the patient as the dose required to clear significant edema and allow the animal to be minimally symptomatic is often close to a dose that may result in electrolyte disturbances. Some degree of experimentation must be performed to best evaluate an individual animal’s needs. In most instances, dogs are given less than 2 mg/kg PO q12h and cats, initially, try 6.25 mg/cat/day for chronic therapy. Some cats require higher doses and some can be maintained on 6.25 mg every other day. Goal is to give the “lowest possible dose of furosemide”. It can be helpful to give owners a dosage range with upper and lower limits of furosemide doses and have them “give more for difficulty breathing or rapid respirations, and give less if the animal appears weak, lethargic, anorexic or depressed.” Measure renal function prior to therapy and 5-10 days after starting drugs. (Rush 2008)

c) In combination with rest, vasodilators and rate-control: 1–4 mg/kg IV, IM or PO q1-12 hours. (Rozanski 2009)

For hypercalcemia/hypercalcuric nephropathy:

a) For adjunctive treatment of moderate to severe hypercalcemia: Volume expansion is necessary prior to use of furosemide; 2–4 mg/kg two to three times daily, IV, SC or PO. (Chew et al. 2003)

For acute oliguric renal failure:

a) Initially 2 mg/kg IV; if no substantial diuresis develops in one hour, the dose may be doubled to 4 mg/kg. If this dose fails to induce diuresis, may increase to 6 mg/kg. If diuresis still does not ensue, very large doses of furosemide, an alternative diuretic (e.g., mannitol), or the combination of furosemide and dopamine may be considered. If furosemide successfully induces diuresis, it may be repeated at 8 hour intervals as needed to sustain diuresis and promote potassium secretion. The need for continued furosemide therapy must be considered in light of its potential side effects. (Polzin 2005), (Polzin 2009)

b) In fluid replete patients, furosemide as a bolus at 1–6 mg/kg IV. If adequate diuresis is not evident in 30 minutes, re-administer initial or higher dose. If diuresis ensues, can repeat dose every 6-8 hours or a CRI at 0.1–1 mg/kg/hr. Fluid balances must be carefully monitored to prevent dehydration and further renal compromise. (Silverstein 2009)

FERRETS:

For adjunctive therapy for heart failure:

a) 2–3 mg/kg IM or IV initially for fulminant CHF; 1–2 mg/kg PO q12h for long-term maintenance therapy (Hoeffer 2000)

b) 1–4 mg/kg PO, SC, IM or IV 2–3 times a day (Williams 2000)

RABBITS/RODENTS/SMALL MAMMALS:

a) Rabbits: For CHF: 2–5 mg/kg PO, SC, IM or IV q12h; For pulmonary edema: 1–4 mg/kg IV or IM q4–6h (Ivey & Morrisey 2000)

b) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 5–10 mg/kg q12h (Adamcak & Otten 2000)

CATTLE:

a) 500 mg once daily or 250 mg twice daily; 2 grams PO once daily. Treatment not to exceed 48 hours post-partum (for udder edema). Package Insert; Lasix®–Hoechst)

b) 2.2–4.4 mg/kg IV q12h (Howard 1986)

HORSES: (Note: Refer to state guidelines for use of furosemide in racing animals)

As a diuretic:

a) For adjunctive therapy for congestive heart failure: Initially, 1–2 mg/kg IM or IV q6–12h to control edema. Long-term therapy: 0.5–2 mg/kg PO or IM q8–12h (Mogg 1999)

b) For adjunctive therapy of acute renal failure: 2–4 mg/kg q6h (Jose-Cunilleras & Hinchcliff 1999)

For epistaxis/EIPH prevention:

a) 500 mg (total dose) 4 hours prior to race. (Hinchcliff et al. 2009)

b) 250 mg IV 4 hours prior to racing (Foreman 1999)

BIRDS:

As a diuretic:

a) 0.05 mg/300 grams body weight IM twice daily (Note: Lories are very sensitive to this agent and can be easily overdosed) (Clubb 1986)

REPTILES:

For most species:

a) 5 mg/kg IV or IM as needed (Gauvin 1993)

Monitoring

- Serum electrolytes, BUN, creatinine, glucose
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated
- Evaluation of ototoxicity, particularly with prolonged therapy or in cats

Client Information

- Clients should contact veterinarian if clinical signs of water or electrolyte imbalance occur, such as excessive thirst, lethargy, lassitude, restlessness, reduced urination, GI distress or fast heart rate.

Chemistry/Synonyms
Gabapentin has analgesic effects and can prevent allodynia (sensation of pain resulting from a normally non-noxious stimulus) or hyperalgesia (exaggerated response to a nociceptive stimulus). Gabapentin is used in the treatment of chronic pain, particularly neuropathic pain in small animals. Gabapentin does not appear to be of significant use for treating acute pain, but it may be of benefit when given preemptively for acute pain (e.g., before surgery); studies are ongoing to evaluate this indication for small animals.

**Pharmacology/Actions**

Gabapentin has analgesic effects and can prevent allodynia (sensation of pain resulting from a normally non-noxious stimulus) or hyperalgesia (exaggerated response to a nociceptive stimulus).

**Uses/Indications**

Gabapentin may be useful as adjunctive therapy for refractory or complex partial seizures. As an analgesic, gabapentin has been demonstrated to be most useful in treating chronic pain, particularly neuropathic pain in small animals. Gabapentin does not appear to be of significant use for treating acute pain, but it may be of benefit when given preemptively for acute pain (e.g., before surgery); studies are ongoing to evaluate this indication for small animals.

**Compatibility/Compounding Considerations**

Gabapentin injection (10 mg/mL) is reportedly physically compatible with all commonly used intravenous solutions and the following drugs: amikacin sulfate, cimetidine HCI, kanamycin sulfate, tobramycin sulfate, and verapamil. It is reportedly physically incompatible with the following agents: ascorbic acid solutions, dobutamine HCl, epinephrine, gentamicin sulfate, netilmicin sulfate and tetracyclines. It should generally not be mixed with antihistamines, local anesthetics, alkaloids, hypnotics, or opiates.

**Storage/Stability**

Gabapentin tablets should be stored in light-resistant, well-closed containers. The oral solution should be stored at room temperature and protected from light and freezing. Gabapentin injection should be stored at room temperature. A precipitate may form if the injection is refrigerated, but will resolubilize when warmed without alteration in potency. The human injection (10 mg/mL) should not be used if it has a yellow color. The veterinary injection (50 mg/mL) normally has a slight yellow color. Gabapentin is unstable at an acid pH, but is very stable under alkaline conditions.
Gabapentin has analgesic effects and can prevent allodynia (sensation of pain resulting from a normally non-noxious stimulus) or hyperalgesia (exaggerated response to painful stimuli). It also has anticonvulsant activity. The mechanism of action of gabapentin, for either its anticonvulsant or analgesic actions is not fully understood, but it appears to bind to CaV2a2-d (alpha2-delta subunit of the voltage-gated calcium channels). By decreasing calcium influx, release of excitatory neurotransmitters (e.g., substance P, glutamate, norepinephrine) are inhibited. While gabapentin is structurally related to GABA, it does not appear to alter GABA binding, reuptake, or degradation, or serve as a GABA agonist in vivo.

Pharmacokinetics

In dogs, oral bioavailability is about 80% at a dose of 50 mg/kg. Peak plasma levels occur about 2 hours post dose. Elimination is primarily via renal routes, but gabapentin is partially metabolized to N-methyl-gabapentin. Elimination half-life is approximately 2–4 hours in dogs.

In cats, gabapentin is well absorbed after oral dosing with a bioavailability average of 90%, but there was significant interpatient variation (50%-120%). Peak levels occurred about 100 minutes after dosing. Volume of distribution is relatively low (apparent Vdss of 0.65 L/kg.) Clearance was about 3 mL/min/kg and mean elimination half-life of 2.8 hours is similar to that of dogs. (Siao et al. 2010)

In four horses given single oral doses of 5 mg/kg, gabapentin was rapidly absorbed with peak levels noted within 2 hours (mean 1.4 hours). Plasma elimination half-life was about 3.4 hours. (Dirikolu et al. 2008)

In humans, gabapentin bioavailability decreases as dosage increases. At doses of 900 mg/day, 60% of the dose is absorbed. Percentage absorbed is reduced as doses are increased to a minimum of 27% of the dose being absorbed when 4800 mg/day is administered. Presence of food only marginally alters absorption rate and extent of absorption. Gabapentin is only minimally bound to plasma proteins; CSF levels are approximately 20% of those in plasma. The drug is not significantly metabolized and is almost exclusively excreted unchanged into the urine. Elimination half-lives in humans are approximately 5–7 hours.

Contraindications/Precautions/Warnings

Gabapentin is considered contraindicated in patients hypersensitive to it. Because gabapentin is eliminated via renal routes (practically 100% in humans), it should be used with caution in patients with renal insufficiency; if required, dosage adjustment should be considered. In dogs, the drug is also metabolized (30–40%) of a dose, so dosage adjustment may not be required in dogs with mild to moderate renal dysfunction.

In general, avoid the use of the commercially available human oral solution (Neurontin®) in dogs as it reportedly contains 300 mg/mL xylitol. As the threshold dose that can cause hypoglycemia in dogs is approximately 100 mg/kg, doses of up to 15 mg/kg in dogs using the solution should be safe, but further data is needed to confirm this. Additionally, xylitol may be hepatotoxic in dogs. Doses of 500 mg/kg of xylitol are currently thought to be the threshold for this toxicity, but there have been anecdotal reports of it occurring at much lower doses. In cats, at the dosages used presently, xylitol toxicity does not appear to be a problem with gabapentin oral solution, but use with caution.

Adverse Effects

Sedation or ataxia are probably the most likely adverse effects seen in small animals. Starting the dose at the lower end of the range and increasing with time, may alleviate this effect. In humans, the most common adverse effects associated with gabapentin therapy are dizziness, somnolence, and peripheral edema. Gabapentin was associated with an increased rate of pancreatic adenocarcinoma in male rats. It is unknown if this effect crosses into other species.

Abrupt discontinuation of the drug has lead to withdrawal-precipitated seizures. In humans, it is recommended to wean off the drug when it is used for epilepsy treatment.

Reproductive/Nursing Safety

In humans, the FDA categorizes gabapentin as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). At high dosages (at or above human maximum dosages), gabapentin was associated with a variety of fetotoxic and teratogenic effects (e.g., delayed ossification, hydronephrosis, fetal loss) in rats, mice and rabbits.

Gabapentin enters maternal milk. It has been calculated that a nursing human infant could be exposed to a maximum dosage of 1 mg/kg/day. This is 5–10% of the usual pediatric (>3 yrs old) therapeutic dose. In veterinary patients, this appears unlikely to be of significant clinical concern.

Overdosage/Acute Toxicity

In humans, doses of up to 49 grams have been reported without fatality. Most likely effects include ataxia, lethargy/somnolence, diarrhea, etc.

The commercially available oral solution contains 300 mg/mL of xylitol; doses of 0.33 mL/kg may cause hypoglycemia or liver toxicity in dogs.

There were 232 exposures to gabapentin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 188 were dogs with 31 showing clinical signs and 43 cases were cats with 13 showing clinical signs. The remaining 1 case involved a bird that did not show any clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, ataxia, vomiting and somnolence. Common findings in cats recorded in decreasing frequency included ataxia, lethargy, and sedation.

Treatment is basically supportive with general decontamination procedures including emesis, activated charcoal, and cathartics. The drug can be removed with hemodialysis. Should xylitol toxicity be suspected secondary to the human liquid formulation, contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving gabapentin and may be of significance in veterinary patients:

- **ANTACIDS**: Oral antacids given concurrently with gabapentin may decrease oral bioavailability by 20%; if antacids are required, separate doses at least 2 hours from gabapentin

- **HYDROCODONE**: Co-administration of gabapentin and hydrocodone may increase the AUC (area under the curve) of gabapentin and increase the efficacy and/or adverse effects of the drug. Gabapentin can reduce the AUC of hydrocodone, potentially reducing the drug’s effectiveness.

- **MORPHINE**: May increase gabapentin levels

Laboratory Considerations

- There are reports of gabapentin causing false-positive **urinary protein** readings on Ames N-Multistix SG dipstick tests. The use of a sulfosalicylic acid precipitation test to determine presence of urine protein is recommended for patients receiving gabapentin.

Doses

**DOGS:**

Note:

Client Information

Clients should report any significant adverse effects such as ataxia or hypersomnolence

Chemistry/Synonyms

Gabapentin occurs as white to off-white crystalline solid that is freely soluble in water. It has a pKa1 of 3.7 and a pKa2 of 10.7. It is structurally related to GABA (gamma-aminobutyric acid).

Gabapentin may also be known as: CI-945, GOE-3450, Aclonium®, Equipax®, Gantin®, Gabarone®, Neurontin®, Neurostil® and Progresse®.

Storage/Stability

The commercially available capsules and tablets should be stored at room temperature (25°C, 77°F); excursions permitted to 15–30°C (59–86°F). The oral liquid should be stored in the refrigerator at 2–8°C (36–46°F).

Compatibility/Compounding Considerations

Compounded preparation stability: Commercially available gabapentin solutions contain amounts of xylitol which may be toxic to canine patients. Gabapentin oral suspension compounded from commercially available tablets has been published (Nahata 1999). Triturating twenty (20) gabapentin 600 mg tablets with 60 mL of Ora-Plus® and qs ad to 120 mL with Ora-Sweet® (or Ora-Sweet® SF) yields a 100 mg/mL oral suspension that retains >90% potency for 56 days stored at both 4°C and 25°C. Liquid formulations of gabapentin are most stable in the pH range of 5.5 to 6.5

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Gabapentin Oral Capsules & Tablets: 100 mg, 300 mg, 400 mg; 600 mg, & 800 mg (film-coated); Neurontin® (Pfizer); generic; (Rx)

Gabapentin Oral Solution: 250 mg/5mL (50 mg/mL) in 470 mL; Neurontin® (Pfizer); (Rx) Note: Contains xylitol. Use with caution in dogs.

Gabapentin occurs as white to off-white crystalline solid that is freely soluble in water. It has a pKa1 of 3.7 and a pKa2 of 10.7. It is structurally related to GABA (gamma-aminobutyric acid).

Gabapentin may also be known as: CI-945, GOE-3450, Aclonium®, Equipax®, Gantin®, Gabarone®, Neurontin®, Neurostil® and Progresse®.

Storage/Stability

The commercially available capsules and tablets should be stored at room temperature (25°C, 77°F); excursions permitted to 15–30°C (59–86°F). The oral liquid should be stored in the refrigerator at 2–8°C (36–46°F).

Compatibility/Compounding Considerations

Compounded preparation stability: Commercially available gabapentin solutions contain amounts of xylitol which may be toxic to canine patients. Gabapentin oral suspension compounded from commercially available tablets has been published (Nahata 1999). Triturating twenty (20) gabapentin 600 mg tablets with 60 mL of Ora-Plus® and qs ad to 120 mL with Ora-Sweet® (or Ora-Sweet® SF) yields a 100 mg/mL oral suspension that retains >90% potency for 56 days stored at both 4°C and 25°C. Liquid formulations of gabapentin are most stable in the pH range of 5.5 to 6.5

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Gabapentin Oral Capsules & Tablets: 100 mg, 300 mg, 400 mg; 600 mg, & 800 mg (film-coated); Neurontin® (Pfizer); generic; (Rx)

Gabapentin Oral Solution: 250 mg/5mL (50 mg/mL) in 470 mL; Neurontin® (Pfizer); (Rx) Note: Contains xylitol. Use with caution in dogs.

Note:

Client Information

Clients should report any significant adverse effects such as ataxia or hypersomnolence

Chemistry/Synonyms

Gabapentin occurs as white to off-white crystalline solid that is freely soluble in water. It has a pKa1 of 3.7 and a pKa2 of 10.7. It is structurally related to GABA (gamma-aminobutyric acid).

Gabapentin may also be known as: CI-945, GOE-3450, Aclonium®, Equipax®, Gantin®, Gabarone®, Neurontin®, Neurostil® and Progresse®.

Gabapentin Oral Capsules & Tablets: 100 mg, 300 mg, 400 mg; 600 mg, & 800 mg (film-coated); Neurontin® (Pfizer); generic; (Rx)

Gabapentin Oral Solution: 250 mg/5mL (50 mg/mL) in 470 mL; Neurontin® (Pfizer); (Rx) Note: Contains xylitol. Use with caution in dogs.
Uses/Indications
Very limited clinical use and research performed with this drug to date have demonstrated limited clinical efficacy. However, it potentially may be useful as a radiosensitizer for non-resectable tumors, as part of combination protocols, or as a single agent for tumors not amenable to more accepted therapies. Follow research reports for the most up-to-date information.

In humans, gemcitabine has shown some efficacy in treating pancreatic carcinoma, small-cell lung carcinoma, lymphoma, bladder and other soft tissue carcinomas.

Pharmacology/Actions
Gemcitabine exhibits cell phase specificity and acts primarily on the S phase. It also inhibits cell progression through the G1/S-phase boundary.

Gemcitabine is metabolized intracellularly to difluorodeoxycytidine monophosphate (dFdCMP) that is then converted into diphosphate (dFdCDP) and triphosphate (dFdCTP) forms, the metabolites that give the drug its activity. The diphosphate inhibits ribonucleotide reductase. The triphosphate competes with deoxycytidine triphosphate (dTCP; the “normal” nucleotide) for incorporation into DNA strands.

Pharmacokinetics
In dogs, gemcitabine exhibits first order elimination and has a terminal half-life of about 1.5–3.2 hours. Volume of distribution (steady-state) is around 1 L/kg. Approximately 80% of the drug is excreted in the urine within 24 hours of dosing, primarily as the uracil metabolite.

In humans, gemcitabine levels achieve steady state in about 15 minutes during a 30 minute infusion. Protein binding is negligible. Volume of distribution is about 50 L/m2. Less than 10% of the drug is excreted unchanged in the urine.

Contraindications/Precautions/Warnings
Gemcitabine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with diminished renal or hepatic function.

Adverse Effects
Gemcitabine may cause myelosuppression and can affect red cell, white cell, and platelet cell lines, but neutrophils and platelets appear to be most affected. Neutrophil nadirs usually occur 3–7 days post treatment. GI effects have been reported in animals receiving the drug, but are usually mild. Retinal hemorrhage could occur in animals receiving gemcitabine.

In a pilot study (Kosarek et al. 2005) in 19 dogs receiving up to 675 mg/m2 biweekly demonstrated “minimal and acceptable toxicity.” Another study (Turner et al. 2006) where dogs with lymphoma were given gemcitabine as single agent therapy at 400 mg/m2 weekly for 3 weeks and then off one week, showed significant decreases in neutrophils and platelets 7 days post treatment. 15 of the 21 dogs in the study required dosage reduction or delay in retreatment. Only 7 of the 21 dogs finished the initial 4 week cycle and a second cycle did not result in any objective therapeutic response. In a study where gemcitabine was combined with carboplatin treatment for carcinomas in dogs adverse effects included mild to moderate GI and hematologic toxicity; 32% of dogs developed grade 3 or 4 neutropenia, 24% developed thrombocytopenia and 73% developed mild to moderate, self-limiting GI toxicity. (Domínguez et al. 2009)

In cats treated with double therapy (carboplatin/gemcitabine), 21% or 50% of treated cats, depending on the dosing protocol used, developed grade 3 or 4 neutropenia or thrombocytopenia and 7% developed grade 3 or 4 GI toxicity. (Martinez-Ruzafa et al. 2009)

Reproductive/Nursing Safety
In pregnant humans, gemcitabine is designated by the FDA as a category D drug (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

It is unknown whether gemcitabine is excreted in maternal milk.

Overdosage/Acute Toxicity
There is no known antidote to gemcitabine in an overdose situation. Myelosuppression should be expected. Treatment is supportive.

Drug Interactions
No specific drug interactions were noted, but toxic effects (myelosuppression, GI) could be additive when used with other drugs that also cause those effects.

Laboratory Considerations

No specific laboratory interactions or considerations noted.
Doses

Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

DOGS/CATS:
Depending on the study, gemcitabine doses for dogs and cats have ranged widely from 45 mg/m²–800 mg/m². Recent studies combining it with carboplatin in dogs and cats have used 2 mg/kg IV over 20-30 minutes no more than once every 7 days.

Monitoring
◆ CBC before each treatment
◆ Fundic exam weekly while on therapy
◆ Prior to therapy, baseline renal and hepatic function and periodically thereafter

Client Information
◆ Owners should understand that veterinary experience with this drug is limited and it must be considered an “investigational” treatment.
◆ Gemcitabine residues can be detected in urine up to 7 days after a dose. If owners must clean up urine from treated dogs, they should take proper precautions, such as wearing gloves.

Chemistry/Synonyms
A synthetic pyrimidine nucleoside cytarabine analog antineoplastic agent, gemcitabine HCl occurs as white to off-white solid. It is soluble in water and practically insoluble in ethanol or polar organic solvents. Its chemical name is 2,2'-difluorodeoxycytidine.

Gemcitabine may also be known as: dFdC, LY-288022, Abine®, Antoril®, Gemcit®; or Gemtrol® and Gemzar®.

Storage/Stability
Store unconstituted gemcitabine at controlled room temperature (20–25°C; 68–77°F). After reconstitution with 0.9% sodium chloride injection without preservatives, the resulting solution may be stored at room temperature for up to 24 hours. Reportedly, when frozen at -20°C, the reconstituted solution is stable for 7 days. Do not refrigerate or re-crystallization may occur. Reconstituted solution should not be greater than 40 mg/mL (at least 5 mL of diluent for 200 mg vial; 25 mL diluent for 1 gram vial). Additional diluent may be added to yield concentrations as low as 0.1 mg/mL.

Compatibility/Compounding Considerations
Gemcitabine injection is reportedly physically incompatible with the following medications when used via Y-site injection: acyclovir, amphotericin B, cefoperazone, cefotaxime sodium, furosemide, imipenem, methotrexate, methylprednisolone sodium succinate, mitomycin, piperaclillin, and prochlorperazine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Gemcitabine HCl lyophilized Powder for Injection: 200 mg (in 10 mL single-use vials) and 1 g (in 50 mL single-use vials); Gemzar® (Lilly); (Rx)

References

Gemfibrozil has been shown to reduce influenza-related mortality in mice and may become an adjunctive treatment for severe influenza.

**Pharmacology/Actions**

Gemfibrozil inhibits lipolysis in adipose issue and reduces hepatic uptake of plasma free fatty acids causing reduced production of triglycerides. Secondarily, gemfibrozil inhibits the synthesis of very low-density lipoprotein (VLDL) carrier apolipoprotein B, which reduces VLDL production and incorporation of long-chain fatty acids into triglycerides.

**Pharmacokinetics**

No pharmacokinetic data for dogs or cats was found. In humans, gemfibrozil is rapidly and completely absorbed from the GI tract. The rate and extent of absorption are greatest when administered 30 minutes before a meal. It is highly bound to plasma protein and highest concentrations of the drug are found in the liver and kidneys. In the liver, 4 major metabolites are formed in humans, which are primarily excreted in the urine. Elimination half-life is about 1.5 hours. Reductions in plasma VDL levels are noted within 5 days; peak reductions occur about 4 weeks after starting therapy.

**Contraindications/Precautions/Warnings**

Contraindications for using gemfibrozil in dogs or cats are not known. In humans, gemfibrozil is contraindicated in patients with severe hepatic or renal dysfunction or with known hypersensitivity to gemfibrozil.

Use with caution in dogs or cats as very limited safety data is available for this medication.

**Adverse Effects**

Because no clinical studies have been published regarding gemfibrozil use in dogs and cats and clinical use has been quite limited, an accurate adverse effect profile is not known. Anecdotal reports are that the drug has been well tolerated in the few patients that have received the medication, but abdominal pain, vomiting, diarrhea, and abnormal liver function tests have been reported.

In humans, the most common adverse effects reported are GI related (dyspepsia, nausea, vomiting, diarrhea, etc.) and CNS related (headache, paresthesias, somnolence, dizziness, fatigue). Other adverse effects reported include myositis, taste alterations, blurred vision, eczema and decreased libido/impotence. Rarely, hypersensitivity reactions, bone marrow depression, and increases in liver function test values (AST, ALT, Alk Phos, bilirubin) have been reported. Long-term studies in rats have demonstrated an increased rate of benign and malignant liver tumors when doses were approximately 1.3X of the human dose.

**Reproductive/Nursing Safety**

Gemfibrozil administered to female rats prior to and during gestation at 0.6–2X the human dose, showed decreased fertility rates and their offspring had an increased incidence of skeletal abnormalities. When given to pregnant rabbits at 1–3X the human dose, litter sizes were decreased and at the highest dose (3X), parietal bone variations were noted. In humans, the FDA categorizes gemfibrozil as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is not known if gemfibrozil enters milk and safe use during nursing cannot be assured.

**Overdosage/Acute Toxicity**

Limited information is available. One 7-year-old child ingested up to 9 grams and recovered with supportive treatment. The reported LD50 (oral) in rats is 1414 mg/kg. Consider gut-emptying protocols for recent large oral ingestions and support as required. Monitor for dehydration and electrolyte imbalance if vomiting and/or diarrhea is severe or persists. Monitor liver function tests.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving gemfibrozil and may be of significance in veterinary patients:

- **THIAZIDE DIURETICS, BETA-BLOCKERS, ESTROGENS:** May possibly increase triglyceride concentrations
- **URSODIOL:** May reduce effectiveness of gemfibrozil
- **WARFARIN:** Gemfibrozil may potentiate anticoagulant effects

**Laboratory Considerations**

- No specific concerns associated with gemfibrozil; see Monitoring

**Doses**

**DOGS/CATS:**

For hypertriglyceridemia that has not been controlled with diet alone:

- **Dogs:** 150 mg–300 mg (total dose) PO q12h;
  - **Cats:** 7.5–10 mg/kg PO q12h
- **Dogs:** 200 mg (total dose) PO once daily;
  - **Cats:** 10 mg/kg PO q12h (Elliott 2005)

**Monitoring**

- Plasma triglycerides; realistic goal for therapy is 400 mg/dL or less
- Baseline and periodic: CBC, liver function tests
- Adverse effects
- If treatment is less effective than hoped, assure that clients have adhered to prescribed diet and dosing schedule before altering dosage

**Client Information**

Clients must understand the use of this drug in animals is "investigational"; although FDA-approved for use in people, little information is known about it for use in dogs and cats.
Clients must understand the use of this drug in animals is “investigational”; although FDA-approved for use in people, little information is known about it for use in dogs or cats.

- Gemfibrozil is used in conjunction with diet modification; lack of adherence to dietary recommendations will likely negate the benefits of using this medication.
- Report any significant adverse effects to the veterinarian, including changes in behavior, activity level, gastrointestinal effects (vomiting, diarrhea, lack of appetite), yellowish eyes or mucous membranes, etc.

**Chemistry/Synonyms**

Gemfibrozil is a fibric acid derivative that occurs as a waxy, crystalline solid that is practically insoluble in water, but soluble in alcohol.

Gemfibrozil may also be known as: CI-719, gemfibrozilo, or gemfibrozilium; many international trade names are available.

**Storage/Stability**

Gemfibrozil tablets or capsules should be stored below 30°C in tight containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Gemfibrozil Oral Tablets: 600 mg; *Lopid®* (Parke-Davis); generic (Rx). **Note:** 300 mg capsules are available in Canada.

**References**

---

**GENTAMICIN SULFATE**

(jen-ta-my-ye-sin) Gentocin®, Garamycin®

**AMINOGLYCOSIDE ANTIBIOTIC**

**Prescriber Highlights**

- Parenteral-amino-glycoside antibiotic that has “good” activity against a variety of bacteria, predominantly gram-negative aerobic bacilli, but also many staphylococci strains
- Because of potential adverse effects, usually reserved for serious infections when given systemically
- Adverse effect profile: Nephrotoxicity, ototoxicity, neuromuscular blockade
- Cats may be more sensitive to toxic effects
- Risk factors for nephrotoxicity: Preexisting renal disease, age (both neonatal & geriatric), fever, sepsis, & dehydration
- Usually dosed once daily

**Uses/Indications**

The inherent toxicity of the amino glycosides limit their systemic (parenteral) use to the treatment of serious gram-negative infections when there is either a documented lack of susceptibility to other less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Various gentamicin products are FDA-approved for parenteral use in dogs, cats, chickens, turkeys, and swine, although the injectable small animal products appear to be no longer marketed. Although routinely used parenterally in horses, gentamicin is only FDA-approved for intrauterine infusion in this species. Oral products are FDA-approved for gastrointestinal infections in swine and turkeys. For more information, refer to the Dosage section below.

**Pharmacology/Actions**

Gentamicin has a mechanism of action and spectrum of activity (primarily gram-negative aerobes) similar to the other amino glycosides. Like the other amino glycoside antibiotics, it acts on susceptible bacteria presumably by irreversibly binding to the 30S ribosomal subunit thereby inhibiting protein synthesis. It is considered a bactericidal concentration-dependent antibiotic.

Gentamicin’s spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *E. coli*, Klebsiella, Proteus, Pseudomonas, Salmonella, Enterobacter, Serratia, and Shigella, Mycoplasma, and Staphylococcus (strains of MRSA are often resistant). Several strains of *Pseudomonas aeruginosa*, Proteus, and Serratia that are resistant to gentamicin may still be treated with amikacin.

Antimicrobial activity of the amino glycosides is enhanced in an alkaline environment.

The amino glycoside antibiotics are inactive against fungi, viruses and most anaerobic bacteria.

**Pharmacokinetics**

Gentamicin, like other amino glycosides, is not appreciably absorbed after oral or intrauterine administration, but is absorbed from topical administration (not skin or urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. After IM administration to dogs and cats, peak levels occur from 1/2 to 1 hour later. Subcutaneous injection results in slightly delayed peak levels and with more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

After absorption, amino glycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids. Amino glycosides are not transported across the placenta. They are found in amniotic fluid and cord blood and the newborn serum amino glycoside level is not different from maternal level. Different amino glycosides have different placental transfer rates; gentamicin is the most rapidly transferred. Aminoglycosides are excreted primarily in urine. The terminal half-life of gentamicin is approximately 2-4 hours. Removal of gentamicin from the serum is biphasic with the elimination half-life of the terminal phase being approximately 27 hours.
Laboratory Considerations

**Drug Interactions**

Ticarcillin (12–20 g/day in humans) is reportedly nearly as effective as hemodialysis, but is not a viable option for most veterinary patients. Should an inadvertent overdosage be administered, three treatments have been recommended.

**Overdosage/Acute Toxicity**

Aminoglycosides can cross the placenta, but study showed no detectable levels in foals when gentamicin was administered to mares at term. In other species, fetal concentrations range from 15–50% of those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. The elimination half-lives for gentamicin have been reported to be 1.82–3.25 hours in horses, 2.2–2.7 hours in calves, 2.4 hours in sheep, 1.8 hours in cows, 1.9 hours in swine, 1 hour in rabbits, and 0.5–1.5 hours in dogs and cats. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

**Contraindications/Precautions/Warnings**

Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections there are no other absolute contraindications to their use. However, they should be used with extreme caution in patients with preexisting renal disease with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs (e.g., “seeing-eye”, herding, dogs for the hearing impaired, etc.). Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity. They should not be used in animals with botulism.

Sighthound dogs may require reduced dosages of aminoglycosides as they have significantly smaller volumes of distribution. Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

IM injections in horses have caused muscle irritation and IV injections are preferred. The risk for antibiotic associated diarrhea/colic in horses due to gentamicin is thought to be low. But gentamicin may promote Beta-2 toxin production by *C. perfringens* and may increase the severity of colitis (McGorum & Pirie 2010).

Aminoglycosides are often considered contraindicated in rabbits as they adversely affect the GI flora balance in these animals, but dosages are listed below. Use with caution.

**Adverse Effects**

The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity is usually manifested by increases in: BUN, creatinine, non-protein nitrogen in the serum, and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest by either auditory and/or vestibular clinical signs and may be irreversible. Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but other forms can occur with any of the drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain/inflammation at injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs, hematologic and hepatic effects have been reported.

**Reproductive/Nursing Safety**

Aminoglycosides can cross the placenta and, while rare, may cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.).

While small amounts of gentamicin may be excreted into milk, the risk to nursing offspring appears minimal.

**Overdosage/Acute Toxicity**

Should an inadvertent overdosage be administered, three treatments have been recommended. 1) Hemodialysis is very effective in reducing serum levels of the drug, but is not a viable option for most veterinary patients. 2) Peritoneal dialysis also will reduce serum levels, but is much less effective. 3) Complexation of drug with tetracycline (12–20 g/day in humans) is reportedly nearly as effective as hemodialysis.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving gentamicin and may be of significance in veterinary patients:

- **BETA-LACTAM ANTIBIOTICS (penicillins, cephalosporins):** May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides in vitro (do not mix together) and in vivo (patients in renal failure)

- **CEPHALOSPORINS:** The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).

- **DIURETICS, LOOP (e.g., furosemide, torsemide) or OSMOTIC (e.g., mannitol):** Concurrent use with loop or osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides

- **NEPHROTOXIC DRUGS, OTHER (e.g., cisplatin, amphotericin B, polymyxin B, or vancomycin):** Potential for increased risk for nephrotoxicity

- **NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL:** Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

**Laboratory Considerations**
**Gentamicin serum concentrations** may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

**Doses**

**Note:** Most infectious disease clinicians now agree that aminoglycosides should be dosed once a day in most patients (mammals). This dosing regimen yields higher peak levels with resultant greater bacterial kill, and as aminoglycosides exhibit a "post-antibiotic effect", surviving susceptible bacteria generally do not replicate as rapidly even when antibiotic concentrations are below MIC. Periods where levels are low may decrease the "adaptive resistance" (bacteria take up less drug in the presence of continuous exposure) that can occur. Once daily dosing may also decrease the toxicity of aminoglycosides as lower urinary concentrations may mean less-uptake into renal tubular cells. However, patients who are neutropenic (or otherwise immunosuppressed) may benefit from more frequent dosing (q8h).

**DOGS:**

For susceptible infections:

- a) For empiric therapy: 10–14 mg/kg once a day (*route not specified; assume IV, SC, IM—Plumb*) (Autran de Morais 2009)
- b) For localized, urinary infections: First dose of 4.4 mg/kg IM, SC and then 2.2 mg/kg IM, SC once daily (q24h) for 7–10 days;
  - For orthopedic and soft tissue infections: 4.4–6.6 mg/kg IV, IM, SC once daily (q24h) for <7 days.
  - For bacteremia, sepsis: 6.6 mg/kg IV, IM, SC once daily (q24h) for <7 days.
  - Monitor renal function by urine sediment examination and serum urea nitrogen levels. (Greene *et al.* 2006)
- c) For Brucellosis: Gentamicin 5 mg/kg SC once daily (q24h) for 7 days; 2-courses of treatment, treating on weeks one and four; plus Minocycline at 25 mg/kg PO once daily (q24h) for 4 weeks. Eventually, doxycycline can be substituted for minocycline at the same dosage to lower cost. Infected animals may need to be treated for two or more 4-week courses. Sequential antibody tests at 3 to 6 monthly intervals are recommended to monitor treatment. Monitor renal function secondary to gentamicin therapy. (Hartmann & Greene 2005)
- d) For Greyhounds and probably other Sighthound breeds: 6 mg/kg IV q24h or 9 mg/kg SC/IM q24h. (KuKanich 2008)

**CATS:**

For susceptible infections:

- a) For empiric therapy: 5–8 mg/kg once a day (*route not specified; assume IV, SC, IM—Plumb*) (Autran de Morais 2009)
- b) 6–8 mg/kg (*route not specified*) once daily (q24h). Neutropenic or immunocompromised patients may still need to be dosed q8h (dose divided). (Trepanier 1999)
- c) 8 mg/kg once daily or 2–4 mg/kg q8h IV, IM or SC (Aucoin 2002)
- d) For localized, urinary infections: 2.2 mg/kg IV, IM, SC once daily (q24h) for <7 days;
  - For bacteremia, sepsis: 4.4 mg/kg IV, IM, SC once daily (q24h) for <7 days.
  - Monitor renal function by urine sediment examination and serum urea nitrogen levels. (Greene *et al.* 2006)

**FERrets:**

For susceptible infections:

- a) 5 mg/kg SC, IM q24h; use with caution or avoid use. (Morrisey & Carpenter 2004)
- b) 4–8 mg/kg IM, SC, IV divided and given 2–3 times daily. Use only when culture and sensitivity dictates. (Williams 2000)

**RABBITS/RODENTS/SMALL MAMMALS:**

- a) Rabbits: 5–8 mg/kg daily dose (may divide into q8h–q24h) SC, IM or IV. Increased efficacy and decreased toxicity if given once daily. If given IV, dilute into 4 mL/kg of saline and give over 20 minutes (Ivey & Morrisey 2000)
- b) Chinchillas, Gerbils, Guinea pigs, Hamsters, Mice, Rats: 2–4 mg/kg SC or IM q8–24h (Adamcak & Otten 2000)
- c) Chinchillas: 2–4 mg/kg SC, IM q8–24h (Hayes 2000)

**HORSES:**

For susceptible infections:

- a) Foals: 11–15 mg/kg q24h (*route not listed; assume IV—Plumb*). Ideally, TDM should be used to reduce risk for nephrotoxicity and optimizing efficacy. (Corley & Hollis 2009)
- b) Adults: 6.6 mg/kg IV or IM—(because IM administration may cause muscle irritation in some horses most prefer using IV) once daily (q24h) (Foreman 1999), (Chaffin 2006), (Haggett & Wilson 2008)
- c) For systemic treatment of susceptible bacterial infections of the reproductive tract: gentamicin 6.6 mg/kg IV (slow infusion) once daily (q24h). For intrauterine infusion: Irrigate uterus (Morresey & Waldridge 2010) for 2-3 days prior to antibiotic infusion to remove inflammatory debris. Gentamicin dosed at 1–2 grams IU. Buffer with bicarbonate (equal volume of 7.5% bicarbonate and diluted in saline) or large volume (200 mL) of saline. Mares with bacterial endometritis should be treated with IU antibiotics for 3-7 days. Treatment length dependent on history, chronicity of infection, bacteria isolated, and mare’s ability to clear uterine fluid. (LeBlanc 2009)
- d) For pleuropneumonia in adults: Initial dose 8 mg/kg IV, adjust as needed based upon therapeutic drug monitoring; or 6.6 mg/kg IV or IM q24h. (Sprayberry 2009)
- e) From a case report of successful treatment of an adult horse with *R. equi*: ceftriaxone (2 mg/kg IV q12h) and gentamicin 6.6. mg/kg IV q24h for 14 days. Thereafter, treatment was changed to doxycycline (10 mg/kg PO q12h for 28 days.) (Morresey & Waldridge 2010)

**SWINE:**

For susceptible infections:

- a) For colibacillosis in neonates: 5 mg PO or IM once (Label directions; Garacin® Pig Pump and Piglet Injection—Schering)
- b) For weanlings and other swine:
Gentamicin Sulfate Soluble Powder: 2 g gentamicin/30 grams of powder in 360-gram jar; (AgriLabs); (OTC)

Gentamicin Soluble Powder: 333.33 mg/g in 360 gram jars. FDA-approved for use in weanling swine. Slaughter withdrawal = 10 days.

Gentamicin Sulfate Injection: 5 mg/mL in 250 mL vials; (IVX), (OTC). FDA-approved for use in old chickens (slaughter withdrawal = 5 weeks) and 1–3 day-old turkeys (slaughter withdrawal=9 weeks) only.

Gentamicin Sulfate Injection: 100 mg/mL in 100 mL and 250 mL vials; (VIVEDA), (OTC). FDA-approved for use in neonatal swine only. Slaughter withdrawal = 14 days.

Gentamicin Sulfate Injection: 5 mg/mL in 250 mL vials; (Gentamx), (OTC). FDA-approved for use in piglets up to 3 days of age. Slaughter withdrawal = 5 days. (Label directions; Garasin® Piglet Injection—Schering-Plough; (OTC))

Gentamicin Sulfate Soluble Powder: 2 g gentamicin/30 grams of powder in 360-gram jar; (Gentamax® Soluble Powder and Oral Solution—Schering)

**BIRDS:**
For susceptible infections:

a) In companion birds: Amikacin is the preferred aminoglycoside, but gentamicin can be used to reduce expense: 2.5–5 mg/kg once per day (Note: route not listed, IM assumed as author lists IM doses for amikacin—Plumb). In severely immunocompromised birds, twice daily administration with a beta-lactam antibiotic may improve treatment success. Birds often show polyuria during treatment, but it usually resolves after short duration (<7 days) of therapy. Concurrent SC fluids may reduce nephrotoxicity. (Flammer 2006)

b) Ratites: 5 mg/kg IM once daily; Note: use only as a last resort as it causes visceral gout (Jenson 1998)

**REPTILES:**
For susceptible infections:

a) For bacterial gastritis in snakes: gentamicin 2.5 mg/kg IM every 72 hours with oral neomycin 15 mg/kg plus oral live lactobacillus. (Burke 1986)

b) For bacterial shell diseases in turtles: 5–10 mg/kg daily in water turtles, every other day in land turtles and tortoises for 7–10 days. Used commonly with a beta-lactam antibiotic. Recommend beginning therapy with 20 mL/kg fluid injection. Maintain hydration and monitor uric acid levels when possible. (Rosskopf 1986)

**Monitoring (Parenteral use)**
- Efficacy (cultures, clinical signs associated with infection)
- Renal toxicity; baseline urinalysis, serum creatinine/BUN. Casts in the urine are often the initial sign of impending nephrotoxicity. Casts or increased serum creatinine may not be good markers in neonates. Frequency of monitoring during therapy is controversial. Frequency of monitoring during therapy is controversial, but daily urinalysis and serum creatinine may not be too frequent.
- Gross monitoring of vestibular or auditory toxicity is recommended
- Serum levels, if possible. Draw levels at 1, 2, and 4 hours post dose. Peak should be at least 20 micrograms/mL and 4 hour sample should be less than 10 micrograms/mL. (Papich 2003)

**Client Information**
- With appropriate training, owners may give subcutaneous injections at home, but routine monitoring of therapy for efficacy and toxicity must still be done.
- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication.

**Chemistry/Synonyms**
An aminoglycoside obtained from cultures of *Micromonaspora purpurea*, gentamicin sulfate occurs as a white to buff powder that is soluble in water and insoluble in alcohol. The commercial product is actually a combination of gentamicin sulfate C1, C2, and C3, but all these compounds apparently have similar antimicrobial activities. Commercially available injections have a pH from 3–5.5.

Gentamicin may also be known as: gentamicin sulphate, gentamicini sulfas, NSC-82261, and Sch-9724; many trade names are available.

**Storage/Stability**
Gentamicin sulfate for injection and the oral solution should be stored at room temperature (15–30°C); freezing or temperatures above 40°C should be avoided. The soluble powder should be stored from 2–30°C. Do not store or offer medicated-drinking water in rusty containers or the drug may be destroyed.

**Compatibility/Compounding Considerations**
While the manufacturer does not recommend that gentamicin be mixed with other drugs, it is reportedly physically compatible and stable in all commonly used intravenous solutions and with the following drugs: bleomycin sulfate, cefoxitin sodium, cimetidine HCl, clindamycin phosphate, methicillin sodium, metronidazole (with and without sodium bicarbonate), penicillin G sodium, and verapamil HCl.

The following drugs or solutions are reportedly physically incompatible or only compatible in specific situations with gentamicin: amphotericin B, ampicillin sodium, carbenicillin disodium, cefamandole naftate, cephalothin sodium, cepapirin sodium, dopamine HCl, furosemide, and heparin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

*In vitro* inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented. Gentamicin is very susceptible to this effect and it is recommended to avoid mixing these compounds together.

Gentamicin Sulfate Injection: 40 mg/mL (as sulfate) in 2 mL & 20 mL vials and 1.5 mL & 2 mL cartridge-needle Units; 10 mg/mL (as sulfate) in 2 mL vials & ADD-Vantage 60 mg, 80 mg & 100 mg vials; 0.8 mg/mL, 0.9 mg/mL & 1 mg/mL (as gentamicin base) in 100 mL single-dose containers; 1.2 mg/mL, 1.4 mg/mL & 1.6 mg/mL (as gentamicin base) in 50 mL single-dose containers; Pediatric Gentamicin Sulfate (Abraxis); Gentamicin Sulfate in 0.9% Sodium Chloride ( Hospira); generic, (Rx)
Topical, otic and ophthalmic labeled products are also available.

References
Reproductive/Nursing Safety

In humans, the FDA categorizes glimepiride as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). In rabbits and rats, glimepiride did not cause teratogenic effects when given at high dosages. There were some intrauterine deaths when maternal hypoglycemia was induced by the drug.

Some glimepiride is excreted into maternal milk of rats. The manufacturer states to discontinue the drug in nursing, human mothers.

Overdosage/Acute Toxicity

Overdoses may result in hypoglycemia, ranging from mild to severe. Treatment consists of glucose administration and intensive monitoring. Because of the drug’s long duration of activity, patients may need to be supported with glucose for at least 48 hours post-ingestion, even after apparent recovery.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glimepiride and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (ketoconazole, itraconazole, fluconazole):** May increase plasma levels of glimepiride
- **BETA-BLOCKERS:** May potentiate hypoglycemic effect
- **CHLORAMPHENICOL:** May displace glimepiride from plasma proteins
- **CORTICOSTEROIDS:** May reduce efficacy
- **DIURETICS, THIAZIDE:** May reduce hypoglycemic efficacy
- **ISONIAZID:** May reduce hypoglycemic efficacy
- **NIACIN:** May reduce hypoglycemic efficacy
- **PHENOTHIAZINES:** May reduce hypoglycemic efficacy
- **PHENYTOIN:** May reduce hypoglycemic efficacy
- **SULFONAMIDES:** May displace glimepiride from plasma proteins
- **SYMPATHOMIMETIC AGENTS:** May reduce hypoglycemic efficacy
- **WARFARIN:** May displace glimepiride from plasma proteins

Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

Doses

- **CATS:**
  
  For treatment of NIDDM:
  
  a) 2 mg (total dose) per cat once daily (Bruyette 2004)
  
  b) 1–2 mg (total dose per cat) PO once daily (Scherk 2005)

Monitoring

- Efficacy: Standard methods of monitoring efficacy for diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels)
- Adverse effects

Client Information

- Clients should understand the “investigational” nature of using this drug in cats and report any untoward effects to the veterinarian.

Chemistry/Synonyms

A sulfonylurea antidiabetic agent, glimepiride occurs as a white to yellowish-white, crystalline, odorless to practically odorless powder. It is practically insoluble in water.

Glimepiride may also be known as: HOE-490, Amarel®, Amaryl®, Amarylle®, Euglim®, Glimepil®, Solosa®, and Roname®.

Storage/Stability

Glimepiride tablets should be stored between 15–30°C (59–86°F) in well closed containers.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Glimepiride Oral Tablets: 1 mg, 2 mg, & 4 mg; Amaryl® (Sanofi-Aventis); generic; (Rx)

References

Uses/Indications
Glipizide may be of benefit in treating cats with type II diabetes if they have a population of functioning beta cells. Perhaps 20%-30% of newly diagnosed cats may benefit (improvement in hyperglycemia) from glipizide, but there is not a way to predict which cats will benefit in advance of a trial. It has been suggested that there are two situations when a glipizide trial can be recommended, 1) If an owner refuses to consider using insulin usually due to a fear of needles, and 2) the cat appears to be relatively well controlled on quite small doses of insulin and the owner would strongly prefer to no longer give insulin (Feldman 2005).

While glipizide potentially could be useful in treating canine patients with type II or III diabetes, however, by the time dogs present with hyperglycemia, they are absolutely or relatively insulinopenic and glipizide would unlikely be effective.

Pharmacology/Actions
Glipizide is a second generation sulfonylurea. Sulfonylureas lower blood glucose concentrations in both diabetics and non-diabetics. The exact mechanism of action is not known, but these agents are thought to exert the effect primarily by stimulating the beta cells in the pancreas to secrete additional endogenous insulin. Extrapancreatic effects include enhanced tissue sensitivity of circulating insulin. Ongoing use of the sulfonylureas appears to enhance peripheral sensitivity to insulin and reduce the production of hepatic basal glucose. The mechanisms causing these effects are yet to be fully explained, however.

Prolonged hyperglycemia may cause beta cell “exhaustion” and permanent damage to beta cells contributing to their death. It has been suggested that by treating all cats initially with insulin to rapidly reduce hyperglycemia may allow increases in beta cell sensitivity and insulin release to occur with time and potentially increase success with glipizide (Sparkes 2009).

Pharmacokinetics
Glipizide is rapidly and practically completely absorbed after oral administration. Transdermal administration on cats does not appear to be adequately absorbed to be useful. The absolute bioavailability reported in humans ranges from 80–100%. Food will alter the rate, but not the extent, of absorption. Glipizide is very highly bound to plasma proteins. It is primarily biotransformed in the liver to inactive metabolites that are then excreted by the kidneys. In humans, half-life is about 2–4 hours.

Contraindications/Precautions/Warnings
Oral antidiabetic agents are considered contraindicated with the following conditions: severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidic conditions. Glipizide should only be used when its potential benefits outweigh its risks during untreated adrenal or pituitary insufficiency; thyroid, renal or hepatic function impairment; prolonged vomiting; high fever; malnourishment or debilitated condition is present.

While glipizide may initially be effective, it may become ineffective in weeks to months after starting therapy; insulin will then be required.

Some patients with type II or type III diabetes may have their disease complicated by the production of excessive amounts of cortisol or growth hormone which may antagonize insulin’s effects. These causes should be ruled out before initiating oral antidiabetic therapy.

Adverse Effects
Approximately 15% of cats receiving glipizide develop gastrointestinal adverse effects (i.e., anorexia, vomiting). Vomiting usually occurs shortly after dosing and will subside in 2–5 days. If it persists or is severe, decrease dose or frequency and, if necessary, discontinue.

Some cats receiving this drug have developed hyperglycemia, but severe hyperglycemia appears to be rare. Should hypoglycemia occur, discontinue glipizide and recheck glucose in one week; may restart at a lower dose or dosing frequency if hyperglycemia is noted.

Increased amyloid deposit formation can occur with glipizide which can potentially cause further destruction of functional beta cells.

Effects on the liver have been reported. Approximately 8% of cats treated with glipizide may develop cholestatic jaundice and have increases in liver enzymes. Serum hepatic enzymes should be checked every 1–2 weeks initially. Discontinue glipizide in cats with elevated enzymes if they develop lethargy, anorexia, vomiting, or if ALT exceeds 500 IU/L; should icterus occur, discontinue glipizide and restart at a lower dose once icterus resolves; discontinue use should icterus reoccurs.

Other adverse effects that are possible (noted in humans) include: allergic skin reactions, and bone marrow suppression.

Glipizide does not appear to be effective in cats demonstrating insulin resistance.

Reproductive/Nursing Safety
Safe use during pregnancy has not been established. Glipizide was found to be mildly fetotoxic in rats when given at doses of 5–50 mg/kg; however, no other teratogenic effects were noted. Use in pregnancy only when benefits outweigh potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy. Use only when the benefits outweigh potential risks.
The following drug interactions have either been reported or are theoretical in humans or animals receiving glipizide and may be of significance in veterinary patients:

**Drug Interactions**

- **ALCOHOL**: A disulfiram-like reaction (anorexia, nausea, vomiting) has been reported in humans who have ingested alcohol within 48–72 hours of receiving glipizide.
- **ANTIFUNGALS, AZOLE (ketoconazole, itraconazole, fluconazole)**: May increase plasma levels of glipizide.
- **BETA-BLOCKERS**: May potentiate hypoglycemic effect.
- **CHLORAMPHENICOL**: May displace glipizide from plasma proteins.
- **CIMETIDINE**: May potentiate hypoglycemic effect.
- **CORTICOSTEROIDS**: May reduce efficacy.
- **DIURETICS, THIAZIDE**: May reduce hypoglycemic efficacy.
- **ISONIAZID**: May reduce hypoglycemic efficacy.
- **MOA INHIBITORS**: May potentiate hypoglycemic effect.
- **NIACIN**: May reduce hypoglycemic efficacy.
- **PHENOTHIAZINES**: May reduce hypoglycemic efficacy.
- **PHENYTOIN**: May reduce hypoglycemic efficacy.
- **PROBENECID**: May potentiate hypoglycemic effect.
- **SULFONAMIDES**: May displace glipizide from plasma proteins.
- **SYMPATHOMIMETIC AGENTS**: May reduce hypoglycemic efficacy.
- **THYROID AGENTS**: May reduce hypoglycemic effect.
- **WARFARIN**: May displace glipizide from plasma proteins.

**Doses**

**CATS:**

For diabetes mellitus:

- In non-ketotic cats that are relatively healthy: Initially monitor weight, urine/glucose/ketones, and several blood glucose measurements. Then give 2.5 mg PO per cat twice daily in conjunction with a meal. During first 24 hours of therapy perform spot blood glucose measurements (every 3–4 hours for the initial 12–18 hours) to check for hypoglycemia. After 2 weeks, monitor again and if hyperglycemia is still present and adverse reactions (vomiting, icterus) have not occurred, increase dose to 5 mg twice daily. Therapy is continued as long as the cat is stable. If euglycemia or hypoglycemia develop, the dosage may be tapered down or discontinued, and blood glucose concentrations re-evaluated 1 week later to assess the need for the drug. If hyperglycemia recurs, the dosage is increased or glipizide is reintroduced, with a reduction in dosage in those cats previously developing hypoglycemia. Discontinue and initiate insulin therapy if clinical signs continue to worsen, the cat becomes ill, develops ketoadosis, blood glucose concentrations remain greater than 15 mmol/L (270 mg/dL) after one or two months of therapy, or the owners become dissatisfied with the treatment. (Herrtage 2009)

- 2.5–5 mg per cat PO twice a day when combined with dietary fiber therapy. Evaluate every one to two weeks for a period of 2–3 months. If fasting blood glucose decreases to less than 200 mg/dL, continue at same dosage and reevaluate in 3–6 months. If fasting blood glucose remains greater than 200 mg/dL after 2–3 months, discontinue and institute insulin therapy (Greco 2000)

- If cat is generally well, weight loss is mild, not ketoadicotic, and does not have peripheral neuropathy, may try glipizide at: 2.5 mg (total dose) PO twice a day. (Daminet 2003)

- 5 mg per cat PO twice daily, may decrease dose if hypoglycemia occurs or increase to 7.5 mg (maximum) twice daily if not controlled. Slightly less than 50% of cats may tolerate the drug, have improved clinical signs and blood glucose levels. Response may be delayed, so it should be given for 4–8 weeks before deciding if it was efficacious (owner opinion, body weight, blood glucose determinations over a one-day period every 4 weeks.) (Feldman 2005)

**Monitoring**

- Weekly exams during first month of therapy, including PE, body weight, urine glucose/ketones, and several blood glucose exams.
- Adverse effects (anorexia, vomiting, icterus), and occasional liver enzymes and CBC.

**Client Information**

- Clients should be informed of clinical signs to watch for that would indicate either hypoglycemia or hyperglycemia and be instructed to report these to the veterinarian.
- Compliance with dosing regimen should also be stressed.

---

**Overdosage/Acute Toxicity**

Oral LD₅₀'s are greater than 4 g/kg in all animal species tested. Profound hypoglycemia is the greatest concern after an overdose. Gut emptying protocols should be employed when warranted. Because of its shorter half-life than chlorpropamide, prolonged hypoglycemia is less likely with glipizide, but blood glucose monitoring and treatment with parenteral glucose may be required for several days. Massive overdoses may also require additional monitoring (blood gases, serum electrolytes) and supportive therapy.

It is unknown if glipizide enters milk.

Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

---

**Chemistry/Synonyms**

---
Chemistry/Synonyms
A sulfonylurea antidiabetic agent, glipizide (also known as glydiazinamide) occurs as a whitish powder. It is practically insoluble in water and has pKa of 5.9.

Glipizide may also be known as: CP-28720, glipizidum, glydiazinamide, or K-4024; many international trade names are available.

Storage/Stability
Tablets should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glipizide Oral Tablets: 5 mg, & 10 mg; Glucotrol® (Pfizer); generic (Rx)

Glipizide Oral Extended Release Tablets: 2.5 mg, 5 mg, & 10 mg; Glucotrol XL® (Pfizer); generic; (Rx)

Glipizide/Metformin Hydrochloride Tablets (film-coated): 2.5 mg glipizide/250 mg or 500 mg metformin; 5 mg glipizide/500 mg metformin; Metaglip® (Bristol-Myers Squibb); generic (Sandoz); (Rx)

References

GLUCAGON (gloo-ka-gon) GlucoGen®
HORMONAL AGENT
Prescriber Highlights

• Hormone to increase blood glucose that may be useful for treating hypoglycemia in small animals & potentially fatty liver syndrome in dairy cows
• May be effective in treating beta-blocker or calcium channel overdoses
• Must be parenterally administered
• When used as CRI, must be in a setting where blood glucose can be monitored
• Unlikely to cause adverse effects

Uses/Indications
In small animals, the primary use for glucagon is to increase blood glucose in patients with excessive insulin levels, either endogenously produced (insulinoma) or exogenously administered (insulin overdose). Glucagon has potential in the treatment of fatty liver syndrome in dairy cattle.

In human medicine, glucagon has been used in treating the cardiac manifestations of beta-blocker and calcium-channel blocker overdoses. One study (Kerns et al. 1997) in dogs, however, demonstrated insulin to be superior to glucagon in treating experimental propranolol overdoses in dogs.

Pharmacology/Actions
Glucagon’s main pharmacologic activities are to increase blood glucose and relax smooth muscle of the GI tract. It primarily increases blood glucose by stimulating hepatic glycogenolysis. The mechanisms of action for its GI effects are poorly understood.

Pharmacokinetics
Glucagon must be administered parenterally; it is destroyed in the gut after oral dosing. After intravenous injection, maximum glucose levels are attained within 30 minutes; hyperglycemic effects persist up to 90 minutes after dosing. Glucagon is degraded in the plasma, liver and kidneys; in humans, plasma half-life is around 10 minutes.

Contraindications/Precautions/Warnings
Glucagon should usually not be used in patients with pheochromocytoma as catecholamines may be released leading to hypertension. When used for insulinoma, it must be in a setting where blood glucose can be closely monitored. While glucagon may be useful for blood glucose elevation in insulinoma patients, in humans its use for this is cautioned as it can increase insulin production, leading to greater hypoglycemia once the drug is discontinued.

Adverse Effects
Glucagon is usually well tolerated, but potentially nausea and vomiting could occur after administration. Hypokalemia and hypersensitivity reactions (very rare) are also possible.

Reproductive/Nursing Safety
In humans, glucagon is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) As an endogenously produced hormone, it is unlikely to cause significant risk to offspring.

It is unknown if glucagon enters maternal milk, but it is unlikely to cause harm to nursing offspring.
Overdosage/Acute Toxicity
Adverse effects seen with overdose include nausea, vomiting, diarrhea, gastric hypotonicity and, possibly, hypokalemia. Because glucagon’s elimination half-life is so short, treatment may not be necessary and would be symptomatic in nature. If the patient is also receiving beta-blockers, greater increases in blood pressure and heart rate may be seen.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving glucagon and may be of significance in veterinary patients:

ANTICOAGULANTS: May have their effects increased when glucagon is concurrently administered; this effect may be delayed. It is suggested to monitor for bleeding and prothrombin activity if glucagon is necessary.

Laboratory Considerations
No glucagon-related laboratory interactions noted.

Doses

**DOGS:**

a) For hypoglycemic (neuroglycopenic) crises in patients with “insulinomas”: 1 mg of glucagon is reconstituted per manufacturer directions and then added to 1000 mL of 0.9% Sodium Chloride; this results in a 1000 ng/mL (nanograms/mL) solution. [Note: Some references state to not mix or dilute with saline solutions, but to use D5W only.] Initially give a 50 ng/kg bolus IV and then administer at a constant rate infusion (CRI) using a suitable pump at a rate of 10–15 ng/kg/minute. May need to increase up to 40 ng/kg/min to maintain euglycemia. (Smith 2002)

b) For refractory hypoglycemic patients with insulinoma: Prepare solution as in “a” above. Give at an initial infusion rate of 5 ng/kg/min and increase as needed. (Garrett 2003)

**CATS:**

a) For hypoglycemic (neuroglycopenic) crises in patients with “insulinomas”: 1 mg of glucagon is reconstituted per manufacturer directions and then added to 1000 mL of 0.9% Sodium Chloride; this results in a 1000 ng/mL solution. [Note: Some references state to not mix or dilute with saline solutions, but to use D5W only.] Initially give a 50 ng/kg bolus IV and then administer at a constant rate infusion (CRI) using a suitable pump at a rate of 10–15 ng/kg/minute. May need to increase up to 40 ng/kg/min to maintain euglycemia. (Smith 2002)

**CATTLE:**

a) For treatment of fatty liver in early lactation dairy cows older than 3.5 years: 5 mg glucagon in 60 mL of normal saline SC q8h (15 mg/day) for 14 days (Bobe et al. 2003)

Monitoring

- Blood glucose
- Serum potassium if used other than for acute treatment

Client Information

- Glucagon could potentially be used for outpatient emergency initial treatment of hypoglycemia, but oral glucose is probably more appropriate for use by clients.
- Glucagon should be used as a CRI only in a setting where blood glucose can be adequately monitored.

Chemistry/Synonyms

A hormone secreted by the alpha2 cells of the pancreas, glucagon is a straight chain polypeptide that contains 29 amino acids whose sequence is consistent throughout mammalian species. It has a molecular weight of 3483. When in crystalline form it is a white- to off-white powder that is relatively insoluble in water at physiologic pH, but is soluble at pH of less than 3 and greater than 9.5. Glucagon may be expressed in terms of International Units (IU; expressed as Units in this reference) or by weight. One International Unit is equivalent to one milligram of glucagon. Commercially available glucagon is now obtained via recombinant DNA sources.

Glucagon may also be known as glucagonum or HGF, and GlucaGen®.

Storage/Stability

The commercially available powder for reconstitution should be stored at room temperature between 20–25°C (68–77°F); avoid freezing and protect from light. Once reconstituted with the supplied diluent the solution should be clear with a water-like consistency and used immediately; any unused portion should be discarded. If the solution contains any gel formation or particles, it should be discarded.

Compatibility/Compounding Considerations

To prepare glucagon for a continuous rate infusion, dilute 1 mg with the supplied diluent or sterile water; roll gently until dissolved, this may then be further diluted in D5W. May be given through a Y-tube or 3-way stopcock if a dextrose solution is running.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

Glucagon Powder for Injections: 1 mg (1 unit) with 1 mL diluent in vials & syringes; GlucaGen® Diagnostic Kit & GlucaGen HypoKit® (Novo Nordisk); Glucagon Emergency Kit® (Eli Lilly); (Rx)

<tbody>
<tr>
<td>Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are four broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antinflammatory agent, 3) as a cytotoxic/antineoplastic agent, and 4) as an immunosuppressant. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders, GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete. For specific dosages and indications refer to the Doses section for each glucocorticoid drug monograph. Glucocorticoids have been used for CNS trauma (especially spinal chord injury) or shock, but their use for these indications are controversial as there is little evidence supporting their use. Relative adrenal insufficiency may occur in critically ill animals, and low or physiologic doses of corticosteroids (having both glucocorticoid and mineralocorticoid activity, e.g., hydrocortisone) may be indicated in patients that have not responded to pressor agents.</td>
<td>Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows: <strong>Cardiovascular System:</strong> Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs’ vasoconstrictive properties and increased blood volume that may be produced. <strong>Cells:</strong> Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes. <strong>CNS/Autonomic Nervous System:</strong> Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity. <strong>Endocrine System:</strong> When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T4) to triiodothyronine (T3) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin. <strong>Hematopoietic System:</strong> Glucocorticoids can increase the numbers of circulating platelets, neutrophils and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells becomes diminished. Glucocorticoids can cause involution of lymphoid tissue. <strong>GI Tract and Hepatic System:</strong> Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulfophthalein) retention time. <strong>Immune System</strong> (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.</td>
</tr>
</tbody>
</table>
**Metabolic effects:** Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glyceral are increased. Protein is mobilized from most areas of the body (not the liver).

**Musculoskeletal:** Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocortilage growth is also inhibited.

**Ophthalmic:** Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

**Renal, Fluid, & Electrolytes:** Glucocorticoids can increase potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

**Skin:** Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

**Contraindications/Precautions/Warnings**
Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

**Adverse Effects**
Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when the drug is given. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with short-term antiinflammatory therapy occur relatively uncommonly. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

In dogs, glucocorticoids can increase liver enzymes (SAP>ALT) and cause vacuolar hepatopathy. Cats may show mild vacuolar changes, but enzymes are generally not affected.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

**Reproductive/Nursing Safety**
Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreatic, and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy.

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns. In humans, several studies suggest that amounts excreted in human breast milk are negligible with prednisone or prednisolone doses of 20 mg/day or less, or methylprednisolone doses less than or equal to 8 mg/day. Large doses for short periods may not harm the infant. Waiting 3–4 hours after the dose before nursing and using prednisolone rather than prednisone may result in a lower corticosteroid dose to offspring.

**Overdose/Acute Toxicity**
Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving glucocorticoids and may be of significance in veterinary patients:

**AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia

**ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.

**ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels

**CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.

**CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear

**DIGOXIN:** Secondary to hypokalemia, increased risk for arrhythmias

**DIURETICS, POTASSIUM-DEPLETING (furosemide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia

**EPHEDRINE:** May increase metabolism

**ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens

**INSULIN:** Requirements may increase in patients receiving glucocorticoids

**KETOCONAZOLE:** May decrease metabolism
MITOTANE: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency

NSAIDS: Administration of other ulcerogenic drugs with glucocorticoids may increase risk

PHENOBARBITAL: May increase the metabolism of glucocorticoids

PHENYTOIN: May increase the metabolism of glucocorticoids

RIFAMPIN: May increase the metabolism of glucocorticoids

VACCINES: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

**Laboratory Considerations**

- Glucocorticoids may increase serum cholesterol and urine glucose levels.
- Glucocorticoids may decrease serum potassium.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce T3 & T4 values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I131 by the thyroid may be decreased by glucocorticoids.
- Reactions to skin tests may be suppressed by glucocorticoids.
- False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.

**Monitoring**

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

**Client Information**

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects progress or become severe.

---

**GLUCOSAMINE/ CHONDROITIN SULFATE**

gluco-kose-a-meen/kon-droy-tin sul-fayt) Cosequin®

**NUTRITIONAL SUPPLEMENT**

**Prescriber Highlights**

- So-called nutraceutical that can be used as an adjunctive treatment for osteoarthritis or other painful conditions in horses, cats, dogs, etc; FLUTD in cats
- Well tolerated, but efficacy is uncertain
- Not a regulated drug; choose products carefully; large variation in commercially available products

**Uses/Indications**

These compounds may be useful in treating osteoarthritis or other painful conditions in domestic animals, but large, well-designed controlled clinical studies proving efficacy were not located. Additionally, since there is no FDA-approval process or oversight for these products, product quality and bioavailability may be highly variable. One study in dogs (McCarthy et al. 2007) showed some positive effect, but this study was not placebo controlled and compared responses versus carprofen. Another placebo-controlled, blinded study in dogs (Moreau et al. 2003), did not demonstrate statistically significant improvement after 60 days of treatment. An article reviewing the quality of evidence supporting the use of glucosamine-based nutraceuticals in equine joint disease, concluded that “… the quality of these studies is generally low. A poorly defined experimental paradigm makes balanced interpretation of individual studies difficult, and analysis of the body of literature as a whole virtually impossible.” (Pearson & Lindinger 2009)

These compounds potentially could be of benefit in cats with FLUTD (feline lower urinary tract disease) because of the presence of glycosaminoglycans as part of the protective layer of the urinary tract. Controlled studies have shown some positive effects in some cats, but overall did not appear to make a significant difference.

**Pharmacology/Actions**

Cartilage cells use glucosamine to produce glycosaminoglycans and hyaluronan. Glucosamine also regulates synthesis of collagen and proteoglycans in cartilage and has mild anti-inflammatory effects due to its ability to scavenge free radicals. Chondrocytes normally produce ample quantities of glucosamine from glucose and amino
Note:

**Doses**

Because of the variability in products available, it is recommended to choose a product that has been tested in the species for which it is marketed; consult the product label.

**DOGS:**

a) For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 13–15 mg/kg (of the chondroitin component) PO once daily (q24h). (Hardie et al. 2003)

b) For adjunctive treatment of cancer pain: Glucosamine/chondroitin: 15–30 mg/kg (of the chondroitin component) PO once daily (q24h) for 4–6 weeks then half the dose. (Lascelles 2003)

c) For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 13–15 mg/kg (of the chondroitin component) PO once daily or every other day (q24–48h). (Hansen 2003)

d) Label Recommendation as a Dietary Supplement for Cosequin®:

For Small Dogs (under 25 lbs): Initially, using Regular Strength capsules for cats and small dogs: under 10 lb.: ½ to 1 capsule daily; 10–24 lb.: 2 capsules daily (1 in AM; 1 in PM). Maintenance Administration (after initial 4–6 week period): under 10 lb. can often have their dosage reduced to ½ capsule daily or 1 capsule every other day. 10 to 24 lb. can often have their dosage reduced to 1 capsule daily.

For Medium and Large Dogs (>25 lbs): Initially, using Cosequin®DS (double strength) tablets or capsules: 25–49 lb.: 2 capsules daily (1 in AM; 1 in PM); 50–100 lb.: 3 capsules daily (2 in AM; 1 in PM); over 100 lb.: 4 capsules daily (2 in AM; 2 in PM). Maintenance Administration (after initial 4–6 week period): dogs can have their total daily dosage gradually lowered until maintenance level is reached.

Amount can be increased at any time depending on the pet’s needs. Tablets can be given as a treat or crumbled and mixed with the pet’s food. The capsules can be pulled apart and the contents sprinkled on the pet’s food. Wet or moist food works best. As an alternative, pets can be pilled or the capsules administered by wrapping in a small piece of food. (Label recommendations; Cosequin®—Nutramax)

**CATS:**

a) For adjunctive treatment of cancer pain: Glucosamine/chondroitin: 15–30 mg/kg (of the chondroitin component) PO once daily (q24h) for 4–6 weeks then half the dose. (Lascelles 2003)

b) For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 15–20 mg/kg (of the chondroitin component) PO once daily or every other day (q24–48h). (Hansen 2003)

c) Label Recommendation as a Dietary Supplement for Cosequin® For Cats: Initially: under 10 lb.: 1 capsule sprinkled on food daily; over 10 lb.: 2 capsules

**Contraindications/Precautions/Warnings**

No absolute contraindications were located for these compounds. As hypersensitivity reactions are a theoretical possibility, animals demonstrating prior hypersensitivity reactions to these compounds should not receive them.

In humans, glucosamine may exacerbate symptoms associated with asthma. Although this has not yet been reported in veterinary patients, caution is advised in patients with bronchoconstrictive conditions.

**Adverse Effects**

These products appear to be very well tolerated in dogs, cats, and horses. Adverse effects could potentially include some minor gastrointestinal effects (flatulence, stool softening). Since these products are often derived from natural sources, hypersensitivity reactions could occur.

**Reproductive/Nursing Safety**

No studies on the safety of these compounds in pregnant or lactating animals have been performed.

**Overdosage/Acute Toxicity**

Oral overdosage is unlikely to cause significant problems. The LD50 for the combined compound in rats is greater than 5 g/kg. Gastrointestinal effects may result. Changes in coagulation parameters could occur, but have not been documented to date.

Products that contain manganese could lead to manganese toxicity if given in very high dosages (above label recommendations) chronically.

**Drug Interactions**

No clinically significant drug interactions have been reported to date in animals. By reducing doxorubicin or etoposide inhibition of topoisomerase II, glucosamine may induce resistance to these agents. High dose chondroitin sulfate and/or glucosamine potentially could enhance the effects of warfarin, heparin, or other drugs that affect coagulation.

**Laboratory Considerations**

- High dose chondroitin and glucosamine theoretically could increase International Normalized Ratio (INR) in patients taking warfarin.

**Pharmacokinetics**

The pharmacokinetics of these compounds are hard to evaluate due to the different salts, lack of standards, etc. Both glucosamine HCl and glucosamine sulfate are absorbed in the gut after the salt is cleaved in the stomach. There exists controversy as to whether either salt of glucosamine is superior to the other. Theoretically, if the amount of glucosamine base contained in the product is equivalent, the amount absorbed should be as well. Most clinical studies in veterinary species have been done with the HCl salt. Purified, low molecular weight chondroitin appears to be absorbed from the gut. Reported bioavailability in horses for chondroitin sulfate is about 25%; glucosamine, about 2%; bioavailability in dogs is reportedly about 5% for chondroitin sulfate and 12% for glucosamine.

Onset of any clinical efficacy may require 2–6 weeks of treatment.

**In vitro** evidence exists, there is not solid evidence that using these compounds together improves clinical effect over either alone, but **in vivo** studies are ongoing.
Bioequivalence between products cannot be assumed and independent analysis has shown a wide variation in products.

Glucosamine and chondroitin sulfate are considered nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by any regulatory bodies. Oste-O-Guard concentrations. There are specific products marketed for use in animals, including None as pharmaceuticals. Supplements are available from a wide variety of sources and dosage forms include tablets, capsules and powder in a variety of forms.

VETERINARY-LABELED PRODUCTS:

### Dosage Forms/Regulatory Status

- Oste-O-Guard®
- Caniflex® Concentrated Powder
- Cosequin®
- Restor-A-Flex®
- OsteO-3®
- Arthri-Nu®
- ProMotion®
- Seraquin®
- Caniflex®
- Equi-Phar Flex®, etc.

Glucosamine and chondroitin sulfate are considered nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by regulatory bodies. Bioequivalence between products cannot be assumed and independent analysis has shown a wide variation in products.

### Client Information

- **Monitoring**
  - Clinical efficacy
  - Side effects are unlikely, but mild gastrointestinal upset has been reported in small animals. Should this be troublesome, contact your veterinarian.
  - Always use within 2–6 weeks of treatment.

- **Chemistry/Synonyms**
  - Glucosamine is most often available as either glucosamine HCl or glucosamine sulfate. It is an amino sugar that is synthesized in vivo by animal cells from glucose and glutamine.
  - Glucosamine (HCl or Sulfate) may also be known as: chitosamine, NSC-758, 2-amino-2-deoxy-beta-D-glucopyranose, G6SD-glucosamine, glucose-6-phosphate, or amino monosaccharide.
  - Chondroitin sulfate is an acid mucopolysaccharide/glycosaminoglycan that is found in most cartilaginous tissues. It is a long chain compound that contains Units of galactosamine and glucuronic acid.

- **Storage/Stability**
  - Because of the multiple products and product formulations available, check label for storage and stability (expiration date) information. Chondroitin sulfate is an extremely hygroscopic compound and, generally, these products should be stored in tight containers at room temperature. Avoid storing in direct sunlight.

### Domesticated Animal Dosages

#### Horses:

- **For navicular syndrome:** Using Cosequin® Concentrated Powder labeled for horses: 16.5 grams (5 scoops) in feed twice daily. (Hanson et al. 2001)
- **Label Recommendation as a Dietary Supplement for Cosequin® Concentrated Powder:** Initially: for horses under 600 lb., 2 scoops in AM and 2 scoops in PM. After 1 week: horses 600–1,200 lb., 3 scoops in AM and 3 scoops in PM; horses over 1,200 lb., 4 scoops in AM and 4 scoops in PM. The initial administration period is 2 to 4 weeks; if horse shows little or no response, extend initial amount for two more weeks.

- **Transition Period:** Do not lower amount until horse has begun to respond. After achieving a good response, reduce total daily amount by one level scoop each week. Gradually reducing the amount will help find an individual maintenance level. Suggested Maintenance Administration: horses under 600 lb., 1 scoop daily; horses 600–1,200 lb., 1–2 scoops daily; horses over 1,200 lb., 2 scoops daily. Amount can be increased at any time.

- Be may be top dressed on sweet feed. Add a small amount of water or molasses to get the powder to stick to dry feed. (Label and insert recommendations; Cosequin® Concentrated Powder—Nutramax Labs)

#### Monitoring

- Clinical efficacy
  - Onset of any clinical improvement may require 2–6 weeks of treatment.
  - Do not switch brands from that prescribed without first contacting your veterinarian.

### Prescriber Highlights

- **Context:**
  - Amino acid that may be useful in preventing/treating GI epithelium damage or pancreatitis (exocrine function)

### References

Little documentation for efficacy, but adverse effects unlikely

Uses/Indications
Glutamine has been used as a GI protectant and in an attempt to enhance GI healing in conditions where GI epithelium is damaged (Parvo enteritis, chemotherapy, etc.), pancreatitis, or when patients are under severe stress (critically ill). Animals that have an adequate dietary protein intake, are unlikely to benefit from exogenously administered glutamine.

A study that evaluated the efficacy of glutamine supplementation in cats with methotrexate-induced enteritis found no difference between cats supplemented with glutamine and those that were not. (Marks et al. 1999)

Pharmacology/Actions
Glutamine is a conditionally essential amino acid that is produced primarily in skeletal muscle and then released into the circulation. Glutamine is required for proper function of the immune system, GI tract, kidneys, and liver. Glutamine also serves as a precursor for glutathione, glutamate, purines, pyrimidines, and other amino acids.

Glutamine’s effects on the gastrointestinal tract are one of the primary areas of interest for its therapeutic use as an exogenously administered drug. When the body is under severe stress, it consumes more glutamine than it can produce and progressive muscle wasting occurs as it tries to meet glutamine requirements. There is some evidence that glutamine may have a role in intestinal cell proliferation and determination. When glutamine is depleted, intestinal epithelium can atrophy, ulcerate, or become necrotic. In patients undergoing cancer chemotherapy or radiotherapy, diminished glutamine levels in the gastrointestinal tract can cause increased GI toxicity. Supplementation of exogenous glutamine may help protect the GI from these effects.

Pharmacokinetics
Little information was located outside of what is described in the pharmacology section.

Contraindications/Precautions/Warnings
Because it is partially metabolized into ammonia and glutamate, use with caution in patients with severe hepatic insufficiency, severe behavior disorders or epilepsy.

Adverse Effects
Glutamine is well tolerated when used orally or intravenously. Potentially, it may have some CNS effects at high dosages.

Reproductive/Nursing Safety
There is insufficient data available documenting the safe use of glutamine during pregnancy or nursing.

Overdosage/Acute Toxicity
Overdosages are unlikely to be harmful. Doses of up to 40 grams per day IV have been tolerated in humans without ill effects. Because glutamine is partially metabolized to ammonia, patients with hepatic insufficiency may be adversely affected.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving glutamine and may be of significance in veterinary patients:

ANTICONVULSANT MEDICATIONS: Glutamine could potentially affect the efficacy of antiseizure medications (phenobarbital, potassium bromide, etc.). It is partially converted into glutamate, which can act as an excitatory neurotransmitter.

LACTULOSE: Theoretically, glutamine may antagonize the effects of lactulose in patients with hepatic encephalopathy.

Laboratory Considerations
• Glutamine may increase serum ammonia or glutamate levels.

Doses

DOGS & CATS:
  For adjunctive treatment of GI inflammatory conditions:
  a) 0.5 grams/kg PO daily (Wynn 2002)
  b) 0.5 gram/kg/day PO divided twice a day in the water or food. (Silverstein 2003)
  c) Animals not eating may benefit from 0.5 grams/kg per day divided into 2-3 doses and dissolved in drinking water. (Laflamme 2009)

Monitoring
• Efficacy

Client Information
• May be administered with food.

Chemistry/Synonyms
Glutamine is an aliphatic amino acid. It occurs as white crystals or crystalline powder and is soluble in water and practically insoluble in alcohol.

Glutamine may also be known as: glutamic acid, GLN, glutamate, glutaminate, levoglutamid, levoglutamine, L-glutamic acid, L-glutamic acid 5-amide, L-glutamine, L-glutamine, and Q.

Storage/Stability
Glutamine tablets and powder should be stored in tight containers at room temperature.
Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Glutamine is considered a nutrient. Glutamine may be purchased as L-glutamine 500 mg tablets, glutamine powder, or glutamic acid in 500 mg tablets, powder. Glutamic acid is rapidly degraded in the body to glutamine. Parenteral forms of glutamate may be available in other countries.

References

**GLYBURIDE**

glye-byoor-ide) DiaBeta®, Micronase®

**SULFONYLUREA ANTIDIABETIC AGENT**

**Prescriber Highlights**

- Human oral antidiabetic agent (Type II) that may be useful in cats
- Glipizide used more often when oral hypoglycemics are tried; glyburide may be useful if glipizide unavailable or if once a day dosing is important
- Contraindications: Severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidic conditions
- Caution: Untreated adrenal or pituitary insufficiency; thyroid, renal, or hepatic function impairment; prolonged vomiting; high fever; malnourishment or debilitated condition
- Adverse Effects: Cats: GI (i.e., vomiting), hypoglycemia, liver toxicity
- Drug interactions
- Do not confuse glipizide, glimepiride & glyburide

**Uses/Indications**

Glyburide is an alternative oral treatment for non-insulin dependent diabetes mellitus (NIDDM) in cats, particularly if glipizide is unavailable or if twice daily administration of glipizide is not tolerated (by cat or owner). Insulin therapy for cats with diabetes is generally preferred over oral treatments.

**Pharmacology/Actions**

Like glipizide and other oral sulfonylureas, glyburide lowers blood glucose concentrations in both diabetic and normal patients. While it is unknown how glyburide precisely lowers glucose, it initially stimulates secretion of endogenous functional beta cells in the pancreas. It also may enhance insulin activity at post receptor sites and reduce basal hepatic glucose production that may explain its effectiveness with long-term administration.

**Pharmacokinetics**

Glyburide appears to be well absorbed but bioavailability data is lacking. Food apparently does not have an effect on the absorptive characteristics of the drug. Glyburide is distributed throughout the body, including into the brain and across the placenta. Glyburide is apparently completely metabolized, presumably in the liver. Metabolites are excreted in both the feces and the urine. While its elimination half-life in cats is not known, once a day dosing appears to be effective in cats with NIDDM.

**Contraindications/Precautions/Warnings**

Oral antidiabetic agents are considered contraindicated with the following conditions: severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidic conditions. Glyburide should only be used when its potential benefits outweigh its risks in patients with untreated adrenal or pituitary insufficiency; thyroid, renal, or hepatic function impairment; prolonged vomiting; high fever; malnourishment or in debilitated condition.

Some patients with type II diabetes may have their disease complicated by the production of excessive amounts of cortisol or growth hormone that may antagonize insulin’s effects. These causes should be ruled out before initiating oral antidiabetic therapy.

**Adverse Effects**

Experience with glyburide is limited in veterinary medicine. Hypoglycemia, vomiting, icterus, and increased ALT (SGPT) levels are all potentially possible. Should toxicity develop, reinstitution of drug therapy may be attempted at a lower dosage after clinical signs resolve.

Other adverse effects that are possible (noted in humans) include: allergic skin reactions, arthralgia, bone marrow suppression, or cholestatic jaundice.

Glyburide may not be effective in cats demonstrating insulin resistance.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown if glyburide is excreted in milk.
Overdosage/Acute Toxicity

Profound hypoglycemia is the greatest concern after an overdose. In humans, severe hypoglycemia has occurred at relatively low dosages. Gut emptying protocols should be employed when warranted. Because its half-life is longer than glipizide, prolonged hypoglycemia may occur and blood glucose monitoring and treatment with parenteral glucose may be required for several days. Massive overdoses may also require additional monitoring (blood gases, serum electrolytes) and supportive therapy.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glyburide and may be of significance in veterinary patients:

- **ALCOHOL:** A disulfiram-like reaction (anorexia, nausea, vomiting) is possible
- **ANTIFUNGALS, AZOLE** (ketoconazole, itraconazole, fluconazole): May increase plasma levels of glyburide
- **BETA-BLOCKERS:** May potentiate hypoglycemic effect
- **CHLORAMPHENICOL:** May displace glyburide from plasma proteins
- **CIMETIDINE:** May potentiate hypoglycemic effect
- **CORTICOSTEROIDS:** May reduce efficacy
- **DIURETICS, THIAZIDE:** May reduce hypoglycemic efficacy
- **ISONIAZID:** May reduce hypoglycemic efficacy
- **MOA INHIBITORS:** May potentiate hypoglycemic effect
- **NIACIN:** May reduce hypoglycemic efficacy
- **PHENOTHIAZINES:** May reduce hypoglycemic efficacy
- **PHENOTYIN:** May reduce hypoglycemic efficacy
- **PROBENECID:** May potentiate hypoglycemic effect
- **SULFONAMIDES:** May displace glyburide from plasma proteins
- **SYMPATHOMIMETIC AGENTS:** May reduce hypoglycemic efficacy
- **THYROID AGENTS:** May reduce hypoglycemic effect
- **WARFARIN:** May displace glyburide from plasma proteins

Doses

- **CATS:**
  - For NIDDM:
    - a) Initial dose at 0.625 mg (1/2 of a 1.25 mg tablet) PO once daily. (Nelson 2000)
    - b) If cat is generally well, weight loss is mild, is not ketoacidotic, and does not have peripheral neuropathy, may try glyburide at: 2.5 mg (total dose) PO twice a day. (Daminet 2003)

Monitoring

- Weekly exams during first month of therapy including PE, body weight, urine glucose/ketones and several blood glucose exams.
- Adverse effects (vomiting, icterus), and occasional liver enzymes and CBC.

Client Information

- Clients should be informed of clinical signs to watch for that would indicate either hypoglycemia or hyperglycemia and be instructed to report these to the veterinarian.
- Compliance with dosing regimen should also be stressed.

Chemistry/Synonyms

An oral sulfonylurea antidiabetic agent, glyburide occurs as a white or nearly white, odorless or almost odorless, crystalline powder. As pH increases, solubility increases. At a pH of 4, solubility in water is about 4 micrograms/mL and at a pH of 9, 600 micrograms/mL. Glyburide has a pKa of 6.8.

Glyburide may also be known as: glibenclamide, glibenclamidum, glybenclamide, glybenzcyclamide, HB-419, and U-26452; many trade names are available.

Storage/Stability

Glyburide oral tablets should be stored in well-closed containers at room temperature.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Glyburide Oral Tablets: 1.25 mg, 2.5 mg, & 5 mg; micronized tablets: 1.5 mg, 3 mg, 4.5 mg & 6 mg; Glynase® PresTab (Pharmacia & Upjohn); DiaBeta® (Hoechst Marion Roussel); generic; (Rx)

Fixed dose combinations of glyburide and metformin are also available.

References

GLYCERIN, ORAL
(gli-ser-in) Osmoglyn®
OSMOTIC AGENT

Prescriber Highlights

- Oral osmotic that reduces intraocular & CSF pressure
- Contraindications: Patients with known hypersensitivity, anuria (well established), severe dehydration, severe cardiac decompensation, acute pulmonary edema.
- Caution: Hypovolemia, cardiac disease, or diabetes
- Adverse Effects: Vomiting (most common)

Uses/Indications
Oral glycerin is used primarily for the short-term reduction of IOP in small animals with acute glaucoma. It may also be considered for use to reduce increased CSF pressure.

The IOPLowering effect of glycerin may be more variable than with mannitol, but since it may be given orally, it may be more advantageous to use in certain cases.

Pharmacology/Actions
Glycerin in therapeutic oral doses increases the osmotic pressure of plasma so that water from extracellular spaces is drawn into the blood. This can decrease intraocular pressure (IOP). The amount of decrease in IOP is dependent upon the dose of glycerin, and the cause and extent of increased IOP. Glycerin also decreases extracellular water content from other tissues and can cause dehydration and decreased CSF pressure.

Pharmacokinetics
Glycerin is rapidly absorbed from the GI tract and decreases in IOP can be seen within 30 minutes; peak serum levels generally occur within 90 minutes and maximum decreases in IOP usually occur within an hour of dosing and persist for up to 10 hours. Glycerin is distributed throughout the blood and is primarily metabolized by the liver. About 10% of the drug is excreted unchanged in the urine. Serum half-life in humans is about 30–45 minutes.

Contraindications/Precautions/Warnings
Glycerin is contraindicated in patients hypersensitive to it. It is also contraindicated in patients with well-established anuria, that are severely dehydrated, severely cardiac decompensated, or with frank or impending acute pulmonary edema.

Glycerin should be used with caution in animals when the blood:ocular barrier is not intact (hyphema, uveitis), and those with hypovolemia, cardiac disease, or diabetes. One reference states that glycerine is contraindicated in dogs with diabetes mellitus, dehydration, and cardiac or renal disease (Reinstein et al. 2009). Another states that heart failure is a contraindication and use should be avoided in patients with chronic renal failure or compromised renal function (Pickett 2009). Acute urinary retention should be avoided during the preoperative period.

Adverse Effects
Vomiting after dosing is the most common adverse effect seen with glycerin use. In humans, headache, nausea, thirst, and diarrhea have also been reported.

Reproductive/Nursing Safety
The safety of this drug in pregnant animals is unknown; use only when potential benefits outweigh the risks of therapy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

No specific information on glycerin was located for lactation safety.

Overdosage/Acute Toxicity
No specific information was located, but cardiac arrhythmias, non-ketotic hyperosmolar coma, and severe dehydration have been reported with the drug.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving glycerin and may be of significance in veterinary patients:

CARBONIC ANHYDRASE INHIBITORS (e.g., acetazolamide, dichlorphenamide): Concomitant administration of carbonic anhydrase inhibitors or topical miotic agents may prolong the IOP-reducing effects of glycerin.

MIOTIC AGENTS, TOPICAL: Concomitant administration topical miotic agents may prolong the IOP-reducing effects of glycerin.

Doses

**DOGS/CATS:**

For acute glaucoma:

a) 1–2 g/kg PO as a 50% oral solution (Herring 2003), (Reinstein et al. 2009)

b) 1–2 mL/kg (of a 90% solution) PO usually as a single dose; withhold water for 3–4 hours after administration. Author uses glycerin often because it is quicker and easier to administer than mannitol and is usually effective. (Collins 2006)
c) As an “emergency drug” in place of aqueous centesis to rapidly reduce IOP: Using glycerin syrup (90%) at 1.1–2.2 mL/kg (0.5–1 mL/lb); mixing with an equal volume of ice cream or milk will help reduce vomiting. (Pickett 2009)

**Monitoring**
- IOP
- Urine output
- Hydration status

**Chemistry/Synonyms**
A trihydric alcohol, glycerin occurs as clear, sweet-tasting, syrupy, hygroscopic liquid that has a characteristic odor. It is miscible with water and alcohol, but not miscible in oils. Glycerin solutions are neutral to litmus.
Glycerin may also be known as: E422, glycerol, glicerol, glycerin, glycercine, and glycerolum; many trade names are available.

**Storage/Stability**
Glycerin oral solution should be stored in tight containers at room temperature; protect from freezing.

**Dosage Forms/Regulatory Status**
**VETERINARY-LABELED PRODUCTS:** None for systemic use.

**HUMAN-LABELED PRODUCTS:**
Glycerin Oral Liquid: 50% (0.6 g glycerin/mL) in 220 mL; Osmoglyn® (Alcon); (Rx)
Glycerin is also available in a topical ophthalmic solution and as suppositories or liquid for rectal laxative use. USP glycerin 90% could be used for oral use in small animals (see doses above).

---

**GLYCOPRYRROLATE**
(glye-koe-pryo-ro-che-late) Robinul®
*ANTICHOLINERGIC (ANTIMUSCARINIC)*

**Prescriber Highlights**
- Synthetic antimuscarinic agent similar to atropine available both orally & parenterally; used for a variety of indications (bradycardia, premed, antidote, etc.)
- Contraindicated in conditions where anticholinergic effects would be detrimental (e.g., narrow angle glaucoma, tachycardias, ileus, urinary obstruction, etc.)
- Adverse effects are dose related & anticholinergic in nature, including: dry secretions; initial bradycardia, then tachycardia; slowing of gut & urinary tract motility; mydriasis/cycloplegia
- Drug interactions

**Uses/Indications**
Glycopyrrolate injection is FDA-approved for use in dogs and cats. The FDA-approved indication for these species is as a preanesthetic anticholinergic agent. The drug is also used to treat sinus bradycardia, sinoatrial arrest, and incomplete AV block, where anticholinergic therapy may be beneficial. When cholinergic agents such as neostigmine or pyridostigmine are used to reverse neuromuscular blockade due to non-depolarizing muscle relaxants, glycopyrrolate may be administered simultaneously to prevent the peripheral muscarinic effects of the cholinergic agent.

**Pharmacology/Actions**
An antimuscarinic with similar actions as atropine, glycopyrrolate is a quaternary ammonium compound and, unlike atropine, does not cross appreciably into the CNS. It, therefore, should not exhibit the same extent of CNS adverse effects that atropine possesses. For further information, refer to the atropine monograph.

**Pharmacokinetics**
Quaternary anticholinergic agents are not completely absorbed after oral administration, but quantitative data reporting the rate and extent of absorption of glycopyrrolate is not available. In dogs, following IV administration, the onset of action is generally within one minute. After IM or SC administration, peak effects occur approximately 30–45 minutes post injection. The vagolytic effects persist for 2–3 hours and the antisialagogue (reduced salivation) effects persist for up to 7 hours. After oral administration, the antimuscarinic effects of glycopyrrolate may persist for 8–12 hours.
Little information is available regarding the distributory aspects of glycopyrrolate. Being a quaternary ammonium compound, glycopyrrolate is completely ionized; therefore, it has poor lipid solubility and does not readily penetrate into the CNS or eye. Glycopyrrolate crosses the placenta only marginally; it is unknown if it is
Glycopyrrolate is eliminated rapidly from the serum after IV administration and virtually no drug remains in the serum 30 minutes to 3 hours after dosing. Only a small amount is metabolized and the majority is eliminated unchanged in the feces and urine.

**Contraindications/Precautions/Warnings**

One manufacturer (Fort Dodge) of the veterinary product lists contraindications to glycopyrrolate’s use in dogs and cats hypersensitive to it and that it should not be used in pregnant animals.

Antimuscarinic agents should be used with extreme caution in patients with known or suspected GI infections. Atropine or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Antimuscarinic agents should be used with caution in patients with hepatic or renal disease, geriatric or pediatric patients, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, or esophageal reflux. These drugs can produce sinus tachycardia and predispose hypotensive patients to cardiac arrhythmias (including ventricular fibrillation).

**Adverse Effects**

With the exceptions of rare CNS adverse effects and being slightly less arrhythmogenic, glycopyrrolate can be expected to have a similar adverse effect profile as atropine. The manufacturer of the veterinary product (Fort Dodge) lists only mydriasis, tachycardia, and xerostomia as adverse effects in dogs and cats at the doses they recommend. For more information, refer to the atropine monograph.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

No specific lactation safety information was found; however, it is unlikely to be excreted into milk in substantial quantities because of its quaternary structure.

**Overdosage/Acute Toxicity**

In dogs, the LD₅₀ for glycopyrrolate is reported to be 25 mg/kg IV. Doses of 2 mg/kg IV daily for 5 days per week for 4 weeks demonstrated no signs of toxicity. In the cat, the LD₅₀ after IM injection is 283 mg/kg. Because of its quaternary structure, it would be expected that minimal CNS effects would occur after an overdose of glycopyrrolate when compared to atropine. See the information listed in the atropine monograph for more information.

**Drug Interactions**

Glycopyrrolate would be expected to have a similar drug interaction profile as atropine. The following drug interactions have either been reported or are theoretical in humans or animals receiving atropine or glycopyrrolate and may be of significance in veterinary patients:

- **AMANTADINE**
- **ANTICHOLINERGIC AGENTS (other)**
- **ANTICHOLINERGIC MUSCLE RELAXANTS**
- **ANTIHISTAMINES (e.g., diphenhydramine)**
- **DISOPYRAMIDE**
- **MEPERIDINE**
- **PHENOTHIAZINES**
- **PROCAINAMIDE**
- **PRIMIDONE**
- **TRICYCLIC ANTIDEPRESSANTS (e.g., amitriptyline, clomipramine)**
- **AMITRAZ**: Atropine may aggravate some signs seen with amitraz toxicity; leading to hypertension and further inhibition of peristalsis
- **ANTACIDS**: May decrease PO atropine absorption; give oral atropine at least 1 hour prior to oral antacids
- **CORTICOSTEROIDS (long-term use)**: may increase intracocular pressure
- **DIGOXIN (slow-dissolving)**: Atropine may increase serum digoxin levels; use regular digoxin tablets or oral liquid
- **KETOCONAZOLE**: Increased gastric pH may decrease GI absorption; administer atropine 2 hours after ketoconazole
- **METOCLOPRAMIDE**: Atropine and its derivatives may antagonize the actions of metoclopramide

**Doses**

**DOGS**:

As an adjunct to anesthesia:
- a) 0.011 mg/kg IV, IM, or SC (Package Insert; Robinul®-V —Fort Dodge)
- b) 0.01–0.02 mg/kg SC or IM (Bellah 1989)

For adjunctive therapy of bradyarrhythmias:
- a) 0.011 mg/kg IV or IM (Russell & Rush 1995)
- b) Associated with anesthesia: 0.005–0.01 mg/kg IV (Pablo 2003)
c) For bradyarrhythmias (sinus bradycardia, high-grade 2nd-degree and 3rd-degree AV block) produced by increased vagal tone: 0.05–0.1 mg/kg IV. (Muir 2008)
To reduce hypersialism:
a) 0.01 mg/kg SC as needed (Krahwinkel 1989)

**CATS:**
As an adjunct to anesthesia:
a) 0.011 mg/kg IM, for maximum effect give 15 minutes prior to anesthetic administration (Package Insert; Robinul®-V—Fort Dodge)
For bradyarrhythmias:
a) 0.005–0.01 mg/kg IV or IM, 0.01–0.02 mg/kg SC (Tilley & Miller 1986)
b) Associated with anesthesia: 0.005–0.01 mg/kg IV (Pablo 2003)

**FERRETS:**
As a premed:
a) 0.01 mg/kg SC or IM (Williams 2000)
b) 0.01–0.02 mg/kg IM or IV (Vella 2009)

**RABBITS/RODENTS/SMALL MAMMALS:**
a) Rabbits: For prevention of bradycardia and to decrease airway and salivary secretions: 0.01–0.1 mg/kg IM, SC; 0.01 mg/kg IV (Ivey & Morrisey 2000)
b) Rabbits: As adjunct to anesthesia: 0.01–0.02 mg/kg SC as needed (Huerkamp 1995)
c) As a preanesthetic: Rodents: 0.01–0.02 mg/kg IM or SC. Rabbits: 0.01–0.1 mg/kg IM or SC. As part of an injectable anesthesia protocol in rabbits: acepromazine (0.2 mg/kg), plus oxymorphone (0.1 mg/kg), plus glycopyrrolate (0.01 mg/kg) IM. (Bennett 2009)

**HORSES:** (Note: ARCI UCGFS Class 3 Drug)
For treatment of bradyarrhythmias:
a) 0.005–0.01 mg/kg (5–10 micrograms/kg) IV (Mogg 1999)
As a bronchodilator:
a) Initially, 2–3 mg IM two to three times daily for a 450 kg animal (Beech 1987)
To control muscarinic adverse effects associated with imidocarb therapy:
a) 0.0025 mg/kg IV (Donnellan et al. 2003)

**REPTILES:**
a) For bradycardia (prolonged or profound) associated with anesthesia: 0.01 mg/kg IM, IV or IC (intracoelomic). (Mehler 2009)

**Monitoring**
- Dependent on route of administration, dose, and reason for use. See the atropine monograph for more information.

**Client Information**
- Parenteral glycopyrrolate administration is best performed by professional staff and where adequate cardiac monitoring is available.
- If animal is receiving glycopyrrolate tablets, allow animal free access to water and encourage drinking if dry mouth is a problem.

**Chemistry/Synonyms**
A synthetic quaternary ammonium antimuscarinic agent, glycopyrrolate occurs as a bitter-tasting, practically odorless, white, crystalline powder with a melting range of 193–198°C. One gram is soluble in 20 mL of water; 30 mL of alcohol. The commercially available injection is adjusted to a pH of 2–3 and contains 0.9% benzyl alcohol as a preservative.

Glycopyrrolate may also be known as: glycopyrronium bromide, AHR-504, Acpan®, AmTech®, Gastrodyn®, Glycostigmin®, and Robinul®.

**Storage/Stability**
Glycopyrrolate tablets should be stored in tight containers and both the injection and tablets should be stored at room temperature (15–30°C).

Glycopyrrolate is stable under ordinary conditions of light and temperature. It is most stable in solution at an acidic pH and undergoes ester hydrolysis at pH’s above 6.

**Compatibility/Compounding Considerations**
Although stability information was not located: glycopyrrolate injection has been mixed in syringes with acepromazine, buprenorphine, morphine and ketamine.

Glycopyrrolate injection is physically **compatible** with glycopyrrolate: atropine sulfate, benzquinamide, chlorpromazine HCl, codeine phosphate, diphenhydramine HCl, droperidol, droperidol/fentanyl, hydromorphone, hydroxyzine HCl, lidocaine HCl, meperidine HCl, meperidine HCl/promethazine HCl, morphine sulfate, neostigmine methylsulfate, oxymorphone HCl, procaine HCl, prochlorperazine HCl, promazine HCl, promethazine HCl, pyridostigmine Br, scopolamine HBr, and trimethobenzamide HCl.

The following drugs are reportedly physically **incompatible** with glycopyrrolate: chloramphenicol sodium succinate, dexamethasone sodium phosphate, diazepam, dimenhydrinate, methohexital sodium, methylprednisolone sodium succinate, pentazocine lactate, pentobarbital sodium, secobarbital sodium, sodium bicarbonate, and thiopental sodium. Other alkaline drugs (e.g., thiamylal) would also be expected to be **incompatible** with glycopyrrolate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

**Dosage Forms/Regulatory Status**
VETERINARY-LABELED PRODUCTS:
Glycopyrrolate for Injection: 0.2 mg/mL in 20 mL vials; Robinul®-V (Pfizer), generic; (Rx). FDA-approved for use in dogs and cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Glycopyrrolate Tablets: 1 mg & 2 mg; Robinul® & Robinul Forte® (Horizon); generic; (Rx)
Glycopyrrolate Injection: 0.2 mg/mL in 1 mL, 2 mL, 5 mL, & 20 mL vials; Robinul® (Robins); generic; (Rx)

References

GOLD SALTS, INJECTABLE GOLD SODIUM THIOMALATE
(gold soo-de-um thye-oh-tha-mate) Aurothiomalate, Aurolate®, Myochrisine®
AUROTHIOGLUCOSE
(aur-oh-thye-oh-gloo-lose) Solganal®
INJECTABLE GOLD IMMUNOSUPPRESSIVES
Prescriber Highlights

- Aurothioglucose may no longer be available commercially; potentially may substitute with gold sodium thiomalate (aurothiomalate)
- Injectable administered gold; for pemphigus complex in small animals or plasmacytic stomatitis/pyodermatitis in cats; may also be useful for pemphigus in goats or horses
- Can be quite toxic & expensive, intensive ongoing monitoring required
- Considered contraindicated in SLE (exacerbates), renal or hepatic disease, preexisting hematologic abnormalities, severe debilitation, or uncontrolled diabetes
- Possible teratogen
- Litany of serious adverse effects possible; pain on injection

Note: Aurothioglucose has traditionally been the injectable gold compound used in veterinary medicine, but it is no longer commercially available. Some now use gold sodium thiomalate (aurothiomalate) in its place. The following monograph primarily applies to aurothioglucose, but the two drugs are thought to have similar actions, adverse effects, etc. Doses specific for gold sodium thiomalate are noted in the dosage section.

Uses/Indications
In human medicine, gold compounds are used primarily as a treatment for rheumatoid arthritis that has not adequately responded to less toxic treatment modalities. In veterinary medicine (primarily small animal medicine), its use has been generally for treating immune-mediated serious skin disorders such as pemphigus complex in dogs or cats and plasmacytic stomatitis/pyodermatitis in cats. Gold salts have also been used to treat goats and horses with pemphigus.

Pharmacology/Actions
Injectable gold compounds have antiinflammatory, antirheumatic, immunomodulating, and antimicrobial (in vitro) effects. The exact mechanisms for these actions are not well understood. Gold is taken up by macrophages where it inhibits phagocytosis and may inhibit lysosomal enzyme activity. Gold also inhibits the release of histamine, and production of prostaglandins. While gold does have antimicrobial effects in vitro, it is not clinically useful for this purpose.

Pharmacokinetics
After IM injection, aurothioglucose is quite rapidly absorbed and peak serum concentrations are reached in 4-6 hours. It is distributed to several tissues (liver, kidney, spleen, bone marrow, adrenals, and lymph nodes), but highest levels are found in the synovium. In plasma, 95% is bound to plasma proteins. Gold salts may be found in the epithelial cells in the renal tubules years after dosing has ended. Plasma half-lives increase in length after multiple doses have been given. These values have ranged from 21–168 hours in humans. Approximately 70% of a dose is excreted by the kidneys, while the remaining 30% is excreted in the feces.

There appears to be no correlation with serum levels and efficacy. It usually takes from 6–12 weeks for a beneficial effect to be noted after beginning therapy.

Contraindications/Precautions/Warnings
Contraindications for chrysotherapy (gold therapy) include patients with renal or hepatic disease, SLE (lupus erythematosus, diabetes mellitus (uncontrolled), severe debilitation, and preexisting hematologic disorders.

Do not administer these compounds intravenously.
Adverse Effects
Veterinary experience with these agents is limited. Pain at the injection site is common and some animals may develop thrombocytopenia with petechiae and ecchymoses. One author (Kummel 1995), reports that four pemphigus canine cases treated with aurothioglucose given immediately after cessation of azathioprine, developed a fatal toxic epidermal necrolysis. Other adverse effects noted in cats or dogs include stomatitis, hepatic necrosis or renal dysfunction.

Adverse reactions seen in people include: mucocutaneous reactions, which are fairly common (15–20%) and are characterized by rashes, (with or preceded by pruritus), and mucosal lesions (usually seen as a stomatitis). Hematologic reactions (thrombocytopenia, leukopenia, aplastic anemias), although rare in humans, can be life threatening. Renal effects are generally mild and if noted early, reversible with cessation of therapy. Proteinuria is an early sign associated with the proximal tubule damage that gold can cause. Reversible pulmonary infiltrates have been noted, but are reversible when therapy is discontinued. Enterocolitis, which may be fatal, has been reported in rare instances.

Because of the serious nature of these adverse reactions, adequate patient monitoring is essential.

Reproductive/Nursing Safety
The safety of aurothioglucose or gold sodium thiomalate has not been established during pregnancy, and these drugs should only be used when the potential benefits outweigh the risks involved. In humans, the FDA categorizes them as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Injectable gold is excreted in milk. Trace amounts appear in the serum and red blood cells of nursing offspring. As this may cause adverse effects in nursing offspring, switching to milk replacer is recommended if gold therapy is to be continued in the dam. Because gold is slowly excreted, persistence in milk will occur even after the drug is discontinued.

Overdosage/Acute Toxicity
Overdosages resulting from a too rapid increase in dosage are exhibited by rapid development of toxic signs, primarily renal (hematuria, proteinuria) and hematologic (thrombocytopenia, granulocytopenia) effects. Other clinical signs include: nausea, vomiting, diarrhea, skin lesions, and fever.

Treat with dimercaprol (BAL) to chelate the gold and treat the hematologic and renal effects supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving injectable gold compounds and may be of significance in veterinary patients:

CYTOTOXIC AGENTS (including high dose corticosteroids): Auranofin’s safety when used with these agents has not been established; use with caution

PENICILLAMINE or ANTIMALARIAL DRUGS: Use with gold salts is not recommended due to the increased potential for hematologic or renal toxicity

Doses
Note: Dosages below are for the product aurothioglucose, unless otherwise noted; however, dosing for both drugs appear to be equivalent.

DOGS:
For canine pemphigus foliaceus/vulgaris:
   a) Gold sodium thiomalate: 1–5 mg IM as a test dose then 1 mg/kg IM once weekly. Need to use initially with glucocorticoids as gold therapy may take 6–8 weeks to take effect. Side effects include skin lesions, thrombocytopenia and toxic epidermal necrolysis. (Logas 2005)
   b) Gold sodium thiomalate: 1–5 mg (1 mg for small patients; 5 mg for large patients) IM as a test dose then 1 mg/kg IM once weekly until remission, then taper to monthly. (Morris 2004)
   c) For those cases where corticosteroids and/or azathioprine are ineffective or causing unacceptable adverse effects: Discontinue azathioprine for one month and then give 1 mg/5 kg of body weight IM weekly for 10 weeks and then monthly thereafter. Note: Before treating, the reader is advised to refer to the full reference for additional information. (Kummel 1995)
   d) 1 mg/kg IM (the paraspinal muscles work best) weekly for 6–12 weeks; then decrease to every other week and if possible, once monthly. Rarely, may be able to discontinue injections if free from clinical signs for 6 months after switching to once monthly injections. Corticosteroids must usually be used with gold therapy. (White 2000)

CATS:
   a) For pemphigus complex or plasmacytic/pododermatitis: Gold sodium thiomalate: 1–5 mg IM as a test dose then 1 mg/kg IM once weekly. Need to use initially with glucocorticoids as gold therapy may take 6–8 weeks to take effect. Side effects include skin lesions, thrombocytopenia and toxic epidermal necrolysis. (Logas 2005)
   b) For pemphigus complex (rescue drug) or plasmacytic/pododermatitis: Gold sodium thiomalate: 1–5 mg (1 mg for small patients; 5 mg for large patients) IM as a test dose then 1 mg/kg IM once weekly until remission, then taper to monthly. (Morris 2004)
   c) 1 mg/kg IM per week. Clinical response may take 6–8 weeks and combination with glucocorticoids is recommended. May be associated with renal dysfunction, drug rupions, hepatic necrosis and thrombocytopenia. (Shaw 2003)
   d) For idiopathic pruritus when nothing else works: 1 mg/kg IM every 7 days until remission (8–20 weeks), then 1 mg/kg IM every 4 weeks (Hnilica 2003)

HORSES:
   a) Give 20 mg IM and then 40 mg IM one week apart. If no adverse effects (stomatitis, urticaria, sloughing, blood dyscrasias), give 1 mg/kg IM weekly until observing a response (6–12 weeks). Tailor maintenance therapy to the individual, which may involve biweekly or monthly therapy. Treatment can be very expensive. Perform weekly CBC/urinalysis for the first month, then monthly if no abnormalities. (Rees 2004)

Monitoring
   Urinalysis—baseline, then weekly
   CBC—baseline, then every 2 weeks; Note: eosinophilia may denote impending reactions
   Renal and hepatic function tests; baseline and periodic. After the patient is on maintenance therapy, hemograms and urinalyses may be done every month or two.
Client Information

Clients should be instructed to notify the veterinarian if pruritus, rash, or diarrhea develops, or if the animal becomes ill or depressed.

Chemistry/Synonyms

Gold sodium thiomalate occurs as an odorless, or practically odorless, yellow powder containing approximately 50% gold. It is very soluble in water. The injection is a light yellow to yellow solution with a pH of 5.8–6.5 and contains benzyl alcohol as a preservative.

Gold sodium thiomalate may also be known as aurothiomalate, Aurolate®, and Myochrisine®.

Storage/Stability

Protect these products from light and store between 15–30° C; avoid freezing. A five-year expiration date is assigned after manufacture. Do not mix with any other compound when injecting.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Gold Sodium Thiomalate Injection: 50 mg/mL in 2 mL & 10 mL vials, and 2 mL & 1 mL fill in 2 mL single-dose vials & 10 mL multiple-dose vials; Aurolate® (Pasadena); Myochrisine® (Taylor); generic; (Rx)

References

GONADORELIN

(goe-nad-o-rell-in) Cystorelin®, Fertagyl®, Factrel®

HORMONAL AGENT

Prescriber Highlights

❖ Hypothalamic hormone used to treat ovarian cysts & other reproductive disorders in a variety of species
❖ Duration of action is very short (minutes)
❖ Contraindications & adverse effects: None reported
❖ No slaughter or milk withdrawal when used as labeled

Uses/Indications

Gonadorelin is indicated (FDA-approved) for the treatment of ovarian follicular cysts in dairy cattle. Additionally, gonadorelin has been used in cattle to reduce the time interval from calving to first ovulation and to increase the number of ovulations within the first 3 months after calving. This may be particularly important in increasing fertility in cows with retained placenta.

In dogs, gonadorelin has been used experimentally to help diagnose reproductive disorders or to identify intact animals versus castrated ones by maximally stimulating FSH and LH production. It has also been used experimentally in dogs to induce estrus through pulsatile dosing. While apparently effective, specialized administration equipment is required for this method.

Gonadorelin has been used in cats as an alternate therapy to FSH or hCG to induce estrus in cats with prolonged anestrus. In Europe, a synthetic analogue buserelin has been used in horses to stimulate cyclic estrus. Its efficacy rates poorly when compared to an artificial light program, however.

In human medicine, gonadorelin has been used for the diagnosis of hypothalamic-pituitary dysfunction, cryptorchidism, and depression secondary to prolonged severe stress.

Pharmacology/Actions

Gonadorelin is a synthetic form of GnRH and stimulates the production and the release of FSH and LH from the anterior pituitary. Secretion of endogenous GnRH from the hypothalamus is thought to be controlled by several factors, including circulating sex hormones.

Gonadorelin causes a surge-like release of FSH and LH after a single injection. In cows and ewes, this can induce ovulation, but not in estrus mares. A constant infusion of gonadorelin will initially stimulate LH and FSH release, but after a period of time, levels will return to baseline.

Pharmacokinetics

After intravenous injection in pigs, gonadorelin is rapidly distributed to extracellular fluid, with a distribution half-life of about 2 minutes. The elimination half-life of gonadorelin is approximately 13 minutes in the pig.

After intravenous injection in humans, gonadorelin reportedly has a plasma half-life of only a few minutes. Within one hour, approximately half the dose is excreted in the urine as metabolites.

Contraindications/Precautions/Warnings

None reported on the label.
Adverse Effects
No reported adverse reactions were located for this agent. Synthetically prepared gonadorelin should not cause any hypersensitivity reactions. This may not be the case with pituitary-obtained LH preparations or hCG.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

No specific lactation safety information was listed for this drug.

Overdosage/Acute Toxicity
In doses of up to 120 micrograms/kg, no untoward effects were noted in several species of test animals. Gonadorelin is unlikely to cause significant adverse effects after inadvertent overdosage.

Drug Interactions
■ None noted

Doses
■ DOGS:
  a) GnRH stimulation test to differentiate castration from cryptorchidism: Take pre-sample, give 50 micrograms gonadorelin (GnRH) IM, 2–3 hours later take post-injection sample. Castrated dogs have testosterone concentrations <0.1 ng/mL and GnRH does not stimulate. (Pinto 2007)
  b) GnRH stimulation test to determine if dog has retained testicle: Take pre-sample, give gonadorelin 2.5 micrograms/kg IM (if very small dog use 25 micrograms total dose instead) and take second sample in 60-90 minutes. (Freshman 2009)
  c) To aid in the descent of cryptorchid testes: 50–100 micrograms SC or IV; if no response give additional dose in 4–6 days (Cox 1986)
  d) To increase libido in male dogs: Anecdotally, 50–100 micrograms IM once daily for 3 days. An elevated progesterone level (>2 ng/mL) measured 1–2 weeks post treatment verifies success. (Purswell 1999)

■ CATS:
  a) To stimulate ovulation after mating: 25 micrograms IM after mating (Morgan 1988)
  b) For infertility, reduced libido, testis descent in male cats: 1 microgram/kg every 2–3 days (Verstegen 2000)
  c) To detect ovarian remnants in queens after ovariohysterectomy: 25 micrograms per cat. A progesterone level (>1 ng/mL) measured 1–2 weeks post treatment verifies presence of ovarian tissue in the abdomen. (Purswell 1999)

■ FERRETS:
  a) 20 micrograms IM; repeat in one week as necessary. Most effective 14 days after onset of estrus (Williams 2000)

■ CATTLE:
  To treat of ovarian cysts in cattle:
  a) 100 micrograms IM or IV (Package Insert; Cystorelin®—Ceva)
  b) 100 micrograms IM per cow (Package insert; Factrel®—Fort Dodge)

■ SHEEP & GOATS:
  a) To induce ovulation outside of the breeding season in the doe: 100 micrograms injected daily for 4–5 days (Smith 1986)

Chemistry/Synonyms
A hormone produced by the hypothalamus, gonadorelin is obtained from natural sources or is synthetically produced. It is a decapeptide that occurs as white or faintly yellowish-white powder. One gram is soluble in 25 mL of water or in 50 mL of methyl alcohol. 50 micrograms of gonadorelin acetate is approximately equivalent to 31 Units. The commercially available products in the United States are the diacetate decahydrate (Cystorelin®, others) and HCl (Factrel®) salts.

Storage/Stability
The manufacturers recommend storing gonadorelin in the refrigerator (2-8°C). There is very little information available on the stability and compatibility of gonadorelin. Because bacterial contamination can inactivate the product, it has been recommended that multi-dose vials be used completely and as rapidly as possible.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Gonadorelin (diacetate tetrahydrate) for Injection: 50 micrograms/mL, 2 mL single-use or 10 mL multi-dose vials; Cystorelin® (Merial); Fertagyl® (Intervet); Fertinal®, Ovacyst®, (Teva); (Rx). FDA-approved for use in dairy cattle. There are no withdrawal times required for either milk or slaughter.

Gonadorelin HCl Solution for Injection: 50 micrograms/mL in 2 mL single-use, and 20 mL multi-dose vials; Factrel® (Pfizer); (Rx). FDA-approved for use in cattle. No withdrawal period required.

**HUMAN-LABELED PRODUCTS:**

Gonadorelin HCl Powder for Injection (lyophilized): 100 micrograms (as hydrochloride) and 500 micrograms (as hydrochloride) with 2.5 mL sterile diluent; Fertagyl® (Merial); Fertinal®, Ovacyst® (Teva); (Rx). FDA-approved for use in humans. No withdrawal period required.
Granisetron is an alternative to other 5-HT3 receptor antagonists (e.g., ondansetron or dolasetron) for the treatment of severe vomiting or prophylaxis before administering antineoplastic drugs such as cisplatin that can cause severe vomiting.

**Pharmacology/Actions**

Granisetron, like ondansetron or dolasetron, exerts its anti-nausea and antiemetic actions by selectively antagonizing 5-hydroxytryptamine3 (5-HT3; serotonin3) receptors. These receptors are found primarily in the CNS chemoreceptor trigger zone, on vagal nerve terminals and enteric neurons in the GI tract. Chemotherapy associated vomiting in cats is believed primarily due to activation of 5-HT3 receptors in the chemoreceptor trigger zone (CTZ), but in dogs, enteric and vagal receptors may be more important.

**Pharmacokinetics**

No pharmacokinetic data for dogs or cats was located. In humans, granisetron is rapidly absorbed after oral dosing and peak levels occur in about 2 hours. Oral bioavailability is only 60% due to first-pass metabolism in the liver. The presence of food can decrease AUC by 5%, but increase peak levels by 30%. Granisetron has a volume of distribution of about 3 L/kg and plasma protein binding is approximately 65%. The drug is metabolized in the liver, primarily via demethylation and oxidation and then conjugation. Less than 20% is excreted unchanged in the urine; the remainder is eliminated in the urine and feces as metabolites. Elimination half-life varies considerably, with reported values from about 1–30 hours. Cancer patients appear to have longer elimination half-lives than do healthy adults.

**Contraindications/Precautions/Warnings**

There are no known contraindications to using this medication in dogs or cats. In humans, granisetron is contraindicated in patients hypersensitive to it and it should not be used to treat vomiting associated with apomorphine (see Drug Interactions).

No dosage adjustments are required in elderly patients or those with impaired renal or hepatic function. Granisetron may mask the signs associated with progressive ileus and/or gastric distention; it should not replace required nasogastric suction.

**Adverse Effects**

Because of limited use in dogs and cats, a comprehensive adverse effect profile for granisetron is not known, however, it appears to be tolerated well.

In humans, the most common adverse effect reported is headache. Other adverse effects that may occur include abdominal pain, constipation or diarrhea, asthenia, or somnolence. Rarely, hypersensitivity reactions or cardiovascular effects (arrhythmias, chest pain, hypotension) have been reported.

**Reproductive/Nursing Safety**

Safety in pregnancy is not clearly established, but high dose studies in rodents and rabbits did not demonstrate overt fetal toxicity or teratogenicity. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known if granisetron enters milk, but it is probably safe to use during nursing.

**Overdosage/Acute Toxicity**

Limited information is available. An overdose of 38.5 mg in a person caused only a slight headache. Observation and, if required, supportive treatment are suggested.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving granisetron and may be of significance in veterinary patients:

- **APOMORPHINE**: Profound hypotension can occur.
KETOCONAZOLE: May inhibit the metabolism of granisetron
PHENOBarBITAL: Can induce the metabolism of granisetron

Laboratory Considerations
No specific laboratory concerns associated with granisetron

Doses

**DOGS/CATS:**
- a) Cats (with pancreatitis): 0.1–0.5 mg/kg PO or IV q12–24h. (Zoran 2006), (Washabau 2006b)
- b) Dogs or Cats: 0.1–0.5 mg/kg PO or IV twice daily. (Washabau 2006a)

Monitoring
Clinical efficacy

Client Information
This drug is usually used on an inpatient basis or during outpatient visits for chemotherapy
If used orally on an outpatient basis, have client contact veterinarian for further instructions if vomiting is not controlled or if the dose is vomited up after administering

Chemistry/Synonyms
Granisetron HCl occurs as a white or almost white powder that is freely soluble in water. Dosages are expressed in terms of the base; 1.12 mg of granisetron HCl is equivalent to 1 mg of granisetron base.
Granisetron may also be known as: granistroni, granisetrono, or BRL-43694A, Aludal®, Eumetic®, Granicip®, Granitron®, Kytril®, Kevatril®, Rigmoz® or Setron®.

Storage/Stability
The commercially available tablets and oral solution should be stored at room temperature (15–30°C) in tight containers and protected from light. The oral solution should be stored in an upright position. The injectable solution should be stored between 15–30°C; preferably at 25°C. Protect from light and do not freeze solution. Once the multi-dose vial is penetrated, it must be used within 30 days.

Compatibility/Compounding Considerations
The injectable solution is compatible with sodium chloride 0.9%, dextrose 5% in sodium chloride 0.45% or 0.9%, and dextrose 5% in water. It is compatible with many drugs at intravenous Y-sites, but is incompatible with amphotericin B.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Granisetron Oral Tablets: 1 mg (1.12 mg as HCl); Kytril® (Roche); (Rx)
- Granisetron Oral Solution: 1 mg/5 mL (1.12 mg/5 mL as HCl; orange flavor; contains sorbitol) in 30 mL bottles; Kytril® (Roche); Granisol® (Hawthorn); (Rx)
- Granisetron Injection Solution: 0.1 mg/mL (0.112 mg/mL as HCl) preservative-free, may contain sodium chloride 9 mg in 1 mL single-use vials; 1 mg/mL (1.12 mg/mL as HCl), regular & preservative-free, in 1 mL single-dose & 4 mL multi-dose vials; Kytril® (Roche); generic; (Rx)
- Granisetron Transdermal Patch: 3.1 mg/24 hours (34.3 mg/52 cm²); Sancuso® (ProStrakan); (Rx)

References

GRISEOFULVIN (MICROSIZE)
GRISEOFULVIN (ULTRAMICROSIZE)
(gri-see-oh-ful-vin) Fulvicin®
ANTIFUNGAL AGENT

Prescriber Highlights
- Fungistatic antibiotic used primarily for ringworm & other dermatophytic infections; no effect on other fungi
- Contraindications: Pregnancy, known hypersensitivity, or hepatocellular failure
- Caution: Kittens may be overly sensitive to the drug; cats with FIV
- Adverse Effects: Anorexia, vomiting, diarrhea, anemia, neutropenia, leukopenia, thrombocytopenia, depression, ataxia, hepatotoxicity, or dermatitis/photosensitivity
Uses/Indications
In veterinary species, griseofulvin is FDA-approved for use in dogs and cats to treat dermatophytic fungal (see below) infections of the skin, hair and claws, and to treat ringworm (caused by *T. equinum* and *M. gypseum*) in horses. It has also been used in laboratory animals and ruminants for the same indications. The oral tablets FDA-approved for dogs and cats are no longer marketed in the USA, but human dosage forms are available.

Pharmacology/Actions
Griseofulvin acts on susceptible fungi by disrupting the structure of the cell’s mitotic spindle, arresting the metaphase of cell division. Griseofulvin has activity against species of *Trichophyton*, *Microsporum* and *Epidermophyton*. Only new hair and nail growth is resistant to infection. It has no antibacterial activity and is not clinically useful against other pathogenic fungi, including Malassezia yeasts.

Pharmacokinetics
The microsized form of the drug is absorbed variably (25–70%); dietary fat will enhance absorption. The ultramicrosize form of the drug may be nearly 100% absorbed. Generally, the ultramicrosize form is absorbed 1.5 times as well as the microsized form for a given patient.

Griseofulvin is concentrated in skin, hair, nails, fat, skeletal muscle, and the liver, and can be found in the stratum corneum within 4 hours of dosing.

Griseofulvin is metabolized by the liver via oxidative demethylation and glucuronidation to 6-desmethylgriseofulvin, which is not active. In humans, the half-life is 9–24 hours. A serum half-life of 47 minutes has been reported for dogs. Less than 1% of the drug is excreted unchanged in the urine.

Contraindications/Precautions/Warnings
Griseofulvin is contraindicated in patients hypersensitive to it or with hepatocellular failure. It should not be used in pregnant animals. It must not be used in horses intended for food.

Because kittens may be overly sensitive to the adverse effects associated with griseofulvin, they should be monitored carefully if treatment is instituted. Cats should be tested for FIV before using griseofulvin because of the possible neutropenic or panleukopenic effects of the drug.

Adverse Effects
Griseofulvin can cause anorexia, vomiting, diarrhea, anemia, neutropenia, leukopenia, thrombocytopenia, depression, ataxia, hepatotoxicity, dermatitis/photosensitivities and toxic epidermal necrolysis. With the exception of GI clinical signs, adverse effects are uncommon at usual doses. Cats, particularly kittens, may be more susceptible to adverse effects (e.g., bone marrow depression) than other species. This could be due to this species’ propensity to more slowly form glucuronide conjugates and thus metabolize the drug at a slower rate than either dogs or humans.

Reproductive/Nursing Safety
Griseofulvin is a known teratogen in cats and, probably, in dogs and horses as well. Dosages of 35 mg/kg given to cats during the first trimester caused cleft palate and other skeletal and brain malformations in kittens. Griseofulvin may also inhibit spermatogenesis. Because dermatophytic infections are not generally life-threatening and alternative therapies are available, use of the drug should be considered contraindicated during pregnancy. However, griseofulvin has been used in mares during the later stages of pregnancy without noted ill effect. (Davis 2008).

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: D (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

No lactation safety information was found.

Overdosage/Acute Toxicity
No specifics regarding griseofulvin overdosage or acute toxicity were located. It is suggested that significant overdoses be handled with gut emptying, charcoal and cathartic administration unless contraindicated. Contact a poison control center for more information.

Horses have received 100 mg/kg PO for 20 days without apparent ill effect.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving griseofulvin and may be of significance in veterinary patients:

- **ALCOHOL**: Griseofulvin may potentiate the effects of alcohol
- **ASPIRIN**: Griseofulvin may decrease salicylate levels
- **CYCLOSPORINE**: Griseofulvin may decrease cyclosporine levels
- **PHENOBARBITAL**: Phenobarbital and other barbiturates have been implicated in causing decreased griseofulvin blood concentrations, presumably by inducing hepatic microsomal enzymes and/or reducing absorption. If phenobarbital and griseofulvin are given concurrently, griseofulvin dosage adjustment may be necessary.
- **THEOPHYLLINE**: In some patients, griseofulvin may decrease theophylline half-life and levels
- **WARFARIN**: Coumarin anticoagulants may have their anticoagulant activity reduced by griseofulvin; anticoagulant adjustment may be required
Doses

Note: all doses are for microsize preparations unless otherwise indicated.

**DOGS:**
For susceptible dermatophytic infections:

a) Microsize: 25 mg/kg q12h PO for 42–56 days; Ultramicrosize: 5–10 mg/kg PO once daily for 42 days. May need to treat longer for Trichophyton than for Microsporum. Give following a fatty meal or administration of corn oil. Continue for at least 2 weeks after resolution of signs and at least 5 months for onychomycosis. (Greene et al. 2006)

b) Microsize: 50 mg/kg PO once daily with fatty meal. Used with topical therapy (see references). May double dose in resistant cases. If GI distress occurs may divide dose and give twice daily with food. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

cats:
For susceptible dermatophytic infections:

a) Microsize: 50–120 mg/kg PO; divided daily. Give with a fatty meal. Ultramicrosize: 10–15 mg/kg PO twice daily. Give for 4–6 weeks or longer, until culture is negative. (Foil 2003)

b) Microsize: 50 mg/kg PO once daily or 25 mg/kg PO q12h for 42–70 days; Ultramicrosize: 5–10 mg/kg PO once daily for 42 days. Give following a fatty meal or administration of corn oil. Continue for at least 2 weeks after resolution of signs and at least 5 months for onychomycosis. (Greene et al. 2006)

c) Microsize: 50 mg/kg PO once daily with fatty meal. Used with topical therapy (see references). May double dose in resistant cases. If GI distress occurs may divide dose and give twice daily with food. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

d) For feline eosinophilic granuloma complex: Microsize: 25 mg/kg PO twice daily with food. Give at least for one month to judge efficacy. (White 2003)

**RABBITS/RODENTS/SMALL MAMMALS:**

a) **Rabbits** for advanced dermatophytosis: Ultramicrosize 6.25 mg/kg PO q12h for 4–6 weeks. Microsize: 25 mg/kg PO q12–24h for one month (Ivey & Morrisey 2000)

b) **Chinchillas:** 25 mg/kg PO once daily for 30–60 days (Hayes 2000)

c) **Gerbils, Guinea pigs, Hamsters, Rats:** 25 mg/kg PO q24h for 14–28 days; **Mice:** 25 mg/kg PO q24h for 14 days; **Chinchillas:** 25 mg/kg PO q24h for 28–40 days (Adamcak & Otten 2000)

d) **Guinea pigs** for dermatophytosis: 25 mg/kg PO (as a suspension) once daily for 28 days. (Johnson 2006b)

e) **Chinchillas:** 25 mg/kg PO once daily (q24h) for 30 days (Johnson 2006a)

**CATTLE (and other ruminants):**
For susceptible dermatophytic infections:

a) Ultramicrosize: 10–20 mg/kg PO once daily for 1–2 weeks. 100 mg/kg PO given twice (or more) 1 week apart may also be effective. Not FDA-approved for use in food animals and can be very expensive. (Pier 1986)

b) 20 mg/kg PO once daily for 6 weeks (Howard 1986)

**HORSES:**
For susceptible dermatophytic infections:

a) Using the microsize (not ultra-microsize) products: 5 mg/kg PO once daily. Smaller doses (1.25 grams) should be used for foals or ponies. If using ultramicrosize (human) formulations the dose should be reduced by 50%. (Davis 2008)

**SWINE:**
For susceptible dermatophytic infections:

a) 20 mg/kg PO once daily for 6 weeks (Howard 1986)

**BIRDS:**

a) **Ratites:** 35–50 mg/kg PO once daily (Jenson 1998)

**Monitoring**

- Clinical efficacy; culture
- Adverse effects
- CBC; before therapy and q1–3 weeks during therapy
- Liver enzymes (if indicated)

**Client Information**

- Clients should be instructed in procedures used to prevent reinfection (destruction of old bedding, disinfection, periodic reexaminations, hair clipping, etc.), and the importance of compliance with the dosage regimen.
- Should animal develop adverse effects other than mild GI disturbances, they should contact their veterinarian.

**Chemistry/Synonyms**

A fungistatic antibiotic produced by species of Penicillium (primarily P. griseofulvum), griseofulvin occurs as an odorless or nearly odorless, bitter tasting, white to creamy white powder. It is very slightly soluble in water and sparingly soluble in alcohol.

Two forms of the drug are available commercially. Microsize griseofulvin contains particles with a predominant size of 4 micrometers in diameter, while the ultramicrosize form particle size averages less than 1 micron in diameter.

Griseofulvin may also be known as: curling factor, griseofulvina, and griseofulvinum; many trade names are available.
The manufacturer states that the use of physostigmine is contraindicated with guaifenesin (see Drug Interactions).

Contraindications/Precautions/Warnings

newborns of mothers who received guaifenesin have not been described.

Gender differences in the elimination half-life of guaifenesin in ponies have been demonstrated, with males having a t½ of approximately 85 minutes, and females a t½ of about 60 minutes. Guaifenesin reportedly crosses the placenta, but adverse effects in offspring have not been described.

Guaifenesin potentiates the activity of preanesthetic and anesthetic agents.

VETERINARY-LABELED PRODUCTS:

Griseofulvin (Microsize) Powder: 2.5 g griseofulvin in 15 g sachets; AmTech® Griseofulvin Powder (Teva); (Rx). FDA-approved for use in horses not intended for food.

The FDA’s “Green Book” still lists several other veterinary FDA-approved griseofulvin products, but it does not appear they are presently being marketed.

HUMAN-LABELED PRODUCTS:

Griseofulvin Microsize Oral Tablets: 500 mg; Grifulvin V® (Ortho); (Rx)

Griseofulvin Microsize Oral Suspension: 125 mL/5 mL in 120 mL; generic; (Rx)

Griseofulvin Ultramicrosize Tablets: 125 mg & 250 mg; Gris-PEG® (Pedinol); (Rx)

References

In veterinary medicine, guaifenesin is used to induce muscle relaxation and restraint as an adjunct to anesthesia for short procedures (30–60 minutes) in large and small animal species. There are combination oral products containing guaifenesin for treating respiratory conditions in horses.

In human medicine, guaifenesin has long been touted as an oral expectorant, but definitive proof of its efficacy is lacking.

Guaifenesin is conjugated in the liver and excreted into the urine. A gender difference in the elimination half-life of guaifenesin in ponies has been demonstrated, with males having a t½ of approximately 85 minutes, and females a t½ of about 60 minutes. Guaifenesin reportedly crosses the placenta, but adverse effects in offspring have not been described.

While the exact mechanism of action for the muscle relaxant effect is not known, it is believed that guaifenesin acts centrally by depressing or blocking nerve impulse transmission at the interneuronal neuron level of the subcortical areas of the brain, brainstem and spinal cord. It relaxes both the laryngeal and pharyngeal muscles, thus allowing easier intubation. Guaifenesin also has mild intrinsic analgesic and sedative qualities.

Guaifenesin potentiates the activity of preanesthetic and anesthetic agents.

Pharmacokinetics

The pharmacokinetics of guaifenesin have not been thoroughly studied in most species. When administered alone to horses IV, recumbency usually occurs within 2 minutes and light (not surgical level) restraint persists for about 6 minutes. Muscle relaxation reportedly persists for 10–20 minutes after a single dose.

Guaifenesin is conjugated in the liver and excreted into the urine. A gender difference in the elimination half-life of guaifenesin in ponies has been demonstrated, with males having a t½ of approximately 85 minutes, and females a t½ of about 60 minutes. Guaifenesin reportedly crosses the placenta, but adverse effects in newborns of mothers who received guaifenesin have not been described.

Contraindications/Precautions/Warnings

The manufacturer states that the use of physostigmine is contraindicated with guaifenesin (see Drug Interactions).

Avoid giving ruminants concentrations of guaifenesin greater than 5% as hemolysis can occur.
Adverse Effects
At usual doses, side effects are transient and generally minor. A mild decrease in blood pressure and increase in cardiac rate can be seen. Thrombophlebitis has been reported after IV injection, and perivascular administration may cause some tissue reaction. Hemolysis may occur in solutions containing greater than a 5% concentration of guaifenesin, but some sources state this is insignificant at even a 15% concentration. Hemolysis may be more of an issue in ruminants than in horses.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is not known whether guaifenesin is excreted in milk.

Overdosage/Acute Toxicity
The margin of safety is reportedly 3 times the usual dose. Clinical signs of apneustic breathing, nystagmus, hypotension, and contradictory muscle rigidity are associated with toxic levels of the drug.

There were 64 exposures to guaifenesin reported to the ASPCA Animal Poison Control Center (APCC) during 2005-2009. In these cases 64 were dogs with only 5 showing clinical signs and 6 cases were cats with only 3 showing clinical signs. The dog received a dosage estimated between 415 and 830 mg/kg and exhibited hypothermia, mild tremors, ataxia and vomiting. The cat received a dosage of 132 mg/kg and exhibited lethargy and anorexia.

No specific antidote is available. It is suggested that treatment be supportive until the drug is cleared to sub-toxic levels.

Drug Interactions
Drug interactions with guaifenesin are not well studied. The following drug interactions have either been reported or are theoretical in animals receiving guaifenesin and may be of significance in veterinary patients:

**PHYSOSTIGMINE**: The manufacturer (Robins) states that physostigmine is contraindicated in horses receiving guaifenesin, but does not elucidate on the actual interaction. It may be logical to assume that other anticholinesterase agents (neostigmine, pyridostigmine, edrophonium) may also be contraindicated.

Doses

**DOGS:**
- a) 110 mg/kg IV for muscle relaxation during certain toxicoses (e.g., strychnine) or tetanus (Morgan 1988)
- b) For chemical restraint for ventilatory support: Combination of guaifenesin 50 mg/mL, ketamine 1 mg/mL, and xylazine 0.25 mg/mL; give 0.55 mL bolus initially followed by 2.2 mL/kg/hr thereafter (Pascoe 1986)

**CATTLE:**
- a) 55–110 mg/kg IV (Mandsager 1988)

**HORSES**: (Note: ARCI UCGFS Class 4 Drug)
- a) 110 mg/kg IV, give first ½–½ of dose until horse falls gently, then give remainder unless respiratory or cardiovascular effects are observed (Package Insert; Guailaxin®—Robins)
- b) To provide muscle relaxation in balanced anesthesia:
  - A CRI of ketamine at 0.8–2.3 mg/kg/hr with guaifenesin at 18–60 mg/kg/hr may reduce MAC requirements by 50%.
  - A CRI of ketamine 1 mg/kg/hr with medetomidine at 0.00125 mg/kg/hr and guaifenesin at 25 mg/kg/hr may reduce MAC requirements by 50%. (Driessen 2008)
- c) In field anesthesia:
  - To augment muscle relaxation in horses that are too light or too tense after alpha-2 agonist + ketamine ± diazepam induction, and do not respond sufficiently to additional increments of alpha-2 agonist or ketamine: Approximately 25–50 mg/kg (250–500 mL of a 5% solution) IV.
  - For long-term IV (>30 minutes) anesthesia using “GKX” or “triple-drip”: Guaifenesin (50 mg/mL), ketamine (1–2 mg/mL; 2 mg/mL concentration used for more painful or noxious procedures), and xylazine (0.5 mg/mL). Most practitioners prefer to induce with xylazine/ketamine or xylazine/diazepam/ketamine and then use GKX for maintenance. Typically the CRI runs at 1.5–2.2 mL/kg/hr depending on the procedure, patient response and ketamine concentration.
  - An alternative to “GKX” is “GKD” where detomidine is substituted for the xylazine and the concentrations of guaifenesin and ketamine are increased. Guaifenesin (100 mg/mL), ketamine (4 mg/mL), and detomidine (0.04 mg/mL). The CRI runs at 0.8 mL/kg/hr for the first hour and 0.6 mL/kg/hour for the final 30 minutes.
  - (Wagner 2009b)
- d) For equine intravenous anesthesia:
  - For normal healthy patients: Administer xylazine (0.44–0.66 mg/kg IV, or 200–300 mg/450 kg horse). Wait for sedation and muscle relaxation to occur (approximately 5 minutes). Guaifenesin (5% solution, or 50 mg/mL) is then rapidly infused using pressurization until marked sedation and muscle relaxation is achieved (generally a total dose of 30–50 mg/kg). Ketamine (2.2 mg/kg IV, 1000 mg/450 kg) should be administered at a point that allows for its slow onset to occur without the patient becoming excessively weak and collapsing from effects of guaifenesin. Recumbency generally occurs approximately 60 seconds following ketamine administration. The slow administration of guaifenesin described below can also be used in normal healthy patients in place of a supplemental dose of xylazine when the level of initial sedation is inadequate.
  - For compromised patients: Try to use a very modest dose of xylazine (0.22–0.44 mg/kg IV, or 100–200 mg/450 kg horse) depending on status and demeanor to minimize its cardiovascular effects in compromised patients. Slow administration of guaifenesin (5% solution) can be used to gradually create the desired level of sedation. It is still important to allow adequate time for centralization of cardiac output to progress sufficiently prior to initiating the rapid phase of guaifenesin administration that precedes the induction bolus. Guaifenesin has a slow onset of action, when used to augment the level of pre-induction sedation. SLOW administration is important to avoid creating an overly weak and ataxic patient while waiting for centralization to progress sufficiently. Guaifenesin is then rapidly infused using pressurization until marked sedation and muscle relaxation is achieved (generally a total dose of 30–50 mg/kg IV). Ketamine (dose decreases as degree of compromise increases, 1.34–1.55 mg/kg IV, or 600–700 mg/450 kg) for extremely compromised patients should be administered at a point that allows for its slow onset to occur without the patient becoming excessively weak and collapsing from the growing effects of guaifenesin. Experience may be required to get the timing right. Recumbency takes even longer (up to a couple minutes) when ketamine dose is increased.
No parenteral preparations are FDA-approved. There are many OTC oral expectorant/cough preparations on the market.

- **Guaifenesin Oral Granules**: 50 mg/packet & 100 mg/packet; *(Reckitt Benkiser)*
- **Guaifenesin Oral Tablets**: 200 mg & 400 mg; 600 mg & 1200 mg (extended-release);

**HUMAN-LABELED PRODUCTS:**

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

There may be veterinary oral cough syrups or tablets containing guaifenesin available labeled for use in small animals.

There are oral products containing guaifenesin and other expectorants (potassium iodide, ammonium chloride) labeled for use in horses, cattle, and sheep, including **EQ**.

There are several oral products containing guaifenesin in combination with an antihistamine (pyrilamine) labeled for use in horses, including **Anhist®** (AHC), & **Hist-EQ® Powder** (Butler); (OTC)

There are oral products containing guaifenesin and other expectorants (potassium iodide, ammonium chloride) labeled for use in horses, cattle, and sheep, including **Spec-Acid®** (AHC), and **Spec-Tuss®** (Neogen); (OTC)

There may be veterinary oral cough syrups or tablets containing guaifenesin available labeled for use in small animals.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**VETERINARY-LABELED PRODUCTS:**

Guaifenesin Injection 50 mg/mL in 500 mL & 1000 mL. There are several GG 5% injection products still listed as FDA-approved in the FDA’s Green Book, but it is believed that there are no products presently being marketed commercially.

There are several oral products containing guaifenesin in combination with an antihistamine (pyrilamine) labeled for use in horses, including **Anhist®** (AHC), & **Hist-EQ® Powder** (Butler); (OTC)

Compatibility/Compounding Considerations

Guaifenesin is physically compatible with sterile water or D₂W. It is also reportedly compatible with ketamine, pentobarbital, thiamylal, thiopental, and xylazine.

As there are apparently no commercially available injections being marketed in the USA, compounding an injection product from a USP grade powder is the only way to obtain a parenteral dosage form. Compounding pharmacies may be able to prepare a sterile product. The commercially available products contain per mL: Guaifenesin 50 mg, Dextrose (anhydrous) 50 mg, Propylene Glycol 20 mg, Dimethyl acetamide 50 mg, Edetate Disodium 0.75 mg, Water for Injection q.s. For stability, it is highly recommended that the compounding pharmacy use this formula.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Guaifenesin Oral Tablets: 200 mg & 400 mg; 600 mg & 1200 mg (extended-release); **Organadin NR®** (Medpointe); **Liquibid®** (Capellon); generic; (Rx); **Mucinex®** (Reckitt Benkiser); **Humibid® Maximum Strength** (Adams); generic; (OTC)

Guaifenesin Oral Granules: 50 mg/packet & 100 mg/packet; **Mucinex® Mini-Melts for Kids** (Reckitt Benkisher); (OTC)

Guaifenesin Syrup/Liquid: 100 mg/5mL in 118 mL, 237 mL & 473 mL; 200 mg/5 mL in 120 mL; **Buckley’s Chest Congestion Mixture®** (Novartis); **Mucinex for Kids®** (Reckitt Benkisher); **Diabetic Tussin®** (Health Care Products); **Robitussin®** (Wyeth); **Siluassin DAS® & SA®** (Silarx); **Scol-Tussin Expectorant** (Scol-Tussin); **Naldeon Senior EX®** (Sandoz); generic; (OTC); **Ganidin NR®** (Cypress); **Guaifenesin NR®** (Silarx); (Rx)

No parenteral preparations are FDA-approved. There are many OTC oral expectorant/cough preparations on the market.

**Monitoring**

- Level of muscle relaxation
- Cardiac and respiratory rate

**Chemistry/Synonyms**

Formerly known as glyceryl guaiacolate, guaifenesin occurs as a white to slightly gray, crystalline powder that may have a characteristic odor. It is nonhygroscopic and melts between 78°–82°C. One g is soluble in 15 mL of water and soluble in alcohol, propylene glycol and glycercin.

Guaifenesin may also be known as: GG, glyceryl guaiacolate, glycerylguayacolum, guaiacol glycerol ether, guaiacyl glycyl ether, guaifenesina, guaifenesinum, guaiaphenesin, and guajacolum glycerolatum; many trade names are available.

**Storage/Stability**

Guaifenesin is stable in light and heat (less than melting point). It should be stored in well-closed containers.

When dissolved into aqueous solutions, guaifenesin may slightly precipitate out of solution when the temperature is less than 22°C (72°F). Slight warming and agitation generally resolubilizes the drug. A microwave oven has been suggested for heating and dissolving the drug. It is recommended that the solution be prepared freshly before use, but a 10% solution (in sterile water) may apparently be stored safely at room temperature for up to one week with only slight precipitation occurring.

**Compatibility/Compounding Considerations**

Guaifenesin is physically compatible with sterile water or D₂W. It is also reportedly compatible with ketamine, pentobarbital, thiamylal, thiopental, and xylazine.

As there are apparently no commercially available injections being marketed in the USA, compounding an injection product from a USP grade powder is the only way to obtain a parenteral dosage form. Compounding pharmacies may be able to prepare a sterile product. The commercially available products contain per mL: Guaifenesin 50 mg, Dextrose (anhydrous) 50 mg, Propylene Glycol 20 mg, Dimethyl acetamide 50 mg, Edetate Disodium 0.75 mg, Water for Injection q.s. For stability, it is highly recommended that the compounding pharmacy use this formula.

**Reference**

HALOTHANE
(ha-loe-thane) Fluothane®
GENERAL ANESTHETIC

Prescriber Highlights

- Classic inhalant general anesthetic; no longer available in many countries
- Contraindications: History or predilection towards malignant hyperthermia; significant hepatotoxicity after previous exposure
- Caution in patients with hepatic function impairment, cardiac arrhythmias, increased CSF or head injury, myasthenia gravis, or pheochromocytoma
- Adverse Effects: Dose related hypotension, malignant hyperthermia-stress syndrome, cardiac depression & dysrhythmias, hepatotoxicity
- May be teratogenic; use with caution in pregnancy
- Drug interactions

Uses/Indications
Halothane in the past was a mainstay general anesthetic in veterinary medicine due to its relative safety, potency, controllability, non-flammability, and comparatively low cost. However, it is no longer available commercially in many countries as it has been replaced by agents that have less cardiodepressant effects such as isoflurane, desflurane and sevoflurane.

Pharmacology/Actions
While the precise mechanism that inhalant anesthetics exert their general anesthetic effect is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Some key pharmacologic effects noted with halothane include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression (pronounced in ruminants), hypotension, vasodilatation, and myocardial depression.

- Minimal Alveolar Concentration (MAC; %) in oxygen reported for halothane in various species: Dog = 0.76; Cat = 0.82; Horse = 0.88; Human = 0.76. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

Pharmacokinetics
Halothane is rapidly absorbed through the lungs. About 12% of absorbed drug is metabolized by the liver to trifluoroacetic acid (only small amounts), chlorine, and bromine radicals that are excreted in the urine. The bulk of the absorbed drug is re-excreted by the lungs and eliminated with expired air. Halothane is distributed into milk.

Contraindications/Precautions/Warnings
Halothane is contraindicated in patients with a history or predilection towards malignant hyperthermia or significant hepatotoxicity after previous halothane exposure (see Adverse Effects below). It should be used with caution (benefits vs. risks) in patients with hepatic function impairment, cardiac arrhythmias, increased CSF or head injury, myasthenia gravis, or pheochromocytoma (cardiac arrhythmias due to catecholamines).

Adverse Effects
Hypotension may occur and is considered dose-related. A malignant hyperthermia-stress syndrome has been reported in pigs, horses, dogs, and cats. Halothane may cause cardiac depression and dysrhythmias. Halothane-induced hypotension may be treated by volume expansion and dobutamine. Lidocaine has been used to treat or prevent halothane-induced cardiac dysrhythmias. In humans, jaundice and a postanesthetic fatal liver necrosis have been reported rarely. The incidence of this effect in veterinary species is not known, however, halothane should be considered contraindicated for future use if unexplained fever, jaundice, or other clinical signs associated with hepatotoxicity occur.

Reproductive/Nursing Safety
Some animal studies have shown that halothane may be teratogenic; use only when benefits outweigh potential risks. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving halothane and may be of significance in veterinary patients:
- **ACETAMINOPHEN**: Is not recommended for use for post-operative analgesia in patients that have received halothane anesthesia
- **ACEPROMAZINE**: Can decrease requirements of halothane by up to 40%
- **AMINOGLYCOSIDES**: Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **LINCOSAMIDES**: Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS**: Additive neuromuscular blockade may occur
- **SUCCYNILCHOLINE**: With inhalation anesthetics, may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia
- **SYMPATHOMIMETICS** (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.): Because halothane sensitizes the myocardium to the effects of sympathomimetics, especially catecholamines, severe ventricular arrhythmias may result. If these drugs are needed, they should be used with caution and in significantly reduced dosages with intensive monitoring
D-TUBOCURARINE: May cause significant hypotension if used with halothane

Laboratory Considerations

- Halothane may transiently increase values of liver function tests.

Doses

**DOGS/CATS:**

- **Note:** Concentrations are dependent upon fresh gas flow rate; the lower the flow rate, the higher the concentration required.
  - a) 3% (induction); 0.5–1.5% (maintenance) (Papich 1992)
  - b) 0.5–3.5%, inhaled (Hubbell 1994)

**RABBITS/RODENTS/SMALL MAMMALS:**

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: Using a non-rebreathing system: Induction: 2%–4%, maintenance: 0.25%–2% (Anderson 1994); (Adamcak & Otten 2000)

**BIRDS:**

- a) Using an anesthetic vaporizer, induction usually occurs in 2–4 minutes at a concentration of 2% for small birds and 2.5%–3% for large birds. Maintenance can generally be maintained at concentrations of 0.5%–1.5%. Recovery usually takes 3–5 minutes. Bradycardia, hypotension and hypothermia may occur, but rapidly resolve once halothane is discontinued. (Bennett 2002)

**HORSES:**

- a) For draft horses: Following induction, the largest ET tube that will comfortably fit (20–40 mm) should be placed and cuff inflated. In an oxygen-enriched semi-closed large animal circle system 4%–5% of halothane is administered initially and is reduced as indicated by physical monitoring of neural reflexes and cardiopulmonary parameters. The goal should be the lowest concentration inhalant anesthetic that provides adequate surgical anesthesia and restraint. Most draft horses can be maintained on 2.5%–3% halothane. (See reference for more information on monitoring and use.) (Geiser 1992)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia

Chemistry/Synonyms

An inhalant general anesthetic agent, halothane occurs as a colorless, nonflammable, heavy liquid. It has a characteristic odor resembling chloroform and a sweet, burning taste. Halothane is slightly soluble in water and miscible with alcohol. At 20°C, halothane’s specific gravity is 1.872–1.877 and vapor pressure is 243 mmHg.

Halothane may also be known as: phthorothanum, Fluothane®, and Ineltano®.

Storage/Stability

Store halothane below 40°C in a tight, light-resistant container. Halothane stability is maintained by the addition of thymol and ammonia. The thymol does not vaporize so it may accumulate in the vaporizer causing a yellow discoloration. Do not use discolored solutions. Discolored vaporizer and wick may be cleaned with diethyl ether (all ether must be removed before reuse).

In the presence of moisture, halothane vapor can react with aluminum, brass, and lead (not copper). Rubber and some plastics are soluble in halothane leading to their rapid deterioration.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None in USA

### HEMOGLOBIN GLUTAMER-200 (BOVINE)

(hee-moe-glo-bin glo-ta-mer)

HG-200, HBOC-301, Oxyglobin®

SEMI-SYNTHETIC HEMOGLOBIN REPLACER; COLLOID

Prescriber Highlights

- Bovine-source polymerized hemoglobin product for the treatment of anemias
- Contraindications: Advanced cardiac disease, renal impairment with oliguria or anuria
- Many potential adverse effects; most are not serious (see below)
Uses/Indications
Hemoglobin glutamer-200 [bovine] (HG-200, HBOC-301, Oxyglobin®) is indicated for the treatment of dogs with anemia, regardless of the cause of anemia (hemolysis, blood loss, or ineffective erythropoiesis). From a prognostic standpoint, the drug should be more valuable in dogs with regenerative anemias (versus nonregenerative anemias). It has also been used extra-label in other species as well, such as cats or foals for neonatal isoerythrolysis.

Its primary benefit is for the patient that is anemic and difficult to transfuse due to unavailability of blood, or when no suitable donors are identified on crossmatch. (Jandrey 2007)

Pharmacology/Actions
The bovine hemoglobin in the product is polymerized into larger molecules to increase safety, efficacy, and intravascular persistence, is shipped in a deoxygenated state and becomes oxygenated once circulated through the lungs. HG-200 does not contain red blood cells and is stroma free. HG-200 releases oxygen to tissue in a mechanism similar to endogenous hemoglobin; thereby increasing plasma and total hemoglobin concentrations, and systemic oxygen content. Because of its small size (in comparison to normal RBC’s), it may better deliver oxygen to cells supplied by severely constricted arteries. HG-200 shifts the oxygen dissociation curve to the right, so oxygen is transferred to tissues more easily. In experimentally-induced hypovolemic shock in dogs, HG-200 caused severe vasoconstriction and decreased cardiac output (Driessen et al. 2001).

HG-200 also has colloidal properties similar to dextran 70 and hetastarch.

Pharmacokinetics
In dogs receiving 15 mL/kg: peak plasma hemoglobin concentrations increased approximately 2.5 g/dL; at 30 mL/kg, approximately 4 mg/dL. Duration of effect continues for at least 24 hours. The plasma half-life in dogs at present labeled dosages is approximately 18–43 hours and HG-200 can be detected in plasma for 5–7 days after a single dose.

As with endogenous hemoglobin, HG-200 is metabolized and eliminated by the reticuloendothelial system. Small amounts of unstabilized hemoglobin (<5%) may be excreted through the kidneys, causing discoloration (red) of the urine.

Contraindications/Precautions/Warnings
As safe use of Oxyglobin® has not been tested for the following conditions and plasma expanders are generally contraindicated in them, the product is labeled as contraindicated in dogs with advanced cardiac disease (i.e., congestive heart failure) or otherwise severely impaired cardiac function or renal impairment with oliguria or anuria. The safety and efficacy of Oxyglobin® has not been evaluated in dogs with DIC, thrombocytopenia with active bleeding, hemoglobinemia and hemoglobinuria, or autoagglutination.

HG-200 is a potent colloid and can cause vasoconstriction. Care must be taken not to volume overload patients when receiving this drug as hydrostatic pressures may be increased and cause pulmonary overload (pleural effusion, pulmonary edema). This is particularly important in cats.

Because of its vasoconstrictive properties, the amount of HG-200 required for fluid resuscitation in trauma patients is approximately 1/3 that of hetastarch (Rudloff & Devey 2009).

Administration of any foreign protein has the potential to cause immunologic reactions. While low levels of IgG antibodies have been detected after multiple dosages, no anaphylactic reactions have been reported thus far. If an immediate hypersensitivity reaction occurs, infusion should be immediately discontinued and appropriate treatment administered. If a delayed type of hypersensitivity reaction occurs, immunosuppressant therapy is recommended.

Adverse Effects
The package insert lists the following frequency of adverse reactions that occurred in greater than 4% of dogs treated with Oxyglobin® (Note: first figure is % of dogs treated; in parentheses: % treated having hemolytic anemia): Discolored mucous membranes 69% (47%); discolored sclera (yellow, red, brown) 56% (48%); discolored urine (orange, red, brown) 52% (41%); discolored skin (yellow) 12% (83%); increased central venous pressure (CVP) 33% (47%); ventricular arrhythmias (AV block, tachycardia, ventricular premature contractions) 15% (78%); echymosis/petechiae 8% (50%); bradycardia 6% (67%); vomiting 35% (72%); diarrhea 15% (67%); fever 17% (40%); death/euthanasia 15% (67%); peripheral edema 8% (25%); hemoglobinuria 6% (67%); dehydration 6% (33%).

Adverse reactions occurring in 4% of the dogs treated with Oxyglobin® include: coughing, disseminated intravascular coagulopathy, melena, nasal discharge/crusts (red), peritoneal effusion, respiratory arrest, and weight loss (5–7% body weight). Adverse reactions occurring in less than 2% of the dogs treated with Oxyglobin® included: abdominal discomfort on palpation, acidosis, cardiac arrest, cardiovascular volume overload (by echocardiography), collapse, cystitis, dark stool, discolored soft stool (red-brown) and tongue (purple), focal hyperemic areas on gums, forelimb cellulitis/fameness, hematemesis or hemoptyosis (unable to differentiate), hypernatremia, hypotension, hypoxemia, lack of neurologic responses, left forebrain signs, nystagmus, pancreatitis, pendulous abdomen, polyuria, pulmonary thromboembolism, ptosis, reddened pinnae with papules/head shaking, reduction in heart rate, thrombocytopenia (worsening), and venous thrombosis.

Increases in IgG antibodies have been detected in dogs receiving multiple courses of HG-200, but no documented cases of anaphylaxis have been reported.

Small amounts of unstabilized hemoglobin (<5%) may be excreted through the kidneys, resulting in transient discoloration (red) of the urine following the infusion. This discoloration of the urine should not be interpreted as due to intravascular hemolysis and has no effect on renal function.

In clinical use, Oxyglobin® has not been demonstrated to affect platelet function or impair coagulation.

Increases in aspartate aminotransferase (AST) and alanine aminotransferase (ALT) not associated with histopathologic changes in the liver, increase in serum total protein, and hemoglobinuria may also be seen.

Reproductive/Nursing Safety
Safe use in breeding dogs and pregnant or lactating bitches has not been determined.

Overdosage/Acute Toxicity
The clinical signs associated with Oxyglobin® administered at 1, 2, and 3 times the recommended dose twice, 3 days apart include yellow-orange discoloration of skin, ear canals, pinnae, mucous membranes (gums), and sclera, red-dark-green-black discoloration of feces, brown-black discoloration of urine, red spotting of skin and/or lips (less common), decreased appetite and thirst, vomiting, diarrhea, and decreased skin elasticity. The frequency and/or intensity of these signs increased with

Potential drug-lab interactions
Availability has been an issue
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. It is prohibited to be at racing premises. See the appendix for more information.

Drug Interactions
Other than concerns with compatibility, (no specific drug interactions have been noted.

Laboratory Considerations
- Hemoglobin-based oxygen carriers (HBOCs) can impact several laboratory tests. The manufacturer maintains a website: www.HBOCLab.com to help guide laboratories and clinicians.
- The presence of HG-200 in serum may cause artifactual increases or decreases in the results of serum chemistry tests, depending on the type of analyzer and reagents used. May cause false increases in AST, or creatinine. May cause false decreases in LDH. May cause unacceptable interference with GGT, albumin, or bilirubin.
- There is reportedly no interference with directly measured hemoglobin tests, but due to the dilutional effects of HG-200, PCV and RBC count are not accurate measures of the degree of anemia for 24 hours following administration. Prothrombin time (PT) and activated partial thromboplastin time (aPTT) determined using methods that are mechanical, magnetic and light scattering are accurate, but optical methods are not reliable while HG-200 is present.

Drugs

**DOGS:**
- For labeled indications: One-time dose of 10–30 mL/kg IV at a rate of up to 10 mL/kg/hr.
  May be warmed to 37°C prior to administration. Blood transfusions are not contraindicated in dogs which receive Oxyglobin® nor is Oxyglobin® contraindicated in dogs which have previously received a blood transfusion. There is no need for typing or crossmatching before use. Should be administered using aseptic technique via a standard intravenous infusion set and catheter through a central or peripheral vein at a rate of 10 mL/kg/hr. Do not administer with other fluids or drugs via the same infusion set. Do not add medications or other solutions to the bag. Do not combine the contents of more than one bag. (Package Insert; Oxyglobin®—Biopure)
- For resuscitation of trauma patients in shock with or without hemorrhage: Empirically, 3–5 mL/kg with concurrent crystalloid at 1/2 to 2 times maintenance. (Gfeller 2002)
- To provide a “bridge” until immunosuppressive drugs take effect in dogs with IMHA with a transfusion reaction: 7–10 mL/kg q12h can maintain hemoglobin levels above 3.5 g/dL; higher doses 30 mL/kg may provide oxygen carrying support for 48–72 hours. (Macintire 2006)
- As an option to provide oxygen carrying capacity in the trauma patient: 10–15 mLs/kg IV given over several hours. Care must be taken not to cause fluid overload. (Waddell 2009)
- As a vasopressor once there is adequate intravascular volume in trauma patients: 3–5 mL/kg IV. (Rudloff & Devey 2009)

**CATS:**
- As an option to provide oxygen carrying capacity in the trauma patient: 5–10 mLs/kg IV given over several hours. Care must be taken not to cause fluid overload especially in cats. (Waddell 2009)

Monitoring
- Hgb; clinical signs of adequate tissue oxygenation
- Signs of circulatory overload (CVP)
- Other adverse effects (see above)

Client Information
- Clients should be informed of the cost/risk/benefit profile for this agent before use.

Chemistry/Synonyms
Oxyglobin® is a sterile, clear, dark purple solution containing 13 g/dL purified, polymerized hemoglobin of bovine origin in a modified lactated Ringer’s solution. It has an osmolality of 300 mOsm/kg and a pH of 7.8. Less than 5% of the hemoglobin are as unstabilized tetramers, and approximately 50% have a molecular weight between 65 & 130 kD, with no more than 10% having a molecular weight >500 kD. The product contains less than the detectable level of 3.5 micrograms/mL free-glutaraldehyde and 0.05 EU/mL, endotoxin.

Hemoglobin glutamer-200 (bovine) may also be known as HBOC-301, Hb-200, or HG-200.

Storage/Stability
The product remains stable at room temperature or refrigerated (2°–30°C) for up to 3 years; expiration date is printed on the bag. Outdated product is not returnable. Do not freeze. It must remain in its over wrap during storage; once removed, it should be used within 24 hours. The foil over wrap serves as an oxygen barrier, protecting the hemoglobin from conversion to methemoglobin.

The manufacturer states that Oxyglobin® is physically compatible with any other IV fluid, but should not be mixed with other solutions or medications in the bag; other intravenous solutions and medications may be administered via a separate site and line, however.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Hemoglobin Glutamer-200 (bovine) in 60 mL and 125 mL ready to use infusion bags; Oxyglobin® (OPK Biotech); (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. It is prohibited to be at racing premises. See the appendix for more information.
HUMAN-LABELED PRODUCTS: None in USA at present

References

HEPARIN SODIUM

*(hep-a-rin)* Unfractionated Heparin, UHF

**ANTICOAGULANT**

**Prescriber Highlights**

- Parenteral anticoagulant used primarily for treatment of DIC (use controversial) & thromboembolic disease
- Contraindications: Known hypersensitivity, severe thrombocytopenia, or uncontrollable bleeding (caused by something other than DIC)
- Adverse Effects: Most common are bleeding & thrombocytopenia
- Protamine may reverse effects
- Intensive monitoring required

**Uses/Indications**

Heparin’s primary uses in small animal medicine have been treatment of disseminated intravascular coagulation (DIC) and prophylaxis of thromboembolic disease. The most recent evidence is strong that prophylactic heparin can reduce incidence in patients at high risk for developing macrovascular thromboembolism. Use for treating DIC has become increasingly controversial and current evidence suggests that heparin should not be used during DIC in patients with concurrent inflammatory processes.

In horses, it has been used in the treatment of DIC and as prophylactic therapy for laminitis. To date, there are no controlled prospective studies that demonstrate efficacy for these indications. Heparin has also been administered systemically (IV, SC) or as a intraperitoneally administered lavage solution to prevent intestinal adhesion formation after surgery. Its efficacy for this indication is questionable.

**Pharmacology/Actions**

Heparin acts on coagulation factors in both the intrinsic and extrinsic coagulation pathways. Low concentrations of heparin when combined with antithrombin III inactivate factor Xa and prevent the conversion of prothrombin to thrombin. In higher doses, heparin inactivates thrombin, blocks the conversion of fibrinogen to fibrin and when combined with antithrombin III inactivates factors IX, X, XI, XII. By inhibiting the activation of factor XIII (fibrin stabilizing factor), heparin prevents the formation of stable fibrin clots. While heparin will inhibit the reactions that lead to clotting, it does not significantly change the concentrations of clotting factors. Heparin does not lyse clots, but it can prevent the growth of existing clots.

Heparin causes increased release of lipoprotein lipase, thereby increasing the clearance of circulating lipids and boosting plasma levels of free fatty acids.

**Pharmacokinetics**

Heparin is not absorbed by the gut when administered orally; it must be given parenterally to be effective. Anticoagulant activity begins immediately after direct IV bolus injection, but may take up to one hour after deep SC injection. When heparin is given by continuous IV infusion, an initial bolus must be administered for full anticoagulant activity to begin.

Heparin is extensively protein bound, primarily to fibrinogen, low-density lipoproteins and globulins. It does not appreciably cross the placenta or enter milk.

Heparin’s metabolic fate is not completely understood. The drug is apparently partially metabolized by the liver and also inactivated by the reticuloendothelial system. Serum half-lives in humans averages 1–2 hours.

In healthy dogs, bioavailability after subcutaneous injection is about 50%. When 200 Units/kg were administered to healthy dogs SC, plasma heparin concentrations were in the therapeutic range between 1 and 6 hours after administration. (Diquelou et al. 2005)

**Contraindications/Precautions/Warnings**

Heparin is contraindicated in patients hypersensitive to it, having severe thrombocytopenia or uncontrollable bleeding (caused by something other than DIC). One author (Green 1989) states that with DIC “heparin should not be given to actively bleeding patients that have severe factor depletion and thrombocytopenia, as fatal hemorrhage may result.”

Use for treating DIC has become increasingly controversial. The most recent evidence suggests that heparin should not be used during DIC in patients with concurrent inflammatory abnormalities. Until further evidence suggests practices to the contrary, heparin should be used with extreme caution in both human and veterinary patients with dysfunctional interactions between inflammatory and hemostatic systems and the endothelium. (Bateman 2005)

Do not administer IM as heparin may cause hematoma formation. Hematomas, pain, and irritation may occur after deep SC dosing. Dogs with renal insufficiency may have lower plasma levels and faster elimination rates of heparin; dosage adjustment may be required.

**Adverse Effects**

Bleeding and thrombocytopenia are the most common adverse effects associated with heparin therapy. Because heparin is derived from bovine or porcine tissues, hypersensitivity reactions may be possible. Less commonly encountered adverse effects that have been reported in animals and/or humans include vasospastic reactions (after several days of therapy), osteoporosis and diminished renal function (after long-term, high-dose therapy), rebound hyperlipidemia, hyperkalemia, alopecia, suppressed aldosterone synthesis and priapism.

The most common adverse effect associated with heparin therapy in horses is anemia which is probably due to erythrocyte agglutination. Erythrocyte counts return to normal within 24 hours of treatment discontinuation.
Reproductive/Nursing Safety

While heparin does not cross the placenta and is generally felt to be the anticoagulant of choice during pregnancy, its safe use in pregnancy has not been firmly established and pregnancy outcomes may be unfavorable. It should be used cautiously and only when clearly necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Heparin is not excreted into milk.

Overdosage/Acute Toxicity

Overdosage of heparin is associated with bleeding. Clinical signs that could be seen before frank bleeding occurs include hematuria, tarry stools, petechiae, bruising, etc. Protamine can reverse heparin’s effects; see the Protamine monograph for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving heparin and may be of significance in veterinary patients:

- **ASPIRIN**: May increase the risk for hemorrhage
- **DEXTRAN**: May increase the risk for hemorrhage
- **NSAIDS**: May increase the risk for hemorrhage
- **WARFARIN**: May increase the risk for hemorrhage
- **DIGOXIN**: Increased risk for cardiac toxicity
- **TETRACYCLINES**: May increase the risk for gastrointestinal bleeding

**Laboratory Considerations**

- Unless heparin is administered by continuous infusion, it can alter prothrombin time, (PT), which can be misleading in patients also receiving a coumarin or an indanedione anticoagulant.
- Heparin can interfere with the results of the BSP (sulfobromophthalein, bromosulfophthalein) test by changing the color intensity of the dye and shifting the absorption peak from 580 nm to 595 nm.
- Heparin can cause falsely elevated values of serum thyroxine if using competitive protein binding methods of determination. Radioimmunoassay (RIA) and protein bound iodine methods are apparently unaffected by heparin.
- When heparin is used as an anticoagulant *in vitro* (e.g., in blood collection containers), white cell counts should be performed within 2 hours of collection. Do not use heparinized blood for platelet counts, erythrocyte sedimentation rates, erythrocyte fragmentation tests, or for any tests involving complement or isoagglutinins. Errors in blood gas determinations for CO2 pressure, bicarbonate concentration, or base excess may occur if heparin encompasses 10% or more of the blood sample.

**Doses**

**DOGS/CATS:**

For adjunctive treatment of DIC (See Contraindications/Warnings above): **Note:** Heparin therapy may be only one aspect of successful treatment of DIC. Alleviation of the precipitating causes, administration of fluids, blood, aspirin, and diligent monitoring of coagulation tests (aPTT, PT), fibrin degradation products, and fibrinogen may all be important factors in the treatment of DIC. Doses of heparin are controversial; dosage ranges and methods may vary widely depending on the clinician/author.

a) 75 Units/kg SC three times daily (Wingfield & Van Pelt 1989)
b) After pH has been corrected and perfusion maximized, transfuse heparinized whole fresh blood or plasma (75 Units/kg heparin) one time. Then begin mini-dose heparin therapy at 5–10 Units/kg/hour by continuous IV infusion or 75 Units/kg SC q8h. Continue without interruption until DIC has completely disappeared. With these doses, bleeding risk is negligible and aPTT monitoring is not necessary, although thrombocytopenia may develop. (Slappendel 1989)
c) Before administering heparin, provide sufficient fresh whole blood to maintain platelet counts above 30,000/microliter and fibrinogen levels over 50 mg/dL. Then give heparin at 50–100 Units/kg SC q6h. Alternatively, dose heparin sufficiently to increase aPTT to 1.5–2 times normal (may be more effective in patients susceptible to thromboembolization). (Green 1989)

For adjunctive treatment of thromboembolic disease:

a) For feline arterial thromboembolism: 250–300 Units/kg SC q8h. First dose is administered IV to cats showing signs of shock. Monitoring aPTT (1.5–2.5 fold) and ACT (15–20 sec) should be regarded as rough guidelines only, as these may still result in heparin levels below the recommended therapeutic range. (Smith 2004)
b) Dogs: For “bridging therapy” while dog is started on warfarin for maintenance therapy for pulmonary thromboembolism: Heparin at 200–500 Units/kg SC q8h initially and then adjusted to reach a target aPTT of 1.5–2 times the treatment values or anti-factor Xa activity between 0.35-0.7 Units/mL. Treat for the first 5-7 days of warfarin therapy or until monitoring has documented adequate prolongation of PT. (Lunsford, K.V. & Mackin, A.J. 2007)
c) For maintenance therapy for arterial thromboembolic disease in cats: 250–300 Units/kg SC every 8 hours for the initial in-hospital therapy. (Lunsford, K. & Mackin, A. 2007)
d) Dogs: To cause anticoagulation without an excessive risk of bleeding: 150–300 Units/kg SC q6-8h. Each animal is individual and may respond differently to this dose, and must be monitored by serial physical examination and by PT and/or other coagulation assay (e.g., thromboelastography). In critically ill animals, constant rate IV infusion of UFH is more likely to result in consistent anti-coagulation and prolongation of PT. A loading dose of 100 Units/kg is followed by a CRI from 20-50 Units/kg/hr. Small changes in the dose can result in large changes in PT, and it is recommended to start at a low dose and slowly titrate higher in increments of 5 Units/kg/hr. To help prevent rebound hypercoagulability, it is recommended to taper the dose gradually, decreasing by 50 Units/kg per dose day over 3-4 days. (Brainard 2008)

To prevent clot formation when performing closed chest lavage with myothery:

- **ASPIRIN**: 125–250 mg/m2
- **OTHER NSAIDS**: Doxycycline
- **DIGOXIN**: 0.125 mg/m2
- **TETRACYCLINES**: 12.5 mg/m2

Errors in blood gas determinations for CO2 pressure, bicarbonate concentration, or base excess may occur if heparin encompasses 10% or more of the blood sample.

**INDICATIONS**

- **DIC**: 250–300 Units/kg SC q8h
- **Arterial thromboembolism**: 250–300 Units/kg SC q8h
- **Pulmonary embolism**: 200–500 Units/kg SC q8h
- **Intraocular hemorrhage in horses**: 150–300 Units/kg SC q6-8h
- **Hemorrhage in cats**: 250–300 Units/kg SC q8h
- **Hemorrhage in dogs**: 150–300 Units/kg SC q6-8h
To prevent clot formation when performing closed chest lavage with pyothorax:
a) Add 1000 U of heparin per liter of lavage fluid (warm normal saline). This fluid is instilled at 20 mL/kg twice daily for 5–7 days. Antibiotics (often penicillin) or enzymes (e.g., streptokinase) may also be added to fluid. (Berkwitt & Berzon 1989)

For hyperadrenocorticotoid dogs undergoing adrenalectomy:
a) At anesthetic induction, give heparinized plasma at a rate of 35 Units/kg, followed on the day of surgery by two doses 8 hours apart of 35 Units/kg. Next day give 25 Units/kg SC and taper over the next 4 days. (Lunsford, K.V. & Mackin, A.J. 2007)

For detection of lipoprotein lipase activity (heparin stimulation test):
a) Measure serum lipids just before and 15 minutes after heparin at 100 Units/kg IV. Lack of increase in lipolytic activity is suggestive of lipoprotein lipase deficiency. (Kay & Richter 1988)

**HORSES:**

For prevention of complications (e.g., venous thrombosis, laminitis, DIC) associated with hypercoagulable states:
a) Initially 150 Units/kg SC. Then 125 Units/kg q12h for 6 doses and then decreased to 100 Units/kg SC every 12 hours. (Rush Moore & Hinchcliff 1994)

For adjunctive treatment of DIC: **Note:** Heparin therapy may be only one aspect of successful treatment of DIC. Alleviation of the precipitating causes, administration of fluids, blood, aspirin, and diligent monitoring of coagulation tests (APTT, PT), fibrin degradation products, and fibrinogen may all be important factors in the treatment of DIC.
a) Heparin at 80–100 Units/kg IV q4–6h (may be added to fluids and given as a slow drip). Low grade DIC may be treated with 25–40 Units/kg SC 2–3 times a day. (Byars 1987)

As adjunctive therapy in endotoxic shock:
a) 40 Units/kg IV or SC 2–3 times a day may prevent the development of microthrombi; additional studies are required to confirm positive benefits (Semrad & Moore 1987)

As adjunctive therapy in the prevention of laminitis:
a) 25–100 Units/kg subcutaneously 3 times daily. Higher doses used when a thrombotic event is underway, lower dosages should have fewer adverse effects and still have antithrombotic activity. Ideally, APTT and ACT should be monitored. Targets are 1.5–2.5 times baseline for APTT and 1.2–1.4 times baseline for ACT. (Brumbaugh et al. 1999)

In an attempt to prevent abdominal adhesions:
a) 30,000–50,000 Units heparin in 10 L of lavage fluid (warm LRS) and administered intraperitoneally via a 32 French fenestrated trocar catheter placed in the right ventral abdomen at the time of surgery. Lavage performed at 12, 18, 36, and 48 hours post-surgery and allowed to drain through a Heimlich valve. Drain removed after final lavage or it becomes occluded. (Eggleston & Mueller 2003)

**Monitoring**

**Note:** The frequency of monitoring is controversial and is dependent on several factors, including heparin dose, patient’s condition, concomitant problems, etc. Because of the high incidence of hemorrhage associated with heparin use, frequent monitoring of aPTT is essential early in therapy (particularly using higher dosages) and in critically ill animals.

- While whole blood clotting time (WBCT), partial thromboplastin time (PTT), and activated partial thromboplastin times (aPTT) may all be used to monitor therapy, aPTT is most often recommended, but newer tests (e.g., thromboelastography) are being utilized.
- Platelet counts and hematocrit (PCV) should be done periodically;
- Occult blood in stool and urine; other observations for bleeding;
- Clinical efficacy

**Client Information**

- Because of the intense monitoring necessary with heparin’s use and the serious nature of the disease states in which it is used, this drug should be utilized only by professionals familiar with it, preferably in an inpatient setting.

**Chemistry/Synonyms**

Heparin is an anionic, heterogeneous sulfated glycosaminoglycan molecule with an average molecular weight of 12,000 that is found naturally in mast cells. It is available commercially as the sodium salt and is obtained from either porcine intestinal mucosa or from bovine lung tissue (sodium salt only). Heparin sodium occurs as white or pale-colored, amorphous, hygroscopic powder having a faint odor. It is soluble in water and practically insoluble in alcohol; the commercial injections have a pH of 5–7.5. Heparin potency is expressed in terms of USP Heparin Units and values are obtained by comparing against a standard reference from the USP. The USP requires that potencies be not less than 120 Units/mg on a dried basis for heparin derived from lung tissue, and 140 Units/mg when derived from all other tissue sources.

Heparin sodium may also be as: heparinum natricum, sodium heparin, and soluble heparin; many trade names are available.

**Storage/Stability**

Heparin solutions should be stored at room temperature (15–30°C) and not frozen. Avoid excessive exposure to heat.

**Compatibility/Compounding Considerations**

Heparin sodium is reportedly physically compatible with the following intravenous solutions and drugs: amino acids 4.25%-dextrose 25%, dextrose-Ringer’s combinations, dextrose-lactated Ringer’s solutions, fat emulsion 10%, Ringer’s injection, Normosol®, aminophylline, amphotericin B with or without hydrocortisone sodium phosphate, ascorbic acid injection, bleomycin sulfate, calcium gluconate, cephalin sodium, chloramphenicol sodium succinate, clindamycin phosphate, dimenhydrinate, dopamine HCl, erythromycin gluceptate, isoproterenol HCl, lidocaine HCl, metronidazole with sodium succinate, mexiteline sodium, norepinephrine bitartrate, potassium chloride, prednisolone sodium succinate, promazine HCl, sodium bicarbonate, verapamil HCl, and vitamin B-complex with or without vitamin C.

Heparin compatibility information conflicts or is dependent on diluent or concentration factors with the following drugs or solutions: dextrose-saline combinations, dextrose in water, lactated Ringer’s injection, saline solutions, ampicillin sodium, cephalothin sodium, dobutamine HCl, hydrocortisone sodium phosphate, and streptokinase.
succinate, methicillin sodium, oxytetracycline HCl, penicillin G sodium/potassium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Heparin sodium is reported physically incompatible when mixed with the following solutions or drugs: sodium lactate 1/6 M, amikacin sulfate, chloroprazone HCl, codeine phosphate, cytarabine, daunorubicin HCl, diazepam, doxorubicin HCl, droperidol HCl with and without fentanyl citrate, erythromycin lactobionate, gentamicin sulfate, hyaluronidase, kanamycin sulfate, levophanol bitartrate, meperidine HCl, methadone HCl, morphine sulfate, pentazocine lactate, phytenoin sodium, polymyxin B sulfate, streptomycin sulfate, and vancomycin HCl.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

- Heparin Sodium Injection: 1000 Units/mL, 2000 Units/mL, 2500 Units/mL, 5000 Units/mL, 10,000 Units/mL, 20,000 Units/mL, & 40,000 Units/mL in 0.5 mL, 1 mL, 2 mL, 4 mL, 5 mL, 10 mL, & 30 mL vials; generic; (Rx).
- Heparin Unit-Dose Sodium Injection: 1000 Units/dose, 2500 Units/dose, 5000 Units/dose, 7500 Units/dose, 10,000 Units/dose and 20,000 Units/dose in 1 mL, 10 mL, & 30 mL Dosette vials, 0.5 mL & 1 mL Tubex, 0.5 mL, 1 mL, 4 mL & 10 mL vials, and 1 mL fill in 2 mL Carpuject (depending on concentration and manufacturer); generic; (Rx).
- Heparin Sodium and 0.9% Sodium Chloride Injection: 1000 & 2000 Units in 500 mL and 1000 mL, respectively; generic; (Rx).
- Heparin Sodium and 0.45% Sodium Chloride Injection: 12,500 in 250 mL & 25,000 Units in 250 mL & 500 mL; generic (Abbott); (Rx).
- Heparin Sodium Lock Flush (IV use) Injection: 1 unit/mL in 1, 2, 2.5, 5 & 10 mL syringes; 10 Units/mL and 100 Units/mL in 1, 2, 5, 10 mL (regular and preservative free), 30 mL & 50 mL vials; 1 mL (regular and preservative free) & 2 mL Dosette vials; 1 mL & 2.5 mL Dosette cartridge needle Units; 1 mL amps; 1 mL, 2 mL, 2.5 mL, 3 mL, and 5 mL disposable syringes; Hep-Lock® and Hep-Loc® U/P (various); Hepflush-10® (American Pharmaceutical Partners); Heparin I.V. Flush (Medefil); generic; (Rx).
- Heparin Sodium Lock Flush (IV use) Injection: 1 unit/mL in 1, 2, 2.5, 5 & 10 mL syringes; 10 Units/mL and 100 Units/mL in 1, 2, 5, 10 mL (regular and preservative free), 30 mL & 50 mL vials; 1 mL (regular and preservative free) & 2 mL Dosette vials; 1 mL & 2.5 mL Dosette cartridge needle Units; 1 mL amps; 1 mL, 2 mL, 2.5 mL, 3 mL, and 5 mL disposable syringes; Hep-Lock® and Hep-Loc® U/P (various); Hepflush-10® (American Pharmaceutical Partners); Heparin I.V. Flush (Medefil); generic; (Rx).

**References**

**Uses/Indications**

Hyaluronate sodium (HS) is useful in the treatment of synovitis not associated with severe degenerative joint disease. It may be helpful to treat secondary synovitis in conditions where full thickness cartilage loss exists.

The choice of a high molecular weight product (MW >1x10<sup>6</sup>) versus a low molecular weight one is quite controversial. One author (Nixon 1992) states that “…low molecular weight products (which tend to be less expensive) can be equally efficacious in ameliorating signs of joint disease. When synovial adhesions and pannus are to be avoided (as in most surgeries for carpal and fetlock fracture fragment removal), higher molecular weight preparations are recommended because they inhibit proliferation of synovial fibroblasts.” However, at the time of writing, there are no controlled studies directly comparing the various products for treating joint disease and product choice is primarily a result of a clinician’s personal preference.

There is considerable interest in oral hyaluronate administration for treating equine joint disease. One blinded, controlled study found the use of an oral gel “nutraceutical” significantly reduced synovial effusion in tarsocrural joints post-arthroscopic surgery for osteochondritis dissecans (OCD) (Bergin et al. 2006).

**Pharmacology/Actions**

Hyaluronate sodium (HS) is found naturally in the connective tissue of both man and animals and is identical chemically regardless of species. Highest concentrations found naturally are in the synovial fluid, vitreous of the eye and umbilical cord. Surfaces of articular cartilage are covered with a thin layer of a protein-hyaluronate complex known as hyaluronic acid. Hyaluronate sodium (HS) is an antioxidant, anti-inflammatory, and anticoagulant with a wide variety of other purported actions, such as anti-aging and anti-cancer effects. It is also a component of the body’s immune system and has been shown to promote wound healing.

**Prescriber Highlights**

- **Parenteral, high viscosity mucopolysaccharide used for synovitis**
- **Contraindications:** None on label
- **Adverse Effects:** Local reactions possible
- **Different products have different dosages, etc:** check label before using

---

**HYALURONATE SODIUM**

**SODIUM HYALURONATE**

It is also a component of the body’s immune system and has been shown to promote wound healing.
found naturally are in the synovial fluid, vitreous of the eye and umbilical cord. Surfaces of articular cartilage are covered with a thin layer of a protein-hyaluronate complex; hyaluronate is also found in synovial fluid and the cartilage matrix. The net effects in joints include a cushioning effect, reduction of protein and cellular influx into the joint, and a lubricating effect. Hyaluronate has a direct antiinflammatory effect in joints by scavenging free radicals and suppressing prostaglandins.

**Pharmacokinetics**

In the equine joint the half life of hyaluronate has been reported to be 96 hours.

**Contraindications/Precautions/Warnings**

No contraindications to HS’s use are noted on the label. HS should not be used as a substitute for adequate diagnosis; radiographic examinations should be performed to rule out serious fractures. Do not perform intra-articular injections through skin that has been recently fired or blistered, or that has excessive scurf and counterirritants on it.

**Adverse Effects**

Some patients may develop local reactions manifested by heat, swelling, and/or effusion. Effects generally subside within 24–48 hours; some animals may require up to 96 hours for resolution. No treatment for this effect is recommended. When used in combination with other drugs, incidence of flares may actually be higher. No systemic adverse effects have been noted.

**Reproductive/Nursing Safety**

While HS is unlikely to cause problems, safe use in breeding animals has not been established and most manufacturers caution against its use in these animals.

**Overdosage/Acute Toxicity**

Acute toxicity studies performed in horses have demonstrated no systemic toxicity associated with overdoses.

**Drug Interactions/Laboratory Considerations**

None were noted.

**Doses**

- **HORSES:**
  
  a) Because of the differences in the commercially available products, see each individual product’s label for specific dosing information. The following are recommended doses from a review article (Goodrich & Nixon 2006) on the medical treatment of osteoarthritis in the horse:

  - *Hylartin-V®:* 20 mg IA
  - *Hyvisc®:* 20 mg IA
  - *Equoron®:* 10 mg IA
  - *Synacid®:* 50 mg IA
  - *Hyalovet®:* 20 mg IA
  - *Legend®:* 40 mg IV (also labeled for IA injection: 20 mg)

  b) To reduce joint effusion post-arthroscopic surgery for osteochondritis dissecans (OCD): 100 mg PO (as an oral gel; *Conquer®*) once daily for 30 days. (Bergin *et al.* 2006)

- **DOGS:**

  a) For the adjunctive treatment of synovitis (rather than the presence of a damaged articular cartilage): Using a high molecular weight compound: 3–5 mg intra-articularly using sterile technique at weekly intervals. Long-term effects are not achieved. (Bloomberg 1992)

**Client Information**

- HS should be administered by a veterinarian only, using aseptic technique.

**Chemistry/Synonyms**

Hyaluronate sodium (HS) is the sodium salt of hyaluronic acid which is a naturally occurring high-viscosity mucopolysaccharide. Much of the commercially available hyaluronic acid products are derived from the combs of roosters.

Hyaluronate sodium may also be known as: HA, hyaluronan, “rooster juice”, hyaluronic acid, and natrii hyaluronas; many trade names are available.

**Storage/Stability**

Store at room temperature or refrigerate depending on the product used—check label; do not freeze. Protect from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

- Hyaluronate Sodium: (average MW of 500,000–730,000) 20 mg/mL in 2 mL disposable syringes; *Hyalovet®* (BIVI); (Rx). FDA-approved for use in horses not intended for food.

- Hyaluronate Sodium Injection: 2 mL vial for IA administration; 4 mL, & 20 mL vials for IV administration; *Legend®* (Bayer); (Rx); FDA-approved for use in horses not intended for food.

- Hyaluronate Sodium Injection: 11 mg/mL in 2 mL syringes; *Hyvisc®* (BIVI); (Rx). FDA-approved for use in horses not intended for food.

- Hyaluronate Sodium: 10 mg/mL (MW 3.5X10^6) in 2 mL disposable syringes; *Hylartin®V* (Pfizer); (Rx). FDA-approved for use in horses not intended for food.

- Hyaluronate Sodium Oral Gel: 10 mg/mL (100 mg/10 mL) (apple-flavored) in 60 mL tubes; *Conquer® Equine Gel* (Kinetic). This product is labeled as a nutritional supplement and is not FDA-approved.

There may also be other hyaluronate products marketed as topical solutions, semen extenders, and oral supplements. These products are not necessarily approved by
The most prevalent adverse effects seen in small animals are hypotension, weakness/lethargy and syncope particularly when doses are increased too fast. Reflex effects also occur such as increased heart rate and cardiac output.

**Contraindications/Precautions/Warnings**

- Known hypersensitivity, coronary artery disease, hypovolemia or preexisting hypotension
- Severe renal disease, intracerebral bleeding, preexisting autoimmune diseases
- Hypotension, reflex tachycardia, sodium/water retention (if not given concurrently with a diuretic), or GI distress (vomiting, diarrhea)
- Drug interactions

**Uses/Indications**

Primary use of hydralazine in veterinary medicine is as an afterload reducer for the adjunctive treatment in CHF in small animals, particularly if mitral valve insufficiency is the primary cause. It is also useful in dogs and cats with large septal defects or severe aortic regurgitation. Hydralazine is usually used in cases where enalapril or another ACE inhibitor is not effective in clinical improving dogs with mitral insufficiency. It is used to treat systemic hypertension, particularly in combination with other drugs (e.g., beta-blockers) to offset hydralazine's tendency to cause reflex tachycardia and fluid retention. Hydralazine is not particularly useful in treating heart failure when myocardial disease is present.

**Pharmacology/Actions**

Hydralazine acts upon vascular smooth muscle and reduces peripheral resistance and blood pressure. Hydralazine is a semicarbazide-sensitive amine oxidase (SSAO) inhibitor. It is believed that hydralazine alters cellular calcium metabolism in smooth muscle, thereby interfering with calcium movements and preventing the initiation and maintenance of the contractile state. Hydralazine has more effect on arterioles than on veins.

In patients with CHF, hydralazine significantly increases cardiac output, and decreases systemic vascular resistance. Cardiac rate may be slightly increased or unchanged, while blood pressure, pulmonary venous pressure, and right atrial pressure may be decreased or unchanged.

When used to treat hypertensive patients (without CHF), increased heart rate, cardiac output and stroke volume can be noted. The renin-angiotensin system can be activated with a resultant increase in sodium and water retention if not given with diuretics or sympathetic blocking drugs.

Parenteral hydralazine administration can cause respiratory stimulation.

**Pharmacokinetics**

In dogs, hydralazine is rapidly absorbed after oral administration with an onset of action within one hour and peak effects at 3–5 hours. There is a high first-pass effect after oral administration. The presence of food may enhance the bioavailability of hydralazine tablets.

- Hydralazine is widely distributed in body tissues. In humans, approximately 85% of the drug in the blood is bound to plasma proteins. Hydralazine crosses the placenta and very small amounts are excreted into the milk.
- Hydralazine is extensively metabolized in the liver and approximately 15% is excreted unchanged in the urine. The half-life in humans is usually 2–4 hours, but may be as long as 8 hours.

Specific pharmacokinetic parameters for this drug in veterinary species are limited, but the duration of action of hydralazine in dogs after oral administration is reportedly 11–13 hours. Vasodilating effects occur within one hour and peak within 3 hours of dosing. Food decreases oral bioavailability in dogs by about 63%. At lower doses there is relatively high first pass effect, but this is apparently a saturable process as bioavailability increases with dose. N-acetylation is a primary enzymatic pathway for hydralazine metabolism and this pathway is mostly absent in dogs leading to concerns for increased risks for toxicity.

**Contraindications/Precautions/Warnings**

Hydralazine is contraindicated in patients hypersensitive to it and those with coronary artery disease. The drug is listed as contraindicated in human patients with mitral valvular rheumatic disease, but it has been recommended for use in small animal patients with mitral valve insufficiency. It is not recommended to use the drug in patients with hypovolemia or preexisting hypotension.

Doses need to be titrated upwards carefully as severe hypotension can result.

Hydralazine should be used with caution in patients with renal disease. Secondary to reduced renal blood flow, hydralazine can activate the renin angiotensin aldosterone system (RAAS) and exacerbate renal injury; pretreatment with an ACE inhibitor and spironolactone is often advised to reduce this risk.

Hydralazine should be used with caution in patients with intracerebral bleeding. In humans, a syndrome resembling systemic lupus erythematosus (SLE) has been documented after hydralazine use. While this syndrome has not been documented in veterinary patients, the drug should be used with caution in patients with preexisting autoimmune diseases.

**Adverse Effects**

The most prevalent adverse effects seen in small animals are hypotension, weakness/lethargy and syncope particularly when doses are increased too fast. Reflex effects also occur such as increased heart rate and cardiac output.

**References**

used for hypertension, a diuretic may not be required. Many clinicians recommend adding a venous dilating agent (e.g., nitroglycerin ointment) to reduce preload.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydralazine and may be of significance in veterinary patients:

- **ACE-INHIBITORS**: May cause additive hypotensive effect; usually used for therapeutic advantage
- **BETA-BLOCKERS**: May cause additive hypotensive effect; usually used for therapeutic advantage
- **DIAZOXIDE**: Potentially could cause profound hypotension
- **DIURETICS**: May cause additive hypotensive effect; usually used for therapeutic advantage
- **FUROSEMIDE**: Hydralazine may increase furosemide’s renal effects
- **MAO INHIBITORS**: May cause additive hypotensive effect
- **SYMPATHOMIMETICS (e.g., epinephrine)**: Hydralazine may cause decreased pressor effect and may cause additive tachycardia

**Doses**

For adjunctive therapy in treatment of heart failure:

- **a)** Effective dose is 0.5–3 mg/kg PO q12h. Dose must be titrated, starting with a low dose and titrating upwards.
  - In dogs not receiving ACE inhibitors: Get initial baseline assessment (mucous membrane color, capillary refill time, murmur intensity, cardiac size on radiographs, and severity of pulmonary edema). Starting dose is 1 mg/kg PO q12h and repeat assessments made in 12–48 hours. If no response identified, increase dosage to 2 mg/kg q12h. Repeat assessments as above and increase to 3 mg/kg PO q12h if no response. Can be titrated with or without blood pressure monitoring. If BP cannot be monitored titration is performed more slowly and clinical and radiographic signs are monitored.
  - If blood pressure measurement available, dosage titration can be made more rapidly than above: Measure baseline blood pressure. Administer 1 mg/kg PO. Repeat BP in 1–2 hours and if it has decreased by at least 15 mmHg, administer q12h from then on. If response inadequate, give another 1 mg/kg and repeat BP measurement in 1–2 hours. This may be repeated until a cumulative dose of 3 mg/kg has been given within a 12 hour period. The resulting cumulative dose becomes the dosage to be given q12h.
  - For dogs with acute, fulminant heart failure due to severe mitral regurgitation and not receiving ACE inhibitors: 2 mg/kg along with IV furosemide. May cause hypotension, but the risks of not effectively treating fulminant pulmonary edema outweigh the risks of treatment.
  - For dogs receiving ACE inhibitors: Give hydralazine with caution as severe hypotension may occur if dosage not titrated carefully. Begin dosing at 0.5 mg/kg with blood pressure monitoring and increase in 0.5 mg/kg increments until a response is identified to a maximum of 3 mg/kg. Consider referral. (Kittleson, M., 2007)

- **b)** For short-term treatment of CHF secondary to valve disease: Initial dose of 1 mg/kg PO. Blood pressure should be monitored; if the desired goal (MAP of 60-80 mmHg) is not achieved with the first 1 mg/kg dose (clinical effects noted within 1 hour and peak levels at 3 hours), an additional 0.5–1 mg/kg can be administered, to a maximum cumulative dose of 3 mg/kg. Once the desired blood pressure has been achieved, the dose can be administered PO q12h. (Erling & Mazzafarre 2008)

For treatment of systemic hypertension:

- **a)** As a fifth step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after 1) enalapril/benazepril (0.5 mg/kg q12h); 2) amlodipine (0.1 mg/kg q24h); 3) amlodipine (0.2 mg/kg q24h); 4) spironolactone (1–2 mg/kg twice daily); 5) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1-2 weeks systolic BP > 160 mmHg. (Henik 2007)

- **CATS:**
  - For adjunctive therapy in treatment of heart failure:
    - a) See (a) above “For adjunctive therapy in treatment of heart failure in dogs”,” but start titration at 2.5 mg (total dose) and if necessary, increase up to 10 mg. (Kittleson, M.D. 1985)
  - For treatment of systemic hypertension:
Hydralazine Injection: 20 mg/mL in 1 mL vials; generic; (Solopak); (Rx)

Hydralazine HCl Oral Tablets: 10 mg, 25 mg, 50 mg & 100 mg;

HUMAN-LABELED PRODUCTS:
The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status
consult specialized references for more specific information.

Compatibility/Compounding Considerations
Hydralazine is reported to be physically compatible with the following infusion solutions/drugs: dextrose-Ringer’s combinations, dextrose-saline combinations, Ringer’s injection, lactated Ringer’s injection, sodium chloride solutions, and dobutamine HCl.

Hydralazine is reported to be physically incompatible with mixed with 10% dextrose or fructose and is reported to be physically incompatible when mixed with the following drugs: aminophylline, ampicillin sodium, chlorothiazide sodium, edetate calcium disodium, hydrocortisone sodium succinate, mephentermine sulfate, methohexital sodium, phenobarbital sodium, and verapamil HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Storage/Stability
Hydralazine tablets should be stored in tight, light resistant containers at room temperature. The injectable product should be stored at room temperature; avoid refrigeration or freezing.

When mixed with most infusion solutions a color change can occur which does not necessarily indicate a loss in potency (if occurred over 8–12 hours).

Chemistry/Synonyms
A phthalazine-derivative antihypertensive and vasodilating agent, hydralazine HCl occurs as an odorless, white to off-white crystalline powder with a melting point between 270–280°C and a pKa of 7.3. One gram is soluble in approximately 25 mL of water or 500 mL of alcohol. The commercially available injection has a pH of 3.4–4.

Hydralazine may also be known as: apressinum, hydralazini, hydrallazine, idralazina, Alphapress®, Apresolin®, Apresolina®, Bionobal®, Cesoline®, Hidral®, Hydroapres®, Hyperex®, Hyperphen®, Ipolina®, Nepres®, Novo-Hylazin®, Nu-Hydral®, Rolazine®, Slow-Apresoline®, and Supres®.

Client Information

Because blood dyscrasias are a possibility, an occasional CBC should be considered.

If possible, arterial blood pressure and venous PO₂. A mean arterial pressure (MAP) of between 60-80 mmHg has been recommended when used in dogs for the short-term treatment of CHF secondary to valve disease (Erling & Mazzaferra 2008).

Compatibility:
When mixed with most infusion solutions a color change can occur which does not necessarily indicate a loss in potency (if occurred over 8–12 hours).

Contraindications:

Hydrochlorothiazide
(hye-dro-klor-o-thye-azide) HydroDIURIL®

THIAZIDE DIURETIC

Prescriber Highlights

- Thiazide diuretic used for nephrogenic diabetes insipidus, hypertension, calcium oxalate uroliths, hypoglycemia, & diuretic for heart failure
- Contraindications: Hypersensitivity; pregnancy (relative contraindication)
- Extreme Caution/Avoid: Severe renal disease, preexisting electrolyte/water balance abnormalities, impaired hepatic function, hyperuricemia, SLE, diabetes mellitus
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrochlorothiazide and may be of significance in veterinary patients:

- Adverse Effects: Hypokalemia, hypochloremic alkalosis, other electrolyte imbalances, hyperuricemia, GI effects
- Many possible drug interactions; lab test interactions

### Uses/Indications
In veterinary medicine, furosemide has largely supplanted the use of thiazides as a general diuretic (edema treatment). But there are times when they can be very useful drugs. Thiazides are still used for the treatment of systemic hypertension, ascites, hypermagnesemia, nephrogenic diabetes insipidus, and to help prevent the recurrence of calcium oxalate uroliths in dogs, and potentially cats. In horses, hydrochlorothiazide may be used as an alternative to acetazolamide for HyPP in horses where dietary therapy alone does not control episodes.

### Pharmacology/Actions
Thiazide diuretics act by interfering with the transport of sodium ions across renal tubular epithelium possibly by altering the metabolism of tubular cells. The principle site of action is at the cortical diluting segment of the nephron. Enhanced excretion of sodium, chloride, and water results. Thiazides increase the excretion of potassium, magnesium, phosphate, iodide, and bromide and decrease the glomerular filtration rate (GFR). Plasma renin and resulting aldosterone levels are increased which contribute to the hypokalemic effects of the thiazides. Bicarbonate excretion is increased, but effects on urine pH are usually minimal. Thiazides initially have a hypercalciuric effect, although with continued therapy calcium excretion this is significantly decreased. Uric acid excretion is decreased by the thiazides. Thiazides can cause or exacerbate hyperglycemia in diabetic patients or induce diabetes mellitus in prediabetic patients.

The antihypertensive effects of thiazides are well known and these agents are used extensively in human medicine for treating essential hypertension. The exact mechanism for this effect has not been established.

Thiazides paradoxically reduce urine output in patients with diabetes insipidus (DI). They have been used as adjunctive therapy in patients with neurogenic DI and are the only drug therapy for nephrogenic DI.

### Pharmacokinetics
The pharmacokinetics of the thiazides have apparently not been studied in domestic animals. In humans, hydrochlorothiazide is about 65–75% absorbed after oral administration. The onset of diuretic activity occurs in 2 hours; peaks at 4–6 hours. The serum half-life is approximately 5.6–14.8 hours and the duration of activity is 6–12 hours. The drug is apparently not metabolized and is excreted unchanged into the urine. Like all thiazides, the antihypertensive effects of hydrochlorothiazide may take several days to occur.

### Contraindications/Precautions/Warnings
Thiazides are contraindicated in patients hypersensitive to any one of these agents or to sulfonamides, and in patients with anuria. In humans, their use is inappropriate during pregnancy in women who are otherwise healthy and have only mild edema.

- Do not use in dogs with absorptive (intestinal) hypercalcuria as hypercalciemia may result.
- Thiazides should be used with extreme caution, if at all, in patients with severe renal disease or with preexisting electrolyte (including hypercalcemia) or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), hyperuricemia, lupus (SLE), or diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (e.g., vomiting, diarrhea, etc.) should be monitored carefully.

### Adverse Effects
Hypokalemia is one of the most common adverse effects associated with the thiazides but rarely causes clinical signs or progresses, however, monitoring of potassium is recommended with chronic therapy.

- Hypochloremic alkalosis (with hypokalemia) may develop, especially if there are other causes of potassium and chloride loss (e.g., vomiting, diarrhea, potassium-losing nephropathies, etc.) or the patient has cirrhotic liver disease. Dilutional hyponatremia and hypomagnesemia may occur. Hyperparathyroid-like effects of hypercalcemia and hypophosphatemia have been reported in humans, but have not led to effects such as nephrolithiasis, bone resorption, or peptic ulceration.
- Hyperuricemia can occur, but is usually asymptomatic.
- Other possible adverse effects include: GI reactions (vomiting, diarrhea, etc.), hypersensitivity/dermatologic reactions, GU reactions (polyuria), hematologic toxicity, hyperglycemia, hyperlipidemias, and orthostatic hypotension.

### Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), thiazides are categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as last resort when the benefit of therapy clearly outweighs the risks.)

- Thiazides may appear in milk and there have been case reports of newborn human infants developing thrombocytopenia when their mothers received thiazides.

### Overdosage/Acute Toxicity
Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures), and GI effects (hypermotility, GI distress). Transient increases in BUN have been reported.

- Treatment consists of emptying the gut after recent oral ingestion using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that may ensue. Monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and cardiovascular status; treat supportively and symptomatically if required.

### Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrochlorothiazide and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Use with thiazides can lead to an increased risk for severe hypokalemia
- **CORTICOSTEROIDS, CORTICOTROPIN**: Use with thiazides can lead to an increased risk for severe hypokalemia
- **DIURETICS**: Use with thiazides can lead to an increased risk for severe hypokalemia
**CORTICOSTEROIDS, CORTICOTROPIN:** Use with thiazides can lead to an increased risk for severe hypokalemia

**DIAZOXIDE:** Increased risk for hyperglycemia, hyperuricemia, and hypotension

**INSULIN:** Thiazides may increase insulin requirements

**LITHIUM:** Thiazides can increase serum lithium concentrations

**METENAMINE:** Thiazides can alkalinize urine and reduce methenamine effectiveness

**NSAIDS:** Thiazides may increase risk for renal toxicity and NSAIDs may reduce diuretic actions of thiazides

**NEUROMUSCULAR BLOCKING AGENTS:** Tubocurarine or other nondepolarizing neuromuscular blocking agents response or duration of effect may be increased

**PROBENECID:** Blocks thiazide-induced uric acid retention (used to therapeutic advantage)

**QUINIDINE:** Half-life may be prolonged by thiazides (thiazides can alkalinize the urine)

**VITAMIN D OR CALCIUM SALTS:** Hypercalcemia may be exacerbated if thiazides are concurrently administered

**Laboratory Considerations**

**AMYLASE:** Thiazides can increase serum amylase values in asymptomatic patients and those in the developmental stages of acute pancreatitis (humans)

**CORTISOL:** Thiazides can decrease the renal excretion of cortisol

**ESTROGEN, URINARY:** Hydrochlorothiazide may falsely decrease total urinary estrogen when using a spectrophotometric assay

**HISTAMINE:** Thiazides may cause false-negative results when testing for pheochromocytoma

**PARATHYROID-FUNCTION TESTS:** Thiazides may elevate serum calcium; recommend to discontinue thiazides prior to testing

**PHENOLSULFONPHTHALEIN (PSP):** Thiazides can compete for secretion at proximal renal tubules

**PHENTOLAMINE TEST:** Thiazides may give false-negative results

**PROTEIN-BOUND IODINE:** Thiazides may decrease values

**TRIODOOTHYRONINE RESIN UPTAKE TEST:** Thiazides may slightly reduce uptake

**TYRAMINE:** Thiazides can cause false-negative results

**Doses**

**DOGS:**

For treatment of nephrogenic diabetes insipidus:

a) Based on a case report: 2 mg/kg PO twice daily with a low sodium diet. (Takemura 1998)

b) 2.5–5 mg/kg PO twice daily (Nichols 1989)

For treatment of systemic hypertension:

a) As a second choice agent, 1 mg/kg PO q12–24h; may combine with spironolactone (1–2 mg/kg PO q12 hours) to reduce potassium loss (Brown & Henik 2000), (Brown 2008)

For prevention of recurrent calcium oxalate uroliths with renal hypercalcuria (usually added when dietary therapy does not adequately control calcium oxalate crystalluria):

a) 2 mg/kg q12h PO (Polzin & Osborne 1985), (Adams 2009)

b) 2.2 mg/kg PO q12h; repeat urinalysis q2–4 weeks and monitor serum electrolytes within several weeks of initial dose and within 2 weeks of dosage adjustment (Lulich et al. 2000)

c) 2–4 mg/kg PO q12h (Bartges 2006)

As a diuretic:

a) For heart failure In combination with furosemide in patients who have become refractory to furosemide alone: 2–4 mg/kg PO q12h (Kittleson 2000), (Kittleson 2006)

b) For adjunctive treatment of heart failure when a dog requires 4–5 mg/kg PO q8h of furosemide and continues to exhibit clinical signs of congestion, reduce the furosemide dose by 50% and add hydrochlorothiazide at 2 mg/kg PO q12h. (Saunders 2008)

c) For ascites secondary to right-sided heart failure; In addition to furosemide (4–6 mg/kg PO q8h), spironolactone (1–2 mg/kg PO q12h), ACE inhibitors, dietary sodium restriction, etc consider: hydrochlorothiazide at 2 mg/kg initially on an every other day bases; monitor electrolytes and renal function. (Connolly 2006)

d) For ascites in patients with liver disease: Using the fixed-dose combination with spironolactone (aka Aldactazide®): Dosed empirically based on the spironolactone content at 0.5–1 mg/kg PO twice daily. (Trepanier 2008)

e) 1–4 mg/kg PO q12h (Haskins 2007)

**CATS:**

For treatment of systemic hypertension:

a) As a second choice agent, 1 mg/kg PO q12–24h; may combine with spironolactone (1–2 mg/kg PO q12 hours) to reduce potassium loss (Brown & Henik 2000), (Brown 2008)

b) 2–4 mg/kg PO q12h. Not effective as a single agent in cats, and may be contraindicated (e.g., chronic renal failure). Possibly helpful acutely with retinal detachment. (Sparkes, 2003)

As a diuretic:

a) For heart failure: In combination with furosemide in patients who have become refractory to furosemide alone: 1–2 mg/kg PO q12h (Kittleson 2000).
b) For ascites in patients with liver disease: Using the fixed-dose combination with spironolactone (aka Aldactazide®): Dosed empirically based on the spironolactone content at 0.5–1 mg/kg PO twice daily. (Trepanier 2008)

To reduce calcium oxalate saturation in urine:

a) Study done in normal cats, unknown what effect HCTZ will have in cats with spontaneously occurring calcium oxalate urolithiasis: 1 mg/kg PO q12h. (Hezel et al. 2007)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)

For adjunctive therapy of hyperkalemic periodic paralysis (HyPP):

a) 0.5–1 mg/kg PO q12h when diet adjustment does not control episodes. (Valberg 2008)

**Client Information**

- Clients should contact veterinarian if clinical signs of water or electrolyte imbalance occur. Clinical signs such as excessive thirst, lethargy, lassitude, restlessness, oliguria, GI distress, or tachycardia may indicate electrolyte or water balance problem.

**Chemistry/Synonyms**

Hydrochlorothiazide occurs as a practically odorless, slightly bitter-tasting, white, or practically white, crystalline powder with pKₐ of 7.9 and 9.2. It is slightly soluble in water and soluble in alcohol.

Hydrochlorothiazide may also be known as: HCTZ, hydrochlorothiazide, or hydrochlorothiazidum; many trade names are available.

**Storage/Stability**

Hydrochlorothiazide capsules and tablets should be stored at room temperature in well-closed containers.

**Compatibility/Compounding Considerations**

**Compounded preparation stability:** Spironolactone and hydrochlorothiazide oral suspension compounded from commercially available tablets has been published (Allen & Erickson 1996). Triturating twenty-four (24) spironolactone and hydrochlorothiazide 25/25 mg tablets with 60 mL of Ora-Plus® and qs ad to 120 mL with Ora-Sweet® (or Ora-Sweet® SF) yields a 5 mg/mL suspension of both spironolactone and hydrochlorothiazide that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of hydrochlorothiazide should be protected from light.

**Dosage Forms/Regulatory Status**

**HUMAN-LABELLED PRODUCTS:**

Hydrochlorothiazide Oral Tablets: 25 mg, 50 mg, & 100 mg; HydroDIURIL® (Merck); Hydro-Par® (Parmed); Ezide® (Econo Med); generic; (Rx)

Hydrochlorothiazide Oral Capsules: 12.5 mg; Microzide® Capsules (Watson); generic; (Rx)

Spironolactone/Hydrochlorothiazide Oral Tablets: 25 mg/25 mg & 50 mg/50 mg; Aldactazide® (Searle); generic; (Rx)

There are other fixed dose combinations available with hydrochlorothiazide, including: hydroalazine, amiloride, propranolol, triamterene, captopril, reserpine, enalapril, guanethidine, metoprolol, timolol, methyldopa or labetolol.

**References**

Opiate

**Prescriber Highlights**

- Opiate agonist used primarily as an antitussive in dogs. Also potentially useful as an oral analgesic for moderate pain in dogs.

- Contraindications: Hypersensitivity to narcotic analgesics, patients receiving monoamine oxidase inhibitors (MAOIs; Selegiline?), diarrhea caused by a toxic ingestion. Any combination product containing acetaminophen must NOT be used in cats.

- Caution: Patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), head injuries or increased intracranial pressure, acute abdominal conditions, & geriatric or severely debilitated patients.

**HYDROCODONE BITARTRATE**

(hye-droe-koe-doe) Tussigon®, Hycofan®
Uses/Indications

Used principally in canine medicine as an antitussive for cough secondary to conditions such as collapsing trachea, bronchitis, or canine upper respiratory infection complex (C-URI, “kennel cough”, canine infectious tracheobronchitis). Its use is generally reserved for harsh, dry, non-productive coughs. Hydrocodone may be useful in treating opioid-related behavior problems in dogs and cats (lick granuloma, stereotypies) by providing an exogenous source of opioid, thereby reducing the need for the self-stimulating behavior.

The human combination products containing hydrocodone and acetaminophen potentially could be useful oral analgesics in dogs (NOT cats).

Pharmacology/Actions

While hydrocodone exhibits the characteristics of other opiate agonists, it tends to have a slightly greater antitussive effect than codeine (on a weight basis). The mechanism of this effect is thought to be as a result of direct suppression of the cough reflex on the cough center in the medulla. Hydrocodone tends to have a drying effect on respiratory mucosa and the viscosity of respiratory secretions may be increased; the addition of homatropine MBr (in Hycodan® and others) may enhance this effect. Hydrocodone may also be more sedating than codeine, but it is not more constipating.

Pharmacokinetics

In humans, hydrocodone is well absorbed after oral administration and has a serum half-life of about 3.8 hours; antitussive effect usually lasts 4–6 hours in adults.

Hydrocodone has an oral bioavailability of 40%-80% in dogs. Hydrocodone is partially metabolized to hydromorphone. The antitussive and analgesic actions of hydrocodone generally persist for 6–12 hours.

Contraindications/Precautions/Warnings

Hydrocodone is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, and those with diarrhea caused by a toxic ingestion (until the toxin is eliminated from the GI tract). All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients.

Hydrocodone products containing acetaminophen (e.g., Vicodin®, Lortab®, etc.) must not be used in cats.

Hydrocodone should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory diseases when respiratory secretions are increased or when liquids are nebulized into the respiratory tract.

Hydrocodone products have a relatively high abuse potential in humans and veterinarians are advised to be on the lookout for drug seeking clients.

Adverse Effects

Side effects that may be encountered with hydrocodone therapy in dogs include sedation, constipation (with chronic therapy), vomiting or other GI disturbances.

Hydrocodone may mask the clinical signs (cough) of respiratory disease and should not take the place of appropriate specific treatments for the underlying cause of coughs.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans).

It is unknown if hydrocodone enters milk; use with caution.

Overdosage/Acute Toxicity

The initial concern with a very large overdose of Hycodan® (or equivalent) would be the CNS, cardiovascular and respiratory depression secondary to the opiate effects.

There were 21 exposures to hydrocodone bitartrate reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspca.org) during 2001–2006. In these cases 18 were dogs and 3 were cats. No clinical signs were reported in these cases.

If the ingestion was recent, emptying the gut using standard protocols should be performed and treatment with naloxone instituted as necessary. The homatropine ingredient may give rise to anticholinergic effects that may complicate the clinical picture, but its relatively low toxicity may not require any treatment. For further information on handling opiate or anticholinergic overdoses, refer to the meperidine and atropine monographs, respectively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrocodone and may be of significance in veterinary patients:

- **ACEPROMAZINE**: Acepromazine and hydrocodone may cause additive hypotension in dogs with collapsing trachea
- **ANTICHOLINERGIC DRUGS**: May cause additive anticholinergic effects
- **ANTIDEPRESSANTS, TRICYCLIC & MOA INHIBITORS**: Use with hydrocodone may potentiate the adverse effects associated with the antidepressant
- **CNS DEPRESSANTS, OTHER**: Other CNS depressants (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.) may cause increased CNS or respiratory depression when used with hydrocodone.

Doses

**DOGS:**
DOGS:

a) For cough: 0.22 mg/kg PO q6–12h; goal is to suppress coughing without causing excessive sedation (Johnson 2000)
b) As an analgesic using the fixed dose combination products with acetaminophen: 0.22–0.5 mg/kg of the hydrocodone component PO q8-12h. Do not exceed 15 mg/kg of the acetaminophen component q8h. (KuKanich 2008)
c) For cough using Hycodan® (or equivalent): ¼ to 1 tablet (5 mg) once to 4 times daily in small and medium sized dogs. For lick granulomas: 5–10 mg (1–2 tablets) per 20 kg of body weight PO three times daily. (Trepanier 1999)
d) For adjunctive treatment of opioid-related stereotypies, lick granuloma: 0.22–0.25 mg/kg PO q8–12h. Supplies exogenous opioids to decrease the need for self-stimulation. (Siebert 2003)

CATS:

a) For adjunctive treatment of opioid-related stereotypies: 1.25–5 mg per cat PO q12h. Supplies exogenous opioids to decrease the need for self-stimulation. (NOTE: Do NOT use any product that contains acetaminophen—Plumb) (Siebert 2003)

Monitoring

Clinical efficacy

Chemistry/Synonyms

A phenanthrene-derivative opiate agonist, hydrocodone bitartrate occurs as fine, white crystals or crystalline powder. One gram is soluble in about 16 mL of water; it is slightly soluble in alcohol.

Hydrocodone bitartrate may also be as: hydrocodone tartrate, dihydrocodeinone acid tartrate, hydrocodone acid tartrate, hydrocodoni bitartras, hydrocone bitartrate, Biocodone®, Dicodid®, Hydrokon®, and Robidone®.

Storage/Stability

Products should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydrocodone Bitartrate Oral Tablets: 5 mg, Homatropine MBr 1.5 mg; Tussigon® (Daniels); Hycodan® (Endo); (Rx, C-III)

Hydrocodone Bitartrate Oral Syrup: 5 mg, Homatropine MBr 1.5 mg (per 5 mL) in 473 mL and 3.8 L; Hycodan® Syrup (Endo); Hydromer® Syrup (Alpharma); Hydromide® Syrup (Major); Hydropane® Syrup (Watson); (Rx, C-III)

The following are representative oral dosage forms containing hydrocodone and acetaminophen and include those most likely to be of benefit in treating dogs (higher ratios of hydrocode:acetaminophen) and are usually stocked at human pharmacies. WARNING: These products must NOT be used in cats:

Hydrocodone/Acetaminophen Oral Tablets: 5 mg/325mg, 5 mg/500 mg (also available in capsules), 7.5 mg/325mg, & 10 mg/325mg. An oral elixir containing hydrocode 2.5mg/5 mL and acetaminophen 167 mg/5 mL (0.5 mg/mL hydrocode and 33.3 mg/mL of acetaminophen) is also readily available. Commonly used trade names for these products include: Vicodin®, Norco®, and Lortabs®.

There are also oral tablets and liquids with hydrocode available in combination with decongestants (pseudoephedrine, phenylephrine, or phenylpropanolamine), antihistamines (chlorpheniramine), analgesics (ibuprofen or aspirin) or expectorants (guaifenesin). In the USA, there are no hydrocode products available as a sole ingredient. All commercially available products containing hydrocode are Class-III controlled substances.

References

HYDROCORTISONE

HYDROCORTISONE SODIUM SUCCINATE
(hye-dro-kor-tip-i-zone) Cortef®, Solu-Cortef®

GLUCOCORTICOID

Prescriber Highlights

• “Benchmark” injectable, oral, & topical glucocorticoid (depending on salt)
• Has both mineralocorticoid & glucocorticoid activity
• If using for therapy, goal is to use as much as is required & as little as possible, for as short an amount of time as possible
• Primary adverse effects are “Cushingoid” in nature with sustained use
• Many potential drug & lab interactions
Uses/indications
Because of its rapid effect and relatively high mineralocorticoid effect, hydrocortisone sodium succinate (Solu-Cortef®) is the most commonly used form of this medication when an acute glucocorticoid/mineralocorticoid effect is desired (e.g., acute adrenal insufficiency). Corticosteroids have not been shown beneficial in treating hypovolemic shock, but low dose glucocorticoids probably reduce mortality associated with septic shock.

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an anti-inflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

Pharmacology/Actions
Glucocorticoids have effects on virtually every cell type and system in mammals. See the Glucocorticoid General Information monograph for more information.

Pharmacokinetics
In humans, hydrocortisone is readily absorbed after oral administration. Hydrocortisone sodium succinate is administered parenterally, and absorption is rapid after IM administration. Duration of activity is 8-12 hours.

contraindications/precautions/warnings
Systemic use of glucocorticoids are generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse effects
Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU), may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when drug is given. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects.

Reproductive/Nursing Safety
Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreatic, and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

overdose/Acute Toxicity
Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrocortisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia; in humans, there have been cases of CHF and cardiac enlargement reported after using hydrocortisone to treat Amphotericin B adverse effects
- **ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels and increase risk for GI ulceration/bleeding
- **BARBITURATES:** May increase the metabolism of glucocorticoids and decrease flumethasone blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIURETICS, POTASSIUM DEPLETING (e.g., spironolactone, triamterene):** Administered concomitantly with glucocorticoids may cause hypokalemia
DIURETICS, POTASSIUM-DEPLETING (e.g., spironolactone, triamterene): Administered concomitantly with glucocorticoids may cause hypokalemia

EPHEDRINE: May reduce hydrocortisone blood levels

ESTROGENS: The effects of hydrocortisone and, possibly, other glucocorticoids, may be potentiated by concomitant administration with estrogens

INSULIN: Insulin requirements may increase in patients receiving glucocorticoids

KETOCONAZOLE AND OTHER AZOLE ANTIFUNGALS: May decrease the metabolism of glucocorticoids and increase hydrocortisone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis

MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin): May decrease the metabolism of glucocorticoids and increase hydrocortisone blood levels

MITOTANE: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency

NSAIDS: Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration

PHENOBARBITAL: May increase the metabolism of glucocorticoids and decrease hydrocortisone blood levels

PHENOBARBITAL: May increase the metabolism of glucocorticoids and decrease hydrocortisone blood levels

RIFAMPIN: May increase the metabolism of glucocorticoids and decrease hydrocortisone blood levels

VACCINES: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

WARFARIN: Hydrocortisone may affect INR’s; monitor

Laboratory Considerations

Hydrocortisone can cross react with cortisol in ACTH response test. This test must be performed before hydrocortisone is administered. (Note: Dexamethasone does not cross react)

Glucocorticoids may increase serum cholesterol

Glucocorticoids may increase urine glucose levels

Glucocorticoids may decrease serum potassium

Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce $T_3$ & $T_4$ values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of $^{131}$I by the thyroid may be decreased by glucocorticoids.

Reactions to skin tests may be suppressed by glucocorticoids

False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids

Glucocorticoids may cause neutrophilia within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation

Glucocorticoids can cause lymphopenia which can persist for weeks after drug discontinuation in dogs

Doses

**DOGS:**

For adjunctive therapy for adrenocortical insufficiency:

a) For adjunctive treatment for acute hypoadrenocortical crisis: Hydrocortisone sodium succinate 0.5 mg/kg/hr as an IV infusion until GI function has returned, the dog is eating and drinking normally and can be changed to oral steroid supplementation. (Church 2009)

b) For adjunctive treatment of acute crisis: Hydrocortisone sodium succinate as a constant CRI of 0.3 mg/kg IV. May also be given IV at 2 mg/kg IV q6h or 2-4 mg/kg IV q8h. (Panciera 2009)

For adjunctive therapy of septic shock:

a) 0.08 mg/kg/hr IV. Low-dose hydrocortisone infusions can reduce the time that vasopressors are required and lead to earlier resolution of sepsis-induced organ dysfunction. (Crowe 2002)

**CATS:**

For adjunctive therapy of septic shock:

a) 0.08 mg/kg/hr IV. Low-dose hydrocortisone infusions can reduce the time that vasopressors are required and lead to earlier resolution of sepsis-induced organ dysfunction. (Crowe 2002)

**CATTLE:**

For adjunctive treatment of photosensitization reactions:

a) 100–600 mg (salt not specified) in 1000 mL of 10% dextrose saline IV or SC. (Black 1986)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)

As a glucocorticoid:

a) Hydrocortisone sodium succinate: 1–4 mg/kg as an IV infusion (Robinson 1987)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
References

There are many OTC and Rx topical and anorectal products available in a variety of dosage forms.

Hydrocortisone Sodium Succinate Injection: 100 mg/vial, 250 mg/vial, 500 mg/vial, 1000 mg/vial (as sodium succinate) in 2 mL, 4 mL and 8 mL

Hydrocortisone Oral Tablets: 5 mg, 10 mg, & 20 mg;

Storage/Stability

Hydrocortisone sodium succinate (HSS) in intact containers should be stored at controlled room temperatures of 68-77°F (20–25°C). After reconstitution, solutions are stable if protected from light and kept at, or below controlled room temperature. The solution should only be used if clear; discard unused solutions after three days. Reconstituted HSS 500 mg/4 mL solution kept frozen for 4 weeks showed no loss of potency.

Hydrocortisone tablets should be stored in well-closed containers. The cypionate oral suspension should be stored in tight, light resistant containers. All products should be stored at room temperature (15–30°C); avoid freezing the suspensions or solutions. After reconstituting solutions, only products that are clear. Discard unused solutions after 3 days.

Compatibility/Compounding Considerations

Hydrocortisone sodium succinate is reportedly physically compatible with the following solutions and drugs: dextrose-Ringer’s injection combinations, dextrose-Ringer’s lactate injection combinations, dextrose-saline combinations, dextrose injections, Ringer’s injection, lactated Ringer’s injection, sodium chloride injections, amikacin sulfate, aminophylline, amphotericin B (limited quantities), calcium chloride/glucanate, cefalothin sodium (not in combination with aminophylline), cephalasin sodium, chloramphenicol sodium succinate, clindamycin phosphate, corticotropin, daunorubicin HCl, dopamine HCl, erythromycin lactobionate, lidocaine HCl, methotrexate sodium, metronidazole with sodium bicarbonate, netilmicin sodium, pentamidine isethionate, pipercillin sodium, polymyxin B sulfate, potassium chloride, prochlorperazine edisylate, sodium bicarbonate, thiopental sodium, vancomycin HCl, verapamil HCl, and vitamin B-complex with C.

Hydrocortisone sodium succinate is reportedly physically incompatible when mixed with the following solutions and drugs: ampicillin sodium, bleomycin sulfate, colistimethate sodium, dimenhydrinate, diphenhydramine HCl, doxorubicin HCl, ephedrine sulfate, heparin sodium, hydralazine HCl, metaraminol bitartrate, methicillin sodium, nafcillin sodium, oxytetracycline HCl, pentobarbital sodium, phenobarbital sodium, promethazine HCl, seobarbital sodium, and tetracycline HCl.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VEGETARIAN-LABELED PRODUCTS:

There are no products containing hydrocortisone (or its salts) known for systemic use. There are a variety of hydrocortisone veterinary products for topical use. A 10 ppb tolerance has been established for hydrocortisone (as the succinate or acetate) in milk.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydrocortisone Oral Tablets: 5 mg, 10 mg, & 20 mg; Cortef® (Upjohn); generic; (Rx)

Hydrocortisone Sodium Succinate Injection: 100 mg/vial, 250 mg/vial, 500 mg/vial, 1000 mg/vial (as sodium succinate) in 2 mL, 4 mL and 8 mL Univials, fliptop vials, Act-O-Vials and vials; Solu-Cortef® (Pfizer); A-Hydrocorr® (Hospira); (Rx)

There are many OTC and Rx topical and anorectal products available in a variety of dosage forms.

References

HYDROGEN PEROXIDE 3% (ORAL)

(hy-dee-ron per-ok-side)

ORAL EMETIC, TOPICAL ANTISEPTIC

Also see the Decontamination information in the appendix

Prescriber Highlights

- Topical antiseptic that is used orally as an emetic in dogs & sometimes cats particularly when clients cannot transport the patient to a veterinary
Topical antiseptic that is used orally as an emetic in dogs & sometimes cats particularly when clients cannot transport the patient to a veterinary hospital in a timely manner

- Many contraindications to use (for emesis)

**Uses/Indications**
Hydrogen peroxide 3% solution can be used as an orally administered emetic in dogs, cats, pigs and ferrets. It is best reserved for those cases when animals cannot be transported to a veterinary hospital in a timely way and immediate emesis is required. Apomorphine for dogs and cats (apomorphine is somewhat controversial for cats), or xylazine for cats are generally preferred emetic agents to be administered in a veterinary practice.

**Pharmacology/Actions**
Orally administered hydrogen peroxide solution (3%) induces a vomiting reflex via direct irritant effects of the oropharynx and gastric lining. After administering PO to dogs or cats, emesis usually ensues within 10 minutes.

**Pharmacokinetics**
No pharmacokinetic information located.

**Contraindications/Precautions/Warnings**
Do not induce emesis in those dogs or cats that are already vomiting, severely lethargic, comatose, debilitated (e.g., respiratory distress, decreased swallowing reflex, bradycardia, etc.), seizing or hyperactive, have had recent abdominal surgery or with megaeosophagus. Emesis is generally contraindicated after ingestions of corrosives/caustics (e.g., acids, alkalis), sharp objects, or bagged illicit drugs. Emesis is usually contraindicated after ingestion of a hydrocarbon or petroleum distillate.

Use caution when attempting to induce emesis in a dog that has ingested a compound that can cause seizures or CNS depression as CNS status may rapidly deteriorate.

Before inducing emesis, obtain a complete history of the ingestion and ensure that vital signs are stable.

Administration and emesis generally must occur within 4 hours (some say 2 hours or 6 hours maximum) of the toxic ingestion.

Do not use emetics in rodents or rabbits.

If home administration of hydrogen peroxide is necessary, be sure that clients use only the 3% medical grade solution and not another more concentrated hydrogen peroxide product.

Because aspiration and/or bradycardia are possible, animals should be closely observed after administration. Suctioning, respiratory and cardiovascular support (e.g., atropine) should be available. Do not allow animal to re-ingest vomitus.

Successful induction of emesis does not ensure that stomach contents have been emptied and significant quantities of the ingested drug/toxin may remain or already been absorbed.

**Adverse Effects**
Aspiration of hydrogen peroxide solution during administration or stomach contents after inducing emesis is possible. Inducing emesis in animals with cardiovascular compromise may cause a vasovagal (bradycardic) response. Gastric ulceration in cats and gastric-dilatation-volvulus in dogs have been reported.

**Reproductive/Nursing Safety**
No specific information was located. While orally administered 3% hydrogen peroxide is unlikely to cause reproductive harm, weigh the risks to the dam and offspring of the ingested toxin versus the risks associated with inducing emesis.

**Overdosage/Acute Toxicity**
Hydrogen peroxide 3% solution is relatively non-toxic (see Adverse Effects) after oral ingestion. Hydrogen peroxide in concentrations of 10% or greater can be very corrosive (severe burns to oral/gastric mucosa) and induce oxygen emboli after oral ingestion.

**Drug Interactions**
- **ACETYLCYSTEINE (oral):** Hydrogen peroxide can oxidize acetylcysteine in the gut and although clinical significance is unclear, alternative emetics (e.g., apomorphine, xylazine) are preferred for acetaminophen overdoses

- **ANTIEMETICS (e.g., ondansetron, maropitant, etc.):** Preadministration or ingestion of these products may negate the emetic effects of hydrogen peroxide

**Doses**
- **DOGS/CATS:** (Note: May also be effective in pot-bellied pigs and ferrets):

  As an emetic:
  - a) 1 teaspoon (5 mL) per 5 lbs. (2.3 kg) of body weight (approximately 2 mL/kg) not to exceed 3 tablespoons (45 mL). Vomiting usually occurs within minutes and can be repeated once if not initially successful. (Richardson 2009)
  - b) 1–2 mL/kg PO up to 2–3 times (Rudloff 2006)
  - c) 1–5 mL/kg PO; generally not to exceed 50 mL for dogs and 10 mL for cats; may repeat one time if after 10 minutes emesis does not occur. Inducing emesis is most effective if administered after a small meal. (Peterson 2006)

**Monitoring**
- Efficacy (emesis, signs associated with toxicity of the substance ingested, blood levels of toxicants if applicable)
- Heart rate/respiration rate & auscultation after emesis
Client Information

- Use only under the direct instructions of a veterinarian or a poison control center
- Only use hydrogen peroxide 3%; stronger concentrations can be very toxic
- Carefully administer; do not allow patient to “inhale” the liquid
- Observe animal after administration, do not allow them to re-ingest the vomited material (vomitus)
- Save all vomitus for the veterinarian to examine

Chemistry/Synonyms

Hydrogen peroxide 3% solution is a clear, colorless liquid containing 2.5–3.5% w/v hydrogen peroxide. Up to 0.05% of the liquid may contain preservatives.

Hydrogen peroxide 3% solution may also be known as dilute hydrogen peroxide solution, hydrogen peroxide solution 10-volume (Note: NOT 10%), or hydrogen peroxide topical solution.

Storage/Stability

Store 3% solutions in airtight containers at room temperature and protected from light.

Hydrogen peroxide 3% can deteriorate with time; outdated or improperly stored products may not be effective as an emetic.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as an oral emetic

HUMAN-LABELED PRODUCTS:

None as an oral emetic. Hydrogen Peroxide 3% Solution is readily available over-the-counter from a variety of manufacturers. It is usually sold in pint bottles.

References

HYDROMORPHONE
(hye-droe-mor-fone) Dilaudid®
OPiate agoNIST

Prescriber Highlights

- Injectable opiate sedative/restraining agent, analgesic, & preanesthetic similar to oxymorphone
- Significantly less expensive than oxymorphone
- Contraindications: Hypersensitivity to it, diarrhea caused by a toxic ingestion, prior to GI obstructive surgery (may cause vomiting)
- Extreme caution: Respiratory disease or acute respiratory dysfunction
- Caution: Hypothyroidism, severe renal insufficiency (acute uremia), adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure & acute abdominal conditions (e.g., colic)
- Adverse Effects Dogs: Nausea/vomiting, defecation, panting, vocalization, & sedation are common. CNS depression, respiratory depression, & bradycardia; decreased GI motility with resultant constipation (with chronic use) possible
- Adverse Effects Cats: Nausea common. Ataxia, hyperesthesia, hyperthermia, & behavioral changes (without concomitant tranquilization) possible.
- Drug-drug; drug-lab interactions
- C-II controlled substance

Uses/Indications

Like oxymorphone, hydromorphone is used in dogs and cats as a sedative/restraining agent, analgesic and preanesthetic. It may also be useful in other species, but little data or experience is available. Because of expense and availability issues with oxymorphone, hydromorphone is rapidly replacing it in veterinary medicine. In dogs and cats, hydromorphone is generally less sedating than morphine, usually causes minimal histamine release after IV administration, and rarely causes vasodilation and hypotension. One randomized, blinded, clinical trial in dogs and cats found hydromorphone’s analgesic efficacy and duration of action similar to oxymorphone, but the incidence of nausea and vomiting was higher with hydromorphone (Bateman et al. 2008).

Pharmacology/Actions

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone, hydromorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS; euphoria, sedation, and confusion. Cardiovascular: bradycardia due to...
central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement and dogs may defecate after morphine injections. These effects are in contrast to the expected effects of sedation and constipation. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis.

Hydromorphone is approximately 5 times more potent an analgesic on a per weight basis when compared to morphine and approximately equal in potency to oxymorphone. At the usual doses employed, hydromorphone alone has good sedative qualities in the dog. Respiratory depression can occur especially in debilitated, neonatal, or geriatric patients. Bradycardia, as well as a slight decrease in cardiac contractility and blood pressure, may be seen. Like oxymorphone, hydromorphone does initially increase the respiratory rate (panting in dogs) while actual oxygenation may be decreased and blood CO₂ levels may increase by 10 mmHg or more. Gastrointestinal effects are common (especially cats) may develop mydriasis.

Pharmacodynamics/Pharmacokinetics
Hydromorphone is absorbed when given by IV, IM, SC, and rectal routes. After hydromorphone is administered subcutaneously to dogs, peak levels occur between 10-30 minutes after dosing. The volume of distribution in dogs is high; > 4 L/kg both with IV and SC dosing. Terminal half-lives are rapid and appear to be route and dose dependent; half-lives are about 35 minutes to an hour long (KuKanich et al. 2008).

The drug is metabolized in the liver, primarily by glucuronidation. Because cats are deficient in this metabolic pathway, half-lives in cats are probably prolonged. The glucuronidated metabolite is excreted by the kidney.

Contraindications/Precautions/Warnings
All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients. Hydromorphone is contraindicated in patients hypersensitive to narcotic analgesics, and those with diarrhea caused by a toxic ingestion (until the tox is eliminated from the GI tract). All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients.

Because it may cause vomiting, hydromorphone use should be considered contraindicated as a preanesthetic med in animals with suspected gastric dilation, volvulus, or intestinal obstruction.

Hydromorphone should be used with extreme caution in patients with head injuries, increased intracranial pressure, and acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Hydromorphone can cause bradycardia and therefore should be used cautiously in patients with preexisting bradyarrhythmias.

Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of hydromorphone and may require lower dosages. Patients with severe hepatic disease may have prolonged duration of action of the drug.

Hyperthermia has been reported in cats with hydromorphone use and some recommend to avoid the use of this drug in cats (Hansen, B. 2008). If used in cats at high dosages, the drug has been recommended to be given along with a tranquilizing agent, as hydromorphone can produce bizarre behavioral changes in this species. This also is true in cats for the other opiate agents, such as morphine.

Opiate analgesics are contraindicated in patients who have been stung by the scorpion species Centruroides sculpturatus Ewing and C. gertschi Stahnke as it may potentiate these venoms.

Adverse Effects
Hydromorphone has a similar adverse effect profile to oxymorphone or morphine in dogs and cats. In dogs, sedation, panting, whining/vocalization, vomiting and defecation are often noted. Vomiting, nausea and defecation may occur more frequently with SC dosing versus intravenous dosing. CNS depression may be greater than desired, particularly when treating moderate to severe pain. In dogs, constant rate IV infusions of >0.05 mg/kg/hr administered for more than 12 hours may cause sedation and adverse effects severe enough to require reducing the rate (Hansen, B. 2008). Dose related respiratory depression is possible, and more likely during general anesthesia. Panting (may occur more often than with oxymorphone) and cough suppression (may be of benefit) may occur.

Opioids can increase body temperature in cats. One study done in eight cats showed that hydromorphone, morphine, butorphanol, and buprenorphine all cause an increase in body temperature in cats and that hydromorphone increased body temperature equivalently to those other drugs. The increased body temperature in all of the experimental treatments was self limiting, and the majority returned to normal within 5 hours. No apparent morbidity or mortality was noted. Administration of ketamine or isoflurane in addition to hydromorphone did not produce a clinically relevant increase in body temperature compared with that of administration of hydromorphone alone (Posner et al. 2010). Should hyperthermia occur, naloxone has been used to rapidly reduce body temperature in cats.

Secondary to enhanced vagal tone, hydromorphone can cause bradycardia. This apparently occurs on par with morphine or oxymorphone. Hydromorphone may cause histamine release that, while significantly less than with morphine and usually clinically insignificant, may be significant in critically ill animals. Constipation is possible with chronic dosing.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Most opiates are excreted into milk, but effects on nursing offspring may not be significant.

Overdosage/Acute Toxicity
Massive overdoses may produce profound respiratory and/or CNS depression in most species. Other effects may include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Mania may be seen in cats. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as naloxone’s effects can diminish before sub-toxic levels of oxymorphone are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression.

In susceptible patients, moderate overdoses may require naloxone and supportive treatment as well.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydromorphone and may be of significance in veterinary patients:

**BUTORPHANOL, NALBUPHINE:** Potentially could antagonize opiate effects.
BUTORPHANOL, NALBUPHINE: Potentially could antagonize opiate effects

CNS DEPRESSANTS, OTHER: Additive CNS effects possible

DIURETICS: Opiates may decrease efficacy in CHF patients

MONOAMINE OXIDASE INHIBITORS (e.g., amitraz and potentially, selegiline): Severe and unpredictable opiate potentiation may be seen; not recommended (in humans) if MAO inhibitor has been used within 14 days

MUSCLE RELAXANTS, SKELETAL: Hydromorphone may enhance effects

PHENOTHIAZINES: Some phenothiazines may antagonize analgesic effects and increase risk for hypotension

TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Hydromorphone may exacerbate the effects of tricyclic antidepressants

WARFARIN: Opiates may potentiate anticoagulant activity

Laboratory Considerations
- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

**DOGS:**
- As an analgesic: 0.1 mg/kg IV or SC q2h or as a CRI at 0.03 mg/kg/hr are suggested doses based on the results of pharmacokinetic study. (KuKanich et al. 2008)
- b) For cancer pain: 0.08–0.2 mg/kg IV, IM, or SC (Lester & Gaynor 2000)
- c) As an analgesic: 0.05–0.2 mg/kg IV, IM, SC q2–4h (Hansen, B 2003), (Hardie 2006)
- d) As an analgesic: 0.2–0.6 mg/kg PO q6–8h; For perioperative pain: 0.1–0.2 mg/kg IV, IM, SC q2–4h (Pascoe 2006)
- e) As a premed prior to moderately painful procedures: 0.1 mg/kg; may be combined with acepromazine (0.02–0.05 mg/kg) in young, healthy patients. As a sedative/restraint agent for fractious or aggressive dogs: 0.1–0.2 mg/kg mixed with acepromazine (0.05 mg/kg) IM. Maximal effect usually reached in about 15 minutes, but an additional wait of another 15 minutes may be necessary in some dogs.
- An alternate induction method (especially in critical patients): hydromorphone 0.05–0.2 mg/kg IV, slowly to effect followed by diazepam 0.02 mg/kg IV (do not mix two drugs together). Endotracheal intubation may be possible after administration, if not, delivery of an inhalant by facemask will give a greater depth of anesthesia. Positive pressure ventilation likely will be necessary. If bradycardia requires treatment, use either glycopyrrolate (0.01–0.02 mg/kg IV) or atropine (0.02–0.04 mg/kg IV). (Pettifer & Dyson 2000)

**CATS:**
- a) As an analgesic: 0.05–0.1 mg/kg IM, IV or SC q2–6 hours (Wagner 2002)
- b) For moderate to severe pain: 0.08–0.3+ mg/kg IV, IM or SC q2–6 hours (Mathews 2000)
- As a premed prior to moderately painful procedures: 0.1 mg/kg; may be combined with acepromazine (0.05–0.2 mg/kg) in young, healthy patients.
- An alternate induction method (especially in critical patients): hydromorphone 0.05–0.2 mg/kg IV, slowly to effect followed by diazepam 0.02 mg/kg IV (do not mix two drugs together). Endotracheal intubation may be possible after administration, if not, delivery of an inhalant by facemask will give a greater depth of anesthesia. Positive pressure ventilation likely will be necessary. If bradycardia requires treatment, use either glycopyrrolate (0.01–0.02 mg/kg IV) or atropine (0.02–0.04 mg/kg IV). (Pettifer & Dyson 2000)

**FERRETS:**
- a) As a pre-op: 0.05–0.1 mg/kg IV; as a CRI post-op: 0.05 mg/kg IV loading dose, then 0.05–0.1 mg/kg/hr (Lichtenberger 2006)

**SMALL MAMMALS:**
- a) Rabbits: 0.05–0.1 mg/kg IV; as a CRI post-op: 0.05 mg/kg IV loading dose, then 0.05–0.1 mg/kg/hr (Lichtenberger 2006)

Monitoring
- Respiratory rate/depth (pulse oximetry highly recommended)
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Cardiac rate
- Analgesic efficacy

Client Information
- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision

Chemistry/Synonyms
A semi-synthetic phenanthrene-derivative opiate related to morphine, hydromorphone HCl occurs as white, fine, crystalline powder. It is freely soluble in water. The commercial injection has a pH of 4–5.5.

Hydromorphone may also be known as: dihydromorphinone hydrochloride, Dolonovag®, Hydal®, HydroStat IR®, Hydromorph®, Opidol®, Palladon®, Palladone®, and Sophidone®.

Storage/Stability
The injection should be stored at room temperature and protected from light. A slight yellowish tint to the solution may occur, but does not indicate loss of potency. The injection remains stable for at least 24 hours when mixed with commonly used IV fluids if protected from light.

Hydromorphone tablets should be stored at room temperature in tight, light resistant containers. The suppositories should be kept in the refrigerator.
## Compatibility/Compounding Considerations

Hydromorphone injection is **compatible** in commonly used IV fluids (for 24 hours when protected from light at 25°C) and with midazolam, ondansetron, potassium chloride, and heparin sodium. Hydromorphone injection mixed in the same syringe with atropine and medetomidine (Domitor®) for use as a pre-op in dogs prior to sevoflurane or propofol anesthesia has been described (Ko 2005). Hydromorphone is **incompatible** with sodium bicarbonate, or thiopental.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

### HUMAN-LABELED PRODUCTS:

- **Hydromorphone HCl Injection:** 1 mg/mL in 1 mL amps & syringes, 2 mg/mL in 1 mL vials, amps & syringes, 20 mL vials & multidose vials; 4 mg/mL in 1 mL amps & syringes; and 10 mg/mL (concentrate) in 1 mL, & 5 mL, single-dose vials & amps and 50 mL single-dose vials; **Dilaudid®** and **Dilaudid-HP®** (Abbott); generic; (Rx, C-II)

- **Hydromorphone HCl Powder for Injection, lyophilized:** 250 mg (10 mg/mL after reconstitution) preservative-free in single-dose vials; **Dilaudid-HP®** (Abbott); (Rx, C-II)

- **Hydromorphone HCl Oral Tablets:** 2 mg, 4 mg, & 8 mg; **Dilaudid®** (Abbott); generic; (Rx, C-II)

- **Hydromorphone HCl Oral Capsules** (extended-release): 8 mg, 12 mg, & 16 mg; **Exalgo®** (Alza); (Rx, C-II)

- **Hydromorphone HCL Oral Liquid:** 1 mg/mL in 4 mL & 8 mL UD patient cups; 250 mL & 473 mL (may contain sodium metabisulfite); **Dilaudid®** (Abbott); generic; (Rx, C-II)

- **Hydromorphone Suppositories:** 3 mg; Hydromorphone HCl (Padlock); **Dilaudid®** (Abbott); (Rx, C-II)

**COLLOID VOLUME EXPANDER**

### Prescriber Highlights

- **Volume expanders used to treat hypovolemia where colloidal therapy required**
- **Different HES molecular weight/degree of substitution products available**
- **Contraindications:** Severe heart failure, severe bleeding disorders, & patients in oliguric or anuric renal failure
- **Caution:** Thrombocytopenia, patients undergoing CNS surgery; liver disease
- **May cause volume overload:** Use with caution in patients with renal dysfunction, congestive heart failure, or pulmonary edema
- **Adverse Effects:** Coagulopathies possible; too rapid administration to small animals (especially cats) may cause nausea/vomiting; hypersensitivity reactions possible but very rare

Note: Nomenclature for these products can be confusing. Hydroxyethyl starch and hetastarch are often used interchangeably, but this is not necessarily true. It is best when examining references to determine not only the % HES used and the fluid in which it is diluted, but the molecular weight/degree of substitution. Be certain when using HES products that you are familiar with the specific product and its respective cautions and uses. The bulk of this monograph pertains to the HES 450/0.7 product which has been used most frequently in veterinary medicine.

### Uses/Indications

There are two principle reasons to choose HES colloid therapy over crystalloid therapy. The first is their better intravascular persistence and more prolonged volume expanding effects, and secondly, in patients with “capillary leak syndrome” who can reduce vascular permeability and down-regulate expression of pro-inflammatory mediators (Boag 2007). Often, in hypovolemic patients where total protein is less than 3.5 g/dL and crystalloid therapy is likely to reduce this level further, colloid therapy (plasma, dextran or hetastarch) is considered as part of intravascular volume restoration options when colloid therapy is required and blood pressure is lower than expected.
Doses
Laboratory Considerations

None reported.

Drug Interactions

Overdosage could result in volume overload in susceptible patients. Dose and monitor fluid status carefully.

Overdosage/Acute Toxicity

category

Reproductive/Nursing Safety

using serum amylase to diagnosis or monitor patients with acute pancreatitis.

several days. Serum amylase levels may be falsely elevated for several days after hetastarch is administered. While clinically insignificant, the changes may preclude

space.

give intramuscularly as bleeding, bruising, or hematomas may occur.

are thought to occur rarely, however.

Contraindications/Precautions/Warnings

It is believed that significant bleeding can occur if hetastarch is used in animals with compromised coagulation systems. For example, use in patients with von

Willebrand’s disease could significantly increase the risk for bleeding. Because of its effect on platelets, hetastarch should be used with caution in patients with

thrombocytopenia and with extreme caution in patients undergoing CNS surgery.

As it has no oxygen carrying capacity, hetastarch is not a replacement for whole blood or red blood cells.

In humans, there is a potential of risk for acute kidney injury with HES, particularly in acute sepsis patients. It is unknown if this risk also occurs in veterinary

patients. Use hetastarch with caution in patients with liver disease due to its effects on indirect serum bilirubin levels.

Because of the danger of volume overload, use of HES for the treatment of shock not accompanied by hypovolemia may be hazardous; it should be used in caution

in patients with renal dysfunction, congestive heart failure or pulmonary edema. Additionally, animals with sepsis, systemic inflammatory response syndrome (SIRS)

or severe trauma may extravasate colloids such as hetastarch into the lungs which could potentially, cause or worsen pulmonary edema. Monitoring for clinical signs of

pulmonary edema and if possible, blood gases is mandatory in these circumstances.

In humans, HES is contraindicated in patients with severe heart failure, severe bleeding disorders and patients in oliguric or anuric renal failure.

Adverse Effects

HES can affect platelet function and coagulation times. It can alter Factor VIII (FVIII) and von Willebrand Factor. At recommended dosages, hetastarch may cause

changes in clotting times and platelet counts due to direct (precipitation of factor VIII) and dilutional causes. A retrospective study in dogs, showed that hetastarch can significantly increase PTT’s, but did not affect survival rates (Helmbold et al. 2009). Clinically, these effects may be insignificant, but patients with preexisting coagulopathies may be predisposed to further bleeding. Potentially, tetrastarch may have less effect on coagulation then hetastarch.

HES is less antigenic than dextran, but can cause sensitivity reactions and interfere with antigen-antibody testing. Anaphylactic reactions and severe coagulopathies are thought to occur rarely, however.

When given via rapid infusion to cats, hetastarch may cause signs of nausea and vomiting; if administered over 15–30 minutes, these signs are eliminated.

Circulatory overload leading to pulmonary edema is possible, particularly when large dosages are administered to patients with diminished renal function. Do not give intramuscularly as bleeding, bruising, or hematomas may occur.

When hetastarch infusions are stopped a “rebound effect” can occur; colloid that has leaked into interstitial spaces can pull additional fluid from the intravascular

space.

In humans, increases in serum indirect bilirubin have occurred occasionally. No effect on other liver function tests were noted and the increases subsided over

several days. Serum amylase levels may be falsely elevated for several days after hetastarch is administered. While clinically insignificant, the changes may preclude using serum amylase to diagnosis or monitor patients with acute pancreatitis.

Reproductive/Nursing Safety

Hetastarch’s safety during pregnancy has not been established, but no untoward effects have apparently been reported. In humans, the FDA categorizes this drug as

category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal

reproduction studies and no adequate studies in humans.)

It is not known whether hetastarch is excreted in milk, but it is unlikely to pose much risk to offspring.

Overdosage/Acute Toxicity

Overdosage could result in volume overload in susceptible patients. Dose and monitor fluid status carefully.

Drug Interactions

None reported.

Laboratory Considerations

Hetastarch (670/0.75) can falsely elevate urine concentration (specific gravity) in dogs (Smart et al. 2009).

Doses

**DOGS/CATS: Note:** All doses are for hetastarch (6% HES 450/0.7; Hespan®) unless otherwise noted.

For use as a plasma volume expander in shock: **Note:** Rate of administration is determined by individual patient requirements (i.e., blood volume, indication, and

patient response); adequate monitoring for successful treatment of shock is mandatory. The following dosages are NOT “Give and forget”; they should be used as

appropriate.

**References**

**HYDROXYUREA**

(hye-drox-ee-yor-e-a) Hydrea®, Droxia®, Mylecel®

**ANTINEOPLASTIC**

**Prescriber Highlights**

- Antineoplastic used for treatment of polycythemia vera, mastocytomas, & leukemias in dogs & cats
- Caution: Anemia, bone marrow depression, history of urate stones, infection, impaired renal function, or in patients who have received previous chemotherapy or radiotherapy
- Adverse Effects: GI effects, stomatitis, sloughing of nails, alopecia, & dysuria; most serious are bone marrow depression & pulmonary fibrosis
- Proven teratogen

**Uses/Indications**

Hydroxyurea may be useful in the treatment of polycythemia vera, mastocytomas, and leukemias in dogs and cats. It is often used to treat dogs with chronic myelogenous leukemia no longer responsive to busulfan. Hydroxyurea, potentially, may be of benefit in the treatment of feline hypereosinophilic syndrome and in the adjunctive treatment of canine meningiomas. It can also be used in dogs for the adjunctive medical treatment (to reduce hematocrit) of right to left shunting patent ductus arteriosus or tetralogy of Fallot.

**Pharmacology/Actions**

While the exact mechanism of action for hydroxyurea has not been determined, it appears to interfere with DNA synthesis without interfering with RNA or protein synthesis. Hydroxyurea apparently inhibits thymidine incorporation into DNA and may directly damage DNA. It is an S-phase inhibitor, but may also arrest cells at the G1-S border.

Hydroxyurea inhibits urease, but is less potent than acetohydroxamic acid. Hydroxyurea can stimulate production of fetal hemoglobin.

**Pharmacokinetics**

Hydroxyurea is well absorbed after oral administration and crosses the blood-brain barrier. Approximately 50% of an absorbed dose is excreted unchanged in the urine and about 50% is metabolized in the liver and then excreted in the urine.

**Contraindications/Precautions/Warnings**

Risk versus benefit should be considered before using hydroxyurea in patients with the following conditions: anemia, bone marrow depression, history of urate stones, current infection, impaired renal function, or in patients who have received previous chemotherapy or radiotherapy.

**Adverse Effects**

Potential adverse effects include GI effects (anorexia, vomiting, diarrhea), stomatitis, sloughing of nails, alopecia, and dysuria. The most serious adverse effects associated with hydroxyurea are bone marrow depression (anemia, thrombocytopenia, leukopenia) and pulmonary fibrosis. If myelotoxicity occurs, it is recommended to halt therapy until values return to normal. Methemoglobinemia has been reported in cats given high dosages (>500 mg).

**Reproductive/Nursing Safety**

Hydroxyurea is a teratogen. Use only during pregnancy when the mother outweigh the risks to the offspring. Hydroxyurea can suppress gonadal function; arrest of spermatogenesis has been noted in dogs. In humans, the FDA categorizes this drug as category D for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although hydroxyurea distribution into milk has not been documented, nursing puppies or kittens should receive milk replacer when the dam is receiving hydroxyurea.

**Overdosage/Acute Toxicity**

Cats given hydroxyurea in doses greater than 500 mg (total) may develop methemoglobinemia. Because of the potential toxicity of the drug, overdoses should be treated aggressively with gut emptying protocols employed when possible. For further information, refer to an animal poison control center.
Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydroxyurea and may be of significance in veterinary patients:

**BONE MARROW DEPRESSANT DRUGS, OTHER (e.g., other antineoplastics, chloramphenicol, flucytosine, amphotericin B, or colchicine):** Other bone marrow depressant drugs may cause additive myelosuppression when used with hydroxyurea

**Laboratory Considerations**

- Hydroxyurea may raise serum uric acid levels; drugs such as allopurinol may be required to control hyperuricemia

**Doses**

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS:**

- For polycythemia vera; chronic myelogenous leukemia:
  - a) 50 mg/kg 3 times per week (Jacobs et al. 1992)
- For polycythemia vera:
  - a) Initially at 20–25 mg/kg PO twice daily; once the hematocrit is below 60% give every other day. (Vail & Thamm 2005)
  - b) 30 mg/kg once daily for one week, then 15 mg/kg once daily until remission; then taper to lowest effective frequency by monitoring hematocrit (Raskin 1994)
  - c) 50–80 mg/kg PO every 3 days (Kitchell & Dhaliwal 2000)

For chronic myelogenous leukemia:

- a) 50 mg/kg PO q24h for 1–2 weeks, then every other day (Couto 2003)

**CATS:**

- For polycythemia vera; chronic myelogenous leukemia:
  - a) 25 mg/kg 3 times per week (Jacobs et al. 1992)
- For polycythemia vera:
  - a) Initially at 10–15 mg/kg PO twice daily; once the hematocrit is below 60% give every other day. (Vail & Thamm 2005)
  - b) 30 mg/kg once daily for one week, then 15 mg/kg once daily until remission; then taper to lowest effective frequency by monitoring hematocrit (Raskin 1994)

**Monitoring**

- CBC with platelets at least every 1–2 weeks until stable; then every 3 months
- BUN/Serum Creatinine; initially before treatment and then every 3–4 months

**Chemistry/Synonyms**

Structurally similar to urea and acetohydroxamic acid, hydroxyurea occurs as white, crystalline powder that is freely soluble in water. It is moisture labile. Hydroxyurea may also be known as: hydroxycarbamide, hydroxycarbamidum, NSC-32065, SQ-1089, WR-83799, Hydrea®, Droxia®, Dacrodil®, Droxia®, Hydrine®, Litalir®, Medroxurea®, Neodrea®, Onco-Carbine®, Oxeron®, and Syreer®.

**Storage/Stability**

Capsules should be stored in tight containers at room temperature. Avoid excessive heat.

**Compatibility/Compounding Considerations**

**Compounded preparation stability:** Hydroxyurea oral suspension compounded from commercially available capsules has been published (Heeney et al. 2004). Triturating ten (10) hydroxyurea 500 mg capsules with room temperature water, stirring, filtering and bringing to a final volume of 50 mL with Syrpall® yields a 100 mg/mL suspension that retains >95% potency for 180 days stored at 25°C. Suspensions of hydroxyurea heated to 41°C result in an immediate 40% loss of drug potency. Compounded preparations of hydroxyurea should be protected from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Hydroxyurea Oral Capsules: 200 mg, 300 mg, 400 mg & 500 mg;
- Hydroxyurea® (Bristol-Myers Squibb); Droxia® (Bristol-Myers Squibb Oncology); generic; (Rx)

**References**

HYDROXYZINE HCL
HYDROXYZINE PAMOATE
(hye-dro-zye-en) Atarax®, Vistaril®
ANTIHISTAMINE

Prescriber Highlights

- Used principally for antihistaminic, antipruritic, & sedative/tranquilization qualities, often in atopic patients
- Contraindications: Hypersensitivity to the drug
- Caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloduodenal obstruction
- Adverse Effects: Sedation most likely; Dogs (rarely): Tremors, seizures; Cats: Polydipsia, depression, or behavioral changes.

Uses/Indications
Hydroxyzine is used principally for its antihistaminic, antipruritic, and sedative/tranquilization qualities, often in atopic patients.

Pharmacology/Actions
Like other H1-receptor antihistamines, hydroxyzine acts by competing with histamine for sites on H1-receptor sites on effector cells. Antihistamines do not block histamine release, but can antagonize its effects. In addition to its antihistaminic effects, hydroxyzine possesses anticholinergic, sedative, tranquilizing, antispasmodic, local anesthetic, mild bronchodilative, and antiemetic activities.

Pharmacokinetics
Hydroxyzine is rapidly and well absorbed after oral administration. Effects generally persist for 6–8 hours in dogs and up to 12 hours in cats. Hydroxyzine is apparently metabolized in liver.

Contraindications/Precautions/Warnings
Hydroxyzine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloduodenal obstruction.

Adverse Effects
The most likely adverse effect associated with hydroxyzine is sedation. In dogs, this is usually mild and transient. Occasionally antihistamines can cause a hyperexcitability reaction. Dogs have reportedly developed fine rapid tremors, whole body tremors and, rarely, seizures while receiving this drug. Cats may develop polydipsia, depression, or behavioral changes while on this medication.

Reproductive/Nursing Safety
At doses substantially greater than those used therapeutically, hydroxyzine has been shown to be teratogenic in lab animals. Use during pregnancy (particularly during the first trimester) only when the benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown if hydroxyzine enters maternal milk; cetirizine a metabolite of hydroxyzine, has been detected in milk.

Overdosage/Acute Toxicity
Overdoses would be expected to cause increased sedation and perhaps, hypotension. At high doses, fine rapid tremors and rarely seizures have been reported. There were 109 exposures to hydroxyzine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 105 were dogs with 39 showing clinical signs, and 4 were cats that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included hyperthermia, lethargy, tachycardia, trembling, tremors, ataxia, and somnolence.

There are no specific antidotes available. Gut emptying protocols should be considered with large or unknown quantity overdoses. Supportive and symptomatic treatment is recommended if necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hydroxyzine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Additive anticholinergic effects may occur when hydroxyzine is used concomitantly with other anticholinergic agents
- **CNS DEPRESSANT DRUGS, OTHER:** Additive CNS depression may be seen if combining hydroxyzine with other CNS depressant medications, such as barbiturates, tranquilizers, etc.
- **EPINEPHRINE:** Hydroxyzine may inhibit or reverse the vasoressor effects of epinephrine; use norepinephrine or metaraminol instead

Laboratory Considerations
- False increases have been reported in 17-hydroxycorticosteroid urine values after hydroxyzine use
- Because antihistamines can decrease the wheal and flare response to skin allergen testing, antihistamines should be discontinued from 3–7 days (depending on the antihistamine used and the reference) before intradermal skin tests

Doses
Hydroxyzine Pamoate Suspension (equivalent to hydroxyzine HCl): 25 mg/5 mL (as pamoate) in 120 mL & 473 mL; Hydroxyzine Pamoate Oral Capsules (equivalent to hydroxyzine HCl): 25 mg, 50 mg, & 100 mg (as pamoate); generic; (Rx) vials; generic; (Rx)

Hydroxyzine HCl Injection: 25 mg/mL (may contain benzyl alcohol) in 1 mL & 2 mL vials and 50 mg/mL (may contain benzyl alcohol) in 1 mL, 2 mL & 10 mL vials.

Hydroxyzine HCl Oral Syrup: 10 mg/5 mL in 118 mL & 473 mL (may contain alcohol); generic; (Rx)

Hydroxyzine HCl Oral Tablets: 10 mg, 25 mg, & 50 mg; generic; (Rx)

HUMAN-LABELED PRODUCTS:

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

Compatibility/Compounding Considerations

The HCl injection has been reported to be physically compatible with the following drugs when mixed in syringes: atropine sulfate, benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, cimetidine HCl, codeine phosphate, diphenhydramine HCl, doxapram HCl, droperidol, fentanyl citrate, glycopyrrolate, hydromorphone HCl, lidocaine HCl, meperidine HCl, methotrimeprazine, metoclopramide HCl, midazolam HCl, morphine sulfate, oxymorphone HCl, pentazocine lactate, procaine HCl, prochlorperazine edisylate, promazine HCl, promethazine HCl, and scopolamine HBr. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

Hydroxyzine HCl Oral Tablets: 10 mg, 25 mg, & 50 mg; generic; (Rx)

Hydroxyzine HCl Oral Syrup: 10 mg/5 mL in 118 mL & 473 mL (may contain alcohol); generic; (Rx)

Hydroxyzine HCl Injection: 25 mg/mL (may contain benzyl alcohol) in 1 mL & 2 mL vials and 50 mg/mL (may contain benzyl alcohol) in 1 mL, 2 mL & 10 mL vials; generic; (Rx)

Hydroxyzine Pamoate Oral Capsules (equivalent to hydroxyzine HCl): 25 mg, 50 mg, & 100 mg (as pamoate); generic; (Rx)

Hydroxyzine Pamoate Suspension (equivalent to hydroxyzine HCl): 25 mg/5 mL (as pamoate) in 120 mL & 473 mL; Vistaril®, Atarax® or Masmoran®.

References

Hydroxyzine may also be known as: hydroxyzine embonate, hydroxyzine pamoate, hydroxyzine HCl, hydroxyzini HCl,

Storage/Stability

Hydroxyzine oral products should be stored at room temperature in tight, light-resistant containers. Avoid freezing all liquid products.
HYOSCYAMINE SULFATE
(hye-oh-ye-ah-meen or hye-ah-skah-meen) Levsin®
ORAL AND INJECTABLE ANTICHOLINERGIC

Prescriber Highlights

- Anticholinergic that may be useful for treating hypermotile GI conditions such as irritable bowel syndrome or bradycardia in dogs
- Limited use in veterinary medicine
- Adverse effects can include mydriasis, xerostomia, constipation, urinary retention, & xerophthalmia

Uses/Indications
Although not commonly used in veterinary medicine, hyoscyamine may be useful as an alternative to other anticholinergic drugs such as glycopyrrolate for treating bradycardia or hypermotile GI conditions such as irritable bowel syndrome in dogs. It potentially could be useful for treating hypersalivation, urinary spasms, vomiting, or reducing secretions peri-operatively, but little is known regarding safety and efficacy in animals when used for these conditions.

In humans, hyoscyamine is used primarily for its effects in reducing GI tract motility or to decrease pharyngeal, bronchial and tracheal secretions.

Pharmacology/Actions
Hyoscyamine is an anticholinergic agent similar to atropine, but more potent both in central and peripheral effects. It inhibits acetylcholine at tissues innervated by postganglionic nerves and smooth muscles that respond to acetylcholine but do not have cholinergic innervation. Pharmacologic effects include dose-related reductions in secretions, gastrointestinal and urinary tract motility, mydriasis, and increased heart rate.

Pharmacokinetics
No pharmacokinetic data was located for veterinary species. In humans, hyoscyamine is rapidly and nearly completely absorbed after oral or sublingual administration. Extended release oral dosage forms may have somewhat reduced oral bioavailability. It is distributed throughout the body, enters the CNS and crosses the placenta. Hyoscyamine is partially hydrolyzed in the liver to tropic acid and tropine. The majority of the drug is excreted unchanged in the urine. Elimination half-life is about 3.5 hours; about 7 hours for the sustained-release product, Levsinex®. Average duration of action in humans is approximately 4-6 hours.

Contraindications/Precautions/Warnings
Hyoscyamine is contraindicated in patients hypersensitive to it. Patients sensitive to one belladonna alkaloid or derivative may be sensitive to another.

Use with caution in patients with renal dysfunction as hyoscyamine elimination may be reduced. Use of anticholinergics should be carefully considered in patients with tachyarrhythmias, cardiac valve disease or congestive heart failure. Patients with myasthenia gravis may have their condition aggravated with concurrent use of hyoscyamine. Other contraindications for using hyoscyamine in humans include: glaucoma (narrow or wide angle), intestinal obstruction, toxic megacolon, intestinal atony, severe ulcerative colitis, obstructive uropathy, or acute hemorrhage.

Adverse Effects
Adverse effects can include mydriasis, xerostomia, constipation, urinary retention, and xerophthalmia. Higher dosages may cause CNS effects (somnolence or excitement) or tachycardia.

Reproductive/Nursing Safety
There is limited information available on the drug’s use during pregnancy. While hyoscyamine crosses the placenta, reproductive studies in animals have not been performed. Two limited studies (322 & 281 pregnancies) in humans have been published evaluating hyoscyamine safety during pregnancy. One study showed no increase in congenital malformations, but the other showed a slight increase above normally expected malformations in infants. In humans, the FDA categorizes hyoscyamine as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Only traces of hyoscyamine are detected in milk. While no problems have been reported and risk to offspring cannot be ruled out, it is probably safe to use in nursing patients.

Overdosage/Acute Toxicity
The LD50 for hyoscyamine in rats is 375 mg/kg. Significant overdosage in animals may be serious and contacting an animal poison control center is advised. Toxicity is exhibited by intensified and prolonged anticholinergic effects; signs include: increased heart rate, CNS effects (behavior changes, depression, seizures), urinary retention, decreased gut sounds/motility, and mydriasis. Protocols to decrease oral absorption should be considered if overdose was recent. Severe anticholinergic effects can be treated with physostigmine or neostigmine, but it is suggested to do so only under the guidance of an animal poison control center. In humans, delirium or excitement has been treated with small doses of short-acting barbiturates or benzodiazepines. Hyoscyamine can be removed by hemodialysis.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving hyoscyamine and may be of significance in veterinary patients:

- **ANTACIDS containing magnesium, aluminum or calcium salts**: May interfere with hyoscyamine absorption
- **ANTICHOLINERGICS, OTHER (atropine, glycopyrrolate, etc.)**: Additive actions and adverse effects can occur
- **ANTIHISTAMINES, FIRST GENERATION (e.g., diphenhydramine)**: Additive actions and adverse effects can occur
- **PROKINETIC AGENTS (e.g., cisapride, metoclopramide)**: Hyoscyamine may counteract their effects
PROKINETIC AGENTS (e.g., cisapride, metoclopramide): Hyoscyamine may counteract their effects

Laboratory Considerations
- No specific concerns noted with hyoscyamine

Doses
- **DOGS:**
  
  **Note:** The following dosages are assumed to be for the immediate release oral dosage forms. Potentially, the extended release tablets or capsules could be effective and reduce dosing frequency, particularly in larger dogs, but no data is available for using them.
  
  a) For irritable bowel syndrome: 0.003–0.006 mg/kg PO two to three times a day (Leib 2005)
  
  b) For long-term management of symptomatic patients with sinus node disease: 0.003–0.006 mg/kg PO q8h (Smith 2004)

Monitoring
- Clinical efficacy
- Adverse effects (e.g., heart rate, bowel or urinary elimination difficulties)

Client Information
- Contact the veterinarian if patient has difficulty urinating or defecating, dry eyes, difficulty swallowing, or demonstrates changes in behavior or activity

Chemistry/Synonyms
Hyoscyamine sulfate is a tertiary amine that occurs as white, odorless, crystals or crystalline powder. One gram is soluble in 0.5 mL of water or in 1 mL of alcohol. It is practically insoluble in ether.

Hyoscyamine may also be known as: daturin, duboisine, tropine-L-tropate. International trade names include: *Egazil Duretter* and *Neo-Allospasmin*.

Storage/Stability
Unless otherwise advised by the manufacturer, hyoscyamine sulfate oral products should be stored at room temperature, in tight containers, and protected from light. The injectable product should be stored at room temperature and protected from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
None as single ingredient products.

HUMAN-LABELED PRODUCTS:
- Hyoscyamine Oral Tablets: 0.125 mg (regular & chewable), & 0.15 mg; *Anaspaz*® (Ascher), *ED-SPAZ*® (Edwards), *HyoMax*® and *HyoMax-FT*® (Aristos); *Levsin*® (Alaven), *Cystospaz*® (PolyMedica); generic; (Rx)
- Hyoscyamine Orally Disintegrating Tablets: 0.125 mg, & 0.25 mg; *Neosol*® (Breckenridge), *NuLev*® (Schwarz), *Symax FastTab*® (Capellon), *Mar-Spas*® (Marel); generic; (Rx)
- Hyoscyamine Sublingual Oral Tablets: 0.125 mg; *Levsin/SL*® (Alaven); *Symax-SL*® (Capellon); generic; (Rx)
- Hyoscyamine Extended/Sustained-Release Oral Tablets: 0.25 mg (0.125 mg immediate-release) & 0.375 mg; *Levbid*® (Alaven), *Symax-SR*® and *Symax Duotab*® (Capellon); generic; (Rx)
- Hyoscyamine Extended/Timed-Release Oral Capsules: 0.375 mg; *Levsinex*® (Alaven); generic; (Rx)
- Hyoscyamine Oral Solution: 0.125 mg/mL in 15 mL; generic; (Rx)
- Hyoscyamine Oral Elixir: 0.025 mg/mL (0.125mg/5mL) in pint bottles generic; (Rx)
- Hyoscyamine Oral Spray: 0.125 mg/spray in 30 mL; *IB-Stat*® (InKline); (Rx)
- Hyoscyamine Injection: 0.05 mg/mL in 1 mL amps & 10 mL vials; *Levsin*® (Alaven); (Rx)

References

IBAFLOXACIN

(Ib-bah-floks-ah-sin) Ibaflin®

ORAL FLUOROQUINOLONE ANTIBIOTIC

Prescriber Highlights
- Oral fluoroquinolone used in dogs & cats primarily in Europe (not available in USA); oral dosage form is a gel in a “dial” syringe
- Similar to other veterinary fluoroquinolones, but may not be as effective against Pseudomonas
- Adverse effects can include diarrhea/soft feces, vomiting, dullness, anorexia & salivation
- No indication of causing ocular toxicity in cats
Uses/Indications
Ibafloxacin is used in dogs and cats to treat infections susceptible to it. It is labeled (in the UK) for treating dogs with dermal infections (superficial and deep pyoderma, wounds, abscesses) and in cats for treating dermal infections (soft tissue infections—wounds, abscesses) and upper respiratory tract infections caused by susceptible bacteria. Ibafloxacin may also be useful in treating urinary tract infections in dogs.

Pharmacology/Actions
Ibafloxacin is a bactericidal fluoroquinolone antibiotic and acts by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), preventing DNA supercoiling and synthesis. It has a similar spectrum of activity as other veterinary commercially available agents (*Enterobacteriaceae, Staphylococcus* spp), but is not very effective against *Pseudomonas* spp, *Streptococcus* spp, or *Proteus mirabilis*.

Ibafloxacin’s primary metabolites, 8-hydroxy-ibafloxacin and 7-hydroxy-ibafloxacin, are also active (but less so than ibafloxacin) and contribute to the drug’s overall efficacy.

Pharmacokinetics
In dogs, oral bioavailability is about 70–80% with peak levels occurring around 1.5 hours after dosing. At 15 mg/kg, Cmax was 6 micrograms/mL; volume of distribution at steady state was 1.1 L/kg. Ibafloxacin is presumably metabolized in the liver to at least two metabolites, 8-hydroxy-ibafloxacin and 7-hydroxy-ibafloxacin. Both metabolites have been shown to be active, but less so than the parent compound. Elimination occurs in both the urine and feces as unchanged drug and glucuronidated metabolites. Total clearance is 8.7 mL/min/kg and elimination half-life, 5.2 hours (Coulet *et al.* 2002).

In cats, ibafloxacin is rapidly absorbed after oral dosing. After dosing with food, peak levels occur in about 2–3 hours. Food slightly delays absorption, but peak levels are doubled and AUC increased when compared to fasted administration. Cats appear to metabolize and eliminate ibafloxacin in a similar manner as dogs; with repeated dosing, cats, unlike dogs, apparently show significant increases over time in both AUC and Cmax of the parent drug and active metabolites (Coulet *et al.* 2005).

In goats, ibafloxacin has a steady state volume of distribution of 1.65 L/kg and an elimination half-life of 3.76 hours. Clearance was 1.05 L/hr/kg. The milk-plasma ratio of drug concentration under the curve was 0.2 (Marin *et al.* 2007).

Contraindications/Precautions/Warnings
The label (UK) states that for the majority of breeds, use is contraindicated in dogs less than 8 months of age and in giant breeds less than 18 months old. It is contraindicated in cats less than 8 months old. It is also contraindicated in dogs or cats with known quinolone hypersensitivity. It is stated that the product should only be used based upon susceptibility testing.

Adverse Effects
Adverse effects reported in dogs and cats include diarrhea, soft feces, vomiting, dullness, anorexia and salivation. These reportedly are mild and transient and occur with low frequency. No reports of ibafloxacin-associated ocular toxicity in cats were found.

In dogs, other fluoroquinolones have, in rare incidences, caused elevated hepatic enzymes, ataxia, seizures, depression, lethargy, or nervousness; these could potentially also occur with ibafloxacin.

Reproductive/Nursing Safety
The label (UK) states that ibafloxacin can be used during pregnancy in dogs, but that safety has not been established in pregnant cats or in lactating dogs and cats.

After dosing to goats, ibafloxacin was detected in milk only in scant quantities.

Overdosage/Acute Toxicity
Specific information not located for ibafloxacin. It is unlikely an acute overdose of ibafloxacin would result in signs more serious than anorexia or vomiting, but the adverse effects noted above could occur. If the overdose occurs in cats, ophthalmic monitoring is recommended. In dogs doses of 75 mg/kg/day (5X) were apparently well tolerated; cats receiving up to 75 mg/kg/day demonstrated salivation and vomiting.

Drug Interactions
Drug interactions associated with other fluoroquinolones would also be expected with ibafloxacin. The label states that ibafloxacin should not be used with NSAIDs in dogs with a history of seizures.

Other drug interactions with oral fluoroquinolones include:

- **ANTACIDS or Supplements containing cations (iron, zinc, magnesium, aluminum, calcium):** May bind to ibafloxacin and prevent its absorption
- **CYCLOSPORINE:** Fluoroquinolones may exacerbate the nephrotoxicity of cyclosporine (used systemically)
- **NITROFURANTOIN:** May antagonize the antimicrobial activity of the fluoroquinolones; concomitant use is not recommended
- **QUINIDINE:** Increased risk for cardiotoxicity
- **SUCRALFATE:** May inhibit absorption of ibafloxacin, separate doses of these drugs by at least 2 hours
- **THEOPHYLLINE:** Ibafloxacin may increase theophylline blood levels

Laboratory Considerations
No specific laboratory concerns noted

Doses

**DOGS/CATS:**

For susceptible infections:

a) Using the 3% oral gel for labeled indications (dogs: dermal infections; cats: dermal or respiratory tract infections): 15 mg/kg PO once daily. The syringe should be adjusted to the calculated dosage by setting the syringe ring (steps of 0.5 mL for the 15 mL syringe). Give at time of feeding. Duration treatment depends upon infection nature and severity; usually a 10-day course is sufficient, but can be extended until response is considered adequate. Reconsider treatment if no overall efficacy.
infection nature and severity; usually a 10-day course is sufficient, but can be extended until response is considered adequate. Reconsider treatment if no improvement in clinical response is seen after 5 days of therapy. In cases of deep pyoderma, reconsider treatment if sufficient improvement not seen in 21 days of treatment. (Label Information; Ibaflin®—Intervet UK)

Monitoring
Clinical efficacy
Adverse effects—GI (vomiting, hypersalivation, diarrhea, anorexia)

Client Information
Give at the time of feeding
Contact veterinarian if vomiting, diarrhea or lack of appetite persist or are severe
Give as directed for the period the veterinarian specifies, even if the patient seems well

Chemistry/Synonyms
Ibafloxacin is a fluoroquinolone with a molecular weight of 275.28 and is available commercially as the racemate. Ibafloxacin may also be known as S-25030 or Ibaflin®.

Storage/Stability
The oral gel should not be stored at temperatures more than 25°C. Once opened, it is recommended that the syringe be used within 8 weeks. Once a course of treatment is completed, dispose of unused product.

VETERINARY-LABELLED PRODUCTS: None in the USA
A 3% Oral Gel (30 mg ibafloxacin per gram of gel; 30.9 mg per mL of gel) in 15 mL syringes with 0.5 mL steps is available and labeled for use in dogs and cats in the UK, and in several other EU countries; Ibaflin® (Intervet); (Rx).
Depending on the market, 7.5% oral gel, 30 mg, 150 mg, 300 mg, and 900 mg tablets may be available for use in dogs.

HUMAN-LABELLED PRODUCTS: None

References

IFOSFAMIDE
(eye-foss-fa-mide) Ifex®
ANTINEOPLASTIC

Prescriber Highlights

- Alkylationg agent that may be useful in treating lymphomas & sarcomas in dogs & cats
- Limited veterinary clinical experience to date
- May be very toxic (myelosuppression, nephrotoxic, bladder toxicity, neurotoxicity, GI, etc.)
- Must be given with saline diuresis & bladder-protective agent (mesna)

Uses/Indications
In small animals, ifosfamide may be of benefit as part of treatment protocols for a variety of neoplasms. Treatment of lymphomas and soft tissue sarcomas with ifosfamide in dogs and cats has been investigated to some extent; some efficacy has been demonstrated. A phase II study in cats with vaccine associated sarcoma, demonstrated a measurable response in 41% of treated cats (Rassnick, Rodriguez et al. 2006).

In humans, ifosfamide is used in various treatment protocols for testicular neoplasms, bone and soft tissue sarcomas, bladder cancer, lung cancer, cervical cancer, ovarian cancer, and some types of lymphomas.

Pharmacology/Actions
Ifosfamide appears to act similarly to other alkylating agents. Its active metabolites interfere with DNA replication and transcription of RNA, thereby disrupting nucleic acid function. It is cycle-phase nonspecific.

Pharmacokinetics
As ifosfamide is a prodrug and does not have pharmacologic activity, it must be biotransformed into active metabolites. Ifosfamide’s pharmacokinetics are very complex and are not well understood. While normally given IV, it is well absorbed after SC injection or oral administration; bioavailabilities via these routes are 90% or greater. Ifosfamide and its metabolites are widely distributed and enter into both bone and CNS. Ifosfamide is converted into its metabolites primarily via oxidative pathways found in the liver and, to a smaller extent, in the lungs. It then is catalyzed (primarily in cells) into the primary active alkylating agent, ifosfamide mustard.
Ifosfamide and its metabolites are primarily excreted via the kidney into urine.

Contraindications/Precautions/Warnings
Because of its toxicity, ifosfamide should only be used by clinicians experienced with the use of cytotoxic agents and able to adequately monitor the effects of therapy. Ifosfamide is contraindicated in patients hypersensitive to it or with severely depressed bone marrow function or active hemorrhagic cystitis. Ifosfamide should be used with extreme caution in patients with impaired renal function.

Ifosfamide must be used in conjunction with mesna to reduce the risk for hemorrhagic cystitis.

Adverse Effects
Dose related myelosuppression occurs with ifosfamide use; neutropenia generally occurs at 5–7 days post treatment, but may be delayed (14–21 days) particularly with repeated dosing. Nadirs in cats are seen typically at day 7 or 8. Platelets can also be significantly impacted. Ifosfamide can damage bladder epithelium, and cause nephrotoxicity with resultant electrolyte abnormalities. Renal toxicity is primarily focused on proximal and distal tubular damage, but glomerular effects may occur. To reduce the incidence of nephrotoxicity and bladder toxicity, saline diuresis is performed (see dosages) and mesna given concomitantly to reduce bladder epithelial toxicity (see below). Volume overload with pulmonary edema may result however, particularly in patients with preexisting cardiac disease. Other adverse effects that may occur include: hypersensitivity reactions, nausea, particularly during infusion, vomiting, neurotoxicity (somnolence to confusion, coma, encephalopathy), alopecia, and abnormal liver function tests.

In studies in cats, when doses were at 900 mg/m² or less, neutrophil counts of <1,000 cells/μL were seen in about 33% of treated cats, but no secondary infections were noted. Some cats did show some mild, self-limiting GI effects (lack of appetite, vomiting, diarrhea). Signs of nausea during IV infusion were seen in about ⅓rd of those treated; pulmonary edema, and hypersensitivity were seen in single cats. Nephrotoxicity was seen in two cats. (Rassnick, Moore et al. 2006), (Rassnick, Rodriguez et al. 2006).

Administering mesna with ifosfamide significantly reduces the incidence and severity of ifosfamide-induced hemorrhagic cystitis and hematuria. Mesna interacts with metabolites of ifosfamide that cause the toxicity. Because mesna is hydrophilic, it does not enter most cells and, therefore, does not appear to significantly reduce the anti-tumor efficacy of ifosfamide. Mesna does not prevent or reduce the incidence of other adverse effects associated with ifosfamide (e.g. myelosuppression, GI effects, neurotoxicity, renal toxicity).

Like other cytotoxic drugs, ifosfamide should be handled and disposed of appropriately.

Reproductive/Nursing Safety
In pregnant humans, ifosfamide is designated by the FDA as a category D drug (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Teratogenic and fetotoxic effects have been demonstrated at usual doses in humans and laboratory animals.

Ifosfamide is excreted in maternal milk. If this drug is being used in lactating mothers, consider using milk replacer.

Overdosage/Acute Toxicity
There is limited information available on acute overdoses. It would be expected that toxicity would be exacerbations of the adverse effects seen at usual doses. No specific antidote (including mesna) is known; treatment is supportive. Methylene blue (50 mg in a 2% aqueous solution IV over 5 minutes) has been suggested to treat ifosfamide-induced encephalopathy in humans.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ifosfamide and may be of significance in veterinary patients:

- BENZODIAZEPINES: A study where mice received benzodiazepines (diazepam, chlordiazepoxide, oxazepam) prior to receiving ifosfamide had increased concentrations of active ifosfamide and showed increased toxicity to the drug; clinical significance has not been determined for human (or dog or cat) patients
- CISPLATIN: Ifosfamide may enhance cisplatin-induced ototoxicity and nephrotoxicity
- MYELOSUPPRESSIVE DRUGS, Other (e.g., other antineoplastics, chloramphenicol, fluycysine, amphotericin B, or colchicine): Other bone marrow depressant drugs may cause additive myelosuppression when used with ifosfamide

Laboratory Considerations
No specific laboratory interactions or considerations were noted.

Doses
Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide and not as a dosage protocol. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Osvald & Moore 2006); (Osvald & Moore 2001)] is strongly recommended.

**DOGS:**
- a) For treating lymphomas and soft tissue sarcomas: Give IV saline at 18.3 mL/kg/hr for 6 hours. Give ifosfamide at 350 mg/m² (if patient weighs less than 10 kg), 375 mg/m² (if greater than 10 kg) IV during the second 30 minutes of the 6-hour infusion. Mesna at a dose of 20% of the ifosfamide dose is given as an IV bolus at the start of the IV infusion and again 2 and 5 hours after the ifosfamide infusion. Repeat every 3 weeks. (Brewer 2003)
- b) As cat dose “b” below, but dog dose: 375 mg/m². (Kitchell 2008)

**CATS:**
- a) Based upon a phase I safety study and a phase II trial for vaccine-related sarcomas, the authors recommend a dose of 900 mg/m² every 3 weeks. Mesna bolus and saline diuresis (30 minutes at 18.3 mL/kg/hr) were first given, then ifosfamide and saline diuresis continued for 5 hours after ifosfamide administration completed. (Rassnick, Moore et al. 2006; Rassnick, Rodriguez et al. 2006)
- b) Normal (0.9%) saline IV diuresis at a fluid rate of 6 times maintenance over 30 minutes. Ifosfamide 900 mg/m² diluted to 20 mg/mL, or less, IV over 20 minutes
Imidacloprid 500 mg/m² divided to 200 mg/m² or less, IV over 20 minutes.
Normal saline IV diuresis at 6 times maintenance over 5 hours
Mesna urothelial protectant at 1g the patient’s calculated mg dose at time zero (immediately before ifosfamide administration), and repeated 2 and 5 hours after ifosfamide This therapy may be repeated on a 21 day basis. (Kitchell 2008)

Monitoring
- CBC with platelets (baseline and before re-dosing)
- Renal function with electrolytes (baseline and before re-dosing)
- Urinalysis baseline and periodic
- Liver function (baseline and periodic)
- Other adverse effects (volume overload/pulmonary edema, neurotoxicity, GI toxicity)
- Efficacy

Client Information
- Clients should understand the relative investigational nature of using ifosfamide in dogs or cats and accept the possibility of severe adverse effects due to its use.
- Owners should be instructed to avoid contact with animal’s saliva or urine for at least 24 hours after dosing.

Chemistry/Synonyms
An alkylating agent structurally related to cyclophosphamide, ifosfamide occurs as a white, crystalline powder with a melting point of 40°C. It is freely soluble in water and very soluble in alcohol. A 10% solution in water has a pH between 4 and 7.

Compatibility/Compounding Considerations
The reconstituted drug is compatible with D₂W, normal saline, or lactated Ringer’s and is stable for up to 24 hours when refrigerated. Ifosfamide is compatible and stable when mixed with mesna in D₂W or lactated Ringer’s.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Ifosfamide Powder: for IV infusion 1 gram with 200 mg amps of Mesnex (mesna) in single dose vials; 3 grams with 400 mg amps of Mesnex (mesna) in single dose vials; Ifex®, Asoifos®, Cuantil®, Duvaxan®, Fentul®, Holaxan®, Holaxane®, Ifex®, IFO-cell®, IFX®, ifocris®, ilem®, Ifomida®, Ifos®, Ifosmixin®, Ifoxan®, Mitoxana®, Seromida®, or Troxano®

Storage/stability
Ifosfamide powder for injection should be stored at 20–25°C (68–77°F). It should be protected from temperatures greater than 30°C (86°F) as the drug may liquefy at temperatures greater than 35°C (95°F). Once reconstituted with sterile water for injection or bacteriostatic water for injection the solution is stable for 24 hours when refrigerated. (Note: One reference states that bacteriostatic water for injection containing benzyl alcohol caused the solution to become turbid at concentrations of ifosfamide greater than 60 mg/mL. No such incompatibility occurred when using bacteriostatic water for injection containing parabens.)

IMIDOCARB DIPROPINATE
(i-mid-oh-karb) Imizol®
ANTIPROTOZOA
Prescriber Highlights
- Antiprotozoal useful against Babesia & related parasites
- Contraindications: Patients exposed to cholinesterase-inhibiting drugs (e.g., pyridostigmine), pesticides, or chemicals
- Caution: Impaired lung, hepatic or renal function; safety in puppies, pregnant, lactating, or breeding animals has not been established
- Adverse Effects: Most common are pain during injection & mild cholinergic signs (salivation, nasal drip, & brief episodes of vomiting); less common: panting, diarrhea, injection site inflammation (rarely ulceration), & restlessness
- Not for intravenous administration
Uses/Indications
Imidocarb is FDA-approved for use to treat Babesia canis infections (babesiosis) in dogs, but the drug may also be efficacious against other babesia species (B. Conradae and North Carolina Babesia species). Imidocarb appears to be more effective against B. canis than B. gibsoni. Imidocarb has been used to treat ehrlichiosis (E. canis) but one study found that when used alone, it did not clear the organism (Eddlestone, S.M. et al. 2006). Imidocarb appears to be effective for hepatozoonosis (H. canis) in dogs and it has also been suggested as a treatment for American canine hepatozoonosis (H. americanum), but it does not clear the encysted stage.

In cats, imidocarb therapy has been recommended for treating cytauxzoonosis (C. felis) and a prospective study is ongoing, but the results are presently unavailable. Imidocarb may be of benefit in treating Babesia and related parasitic diseases in a variety of domestic and exotic animals.

Pharmacology/Actions
Imidocarb is thought to act by combining with nucleic acids of DNA in susceptible organisms, causing the DNA to unwind and denature. This damage to DNA is believed to inhibit cellular repair and replication.

Pharmacokinetics
No specific information was located for this drug.

Contraindications/Precautions/Warnings
Do not use imidocarb in patients exposed to cholinesterase-inhibiting drugs, pesticides, or chemicals. The manufacturer states to consider risks versus benefits before treating dogs with impaired lung, hepatic, or renal function. Donkeys appear to be sensitive to the toxic effects of the drug.

Do not administer intravenously. In cats, puppies and debilitated dogs, pretreatment with atropine or glycopyrrolate has been advised.

Adverse Effects
Most commonly reported adverse effects in dogs include pain during injection and mild cholinergic signs (salivation, nasal drip and brief episodes of vomiting). Less commonly reported effects include panting, diarrhea, injection site inflammation (rarely ulceration), and restlessness. Rarely, severe renal tubular or hepatic necrosis has occurred. Imidocarb has reportedly caused an increase incidence of tumor formation in rats. Cholinergic adverse effects can be treated with an antimuscarinic (e.g., atropine, glycopyrrolate) if necessary.

Horses given high therapeutic dosages (4 mg/kg) develop lacrimation, sweating, and serous nasal discharge for 30 minutes after treatment.

Reproductive/Nursing Safety
Safety in puppies, pregnant, lactating, or breeding animals has not been established.

Overdosage/Acute Toxicity
Dogs receiving a dosage of 9.9 mg/kg (1.5X labeled dose) showed signs of liver injury (slightly increased liver enzymes), pain and swelling at the injection site, and vomiting. Overdoses or chronic toxicity may present with cholinergic signs (vomiting, weakness, lethargy, salivation) or adverse changes in liver, kidney, lung, or intestinal function. Treatment with atropine may be useful to treat cholinergic signs associated with imidocarb.

The LD-50 in horses is reportedly 16 mg/kg.

Drug Interactions
The manufacturer warns not use imidocarb in patients exposed to cholinesterase-inhibiting drugs, pesticides, or chemicals.

Laboratory Considerations
- Imidocarb IM injections may cause significant increases in creatine kinase (CK).

Doses

**DOGS:**

For treatment of babesiosis:

a) 6.6 mg/kg IM or SC; repeat dose in 2 weeks (Package Insert; Imizol®—Schering)

b) 5–6.6 mg/kg IM or SC; repeat in 14 days or 7.5 mg/kg IM or SC once. A single dose of 6 mg/kg the day following a dose of diminazene at 3.5 mg/kg has also been shown to clear the infection. (Taboada & Lobetti 2006)

For treatment of Ehrlichiosis:

Note: A study (Eddlestone, S. et al. 2005; Eddlestone, S.M. et al. 2006) demonstrated that imidocarb alone was not effective in clearing Ehrlichia canis from the blood of experimentally infected dogs.

a) In particularly severe cases, imidocarb at 5 mg/kg SC (in a single injection or two injections 15 days apart) with doxycycline at 10 mg/kg/day for 28 days (Sainz 2002)

For treatment of hepatozoonosis (H. canis):

a) 5 mg/kg IM or SC; every 14 days until parasitemia clears. Usually 1–2 injections are sufficient. (Macintire 1999)

**CATS:**

For treatment of Cytauxzoon felis:

a) 3–4 mg/kg IM; repeated 7 days after initial dose. Efficacy not proven. Cholinergic effects can be mitigated by pre-treating with atropine. Must also give supportive therapy (IV fluids, prophylactic heparin, nutritional/nursing care, analgesia, and potentially transfusion). This dose is from a prospective clinical trial to determine efficacy and adverse effects. (Cohn, L. 2006; Cohn, L.A. 2009)

b) 5 mg/kg IM once and then 14 days later. (Greene et al. 2006)

For treatment of feline hemoplasmosis (Haemobartonellosis; Mycoplasma haemofelis, Mycoplasma Haemominutum):
a) Doxycycline is preferred, but in cats intolerant of doxycycline the following alternatives may be effective: imidocarb can be used at 5 mg/kg IM, SC every 14 days until able to maintain a normal PCV. Other optional treatment includes enrofloxacin at 5 mg/kg PO daily or marbofloxacin at 2.75 mg/kg PO daily. (Lappin, M. 2002), (Lappin, M. 2006)

For treatment of feline clinical ehrlichiosis or anaplasmosis:

a) As an alternative to doxycycline, imidocarb can be used at 5 mg/kg IM every 14 days for at least 2-4 treatments. (Lappin, M.R. 2008)

**HORSES:**

For treatment of equine piroplasmosis (*Babesia caballi; Babesia equi*):

a) 2.2 mg/kg IM will generally allow clinical signs to subside. To eliminate *B. caballi* inject 2 mg/kg IM once a day for 2 days. *B. equi* more difficult to eliminate; there has been some success reported when imidocarb is given at 4 mg/kg IM at 72 hour intervals for 4 doses. (Sellon 2004)

**SHEEP:**

For treatment of babesiosis:

a) 1.2 mg/kg IM; repeat in 10–14 days (McHardy *et al.* 1986)

---

**Monitoring**

- Efficacy
- Adverse effect profile

**Chemistry/Synonyms**

Imidocarb dipropionate is a diamidine of the carbanilide series of antiprotozoal compounds.

Imidocarb may also be known as 4A65 (imidocarb hydrochloride) and *Imizol®*.

**Storage/Stability**

The injection should be stored between 2°–25°C (36°–77°F) and protected from light.

**IMIPENEM-CILASTATIN SODIUM**

(ih-me-peh-nem sye-la-stah-tin) Primaxin®

**CARBAPENEM ANTIBIOTIC**

**Prescriber Highlights**

- Broad spectrum antibiotic/deactivating enzyme inhibitor combination used for serious infections where a single agent is desired
- Contraindications/Cautions: Patients hypersensitive to it or other beta-lactams, patients with renal impairment (dosages adjustment may be required), CNS disorders (e.g., seizures, head trauma)
- Adverse Effects: GI effects, CNS toxicity (seizures, tremors), hypersensitivity, & infusion reactions (thrombophlebitis)
- Too rapid IV infusions may cause GI or CNS toxicity, or other untoward effects; Rarely: increases in renal or hepatic function tests; hypotension or tachycardia
- Separate dosage forms for IM or IV use
- Can be expensive

**Uses/Indications**

Imipenem may be useful in equine or small animal medicine to treat serious infections when other less expensive antibiotics are ineffective or have unacceptable adverse effect profiles. The carbapenems, including imipenem, ertapenem, and meropenem are particularly valuable when treating serious multi-drug resistant gram-negative infections.

**Pharmacology/Actions**

This fixed combination of a carbapenem antibiotic (imipenem) and an inhibitor (cilastatin) of dehydropeptidase I (DHP I) has a very broad spectrum of activity.
Imipenem is generally considered to be a bactericidal agent, but may be static against some bacteria. It has an affinity for and binds to most penicillin-binding protein sites, thereby inhibiting bacterial cell wall synthesis.

Imipenem has activity against a wide variety of bacteria, including gram-positive aerobic cocci (including some bacteriostatic activity against some enterococci), gram-positive aerobic bacilli (including static activity against Listeria), gram-negative aerobic bacteria (Haemophilus, Enterobacteriaceae, many strains of Pseudomonas aeruginosa), and anaerobes (including some strains of Bacteroides).

Imipenem is not efficacious for treating infections caused by methicillin-resistant staphylococci or resistant strains of Enterococcus faecium.

Cilastatin inhibits the metabolism of imipenem by DHP 1 on the brush borders of renal tubular cells. This serves two functions: it allows higher urine levels and may protect against proximal renal tubular necrosis that can occur when imipenem is used alone.

**Pharmacokinetics**

Neither drug is absorbed appreciably from the GI tract and, therefore, they are given parenterally. Bioavailability after IM injection is approximately 95% for imipenem and 75% for cilastatin. In dogs, bioavailability of imipenem after SC injection is complete. Imipenem is distributed widely throughout the body, with the exception of the CSF. Imipenem crosses the placenta and is distributed into milk. When given with cilastatin, imipenem is eliminated by both renal and non-renal mechanisms. Approximately 75% of a dose is excreted in the urine and about 25% is excreted by unknown non-renal mechanisms. Half-lives in patients with normal renal function range from 1–3 hours on average. In horses average elimination time is 70 minutes; 60 minutes in dogs.

**Contraindications/Precautions/Warnings**

The potential risks versus benefits should be carefully weighed before using imipenem/cilastatin in patients hypersensitive to it or other beta-lactam antibiotics (e.g., penicillins, cephalosporins as partial cross-reactivity may occur), with renal function impairment (dosages may need to be reduced or time between doses lengthened), or with CNS disorders (e.g., seizures, head trauma) as CNS adverse effects may be more likely to occur.

Do not give this drug via rapid IV infusion as seizures are possible. In humans, it is recommended to give doses of 500 mg or less over 20–30 minutes, and doses over 500 mg over 40–60 minutes. If given IM (or SC), the specific IM product should be used.

**Adverse Effects**

Potential adverse effects include: GI effects (vomiting, anorexia, diarrhea), CNS toxicity (seizures, tremors), hypersensitivity (pruritus, fever to anaphylaxis) and infusion reactions (thrombophlebitis; too rapid IV infusions may cause GI or CNS toxicity. Rapid IV infusion or multiple high doses to animals with reduced renal function (including neonates and geriatric animals) may increase the risk for seizures.

Imipenem may be administered IM (and some have used it SC), but it can cause severe pain at the injection site and neurovascular damage. It is suggested to dilute the IM form in 1% lidocaine to relieve the associated pain. Rarely, transient increases in renal (BUN or serum creatinine values) or hepatic (AST/ALT/Alk Phosphatase) function tests may be noted, as well as, hypotension or tachycardias.

**Reproductive/Nursing Safety**

While no teratogenic effects have been noted in animal studies, safe use during pregnancy has not been firmly established. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

While imipenem enters milk, no adverse effects attributable to it have been noted in nursing offspring.

**Overdosage/Acute Toxicity**

Little information is available. The LD50 of imipenem:cilastatin in a 1:1 ratio in mice and rats is approximately 1 gram/kg/day. Acute overdoses should be handled by halting therapy then treating supportively and symptomatically.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving imipenem-cilastatin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES**: Additive effects or synergy may result when aminoglycosides are added to imipenem/cilastatin therapy, particularly against Enterococcus, *Staph. aureus,* and *Listeria monocytogenes.* There is apparently neither synergy nor antagonism when used in combination against Enterobacteriaceae, including *Pseudomonas aeruginosa.*

- **BETA-LACTAM ANTIBIOTICS**: Antagonism may occur when used in combination with other beta lactam antibiotics against several Enterobacteriaceae (including many strains of *Pseudomonas aeruginosa* and some strains of Klebsiella, Enterobacter, Serratia, Enterobacter, Citrobacter, and Morganella); clinical importance of this interaction is unclear, but at present it is not recommended to use imipenem in conjunction with other beta-lactam antibiotics.

- **CHLORAMPHENICOL**: May antagonize the antibacterial effects of imipenem (*in vitro* evidence)

- **PROBENECID**: May increase concentrations and elimination half-life of cilastatin, but not imipenem; concurrent use not recommended

- **TRIMETHOPRIM/SULFA**: Synergy may occur against *Nocardia asteroides* when imipenem is used in combination with trimethoprim/sulfa

**Laboratory Considerations**

- Imipenem may cause a false-positive urine glucose determination when using the cupric sulfate solution test (e.g., *Clinistest®*, Benedict’ solution or Fehling’s solution. Enzymatic glucose oxidase based tests are not affected (e.g., *Tes-Tape®*, *Clinistix®*).

**Doses**

**Note:** When giving IM, the manufacturer recommends a 21g needle (deep IM) with aspiration, to avoid IV administration.

**DOGS/CATS:**

- For susceptible infections:
  a) 5–10 mg/kg IV, SC or IM (IM form is different) q8h (Aucoin 2002)
  b) 5–10 mg/kg IV (given over 30 minutes) q6h or IM q6h (mixed with 1% lidocaine to reduce pain). **Note:** Cannot interchange IV and IM dosage forms. (Trepanier 1999)
  c) For tissue infections: 3–7.5 mg/kg IV, SC or IM q4–6h for 3–5 days; for sepsis, more resistant organisms give 5 mg/kg IV q4h (multi-drug resistant bacteria)

- For anaerobic bacteria:
  b) 5–10 mg/kg IV (given over 30 minutes) q6h or IM q6h (mixed with 1% lidocaine to reduce pain).

- For pseudomonas infections: 5–10 mg/kg IV, SC or IM q4–6h for 3–5 days; for severe infections 7.5 mg/kg IV q4h.

- For resistant bacteria:
  b) 5–10 mg/kg IV (given over 30 minutes) q6h or IM q6h (mixed with 1% lidocaine to reduce pain).
c) For tissue infections: 3–7.5 mg/kg IV, SC or IM q4–6h for 3–5 days; for sepsis, more resistant organisms give 5 mg/kg IV q4h (multi-drug resistant bacteria may require q2h dosing) for 3–5 days (Greene et al. 2006)

d) For treatment of Nocardiosis: 2–5 mg/kg IV q8h (Lemarie 2003)

**HORSES:**

For susceptible infections:

a) Adult horses: 10–20 mg/kg via slow IV (over a 10 minute period) q6h; alternatively a CRI of 16 micrograms/kg/minute should maintain synovial concentrations greater than 1 microgram/mL. (Orsini et al. 2005)

b) Foals: 10–20 mg/kg IV q6h (Haggett & Wilson 2008; Wilkins 2004)

c) Foals: 10–15 mg/kg IV q6-12h; IM if diluted into 1% lidocaine. May give as a CRI at 0.4–0.8 mg/kg/hr. (Corley & Hollis 2009)

**Monitoring**

- Efficacy
- Adverse effects (including renal and hepatic function tests if treatment is prolonged or patient’s renal or hepatic functions are in question)

**Client Information**

- Imipenem/cilastatin should be administered in an inpatient setting.
- Clients should be informed of the cost of using this medication.

**Chemistry/Synonyms**

Imipenem monohydrate is a carbapenem antibiotic that occurs as white or off-white, non-hygroscopic, crystalline compound. At room temperature, 11 mg are soluble in 1 mL of water. Cilastatin sodium, an inhibitor of dehydropeptidase I (DHP I), occurs as an off-white to yellowish, hygroscopic, amorphous compound. More than 2 grams are soluble in 1 mL of water.

The commercially available injections are available in a 1:1 fixed dose ratio. The suspensions for IM use are white to light tan in color. Imipenem may also be known as: N-formimidoyl thienamycin, imipemide, MK-787, and MK-0787; multi-ingredient preparations: *Imipem®, Klonam®, Primaxin®, Tenacid®, Tienam®, Tracix®, and Zienam®.*

**Storage/stability**

Commercially available sterile powders for injection should be stored at room temperature (<25°C). After reconstitution, the solution is stable for 4 hours at room temperature; 10 hours when refrigerated. If other diluents are used, stability times may be reduced (see package insert). Do not freeze solutions. The manufacturer does not recommend admixing with other drugs.

- After reconstitution the sterile powder for suspension with 1% lidocaine HCl injection, the suspension should be used within one hour.

**Compatibility/Compounding Considerations**

The following drugs are reportedly compatible with imipenem/cilastatin for IV infusion at a Y-site: aztreonam, cefepime, diltiazem, famotidine, insulin, ondansetron, and propofol.

- To dilute the IM form of the drug with lidocaine: Use 1% lidocaine solution (without epinephrine). Prepare the 500 mg vial with 2 mL lidocaine and the 750 mg vial with 3 mL lidocaine.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Imipenem Cilastatin Powder for Injection: 250 mg imipenem equivalent and 250 mg cilastatin equivalent (0.8 mEq sodium); 500 mg imipenem equivalent and 500 mg cilastatin equivalent (1.4 mEq sodium) in vials; infusion bottles and ADD-Vantage vials; *Primaxin® I.V. (Merck); (Rx)*
- Imipenem Cilastatin Powder for Injection: 500 mg imipenem equivalent and 500 mg cilastatin equivalent (1.4 mEq sodium) in vials; *Primaxin® I.M. (Merck); (Rx)*

**References**

---

**IMIPRAMINE HCL**
**IMIPRAMINE PAMOATE**
*(im-ip-ra-meen) Tofranil®*
**TRICYCLIC ANTIDEPRESSANT**

**Prescriber Highlights**

- Tricyclic “antidepressant” used primarily for cataplexy & urinary incontinence (dogs/cats) narcolepsy & ejaculatory dysfunction (horses)
- May reduce seizure thresholds in epileptic animals

---
• Very toxic in overdoses to both animals & humans
• May be teratogenic
• Adverse Effects: Sedation & anticholinergic effects (tachycardia, hyperexcitability, tremors) most likely

Uses/Indications
In dogs and cats, imipramine has been used to treat cataplexy and urinary incontinence. In horses, imipramine has been used to treat narcolepsy and ejaculatory dysfunction (no parenteral dosage forms available).

Pharmacology/Actions
Imipramine and its active metabolite, desipramine, have a complicated pharmacologic profile. From a slightly oversimplified viewpoint, they have 3 main characteristics: blockage of the amine pump, thereby increasing neurotransmitter levels (principally serotonin, but also norepinephrine), sedation, and central and peripheral anticholinergic activity. While not completely understood, it is thought that the antienuretic activity of imipramine is related to its anticholinergic effects, but imipramine may also have some alpha adrenergic agonist activity. In animals, tricyclic antidepressants are similar to the actions of phenothiazines in altering avoidance behaviors.

Pharmacokinetics
Imipramine is rapidly absorbed from both the GI tract and from parenteral injection sites. Peak levels occur within 1–2 hours after oral dosing. Imipramine and desipramine enter the CNS and maternal milk in levels equal to that found in maternal serum. The drug is metabolized in the liver to several metabolites, including desipramine, which is active. In humans the terminal half-life is approximately 8–16 hours.

Contraindications/Precautions/Warnings
These agents are contraindicated if prior sensitivity has been noted with any other tricyclic. Concomitant use with monoamine oxidase inhibitors is generally contraindicated.

Adverse Effects
While there is little experience with this drug in domestic animals, the most predominant adverse effects seen with the tricyclics are related to their sedating and anticholinergic (dry mouth, constipation, tachycardia, hyperexcitability, tremors) properties. They can cause CNS stimulation (seizures) however, and adverse effects can run the entire gamut of systems including hematologic (bone marrow suppression), GI (diarrhea, vomiting), endocrine, etc.

Reproductive/Nursing Safety
Isolated reports of limb reduction abnormalities have been noted; restrict use to pregnant animals when the benefits clearly outweigh the risks. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Overdosage/Acute Toxicity
Overdosage with tricyclics can be life-threatening (arrhythmias, cardiorespiratory collapse). Because the toxicities and therapies for treatment are complicated and controversial, it is recommended to contact a poison control center for further information in any potential overdose situation.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving imipramine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Because of additive effects, use with imipramine cautiously
- **CIMETIDINE:** May inhibit tricyclic antidepressant metabolism and increase the risk of toxicity
- **CISAPRIDE:** Increased risk for prolonged QT interval
- **CLONIDINE:** Tricyclics may increase blood pressure
- **CNS DEPRESSANTS:** Because of additive effects, use with imipramine cautiously
- **LEVODOPA:** Imipramine may decrease levodopa oral absorption
- **PHENOBARBITAL:** May decrease tricyclic levels
- **QUINIDINE:** Increased risk for QTc interval prolongation and tricyclic adverse effects
- **RIFAMPIN:** May decrease tricyclic blood levels
- **SSRIS (e.g., fluoxetine, paroxetine, sertraline, etc.):** Increased risk for serotonin syndrome
- **SYMPATHOMIMETIC AGENTS:** Use in combination with sympathomimetic agents may increase the risk of cardiac effects (arrhythmias, hypertension, hyperpyrexia)
- **MONOAMINE OXIDASE INHIBITORS (including amitraz, and possibly selegiline):** Concomitant use (within 14 days) with monoamine oxidase inhibitors is generally contraindicated (serotonin syndrome)
- **THYROID AGENTS:** May increase risk for cardiac arrhythmias

Laboratory Considerations
- **ECG:** Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG
ECG:
Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG.

GLUCOSE, BLOOD:
Tricyclics may alter (increase or decrease) blood glucose levels.

**Doses**

**DOGS:**
For urethral incompetence:
- a) 5–15 mg (total dose) PO q12h (Labato 1994), (Bartges 2006)
- b) For urinary incontinence when other agents fail: 5–20 mg (total dose) PO q12h (Lane 2000)
For cataplexy:
- a) 0.5–1 mg/kg PO q8h; titrate dose based on clinical effect (Fenner 1994); (Coleman 1999)
For behavior-related conditions:
- a) For adjunctive treatment of separation anxiety or other tricyclic antidepressant-responsive behavior disorders: 2.2–4.4 mg/kg PO once to twice daily (Marder 1991)
- b) For adjunctive treatment of pain:
  - a) 0.5–1 mg/kg PO q8h (Lester & Gaynor 2000)

**CATS:**
For urethral incompetence:
- a) 2.5–5 mg (total dose) PO q12h (Labato 1994)(Bartges 2006)
For adjunctive cancer pain treatment:
- a) 2.5–5 mg (total dose) PO q12h (Lester & Gaynor 2000)

**Horses:**
(ARCI UCGFS Class 2 Drug)
- Note: The injectable product is no longer marketed in the USA.
  - a) For pharmacologic induced ejaculation: 2 mg/kg IV. If imipramine alone does not induce erection and ejaculation in 10–15 minutes, give xylazine 0.2–0.3 mg/kg IV. (Samper 2004)
- b) For narcolepsy/cataplexy: 0.55 mg/kg IV or 250–750 mg (total dose) orally. PO administration produces inconsistent results. (Andrews & Matthews 2004)

**Monitoring**

- Efficacy
- Adverse effects

**Client Information**

- All tricyclics should be dispensed in child-resistant packaging and kept well away from children or pets.
- Inform clients that several weeks may be required before efficacy is noted and to continue dosing as prescribed.

**Chemistry/Synonyms**

A tricyclic antidepressant agent, imipramine is available commercially in either the hydrochloride or pamoate salts. Imipramine HCl occurs as an odorless or practically odorless, white to off-white crystalline powder that is freely soluble in water or alcohol. Imipramine pamoate occurs as a fine yellow powder that is practically insoluble in water, but soluble in alcohol. The HCl injection has a pH of 4–5.

Imipramine HCl may also be known as: imipramini chloridum, imipramini hydrochloridum, imizine, Antidep®, Celamine®, Depramina®, Depsonil®, Elepsin®, Ethipramine®, Imipra®, Imiprex®, Imiprin®, Imp-Tab®, Impri!, Janimine®, Melipramine®, Mirpalin®, Novo-Pramine®, Praminan®, Primoni!, Pryleugan®, Sermonil®, Surplix®, Talprimar®, and Tofranil®.

**Storage/Stability**

Imipramine HCl tablets and the pamoate capsules should be stored in tight, light resistant containers, preferably at room temperature. The HCl injection should be stored at temperatures less than 40°C and freezing should be avoided. Expiration dates for oral HCL products are from 3–5 years after manufacture; for the pamoate, 3 years.

Imipramine HCl will turn yellow to reddish on exposure. Slight discoloration will not affect potency, but marked changes in color are associated with a loss of potency.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Imipramine HCl Tablets: 10 mg, 25 mg & 50 mg; Tofranil® (Norvartis), generic; (Rx)
- Imipramine Pamoate Capsules: 75 mg, 100 mg, 125 mg & 150 mg; Tofranil®-PM (Norvartis), generic; (Rx)

Prescriber Highlights

- Potentially useful for canine immune-mediated diseases (e.g., IMHA, pIMT, immune-mediated dermatopathies)
- Limited experience in dogs
- Hypersensitivity reactions possible
- Very expensive

Uses/Indications
In veterinary medicine, intravenous immune globulin (human) or IVIG has been used, and may be useful for treating immune-mediated hemolytic (IMHA), immune-mediated dermatopathies, and immune-mediated thrombocytopenia (pIMT) particularly in patients that have failed other treatments. Limited retrospective and prospective studies have demonstrated mixed results, but the data, while very limited, suggests that IVIG may be most useful in treating primary immune-mediated thrombocytopenia in dogs. Definitive studies evaluating the safety and efficacy of IVIG in veterinary patients are not available and because of the drug’s significant expense are unlikely in the foreseeable future. Some question whether the drug should be used at all in veterinary patients as supply is limited and some countries ration its use in humans.

A prospective, randomized, double-blinded, controlled trial of IVIG (with glucocorticoids) in 28 dogs with recently diagnosed IMHA was recently published (Whelan et al. 2009). There were no statistically significant differences between the treated and placebo groups in survival, length of hospitalization, time to hematocrit stabilization, and transfusion requirements. While the study population was relatively small, the authors concluded that the cost of the treatment does not lend support to its use as an early intervention treatment in dogs.

In humans, IVIG has been used for a variety of immune system-related conditions including primary and secondary immunodeficiencies, graft versus host disease, Guillain-Barre syndrome, chronic inflammatory demyelinating polyneuropathy, autoimmune hemolytic anemia, juvenile idiopathic arthritis, myasthenia gravis, toxic epidermal necrolysis, systemic vasculitis, and sepsis.

Pharmacology/Actions
Immunoglobulins are produced by B lymphocytes as part of the humoral response to foreign antigens. IVIG antibodies act through a variety of mechanisms, including antimicrobial or antitoxin neutralization. Its efficacy for treating autoimmune disorders may be due to: providing anti-idiotypic antibodies that neutralize autoantibodies; negative feedback and down-regulation of antibody production; binding to CD5 receptors, interleukin (IL)-1a, IL-6, tumor necrosis factor-alpha, and T-cell receptors; and suppressing pathogenic cytokines and phagocytes.

Pharmacokinetics
Elimination half-life in dogs is reported to be 7–9 days. In humans, the onset of actions is rapid. Immunoglobulins are primarily eliminated by catabolism and the mean half-life is about 3 weeks. Fever or infection may decrease antibody half-life because of increased catabolism or consumption.

Contraindications/Precautions/Warnings
Dogs that have had prior hypersensitivity reactions after receiving human albumin, should not receive IVIG. Trace amounts of human albumin may be found in IVIG.

In humans, many adverse reactions are associated with administering IVIG at rates higher than recommended. Follow infusion rate guidelines carefully. At doses used in dogs (0.5–1.5 grams/kg), IVIG is generally infused over a 6–12 hour period.

The FDA has placed a “Black Box Warning” on the labeling of IVIG for use in humans as IVIG has been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death.

Adverse Effects
In dogs, IVIG can cause increased blood pressure. Local reactions at or near the injection site are possible. Anecdotal reports of anaphylaxis have been reported in dogs receiving IVIG. IVIG can contain trace amounts of human albumin that has been associated with hypersensitivity reactions in dogs. As IVIG can have colloid-like properties, volume overload is possible. Thrombotic events have been reported in humans and are possible in dogs.

In humans, adverse effects of IVIG in people are relatively uncommon and most are transient, self-limiting and include fever, chills, facial flushing, headache, and nausea. Thrombotic events have been reported. Rarely, acute renal failure, acute tubular necrosis, osmotic nephrosis, and proximal tubular nephropathy have been reported in humans. Increases in creatinine and BUN have been seen as soon as 1-2 days following infusion. Hypersensitivity reactions, including anaphylaxis have been reported, but are very rare in human patients.

Reproductive/Nursing Safety
In humans, the FDA has placed IVIG in category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans. However, there does not appear to be a significant risk to offspring.

The drug appears to be safe for use during lactation and nursing.

Overdosage/Acute Toxicity
Fluid volume overload is possible. Other reactions could include pain and tenderness at the injection site.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving IVIG and may be of significance in veterinary patients:
**Laboratory Considerations**

**BLOOD GLUCOSE:** Falsely elevated blood glucose measurements can occur when using the glucose dehydrogenase pyrroloquinoline quinone (GDH-PQQ) based test. Consider using tests that are not affected, including the glucose oxidase, glucose dehydrogenase nicotine adenine dinucleotide (GDH-NAD), or glucose dehydrogenase flavin adenine dinucleotide (GDH-FAD) methods.

**COOMBS TEST:** In humans, the transitory rise of the various passively transferred antibodies may cause positive serological testing results, potentially altering the test’s results and interpretation.

**Doses**

**DOGS:**

a) Various dosages have been used in dogs ranging from 0.3–1.5 grams/kg which translates into an estimated $400 to $1500 associated with the cost of the drug alone. Recommendations that IVIG should be considered when dogs with IMHA or ITP fail to respond to conventional therapy must be weighed against the additional cost after clients have already spent a considerable amount of money during initial treatment. From a healthcare system point of view this would appear to be unjustifiable and probably would not be recommended, however, on an individual patient basis, clients and clinicians may find such therapy offers some degree of hope and cost-analyses may not dissuade its usage. (Chan 2009)

b) IVIG has shown some benefit in IMHA patients that are refractory to conventional treatment. It is given at a dose of 0.5–1.5 grams/kg IV over 12 hours. (Macintire 2006)

c) For primary immune-mediated thrombocytopenia (pIMT): In the study, dogs in the treatment group received a single IV infusion of IVIG at 0.5 grams/kg. (Bianco et al. 2007)

d) For refractory cases of erythema multiforme, Stevens-Johnson syndrome/toxic epidermal necrolysis, and other cutaneous adverse drug reactions, treatment with human IVIG may be effective. A 5–6% solution is given at 0.5–1 grams/kg IV over a 4-6 hour period, 1-2 times, 24 hours apart. This treatment may need to be repeated for 3-4 days in a row. Further study is needed. (Jazic 2010)

**Monitoring**

- Vital signs: including blood pressure, temperature
- Lung auscultation to assess for volume overload
- Renal function tests and urine output
- Efficacy (depending on purpose for use)

**Client Information**

- It is imperative that before use, clients understand that this drug is not commonly used in veterinary medicine, and the costs and risks associated with its use.

**Chemistry/Synonyms**

IVIG consists of fractionated immunoglobulins, and is primarily intact IgG. It is obtained from pooled human plasma (1,000–60,000 human donors). It may also contain trace amounts of IgM, IgA, soluble CD4, CD8 and HLA molecules, and some cytokines. Further processing is performed to inactivate viruses and remove IgG aggregates and other contaminants. Stabilizing agents can include polyethylene glycol, glycine, sorbitol, polysorbate 80, and sugars (maltose, glucose, sucrose).

Immune globulin (human) may also be known as hIVIG, IVIG, IGIV, immunoglobuline, or immunoglobulas.

**Storage/ Stability**

IVIG products are usually stored at room temperature, but specific storage requirements vary with each product; refer to the label. These products should not be frozen.

**Compatibility/ Compounding Considerations**

IVIG should not be mixed with other medications. One product’s label (Privigen®) states that it can be diluted with 5% dextrose in water (D5W) if necessary.

**Dosage Forms/ Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Immune Globulin (Human) Injection 5% (50 mg/mL) preservative-free in 10 mL, 20 mL, 50 mL, 100 mL, & 200 mL (0.5 gram, 1 gram, 2.5 grams, 5 grams, & 10 grams—depending on product) single use bottles; Felbogamma® (Grifols), Octagam® (Octapharm), Gammavaler® (FFF); (Rx)

- Immune Globulin (Human) Injection 10% (100 mg/mL) preservative-free in 10 mL, 20 mL, 50 mL, 100 mL, & 200 mL (1 gram, 2 grams, 10 grams, & 20 grams—depending on product) single use bottles; Gammunex® (Talecris), Gammagard® (Baxter), Privigen® (AventisB); (Rx)

- Immune Globulin (Human) Lyophilized Powder for Solution 0.5 gram, 3 grams, 6 grams & 12 grams—depending on product; Carimune NF® (ZLB), Gammagard S/D® (Baxter); (Rx)

**References**

INAMRINONE LACTATE
(in-am-ri-none) Amrinone, Incon®
INOTROPIC AGENT
Prescriber Highlights

- Second-line agent for short-term management of CHF
- Contraindicated with severe aortic or pulmonic valve disease; use extreme caution with hypertrophic cardiomyopathy
- Monitoring of cardiac effects & adverse effects mandatory
- Very Expensive

Uses/Indications
Inamrinone is considered a second line agent for the short-term management of CHF. It was originally called amrinone, but was changed to inamrinone presumably to avoid confusion with amiodarone.

Pharmacology/Actions
The exact mechanisms of amrinone’s cardiac effects are not well understood. It is thought the primary effects are due to its vasodilatory effects, thereby reducing both preload and afterload. Because it inhibits phosphodiesterase, it may directly stimulate cardiac contractility.

Pharmacokinetics
Although no oral commercial dosage forms are available, inamrinone is rapidly absorbed after oral administration. After initial intravenous injection, effects begin within 2–3 minutes and peak effects occur within 10 minutes. Cardiac effects generally correlate with the drug’s serum level. Amrinone’s distribution characteristics are not well described. In humans, it has an apparent volume of distribution of 1.2 L/kg. It exhibits low to moderate protein binding (10–49%). It is unknown if it crosses the placenta, blood-brain barrier, or enters into maternal milk. Inamrinone is eliminated primarily via the kidneys. About 63% of a dose is excreted (10–40% unchanged) into the urine. The duration of effect (in humans) is dose related lasting from 30 minutes after a 0.75 mg/kg IV dose to 2 hours after a 3 mg/kg dose. Plasma half-lives may be prolonged in patients with CHF.

Contraindications/Precautions/Warnings
Inamrinone is considered contraindicated when severe aortic or pulmonic valve disease is present or in patients hypersensitive to it or bisulfites. The potential risks versus benefits of therapy with inamrinone should be carefully considered in patients with hypertrophic cardiomyopathy.

Adverse Effects
Use in domestic animals is very limited. Adverse effects that potentially could be seen include arrhythmias (drug is not inherently arrhythmogenic, but CHF patients are more susceptible to arrhythmias secondary to any drug), hypotension, GI effects (vomiting, diarrhea), thrombocytopenia (particularly with prolonged therapy), hepatoxicty, and hypersensitivity reactions (variable symptomatology: pericarditis to myositis, etc.). Inamrinone should only be used in settings where appropriate monitoring may be employed.

Reproductive/Nursing Safety
Reproductive safety data are conflicting; use only when benefits outweigh risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether inamrinone is secreted in milk; exercise caution.

Overdosage/Acute Toxicity
Only one case (human) of accidental massive overdose resulting in death has been reported (causal relationship not unequivocally established). Because hypotension is the primary problem that would generally be seen, circulatory support should be instituted.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving inamrinone lactate and may be of significance in veterinary patients:

- DIGOXIN: Digoxin and other inotropic cardiac glycosides have an additive effect with inamrinone; this is generally considered a positive drug interaction.
- DISOPYRAMIDE: May cause excessive hypotension when used with inamrinone.

Doses

For DOGS:

- 1–3 mg/kg IV as a slow IV bolus followed by a 10–100 micrograms/kg/min IV CRI; ½ the initial bolus may be administered 20–30 minutes after the first bolus. (Kittleson 2006)
- 1–3 mg/kg IV followed by a 30–100 micrograms/kg/min IV CRI (Muir & Bonagura 1994)
- 2 mg/kg bolus IV, followed by 30–300 micrograms/kg/min IV infusion (Fox 2003)
- For patients coming off cardiopulmonary bypass with poor cardiac contractility: 0.25–0.6 mg/kg loading, then 5–45 micrograms/kg/min CRI (Nelson 2003)
- As an alternative to dopamine or dobutamine for the adjunctive treatment (with fluids, IV calcium, and potentially glucagon) for calcium channel blocker overdose: 30–100 micrograms/kg/min CRI. (Holder 2000)
**CATS:**

a) 1–3 mg/kg IV followed by 30–100 micro-grams/kg/min IV infusion (Muir & Bonagura 1994)
b) 1–3 mg/kg IV as a slow IV bolus followed by a 10–100 micrograms/kg/min IV CRI; ½ the initial bolus may be administered 20–30 minutes after the first bolus. (Kittleson 2006)

**Monitoring**

- Blood pressure
- Heart rate/rhythm; continuous ECG recommended
- Body weight
- Platelet counts

**Client Information**

- Clients should be made aware of the “investigational nature” of the use of this drug in dogs or cats

**Chemistry/Synonyms**

Formerly known as amrinone lactate, inamrinone is unrelated structurally to cardiac glycosides or catecholamines, and is a bipyrdine cardiac inotropic agent. It occurs as a pale yellow, crystalline powder and is insoluble in water and slightly soluble in alcohol. The commercially available injection has a pH adjusted to 3.2–4 and an osmolality of 101 mOsm/L.

Inamrinone may also be known as: amrinone, Win-40680, Amcoral®, Inocor®, Vesistol®, and Wincoram®.

**Storage/Stability**

The commercially available injection should be stored at room temperature and protected from light. It is stable for 2 years after manufacture.

**Compatibility/Compounding Considerations**

Inamrinone lactate for injection is reportedly **compatible** with 0.45% or 0.9% sodium chloride injection, propranolol HCl, and verapamil HCl. It is reportedly **incompatible** with solutions containing dextrose or sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Inamrinone Lactate for Injection: 5 mg/mL (as lactate) in 20 mL amps; generic (Abbott Hospital); (Rx)

Note: Insulin preparations available to the practitioner are in a constant state of change. It is highly recommended to review current references or sources of information pertaining to insulin therapy for dogs and cats to maximize efficacy of therapy and reduce the chance for errors.

**Prescriber Highlights**

- Pancreatic hormone used to treat diabetic ketoacidosis, uncomplicated diabetes mellitus, & as adjunctive therapy in treating hyperkalemia
- Contraindications: No absolute contraindications except during episodes of hypoglycemia
- Adverse Effects: Hypoglycemia, insulin-induced hyperglycemia (“Somogyi effect”), insulin antagonism/resistance, rapid insulin metabolism, & local reactions to the “foreign” proteins
- Do not confuse insulin types, strengths, syringes
- Drug Interactions

Monograph by Dinah Jordan, PharmD, DICVP
Uses/Indications

Insulin preparations are used for the adjunctive treatment of diabetic ketoacidosis (DKA), uncomplicated diabetes mellitus, and as adjunctive therapy in treating hyperkalemia. Veterinary use of insulin has been primarily in dogs and cats, although there are documented reports in a number of other species, including, but not limited to, birds, guinea pigs, ferrets, horses, and cattle.

Regular insulin is commonly used for stabilization of the diabetic patient and is the only formulation labeled for intravenous administration (IV); it is also administered by intramuscular (IM) and subcutaneous (SC) injection. Intravenous administration of regular insulin is recommended in patients with poor tissue perfusion, shock, or cardiovascular collapse, or in patients requiring insulin for the treatment of severe, life-threatening hyperkalemia causing cardio toxicity (*i.e.*, >8 mEq/L). While historically, regular insulin was the only insulin preparation recommended for treatment of DKA in veterinary patients, new information suggests that other preparations may be equally effective. A study demonstrated that lispro insulin administered as an intravenous continuous rate infusion was a safe and effective alternative to regular insulin treatment in dogs with DKA (Sears *et al.* 2009). Another study demonstrated that intramuscular administration of glargine is effective for treatment of feline DKA (Marshall *et al.* 2010) and another study showed that a combination of glargine administered subcutaneously every 12 hours and regular insulin administered IM up to every 8 hours resolved DKA faster in cats than a protocol using regular insulin in a CRI (Buob *et al.* 2010). Once the patient is stabilized, longer acting insulin products are given subcutaneously for maintenance insulin therapy.

Pharmacology

Insulin is a hormone secreted by the beta cells of the pancreatic islets of Langerhans. Eliciting multiple biological responses, insulin initiates its actions by binding to cell-surface receptors, present in varying numbers in virtually all mammalian cells. This binding results in a cascade of intracellular events which can be studied in detail by consulting a physiology text.

Insulin is the primary hormone responsible for controlling the uptake, utilization, and storage of cellular nutrients. Insulin affects primarily liver, muscle, and adipose tissues, but also exerts potent regulatory effects on other cell types as well. Insulin stimulates carbohydrate metabolism in cardiac, skeletal, and adipose tissue by facilitating the uptake of glucose by these cells. Other tissues, such as brain, nerve, intestinal, liver, and kidney tubules, do not require insulin for glucose transport. Liver cells do need insulin to convert glucose to glycogen (for storage), and the hypothalamus requires insulin for glucose entry into the satiety center. Insulin has a direct effect on fat and protein metabolism. The hormone stimulates lipogenesis, increases protein synthesis, and inhibits lipolysis and free fatty acid release from adipose tissues. Insulin promotes an intracellular shift of potassium and magnesium. Exogenous insulin elicits all the pharmacologic responses usually produced by endogenous insulin.

Pharmacokinetics

Insulin is metabolized mainly by the liver and kidneys (also muscle and fat to a lesser degree) by enzymatic reduction to form peptides and amino acids. About 50% of the insulin that reaches the liver via the portal vein is destroyed and never reaches the general circulation. Insulin is filtered by the renal glomeruli and is reabsorbed by the tubules, which also degrade it. Severe impairment of renal function appears to affect the rate of clearance of circulating insulin to a greater extent than hepatic disease.

Hepatic degradation of insulin operates near its maximal capacity and cannot compensate for diminished renal breakdown of the hormone. The half-life of endogenous insulin is less than ten minutes in normal subjects and in patients with uncomplicated diabetes.

**Note:** The pharmacokinetics of various insulin formulations can vary widely from published values between species, among individuals within a species, and within the same individual patient from day to day. Therefore, the values should only be used as a general reference guide.

**Regular insulin injection:** When the recombinant human insulin product is given IV to dogs and cats, it has an immediate onset of action, with maximum effects occurring at 0.5–2 hours; duration of action is 1–4 hours. Following IM administration, onset is 10–30 minutes; peak 1–4 hours; and duration 3–8 hours. Following subcutaneous administration, onset is generally 10–30 minutes; peak from 1–5 hours; duration 4–10 hours. Although the kinetics of all insulin products vary markedly for the individual product between species, regular insulin appears to exhibit the most similar properties.

**Insulin lispro injection:** While published studies are lacking, the pharmacokinetics of lispro and regular insulin in dogs and cats when administered intravenously appear to be comparable to humans.

**Isophane insulin suspension (NPH):** NPH is administered by the subcutaneous route only. Following SC administration of the recombinant human insulin product, onset is 0.5–2 hours in dogs and cats; peak is 2–10 hours in dogs and 2–8 hours in cats; and duration is 6–18 hours in dogs and 4–12 hours in cats.

**Porcine insulin zinc suspension (Lente):** Lente is classified as intermediate-acting; it has two peaks of activity following subcutaneous administration (the first at around 4 hours and the second at around 11 hours). The duration of activity varies between 14 and 24 hours. The peak(s), duration of activity, and dose required to adequately control diabetic signs will vary between dogs. Following SC administration of the recombinant human insulin lente product, onset is 0.5–2 hours in dogs and cats. Pharmacokinetics of the purified pork product are similar to the human product.

**Protamine zinc suspension (PZI):** Following SC administration, onset is 1–4 hours in dogs and cats; peak is 4–8 hours; duration is 6–28 hours in dogs; 6–24 hours in cats.

**Insulin glargine injection:** Following subcutaneous injection, the acidic solution is neutralized and microprecipitates are formed that slowly release small amounts of insulin glargine. This action results in a relatively constant concentration/time profile over 24 hours with no pronounced peak in humans. A small study compared equal doses of insulin glargine, PZI (mixed beef/pork), and purified pork lente insulin in 9 healthy cats. Results showed no significant difference in onset of action or nadir glucose concentrations among the insulins; time to reach nadir glucose concentration was longer for glargine (~16 hours) vs. PZI (~6 hours) and lente (~4.5 hours). Duration was significantly shorter for lente than for glargine or PZI, with glargine and PZI not significantly different. The study in healthy cats also showed there were definite peaks in insulin concentration and glucose lowering effects of glargine. (Marshall & Rand 2004) If glargine is diluted or administered either IM or SC, onset is ~0.5 hours and peak is ~4 hours.

**Insulin detemir injection:** A comparison study of glargine and detemir in 10 young healthy cats showed that following administration of 0.5 Units/kg SC, the, onset of action was 1.8 ± 0.8 and 1.3 ± 0.5 hours for insulin detemir and insulin glargine respectively. End of action of insulin detemir was reached at 13.5 ± 3.5 hours and for insulin glargine at 11.3 ± 4.5 hours. Time-to-peak action of insulin detemir was reached at 6.9 ± 3.1 hours and for insulin glargine at 5.3 ± 3.8 hours. The time-action curves of both insulin analogs varied between relatively flat curves in some cats and peaked curves in others (Gilor *et al.* 2010).

Contraindications/Precautions/Warnings

Because there are no alternatives for insulin when it is used for diabetic indications, there are no absolute contraindications to its use except during episodes of hypoglycemia. If animals develop hypersensitivity (local or otherwise) or should insulin resistance develop, a change in type or species of insulin should be tried. Pork insulin is identical to canine insulin and is considered the insulin source of choice for diabetic dogs. Human insulin has a low potential for producing insulin antibodies in dogs (~5%), while beef/pork insulin produces antibody formation in a higher percentage of dogs (~45%) and is associated with insulin resistance and poor or erratic glycemic control.
Treatment of diabetes mellitus and in particular, diabetic ketoacidosis is complex. Insulin is only one component of therapy; fluid and electrolytes, acid/base, and if necessary, antimicrobial therapy must also be employed. Adequate patient monitoring is mandatory. The reader is strongly encouraged to refer to more thorough discussions of treatment in veterinary endocrinology or internal medicine references for additional information.

**DOGS**:

1. Using regular insulin, choose either the intermittent IM technique or low-dose IV infusion technique.

2. For adjunctive therapy of diabetic ketoacidosis:
   - a) Using regular insulin, choose either the intermittent IM technique or low-dose IV infusion technique.

**HYPOLYCEMIA**

Mild hypoglycemia may be treated by offering the animal its usual food. More serious symptoms (such as seizure) should be treated with oral dextrose solutions (e.g., Karo® syrup) rubbed on the oral mucosa (not poured down the throat) or by intravenous injections of 50% dextrose solutions (small amounts, slowly administered—usually 2–15 mL). If the animal is seizing, fingers should not be placed in the animal’s mouth. Once the animal’s hypoglycemia is alleviated (response usually occurs within 1–2 minutes), it should be closely monitored (both by physical observation and serial blood glucose levels) to prevent a recurrence of hypoglycemia.

**INSULIN INTERACTIONS**

The following drugs or drug classes may potentiate the hypoglycemic activity of insulin:

- **ALCOHOL**
- **ANABOLIC STEROIDS** (e.g., stanozolol, boldenone)
- **ANGIOTENSIN CONVERTING ENZYME INHIBITORS** (e.g., captopril, enalapril)
- **ASPIRIN** or other salicylates
- **DISOPYRAMIDE**
- **FLUOXETINE**
- **MONOAMINE OXIDASE INHIBITORS**
- **SOMATOSTATIN DERIVATIVES** (e.g., octreotide)
- **SULFONAMIDES**

The following drugs or drug classes may decrease the hypoglycemic activity of insulin:

- **CALCIUM CHANNEL BLOCKERS** (e.g., diltiazem)
- **CORTICOSTEROIDS**
- **DANAZOL**
- **DIURETICS**
- **ISONIAZID**
- **NIACIN**
- **PHENOTHIAZINES**
- **THYROID HORMONES** (can elevate blood glucose levels in diabetic patients when thyroid hormone therapy is first initiated)

**DOSES**

Note: Treatment of diabetes mellitus and in particular, diabetic ketoacidosis is complex. Insulin is only one component of therapy; fluid and electrolytes, acid/base, and if necessary, antimicrobial therapy must also be employed. Adequate patient monitoring is mandatory. The reader is strongly encouraged to refer to more thorough discussions of treatment in veterinary endocrinology or internal medicine references for additional information. Biologic insulin formulations: Anabolic steroids (e.g., stanozolol, boldenone) or certain salicylates (e.g., aspirin) can mask or potentiate the hypoglycemic activity of insulin. A physical examination of the patient should be performed and the patient should be observed closely for hypoglycemic signs. Adverse effects of insulin therapy may include hypoglycemia (see overdosage below), insulin-induced hyperglycemia (“Somogyi effect”), insulin antagonism/resistance, rapid insulin metabolism, and local reactions to the “foreign” proteins.

**CLONIDINE; RESEPPINE:** Can mask the signs associated with hypoglycemia

**DIGOXIN:** Can mask the signs associated with hypoglycemia

**MONOAMINE OXIDASE INHIBITORS**

**SOMATOSTATIN DERIVATIVES**

**SULFONAMIDES**

**THYROID HORMONES**

**CALCIUM CHANNEL BLOCKERS**

**CORTICOSTEROIDS**

**DANAZOL**

**DIURETICS**

**ISONIAZID**

**NIACIN**

**PHENOTHIAZINES**

**THYROID HORMONES**

**CALCIUM CHANNEL BLOCKERS**

**CORTICOSTEROIDS**

**DANAZOL**

**DIURETICS**

**ISONIAZID**

**NIACIN**

**PHENOTHIAZINES**

**THYROID HORMONES**
**BIRDS:**

Diabetes mellitus is most common in budgies, cockatiels, and toucans. Blood glucose levels in diabetic birds range from 600–2000 mg/dL (Definitive diagnosis requires persistently elevated blood glucose levels >800 mg/dL). Insulin therapy is sometimes hindered by the highly variable dose needed for individual birds, the development of insulin resistance, and the development of pancreatic atrophy and pancreatic insufficiency.

For adjunctive treatment of severe hyperkalemia (>8 mEq/L):

- **Cats:** For adjunctive treatment of diabetic ketoacidosis:
  a) Use the same protocol using regular insulin as described above in “a” for dogs (Hess, R. 2010; Nelson & Elliott 2003a)
  b) Using insulin glargine: 2 Units per cat SC and 1 Unit per cat IM (regardless of body weight) initially; repeat the IM dose 4 or more hours later if the blood glucose concentration is greater than 14 to 16 mMol/L (250-290 mg/dL); repeat the SC dose every 12 hours. (Rand 2010a)
  For initial insulin treatment of uncomplicated diabetes mellitus:
  a) Using regular insulin 0.25–0.5 Units/kg slow IV bolus followed by 50% dextrose (4 mL/U of administered insulin); or give regular 0.5–1 Units/kg in parenteral fluids plus 2 grams dextrose per unit insulin administered (Nelson & Elliott 2003b)
  b) Vetsulin®: 0.5 Units/kg SC twice daily. (Bruyette 2010)
  c) Intermediate-acting insulin (i.e., NPH, Lente) is the initial insulin of choice for establishing control of glycemia in diabetic dogs. Recombinant human or porcine source insulin should be used to minimize development of insulin antibodies. Insulin therapy is begun with recombinant human NPH or porcine Lente Vetsulin® at an approximate dosage of 0.25 Units/kg twice a day. Insulin glargine (Lantus®) is used in poorly-controlled diabetic dogs where NPH and Lente insulin are ineffective because of problems with too short a duration of insulin effect. (Nelson 2006)
  d) Glargine: 0.25–0.5 Units/kg SC q12h. (Fracassi et al. 2010)
  e) Insulin detemir: 0.1–0.2 Units/kg SC q 12 hours. Note the lower starting dose for detemir. Canine insulin receptors appear to be 4x more sensitive than human receptors to detemir. (Ford et al. 2010)
  - **BIRDS:**

  - a) Using regular insulin, choose either the intermittent IM technique or low-dose IV infusion technique.
  - **Intermittent IM technique:** Initial Dose: 0.2 Units/kg IM into muscles of the rear legs; repeat IM doses of 0.1 Units/kg hourly. Initial doses (first 2 to 3 injections) may be reduced by 25–50% in animals with severe hypokalemia. Goal is to slowly lower blood glucose to 200–250 mg/dL over a 6–10 hour period. As blood glucose approaches 250 mg/dL, switch to IM regular insulin at 0.1–0.3 Units/kg q4–6h or subcutaneous (if hydration status is good) q6–8h. Goal is to keep blood glucose in the 150–300 mg/dL range. Giving 5% dextrose IV is necessary during this stage.
  - **Constant Low-Dose Infusion Technique:** Administer insulin infusion in an IV line separate from that for fluid therapy. Initial doses may be reduced by 25–50% in animals with severe hypokalemia. Adjust infusion rate based upon hourly blood glucose determinations. An hourly reduction in blood glucose by 50–100 mg/dL is ideal. Once blood glucose approaches 250 mg/dL, switch to IM regular insulin every 4–6 hours or to subcutaneous regular insulin at 0.1–0.4 Units/kg q6–8h if hydration status is good. Goal is to keep blood glucose in the 150–300 mg/dL range. Giving 5% dextrose IV is necessary during this stage. Alternatively, may continue IV infusion at a decreased rate until exchanged for a longer-acting product. (Nelson 2008; Nelson & Elliott 2003a)
  - b) For IV infusion: Preparation of insulin infusion by adding 2.2 Units/kg regular insulin to 250 ml of 0.9% sterile saline for injection. Run approximately 50 mL of the insulin-containing fluid through the drip set prior to administration (See adsorption). (Hess, R.S. 2008)
  - For initial insulin treatment of uncomplicated diabetes mellitus:
    a) Using regular insulin, choose either the intermittent IM technique or low-dose IV infusion technique.
    b) Using regular insulin 0.25–0.5 Units/kg slow IV bolus followed by 50% dextrose (4 mL/U of administered insulin); or give regular 0.5–1 Units/kg in parenteral fluids plus 2 grams dextrose per unit insulin administered (Nelson & Elliott 2003b)
    - **Cats:** For adjunctive treatment of severe hyperkalemia (>8 mEq/L):
      a) Give regular insulin 0.25–0.5 Units/kg slow IV bolus followed by 50% dextrose (4 mL/U of administered insulin); or give regular 0.5–1 Units/kg in parenteral fluids plus 2 grams dextrose per unit insulin administered (Nelson & Elliott 2003b)
Insulin is a small protein; human insulin has a molecular weight of 5808. Insulin secretion is a tightly regulated process designed to provide stable concentrations of glucose in blood during fasting and feeding. This regulation is achieved by the coordinated interplay of various nutrients, gastrointestinal and pancreatic hormones, and autonomic neurotransmitters. The primary stimulus for secretion of endogenous insulin is glucose. The endocrine component of the pancreas is organized as discrete islets (islets of Langerhans) that contain four cell types, each of which produces a different hormone. Insulin is produced in the beta cells, which comprise 60–80% of the islet. Insulin is a protein consisting of two chains, designated A and B, with 21 and 30 amino acids respectively that are connected by two disulfide bonds. The amino acid composition of insulin has been determined in various species of animals. The insulin of dogs, pigs, and certain whales (sperm and fin) is identical in structure; sheep insulin is identical to goat. Cattle, sheep, horses, and dogs differ only in positions 8, 9, and 10 of the A chain. Porcine insulin differs from human insulin by one amino acid [alanine instead of threonine at the carboxy terminal of the B chain (Sims et al. 1967)]. Pigs, horses, and cows each differ from human insulin by additional alterations in the A chain (six additional positions). Feline insulin is most similar to bovine insulin, differing by only 1 amino acid (at position 18 of the A chain). Human insulin and bovine insulin differs by two additional alterations in the A chain (threonine and isoleucine in positions A8 and A10 are replaced by alanine and valine, respectively). Of the domestic species, feline insulin is most similar to bovine insulin, differing by only 1 amino acid (at position 18 of the A chain). Human insulin differs from rabbit insulin by a single amino acid. There is a single insulin gene and a single protein product in most mammalian species (multiple insulin appears to occur frequently among fishes).

Improper injection techniques should be taught and practiced with the client before the animal’s discharge. The symptoms of hypoglycemia should be thoroughly reviewed with the owner. A written protocol outlining monitoring procedures and treatment steps for hypoglycemia should be sent home with the owner. When traveling, insulin should not be left in carry-on luggage that will pass through airport surveillance equipment. Generally, insulin stability is not affected by a single pass through surveillance equipment; however, longer than normal exposure or repeated passes through surveillance equipment may alter insulin potency.

Chemistry and Biosynthesis

The endocrine component of the pancreas is organized as discrete islets (islets of Langerhans) that contain four cell types, each of which produces a different hormone. Insulin is produced in the beta cells, which comprise 60–80% of the islet. Insulin is a protein consisting of two chains, designated A and B, with 21 and 30 amino acids respectively that are connected by two disulfide bonds. The amino acid composition of insulin has been determined in various species of animals. The insulin of dogs, pigs, and certain whales (sperm and fin) is identical in structure; sheep insulin is identical to goat. Cattle, sheep, horses, and dogs differ only in positions 8, 9, and 10 of the A chain. Porcine insulin differs from human insulin by one amino acid [alanine instead of threonine at the carboxy terminal of the B chain (i.e., in position B 30)], and bovine insulin differs by two additional alterations in the A chain (threonine and isoleucine in positions A8 and A10 are replaced by alanine and valine, respectively). Of the domestic species, feline insulin is similar to bovine insulin, differing by only 1 amino acid (at position 18 of the A chain). Human insulin differs from rabbit insulin by a single amino acid. There is a single insulin gene and a single protein product in most mammalian species (multiple insulin appears to occur frequently among fishes).

For therapeutic purposes, doses and concentrations of insulin are expressed in Units. This is sometimes abbreviated as “U”, but this practice is discouraged to reduce the chance for transcription and dosage errors. One unit of insulin is equal to the amount required to reduce the concentration of blood glucose in a fasting rabbit to 45 mg/dL (2.5 mM). All commercial preparations of human insulin currently manufactured in the U.S. are supplied in solution or suspension at a concentration of 100 Units/mL, which is approximately 3.6 mg of insulin per milliliter; likewise, one unit of insulin equals about 36 micrograms of insulin.

Insulin is a small protein; human insulin has a molecular weight of 5808. Insulin secretion is a tightly regulated process designed to provide stable concentrations of glucose in blood during fasting and feeding. This regulation is achieved by the coordinated interplay of various nutrients, gastrointestinal and pancreatic hormones, and autonomic neurotransmitters. The primary stimulus for secretion of endogenous insulin is glucose.

Regular insulin is a rapid-acting sterile solution prepared by precipitating insulin in the presence of zinc chloride to form zinc insulin crystals. Regular insulin 100 Units/mL is a clear and colorless or almost colorless solution. Discoloration, turbidity, or unusual viscosity indicates deterioration or contamination.

Insulin lispro injection, USP (rDNA origin) is a human insulin analog that is rapid-acting and is synthesized in a special non-pathogenic laboratory strain of Escherichia coli that has been genetically altered. The sterile solution consists of zinc-insulin lispro crystals dissolved in a clear aqueous fluid.

Isophane insulin, more commonly known as NPH, is an intermediate-acting, sterile suspension of zinc insulin crystals and protamine sulfate in buffered water for injection.
Porcine Lente insulin is a sterile aqueous suspension of purified pork Lente insulin consisting of 30% amorphous zinc insulin and 70% crystalline zinc insulin. It is available only as a U-40 insulin concentration and is a cloudy or milky suspension of a mixture of characteristic crystals and particles with no uniform shape. Proamine zinc suspension (PZI) is composed of 90% beef/10% pork insulin combined with zinc and protamine (a protein extracted from salmon testes), which slow the release of the insulin into tissues. PZI is clear (not cloudy) with white sediment (no clumps), that when mixed gently, looks like watery milk. It is available only as a U-40 insulin concentration.

Insulin glargine is a long-acting human insulin analog produced by recombinant DNA technology utilizing a non-pathogenic laboratory strain of E. coli. It differs from human insulin in that the amino acid asparagine at position A21 is replaced by glycine, and two arginines are added to the C-terminus of the B chain. The injection consists of insulin glargine dissolved in a clear aqueous fluid. It is available only as a U-100 insulin concentration.

Insulin detemir is a long-acting human insulin analog produced by recombinant DNA technology using a genetically modified strain of Saccharomyces cerevisiae. Insulin detemir differs from human insulin in that the amino acid threonine in position B30 has been omitted, and a C14 fatty acid chain has been attached to the amino acid B29. It is a clear, colorless, aqueous solution.

All human, purified pork, and beef/pork insulin products have a neutral pH of approximately 7–7.8, while insulin glargine has an acidic pH of approximately 4.

Stability/Storage

Manufacturers of insulin recommend that all insulin products be stored in the refrigerator but protected from freezing temperatures (do not store at temperatures <36°F or <2°C). Freezing may alter the protein structure, decreasing potency. Particle aggregation and crystal damage may be visible to the naked eye or may require microscopic examination. Higher temperature (>86°F or >30°C) extremes and direct exposure to sunlight should be avoided (such as might occur when insulin is stored in a car glove compartment or on a window sill), since insulin transformation products and fibril formation may occur. Although the manufacturers recommend a maximum of 30 days storage at room temperature (except for detemir, which is 42 days), studies have actually shown that regular insulin maintains stability of 24–30 months at 25°C. One study showed a 5% loss of biological potency after about 36 months at 25°C.

According to the manufacturer’s label, insulin glargine has a discard date of 28 days after the initial puncture of the vial (consistent with all human-labeled insulin products except for detemir, which has a discard date of 42 days) and stored at room temperature, although clinical reports indicate that opened vials stored in the refrigerator can be used for up to 6 months; discard vial immediately if there is any discoloration. Bacterial contamination and precipitation associated with pH change can cause cloudiness (Rand 2010b).

For animals requiring small doses of glargine, the 3 mL cartridge may be preferable to the 10 mL vial to prevent the need for extended use beyond the recommended discard date. Flocculation of NPH human insulin may appear 3–6 weeks after opening the vial. Deterioration in glycemic control may appear before frosting of the vial. If unexplained hyperglycemia is observed, a new vial of insulin should be used.

Regular and NPH insulin may be stored in plastic or glass syringes under refrigeration for 5–7 days without loss of potency. One study found no degradation after 14 days storage under refrigeration. Other sources state that prefilled insulin syringes are stable for 30 days when stored in the refrigerator. It is generally accepted that syringes of insulin can be stored for 28 days under refrigeration without fear of potency loss.

Compatibility/Compounding Considerations

Regular insulin is reportedly physically compatible with following drugs/solutions: normal saline, TPN solutions (4% amino acids, 25% dextrose with electrolytes and vitamins; must occasionally shake bag to prevent separation), bretyllium tosylate, cimetidine HCl, lidocaine HCl, oxytetracycline HCl, and verapamil HCl. Regular insulin may be mixed with other insulin products (except for glargine) used in veterinary medicine (e.g., NPH, PZI, etc.).

Regular insulin is reportedly physically incompatible when mixed with the following drugs/solutions: aminophylline, amobarbital sodium, chlorothiazide sodium, cytarabine, dobutamine HCl, nitrofurantoin sodium, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, secobarbital sodium, sodium bicarbonate, sulfisoxazole sodium, and thiopental sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Diluting insulin: Other than for immediate use, insulin should only be diluted using product-specific sterile diluents supplied by the manufacturer. Diluents for Regular insulin (Humulin R) and NPH insulin (Humulin N) and sterile vials can be obtained by telephoning the manufacturer. Diluted insulin is stable for 4 (preferred) to 6 weeks and should be stored in the refrigerator. For immediate use, insulin products (except glargine) can be diluted with normal saline for injection, but the potency cannot be predicted after 24 hours. Insulin glargine must not be diluted or mixed with any other insulin or solution because the prolonged action is dependent on its pH.

Adsorption: The adsorption of regular insulin to the surfaces of IV infusion solution containers, glass and plastic (including PVC, ethylene vinyl acetate, polyethylene, and other polyolefins), tubing, and filters has been demonstrated. Estimates of loss of potency range from 20–80%, although reports of 20–30% are more common. The percent adsorbed is inversely proportional to the concentration of the insulin, and may include other factors such as the amount of container surface area, the fill volume of the solution, the type of solution, type and length of administration set, temperature, previous exposure of tubing to insulin, and the presence of other drugs, blood, etc. The adsorption process is instantaneous, with the bulk of insulin adsorption occurring within the first 30–60 minutes. To saturate binding sites and prevent unexplained hyperglycemia is observed, a new vial of insulin should be used.

Insulin Syringes: Syringes are designed for use with a specific strength of insulin, with the needle covers color-coded according to strength. U-40 syringes have a red top, while U-100 syringes have an orange top. U-40 syringes contain 1 Unit of insulin. U-40 syringes contain ½ cc (equivalent to 0.5 mL) and have 20 unit marks. Measuring U-40 insulin to the one unit

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Porcine Lente insulin is a U.S. and Canadian FDA-approved for use in horses and other non-ruminant species. Regular insulin Lente is an FDA-approved for use in dogs, cats, and horses. Vetsulin® (Intervet/Schering Plough); (Rx). FDA-approved for use in dogs and cats. Protamine zinc suspension (PZI) is FDA-approved for use in horses, cats, and dogs.
Porcine insulin zinc suspension 40 Units/mL in 10 mL vials, intermediate-acting; Vetsulin® (Intervet/Schering Plough); (Rx). FDA-approved for use in dogs and cats.

Note: Vetsulin® not currently (February 2011) available in the USA due to manufacturing issues. Caninsulin® (Intervet/Schering Plough) is available in Canada & Europe.

Proteamine (recombinant human) insulin (PZI) aqueous suspension 40 Units/mL in 10 mL vials; ProZinc® (BIVI); Rx. FDA-approved for use in cats.

HUMAN-LABELLED PRODUCTS:

Note: Partial listing; includes only those products generally used in veterinary medicine.

Short-Acting:

Insulin, Regular Injection Human (rDNA): 100 Units/mL in 10 mL vials; Humulin®R (Lilly); Novolin®R (Novo Nordisk); (OTC)

Insulin Lispro Injection Human (rDNA): 100 Units/mL in 3 mL & 10 mL vials, Humalog® (Lilly); (Rx)

Intermediate-Acting:

Isophane (Neutral Protamine Hagedorn; NPH) Human (rDNA): 100 Units/mL in 10 mL vials, 5 x 1.5 mL prefilled syringes & 5 x 3 mL pen insulin delivery devices; Humulin®N (Lilly); Novolin®N & Prefilled (Novo Nordisk); (OTC)

NPH/Regular Insulin Mixtures: Human (rDNA) 100 Units/mL 70% isophane insulin (NPH) & 30 % insulin injection (regular) in 5 x 3 mL disposable pen insulin delivery devices, 10 mL vials & 5 x 1.5 mL prefilled syringes; Humulin® 70/30 (Lilly); Novolin® 70/30 & Prefilled (Novo Nordisk); (OTC)

Human (rDNA) Injection (suspension): 100 Units/mL; 50% isophane insulin (NPH) & 50% insulin injection (regular) in 10 mL vials; Humulin® 50/50 (Lilly); (OTC)

Long-Acting:

Insulin Glargine Injection Human (rDNA) 100 Units/mL in 10 mL vials & 3 mL cartridge system; Lantus® (Aventis); (Rx)

Insulin Detemir Injection Human (rDNA) 100 Units/mL in 10 mL vials; Levemir® (Novo Nordisk); (Rx)

References

Despite rapid antibody development when injected parenterally and little, if any, absorption after oral administration, the drug does appear to have some efficacy for certain diseases, either via direct antiviral action or more likely, an immunomodulatory effect. Interferon-alpha has been used in dogs for the adjunctive treatment of viral- or immunosuppression-related conditions, such as papillomas, pododermatitis, or digital keratomas. Some work has been done in dogs evaluating it as an adjunctive treatment for certain neoplastic diseases (e.g., hemangiosarcoma).

In summarizing the in vitro, controlled study and clinical efficacy status in vivo for human interferon-alpha use in virus infected cats, one author (Hartmann 2008) reports: High dose SC administration to cats does not appear to be clinically effective for FIV or FeLV infections. Low dose oral treatment does appear to have some efficacy for FIV in cats. Low dose oral therapy does not appear to be effective for FeLV, FHV-1, or FCV (feline calicivirus), and is contraindicated in FIP. Topical administration to FHV-1 infected cats may have some efficacy (see topical ophthalomology section). Feline interferon-omega has recently become available in several countries and it may be useful in treating viral diseases in both cats and dogs. A separate monograph for that agent follows this one.

Immunomodulator

Prescriber Highlights

- Cytokine used to alleviate clinical effects of certain viral diseases; little scientific info available to document safety/efficacy in small animals
- Caution: Preexisting autoimmune disease, severe cardiac disease, pulmonary disease, “brittle” diabetes, Herpes infections, hypersensitivity to the drug, or CNS disorders
- Adverse Effects: In cats, adverse effects are apparently uncommon with PO; higher dosages given parenterally may cause malaise; fever; allergic reactions, myelotoxicity & myalgia are possible

Uses/Indications

Interferon alfa use in veterinary medicine has primarily been centered on its SC, or oral/buccal administration in cats to treat a variety of virus-induced diseases. Despite rapid antibody development when injected parenterally and little, if any, absorption after oral administration, the drug does appear to have some efficacy for certain diseases, either via direct antiviral action or more likely, an immunomodulatory effect. Interferon-alpha has been used in dogs for the adjunctive treatment of viral- or immunosuppression-related conditions, such as papillomas, pododermatitis, or digital keratomas. Some work has been done in dogs evaluating it as an adjunctive treatment for certain neoplastic diseases (e.g., hemangiosarcoma).
**Pharmacology/Actions**

The pharmacologic effects of the interferons are widespread and complex. Suffice it to say, that interferon alfa has antiviral, antiproliferative, and immunomodulating effects. Its antiproliferative and antiviral activities are thought to be due to its effects on the synthesis of RNA, DNA, and cellular proteins (oncogenes included). The mechanisms for its antineoplastic activities are not well understood, but are probably related these effects as well.

**Pharmacokinetics**

Interferon alfa is poorly absorbed after oral administration due to its degradation by proteolytic enzymes and studies have not detected measurable levels in the systemic circulation, however, there may be some absorption via upper GI mucosa. It may have some immunomodulating effect via stimulation of local lymphoid tissues.

Interferon alfa is widely distributed throughout the body, although it does not penetrate into the CNS well. It is unknown if it crosses the placenta. Interferon alfa is freely filtered by the glomeruli, but is absorbed by the renal tubules where it is metabolized by brush border or lysosomes. Hepatic metabolism is of minor importance. The plasma half-life in cats has been reported as 2.9 hours.

**Contraindications/Precautions/Warnings**

When used parenterally, consider the risks versus benefits in patients with preexisting autoimmune disease, severe cardiac disease, pulmonary disease, “brittle” diabetes, Herpes infections, hypersensitivity to the drug, or CNS disorders.

One author states that low dose oral therapy is contraindicated in cats with FIP (Hartmann 2008).

**Adverse Effects**

When used orally in cats, adverse effects are apparently uncommon. Higher dosages given parenterally to cats may cause malaise; fever, allergic reactions, myelotoxicity, and myalgia are possible. Cats given human interferon-alfa parenterally may develop significant antibodies to it after 3-7 weeks of treatment with resultant loss of efficacy.

When used systemically in humans, adverse effects have included anemia, leukopenias, thrombocytopenia, hepatotoxicity, neurotoxicity, taste sensation changes, anorexia, nausea, vomiting, diarrhea, dizziness, “flu-like” syndrome, transient hypotension, skin rashes, and dry mouth. Except for the “flu-like“ syndrome, most adverse effects are dose-related and may vary depending on the condition treated.

**Reproductive/Nursing Safety**

Safety during pregnancy has not been established; high parenteral doses in monkeys did not cause teratogenic effects, but did increase abortifacient activity. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is not known whether this drug is excreted in milk.

**Overdosage/Acute Toxicity**

No information was located. Determine dosages carefully.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving interferon and may be of significance in veterinary patients:

**ACYCLOVIR, ZIDOVUDINE, VIDARABINE**: Additive or synergistic antiviral effects may occur when interferon alfa is used in conjunction with zidovudine (AZT) or acyclovir. This effect does not appear to occur with vidarabine, although increased toxicities may occur. The veterinary significance of these potential interactions is unclear.

**Doses**

**DOGS:**

a) For cutaneus T-cell lymphoma and severe cases of oral/cutaneus papillomas: 1.5–2 million Units/m2 SC 3 times weekly (White 2000)

b) As an immunostimulant for the adjunctive treatment of certain dermatologic conditions (e.g., pododermatitis, papillomas, digital keratomas): 1000 Units PO once daily (given as 1000 Unit/mL solution). (Yu 2008)

c) For chronic FHV-1 infections: 30 Units per cat PO daily; 7 days on, 7 days off; repeat cycle. May also use topical ophthalmic therapy: one drop of 25–50 Units/mL of saline in affected eye(s) q4–6 hours. (Powell 2002)

d) For acute life-threatening FHV-1 infections in kittens: 10,000 Units/kg SC daily for up to 3 weeks (Lappin 2003)

**CATS:**

For treatment of virus infections:

a) FeLV-infected cats: Low dose: 30 Units/cat PO daily; 7 days on, 7 days off); Hi dose: 10,000–1,000,000 Units/kg SC once daily. Little in the way of large, controlled trials to determine which, if any, immunomodulating therapies (interferon or other agents) are likely to benefit FeLV-infected cats. (Levy 2004)

b) For FIV: 30 Units per cat PO daily; 7 days on, 7 days off (Barr & Phillips 2000)

c) For chronic FHV-1 infections: 30 Units per cat PO daily; 7 days on, 7 days off; repeat cycle. May also use topical ophthalmic therapy: one drop of 25–50 Units/mL of saline in affected eye(s) q4–6 hours. (Powell 2002)

d) For acute life-threatening FHV-1 infections in kittens: 10,000 Units/kg SC daily for up to 3 weeks (Lappin 2003)

**Client Information**

Owners should be made aware of the “investigational” nature of this compound and understand that efficacy and safety have not necessarily been established.

**Chemistry/Synonyms**

Prepared from genetically engineered cultures of E. coli with genes from human leukocytes, interferon alfa-2a is commercially available as a sterile solution or sterile powder. Human interferon alfa is a complex protein that contains 165 or 166 amino acids.

Interferon may also be known as: IFN-alpha, interferon-alpha, Ro-22-8181 (interferon alfa-2a), Sch-30500 (interferon alfa-2b); there are many internationally registered trade names available.

**Storage/stability**

Commercially available products should be stored in the refrigerator; do not freeze the accompanying diluent. Do not expose solutions to room temperature for longer than 24 hours. Do not vigorously shake solutions.

**Client Information**

Prepared from genetically engineered cultures of E. coli with genes from human leukocytes, interferon alfa is commercially available as a sterile solution or sterile powder. Human interferon alfa is a complex protein that contains 165 or 166 amino acids.

Interferon may also be known as: IFN-alpha, interferon-alpha, Ro-22-8181 (interferon alfa-2a), Sch-30500 (interferon alfa-2b); there are many internationally registered trade names available.

**Storage/stability**

Commercially available products should be stored in the refrigerator; do not freeze the accompanying diluent. Do not expose solutions to room temperature for longer than 24 hours. Do not vigorously shake solutions.
Compatibility/Compounding Considerations

To prepare a 3 Unit/mL solution for oral administration: Using the 3 million Unit vial (see below), dilute the entire contents into 100 mL of sterile water; mix well. Resulting solution contains approximately 30,000 Units/mL. Take 0.1 mL of this solution and add to one liter of sterile saline that has 4 mL of 25% albumin added to it. Albumin is optional but adds stability. Solution is now 3 Units/mL. Divide into aliquots of 15 mL and freeze, preferably at −70°C. Thaw as needed and keep refrigerated. Discard unused portion after 60 days. Discard unused 30,000 Units/mL solution within 2–3 hours of making initial dilutions.

Preparation of solution for 30 Units/mL oral administration: Using the 3 million Unit vial (see below), dilute the entire contents into a 1 L bag of sterile normal saline; mix well. Resulting solution contains approximately 3,000 Units/mL. Divide into aliquots of either 1 or 10 mL and freeze. By diluting further 100 fold (1 mL of 3000 Units/mL solution with 100 mL of sterile saline, or 10 mL with 1000 mL of sterile saline) a 30 Units/mL solution will result. Some have advised aliquoting the diluted solution into 1 mL volumes for freezing up to a year; defrost as necessary. Once defrosted, the drug can be refrigerated up to one week. Freezing the most dilute solutions is associated with loss in activity unless protein such as albumin (see above) is added during dilution. (Greene et al. 2006)

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None

HUMAN-LABELLED PRODUCTS:

Interferon Alfa-2a (recombinant rIFN-A; IFLrA) Injection: Prefilled syringes: 3 million IU/syringe (0.5 mL single-use syringes); 6 million IU/syringe (0.5 mL single-use syringes); 9 million IU/syringe (0.5 mL single-use syringes); Roferon-A® (Hoffman La-Roche); (Rx)

Interferon Alfa-2b (recombinant IFN-alpha2; rIFN-a2; a-2-interferon) Powder for Injection: 5 million Units/vial; 10 million Units/vial; 18 million Units/vial; 25 million Units/vial & 50 million Units/vial in vials with a mL, 2 mL or 5 mL diluent/vial; Intron A® (Schering); (Rx)

Interferon Alfa-2b (recombinant IFN-alpha2; rIFN-a2; a-2-interferon) Injection: 3 million Units/dose; 5 million Units/dose, & 10 million Units/dose in multidose pens; Intron A® (Schering); (Rx)

Interferon Alfa-2b (recombinant IFN-alpha2; rIFN-a2; a-2-interferon) Solution for Injection: For injection: 3 million Units/vial, 5 million Units/vial; 10 million Units/vial; 18 million Units/vial & 25 million Units/vial in vials, Pak-3, -5, -10 (vials & syringes); & in multidose vials (22.8 millionUnits/3.8 mL/vial or 32 million Units/3.2 mL/vial); Intron A® (Schering); (Rx)

Interferon Alfa-N3 (human leukocyte derived) Injection: 5 million Units/mL. (8 mg NaCl, 1.74 mg Na phosphate dibasic, 0.2 mg K phosphate monobasic, 0.2 mg KCl) in 1 mL vials; Alferon N ® (Interferon Sciences Inc.); (Rx)

References

INTERFERON-Ω (OMEGA)

(in-ter-fer-on oh-mee-ga)Virbagen Omega®

Recombinant Omega Interferon of Feline Origin, rFelFN-w

IMMUNOMODULATOR

Prescriber Highlights

• Immunomodulating cytokine labeled for treating FeLV & FIV in cats & Parvo in dogs; not commercially available in USA. May potentially be effective in treating canine atopic dermatitis.

• Appears to be well tolerated; adverse effects include: hyperthermia, vomiting, diarrhea (cats), fatigue (cats)

• Increases in ALT & decreases in RBC, WBC, & platelet counts have been seen

• Treatment may be very expensive

Uses/Indications

Omega interferon (feline) is labeled (in the EU) for dogs 1 month of age or older for the reduction in mortality and clinical signs of parvovirus (enteric form). In cats 9 weeks of age or older, it is labeled for treating FeLV and/or FIV, in non-terminal clinical stages. It may be of benefit in treating canine distemper, canine atopic dermatitis, acute feline calcivirus infections, FIP, or topically for feline herpetic keratitis, but data is still being gathered to document efficacy.

In summarizing the in vitro, controlled study and clinical efficacy status in vivo for feline interferon-omega use in virus infected cats and dogs, one author (Hartmann 2008) reports: that controlled studies have been done for FIV (ineffective), FeLV (some effect), and canine parvovirus (effective). Controlled studies have not been performed for FHV-1 (possibly effective), FCV (possibly effective), FIP (possibly effective) or feline panleukovirus (likely effective).

Pharmacology/Actions

Omega interferon is a type 1 interferon related to alpha interferon. Its principle action is not as a direct anti-viral, but by acting on virus-infected cells inhibiting mRNA and translation proteins thereby inhibiting viral replication. It may also nonspecifically enhance immune defense mechanisms.
Pharmacokinetics
It has been stated that omega interferon pharmacokinetics in dogs and cats is similar to that of human interferons. After intravenous injection, omega interferon is rapidly bound to specific receptor sites on a variety of cells. Highest tissue levels are found in the liver and kidneys. Interferon is filtered in the renal glomeruli and catabolized in the kidneys. In dogs, volume of distribution at steady state is about 0.1L/kg. Biphasic elimination occurs with an alpha half-life of 3.14 hours and a beta half-life of 0.24 hours. Total body clearance is 6.9 mL/min/kg.

Contraindications/Precautions/Warnings
The manufacturer cautions against vaccinating dogs currently being treated with omega interferon and not to vaccinate until the patient appears to have recovered. As both FeLV and FIV infections are known to be immunosuppressive, the manufacturer states that cat vaccinations are contraindicated during and after omega interferon treatment.

There are several different interferons available for use in humans (several sub-types of alpha, beta, or gamma interferon); one cannot be substituted for another.

Adverse Effects
In cats and dogs, hyperthermia (3–6 hours post-dose) and vomiting have been reported. Slight decreases in RBCs, platelets and WBCs, and increased ALT have been observed but, reportedly, these indices return to normal within a week of the last injection.

Additionally, soft feces/mild diarrhea and transient fatigue may be noted in cats. Intravenous administration to cats may cause increased incidence and severity of adverse effects, but in cats, adverse effects occur uncommonly.

Dogs may develop antibodies to interferon omega if treatment is prolonged (beyond labeled dosage period) or repeated.

Reproductive/Nursing Safety
Safety during pregnancy or lactation has not been established.

Overdosage/Acute Toxicity
10X overdoses in dogs and cats caused mild lethargy/somnolence, slight hyperthermia, slight increases in respiratory and heart rates. In animals tested, signs resolved within 7 days and no treatment was required.

Drug Interactions
No reported drug interactions at the time of writing, but use caution when using other drugs that can be hepatotoxic or myelosuppressive.

Laboratory Considerations
- No specific concerns were noted

Doses
- **DOGS:**
  a) For treatment of parvovirus as labeled: 2.5 million Units/kg IV once daily for 3 days. The earlier the dog is treated, the more likely of success. (Label information; Virbagen Omega®—Virbac UK)
  b) For treatment of atopic dermatitis: Per injection: Dogs 8-15 kg = 1 million Units; 15-29 kg = 2 million Units; 29–40 kg = 3 million Units; 29–40 kg = 4 million Units. In the study, doses were administered. In the study, dogs were dosed SC on days: 0, 3, 7, 14, 21, 35, 56, 90, 120, & 150. Further larger-scale studies needed to confirm that low dose rFeIFN-omega is cost-effective and safe option for long-term treatment. (Carlotti et al. 2009)
- **CATS:**
  a) For treatment of FeLV or FV as labeled: 1 million Units/kg SC once daily for 5 days. Three separate 5-day treatments performed at day 0, day 14, and day 60. (Label information; Virbagen Omega®—Virbac UK)
  b) From a case report treating a cat with FHV-1 facial dermatitis: Day 0: Cat sedated with propofol and rFeIFN- 1.5 million Units/kg injected, half of which was injected peri-lesionally and intradermally and the other half subcutaneously on the lateral thorax. Day 2 and day 9: 1.5 million Units/kg injected SC on the lateral thorax. On days 19, 21, and 23: 0.75 million Units/kg injected peri-lesionally and intradermally as well as 0.75 million Units/kg SC on the lateral thorax. The cat was sedated as described above when peri-lesional and intradermal injections made. (Gutzwiller et al. 2007)

Monitoring
- Monitor for efficacy for infection treated
- CBC and hepatic function tests suggested

Client Information
- This drug is best administered on an inpatient basis where the patient may be observed and supported

Chemistry/Synonyms
Interferon omega of feline origin is a type 1 recombinant interferon obtained from silkworms after inoculation with a recombinant baculovirus. It is provided commercially as a lyophilisate powder with a separate solvent.

Recombinant omega interferon of feline origin may also be known as: Interferon omega, omega interferon, interferon-w, IFN-w, IFN-w (feline recombinant), rFelIFN-w, and Virbagen Omega®.

Storage/stability
The commercial veterinary product should be stored in its original carton refrigerated (4°C ± 2°C) and protected from freezing. It has a designated shelf life of 2 years when properly stored. Once reconstituted with the supplied isotonic sodium chloride solution, it should be used immediately as it contains no preservative, however, the solution is reported to be stable for at least 3 weeks when refrigerated. No data was located on the stability of the reconstituted solution when frozen.

Compatibility/Compounding Considerations
- The manufacturer states: Do not mix with any other vaccine/immunological product, except the solvent supplied for use with the product.
The manufacturer states: Do not mix with any other vaccine/immunological product, except the solvent supplied for use with the product.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None in the USA

In the EU:

Recombinant Omega Interferon of Feline Origin 10 million Units/vial; Virbagen Omega® (Virbac); (Rx). Licensed for dogs and cats. A 5 million Unit vial may be available in some countries.

The FDA may allow legal importation into the USA of this medication for compassionate use in animals; for more information, see the Instructions for Legally Importing Drugs for Compassionate Use in the USA found in the appendix.

**HUMAN-LABELED PRODUCTS:** None

**References**

**IODIDE, SODIUM**

**IODIDE, POTASSIUM**

(eye-oh-dide) SSKI, Iodoject®

**ANTIFUNGAL, NUTRITIONAL**

**Prescriber Highlights**

- Iodides used for actinobacillosis in ruminants, sporotrichosis in horses, dogs, & cats
- Contraindications: Iodide hypersensitivity, lactating animals, hyperthyroidism, renal failure, or dehydration
- Do not inject IM; give IV slowly & with caution to horses as severe generalized reactions have been reported
- May cause abortion in cattle
- Adverse Effects: Iodism: Excessive tearing, vomiting, anorexia nasal discharge, muscle twitching, cardiomyopathy, scaly haircoats/dandruff, hyperthermia, decreased milk production & weight gain, coughing, inappetence, & diarrhea
- Cats more prone to developing toxicity

**Uses/Indications**

The primary use for sodium iodide is in the treatment of actinobacillosis and actinomycosis in cattle. It has been used as an expectorant with little success in a variety of species and occasionally as a supplement for iodine deficiency disorders. In horses, dogs and cats, oral sodium or potassium iodide has been used in the treatment of sporotrichosis. Use in cats is controversial as they may be prone to developing adverse effects; cats may require other antifungal (e.g., itraconazole) therapy. Potassium iodide has also been used as an expectorant, but documentation of efficacy is lacking.

**Pharmacology/Actions**

While the exact mode of action for its efficacy in treating actinobacillosis is unknown, iodides probably have some effect on the granulomatous inflammatory process. Iodides have little, if any, *in vitro* antibiotic activity.

**Pharmacokinetics**

Little published information appears to be available. Therapeutic efficacy of intravenous sodium iodide for actinobacillosis is rapid, with beneficial effects usually seen within 48 hours of therapy.

**Contraindications/Precautions/Warnings**

Sodium iodide injection labels state that it should not be given to lactating animals or to animals with hyperthyroidism. Do not inject intramuscularly (IM).

- Iodides given parenterally should be administered slowly intravenously and with caution to horses; severe generalized reactions have been reported.
- Should not be used in animals in renal failure or that are severely dehydrated.

**Adverse Effects**

In ruminants, the adverse effect profile is related to excessive iodine (see Overdosage below). Young animals may be more susceptible to iodism than adults.

- Foals have developed goiter when mares have been excessively supplemented.
- Chronic use or overdoses may cause iodism. Cats are apparently more prone to developing this than other species. Signs can include vomiting, inappetence, depression, twitching, hypothermia, and cardiovascular failure.
- The taste of the liquid is very unpleasant and animals may avoid dosing. Giving with food or a fatty liquid (whole milk, ice cream) may improve palatability and reduce nausea and vomiting. Cats reportedly tolerate the taste of sodium iodide better then potassium iodide. There are potassium iodide oral tablets 130 mg available (OTC, for reducing risk for thyroid cancer after radioactive isotope exposure) that may be useful in small dogs or cats that cannot tolerate oral solutions.

**Reproductive/Nursing Safety**

Avoid the use of iodides during pregnancy in ruminants. Little information for cats contains no data to suggest nursing safety is contraindicated. Check literature for nursing safety in dogs.
Anecdotal reports that iodides can cause abortion in cattle persist and label information of some veterinary products state not to use in pregnant animals. Clearly, potential risks versus benefits of therapy must be weighed. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Iodides are excreted in milk. If iodides are required in the nursing dam, switch to milk replacer.

Overdosage/Acute Toxicity
Excessive iodine in animals can cause excessive tearing, vomiting, anorexia, nasal discharge, muscle twitching, cardionmyopathy, scaly haircoats/dandruff, hyperthermia, decreased milk production and weight gain, coughing, inappetence, and diarrhea.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving iodide and may be of significance in veterinary patients:

- **ANTITHYROID MEDICATIONS:** Iodides may decrease the efficacy of antithyroid medications
- **THYROID SUPPLEMENTS:** Iodides may enhance the efficacy of thyroid medications

Doses

**DOGS:**
- For Sporotrichosis:
  a) Using SSKI: 40 mg/kg PO q8h for at least 60 days (Greene & Watson 1998)
  b) Using SSKI: 40 mg/kg PO q12h with food; itraconazole less likely to have adverse effects (Grooters 2005)

**CATS:**
- For Sporotrichosis:
  a) 20 mg/kg PO q12–24h for at least 60 days (Greene & Watson 1998)
  b) Using SSKI: 20 mg/kg PO q12–24h with food; itraconazole less likely to cause adverse effects (Grooters 2005)

**CATTLE, SHEEP & GOATS:**
- For treatment of actinobacillosis (woody tongue): 70 mg/kg IV given as a 10% or 20% solution; repeat at least one more time at a 7–10 day interval. Refractory cases may require more frequent (2–3 day intervals) treatment. Severe, generalized, or refractory cases may require adjunctive treatment with antibiotics (sulfas, aminoglycoside or tetracyclines). (Smith 1996)

**HORSES:**
- For treatment of sporotrichosis: Sodium iodide 20–40 mg/kg orally daily for several weeks (Fadok 1992)
  b) Loading dose of sodium iodide at 20–40 mg/kg IV for 2–5 days, then 20–40 mg/kg PO once daily for at least 3 weeks after all clinical lesions disappear. May administer via oral syringe or mixed in sweet feed. Topical hot packs of 20% sodium iodide may be used on open wounds. (Rees 2004)
  c) For Conidiobolomycosis: A mare with C. coronatus granulomatous tracheitis was successfully treated with 20% sodium iodide at 44 mg/kg IV for 7 days, then ethylenediamine dihydroiodide (iodide powder, granules) at 1.3 mg/kg PO q12h for 4 months, then q24h for 1 year, then once per week. Excessive lacrimation was occasionally noted, but resolved if the drug was held for one day. (Stewart & Salazar 2005)

Monitoring
- Clinical efficacy
- Signs of iodism (excessive tearing, nasal discharge, scaly haircoats/dandruff, hyperthermia, decreased milk production and weight gain, coughing, inappetence, and diarrhea

Client Information
- Although formal withholding times were not located, there is concern about using this product in food animals about to be slaughtered. In the interest of public health, contact FARAD (see appendix) for guidance.
- When giving orally in small animals, give with food or a fatty liquid (whole milk, cream) as the taste is extremely unpleasant and nausea or vomiting may otherwise occur.

Chemistry/Synonyms
Sodium iodide occurs as colorless, odorless crystals or white crystalline powder. It develops a brown tint upon degradation. Approximately 1 gram is soluble in 0.6 mL of water and 2 mL of alcohol.

Potassium iodide occurs as a clear to white granular powder. Approximately 1 gram is soluble in 0.7 mL of water. One gram (one mL) of SSKI contains 6 mEq of potassium.

Potassium iodide oral solution may also be known as SSKI (super saturated potassium iodide), or Pima®.

Storage/stability
Commercially available veterinary injectable products should generally be stored at room temperature (15–30° C).

Supersaturated potassium iodide (SSKI) solution should be stored below 40°C (104°F) and preferably between 15–30°C (59–86°F) in a tight, light-resistant container; protect from freezing. Crystallization can occur, particularly if stored at low temperatures; re-warming the contents and shaking will usually redissolve the crystals. If oxidation occurs, the solution will turn brownish yellow in color; discard should this occur.

Compatibility/Compounding Considerations
Sodium iodide injection is reportedly physically incompatible with vitamins B and C injection.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Sodium Iodide Injection: 20 grams/100 mL (20%; 200 mg/mL) in 250 mL vials—available as multi- or single use vials; generic; (Rx). Labeled for use in non-lactating cattle.

Oral iodide powders/granules for addition to feeds are available. Active ingredient is ethylenediamine dihydroiodide.

**HUMAN-LABELED PRODUCTS:**

Potassium Iodide Solution: 1 gram potassium iodide/mL; 325 mg potassium iodide/5 mL in 30 mL, pt & gal; SSKI® (Upsher-Smith); generic; (Rx)

Potassium Iodide Oral Syrup: 62.5 mg potassium iodide/mL in pints and gallons; Pima® (Fleming); (Rx)

Potassium Iodide Oral Tablets 65 mg, & 130 mg; Thyrosafe® (Recip), losat® (Anbex); (OTC)

There are also radioactive iodine compounds available for thyroid diagnostic and treatment.

**References**

**Uses/Indications**

Iohexol can be used as a contrast agent for a variety of radiographic imaging procedures in veterinary patients, and can be used as a marker agent for estimating glomerular filtration rates (GFR) in dogs or cats. The current usual laboratory measures of renal function (plasma/serum creatinine, plasma/blood urea nitrogen) are not very sensitive indicators for detecting early kidney disease or monitoring real-time renal function status, so other tests are needed. This is an area of intense research interest; it is hoped that, ultimately, results from a simple one or two sample test incorporated with patient characteristics that estimate extra-cellular fluid volume (e.g., age, weight, breed, etc.) can be inserted into an equation that then can be used to reasonably estimate renal function status. Iohexol clearance closely mimics inulin clearance, but iohexol has the advantages of being readily available in dosage forms amenable for clinical use, less expensive than inulin, and being stable in plasma or urine.

Iohexol, when used as a contrast agent can be administered (depending on product and procedure) via intravascular (venous and arterial), intrathecal, intracavitary, or oral routes.

**Pharmacology/Actions**

Iohexol is a near ideal marker for measuring glomerular filtration rate and thereby, renal function. Its protein binding is negligible, it is nearly 100% excreted unchanged in the urine within 24 hours and can be measured in plasma using a variety of assays.

When used as a radio contrast agent, organic iodine is relatively radiopaque and can help define adjacent structures.

Iohexol has a lower osmolality when compared with conventional (ionic) radio contrast agents, and has been associated with (in humans) a lower incidence of side effects such as pain, heat sensations, adverse hemodynamic changes, EKG changes, endothelial and erythrocyte damage.

**Pharmacokinetics**

After intravascular administration, iohexol is rapidly distributed throughout the circulation. Protein binding is very low (<1%). Within 24 hours, nearly 100% of a dose is excreted in the urine in patients with normal renal function. In dogs, mean pharmacokinetic parameters reported include: volume of distribution (Vdss): 221 mL/kg; clearance in dogs is about 2.5–2.9 mL/kg/minute; mean residence time: 82 minutes; elimination half-life: 75 minutes (Heiene et al. 2010, (Goy-Thollot et al. 2006). Mean clearance of iohexol in cats reported include: 2.3 mL/kg/minute (Heiene et al. 2009), and 2.75 mL/kg/minute (Goy-Thollot et al. 2006).

Iohexol has an elimination half-life of about 2 hours in human patients.

**Contraindications/Precautions/Warnings**

Iohexol is contraindicated in patients with a prior hypersensitivity reaction.

**Adverse Effects**

When used intravascularly, iohexol appears to be well tolerated, but usage in dogs or cats has been limited. Hypersensitivity reactions with iohexol can occur, but in humans, only very rarely. Nephrotoxicity from iohexol is potentially possible, but the risk appears slight. Iohexol is considered to be one of the agents used for contrast studies with the lowest toxicity for humans.

**Reproductive/Nursing Safety**

While iohexol use in the latter stages of pregnancy potentially carries some fetal risk (thyroid function in newborns), the FDA has designated it as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later gestation).
Iohexol is distributed into milk in very low quantities, but no adverse effects have been seen in breastfeeding infants whose mothers received iohexol; the American Academy of Pediatrics considers that iohexol is usually compatible with breastfeeding.

Overdosage/Acute Toxicity

The adverse effects of intravenous overdosage can be serious and life-threatening and primarily affect the pulmonary and cardiovascular systems. Clinical signs can include: cyanosis, bradycardia, acidosis, pulmonary hemorrhage, convulsions, coma, and cardiac arrest. Treatment is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving iohexol and may be of significance in veterinary patients:

**DRUGS THAT MAY PROLONG QTc INTERVALS (e.g., amiodarone, cisapride, procainamide, quinidine, sotalol, cisapride, dolasetron, moxifloxacin):**

Iohexol may cause additive prolongation of QTc interval. Iohexol does not cause as much QTc prolongation (in humans) as diatrizoate.

**IODINE ISOTOPES:** Iohexal may alter binding to thyroid tissue for up to two weeks

**PHENOTHIAZINES:** Iohexal (especially when used intrathecally) may increase risk for lowering seizure threshold

Laboratory Considerations

**Thyroid Function Tests:** If iodine-containing isotopes are to be used for diagnosing thyroid disease, prior use of iohexol can reduce the iodine-binding capacity of thyroid tissue for up to 2 weeks. Thyroid function tests that do not depend on iodine estimation are not affected.

Doses

**DOGS/CATS:**

To estimate GFR: At the time of writing, the widespread clinical use or usefulness for limited-sample iohexol clearance determination in dogs and cats has yet to be realized, but the following illustrate that significant work is being performed and results are promising for use in clinical settings. Follow the current literature and scientific proceedings for more information as it becomes available.

a) Dogs: Comparing iohexol clearance using a limited sampling (2-4 sample) method versus a 9-sample method; study done in healthy dogs: Using iohexol 300 mg/mL given IV over a minute. Doses administered varied from 129–658 mg/kg of iohexol. The lower doses were initially given to dogs early in the study due to concerns for toxicity, but resulted in many samples with plasma concentrations too low for accurate analysis. No toxicity was seen at the higher dose. Using the 2-sample method, samples were obtained at 2 and 3 hours post dose; 3-sample method at 2, 3, and 4 hours post-dose. Clearance was predicted via a trapezoidal method using an empirical polynomial regression equation. Authors concluded that limited sample methods for iohexol clearance may be acceptable in most situations in which available resources do not allow determination of the complete plasma disappearance curve. (Heiene et al. 2010)

b) Dogs and Cats: Using a single sampling method to estimate iohexol clearance: In the study, dogs were administered iohexol 300 mg/mL at a dose of 90 mg iodine content/kg in non-azotemic animals and 45 mg iodine content/kg in azoicemic animals IV. Three samples were drawn (at 120, 180, & 240 minutes in non-azotemic animals; 120, 240, & 360 minutes in azoicemic animals). The 120 minute sample was used to assess the validity of a single-sample method. After receiver operating characteristics (ROC) analysis was performed to assess the sensitivity and specificity of the single sampling methods for detection of decreasing GFR in dogs and cats, results for sensitivity and specificity for dogs were 98% and 93%, respectively, and in cats, the sensitivity and specificity were 98% and 93%, respectively. No adverse effects were seen in the dogs or cats studied (N = 779 dogs; 339 cats). (Miyagawa et al. 2010)

As a contrast agent:

a) For patients with suspected GI perforation: Newer non-ionic iodinated contrast media (e.g., iohexol) with lower osmolality (520 mOsm/mL, undiluted iohexol, 240 mg Iodine/mL) are now recommended for patients with suspected GI perforation. In cats, the recommended dose is a 1:3 dilution of iohexol 240 at 10 mL/kg of body weight. In dogs, a similar dosage is recommended (700–875 mg Iodine/kg, 10 mL/kg). Best administered via orogastric tube (dogs) or nasogastric/nasoesophageal tube (cats). Radiographs should be obtained immediately following the administration of contrast material; additional sets of radiographs can be obtained at 15, 30, and 60 minutes. (Saunders 2008)

b) BIRDS:

As a contrast agent:

a) Indications for contrast imaging may include differentiation of abdominal masses, organ placement or displacement, assessment of GI abnormalities (perforation, foreign body), or GI transit time (proventricular dilatation disease). Contrast agents safe for use in the avian patient include barium sulfate or iohexol administered directly into the crop by gavage. (Retrograde administration of contrast medium directly into the cloaca may help to evaluate cloacal abnormalities.) Survey radiographs (without contrast) should precede the use of contrast agents. The number of images and intervals are based on the agent used and the purpose of the study. If perforation is suspected, iohexol is preferred over barium sulfate. Dosing is based on the estimated crop volume of 25-30 mL/kg. Iohexol may be diluted 1:1 with water. (Murray 2008)

Monitoring

- No specific monitoring outside of adverse effects

Chemistry/Synonyms

Iohexol is a nonionic iodinated contrast agent that occurs as a white to off-white, hygroscopic, odorless powder; it is very soluble in water and in methyl alcohol; practically insoluble or insoluble in chloroform and ether. Commercial products list the concentration of the product as organic iodine concentration per mL. For example, **Omnipaque® 180** contains iohexol 288 mg/mL, equivalent to 180 mg/mL of organic iodine content. Physical properties of iohexol injection include:

Iohexol may also be known as WIN-39424, iohexolum, ioheksoli, or ioheksolis. A common trade name is **Omnipaque®**.
Storage/Stability
Iohexol should be stored at room temperature 25°C (68°F); excursions permitted between 15°-30°C. Protect from light.

Compatibility/Compounding Considerations
Depending on concentration, the following drugs are reported compatible with iohexol: ampicillin, chloramphenicol sodium succinate, cimetidine, diazepam, diphenhydramine, epinephrine, gentamicin, heparin, hydrocortisone sodium succinate, lidocaine, methylprednisolone sodium succinate, nitroglycerin, protamine, and vasopressin. Because compatibility depends on several factors and is time dependent, it is advisable to contact a hospital pharmacist before admixing drugs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Iohexol Injection (preservative-free; concentrations are listed as organic iodine content per mL) 180 mg/mL, 240 mg/mL, 300 mg/mL & 350 mg/mL in 10 mL, 20 mL, 30 mL, 50 mL, 100 mL, 150 mL, 200 mL, & 500 mL vials, bottles, syringes or cartridges (depending on concentration); Omnipaque® (GE Healthcare); (Rx)

References

IPODATE SODIUM
(eye-poe-date)
ANTITHYROID AGENT
Prescriber Highlights

- Organic iodine compound that may be useful in some cats for medical treatment of hyperthyroidism
- Very limited experience
- Less effective for cats with severe hyperthyroidism
- Efficacy may be transient
- Dosage forms must be compounded

Uses/Indications
Ipodate may be useful in some cats for the medical treatment of hyperthyroidism when methimazole (or carbimazole) cannot be tolerated. Because it uses a different mechanism of action than methimazole, ipodate may, potentially, be useful in reducing methimazole dosages (and hence toxicity).

Pharmacology/Actions
Ipodate’s efficacy in treating hyperthyroidism is thought to be primarily due to inhibition of the conversion of T4 to T3. Ipodate may also block T3 receptors and thereby protecting the heart from the hypertrophic effects of hyperthyroidism. It may block the actions of TSH.

Pharmacokinetics
The drug is well absorbed after oral administration. Other pertinent pharmacokinetic data for cats is unavailable.

Contraindications/Precautions/Warnings
Ipodate is contraindicated in patients with known hypersensitivity to it. It should be used with caution in patients who have had previous reactions to iodine compounds. Humans with hepatic dysfunction should not receive multiple doses of the drug as renal toxicity has resulted in a few patients. It is recommended for use with caution in human patients with hyperuricemia (possible uric acid nephropathy).

Adverse Effects
Cats reportedly tolerate ipodate well, but may become refractory to treatment after a relatively short time. Oral iodine containing products can cause GI distress (nausea, vomiting, diarrhea, cramping, inappetence). Drug-induced pemphigus is a possibility. Skin rashes, itching, dizziness and headache have been reported by human patients.

Reproductive/Nursing Safety
If administered to pregnant cats, congenital hypothyroidism is a possibility.

Overdosage/Acute Toxicity
No specific information located. Cats have reportedly tolerated daily doses up to 400 mg.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ipodate and may be of significance in veterinary patients:
The following drug interactions have either been reported or are theoretical in humans or animals receiving ipodate and may be of significance in veterinary patients.

**IODINE, RADIOACTIVE:** Ipodate may interfere with radioactive iodine therapy. It is suggested to treat no sooner than 2 weeks after discontinuing ipodate (3–4 weeks or more if possible).

**Laboratory Considerations**
- Ipodate may increase BSP retention times and serum bilirubin levels
- False positive urine protein determinations may occur
- Ipodate can interfere with thyroid scanning

**Doses**
- **CATS:**
  
  For medical treatment of hyperthyroidism in patients who cannot tolerate methimazole and whose owners will not permit surgery or radioiodine therapy:
  
  a) 100–200 mg (total dose; empiric) PO once daily (Lorenz & Melendez 2002; Trepanier 2006)
  
  b) 50 mg per cat PO twice daily, if “good” clinical response not obtained, at 2 week intervals may increase dose to 150 mg/day (100 mg AM, 50 mg PM) and then to 200 mg/day (100 mg twice daily). Cats with severe hyperthyroidism are less likely to respond. (Murray & Peterson 1997)
  
  c) For use before surgery: 15 mg/kg PO q12h. (Jones 2006)

**Monitoring**
- Clinical efficacy (heart rate, body weight, etc.)
- Serum T3 (Note: T4 did not change—remained high in study group)

**Client Information**
- It must be stressed to owners that this drug will decrease excessive thyroid hormones, but does not cure the condition and that compliance with the treatment regimen is necessary for success.
- Long-term efficacy is questionable.

**Chemistry/Synonyms**
An orally administered radiopaque organic iodine compound, ipodate sodium occurs as a white to off-white, fine crystalline powder. It is freely soluble in alcohol and water. Each 500 mg capsule contains 61.4% (or 333.4 mg) of iodine.

  - Ipodate calcium may also be known as: calcium iopodate, calcium ipodate, ipodate calcium, Solu-Biloptin®, and Solubiloptine®.
  - Ipodate sodium may also be known as: sodium iopodate, sodium ipodate, NSC-106962, Bilivist®, Biloptin®, and Oragrafin®.

**Storage/Stability**
Store capsules in tight containers and protect from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
None; must obtained via a compounding pharmacy.

**Note:** Most of the studies using ipodate in cats have been done with calcium ipodate. It is likely that sodium ipodate would be fairly equivalent. If the compounding pharmacy has access to calcium ipodate, it is suggested to use that form. Other options that have been used anecdotally in cats at similar dosages include iopanoic acid or diatrizoate meglumine (Trepanier 2006).

**IPRATROPIUM BROMIDE**
(eye-prah-troh-pee-um) Atrovent®

**INHALED ANTIMUSCARINIC**

**Prescriber Highlights**

- Inhaled antimuscarinic agent for adjunctive treatment of bronchoconstrictive conditions
- Very little information available for use in small animals
- Likely safe
- May need to be administered quite often, duration of activity is relatively short
Uses/Indications
Locally administered (inhaled) ipratropium bromide can be used for the adjunctive treatment of bronchospastic conditions.

Pharmacology/Actions
Ipratropium inhibits vagally mediated reflexes by antagonizing acetylcholine. Increases in intracellular concentrations of cyclic guanosine monophosphate (cyclic GMP) secondary to acetylcholine are prevented, thereby reducing bronchial smooth muscle constriction. Unlike atropine, ipratropium does not reduce mucociliary clearance.

Pharmacokinetics
Because the medication is inhaled, minimal drug is absorbed in the systemic circulation. In humans, elimination half-life is about 2 hours. In healthy cats with experimentally induced bronchospasm, inhaled (neb) ipratropium gave maximal efficacy for about 4 hours. When combined with albuterol (salbutamol), increased efficacy resulted. (Leemans et al. 2006) In horses, onset of action is approximately 30 minutes and duration of effect is approximately 4–6 hours.

Contraindications/Precautions/Warnings
Ipratropium is contraindicated in patients hypersensitive to it or other atropine derivatives.

Adverse Effects
Adverse effects are unlikely to be significant. Tracheal or bronchial irritation (coughing) have been reported on occasion. Allergic responses are possible and some patients develop anticholinergic effects.

Reproductive/Nursing Safety
Large oral dosages in laboratory animals did not cause teratogenic effects. In humans, the FDA categorizes ipratropium as category B for use during the first two trimesters of pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Ipratropium is likely to be safe to use during nursing.

Overdosage/Acute Toxicity
Overdosage is unlikely to be a cause for concern. The drug is not well absorbed orally or after inhalation and oral LD50 values for laboratory animals were greater than 1 gram/kg.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ipratropium and may be of significance in veterinary patients:

ANTICHOLINERGIC DRUGS: May cause additive antimuscarinic effects

BETA-ADRENERGIC AGONISTS (e.g., albuterol): May have additive therapeutic effects

Laboratory Considerations
No specific concerns were noted

Doses
HORSES:
  a) For adjunctive treatment of RAO, heaves (mild to moderate disease): 180 micrograms inhaled aerosol q4-6h for 14 days. (Rush, B & Grady 2008)
  b) For adjunctive treatment of RAO/heaves (moderate to severe disease): 90–180 micrograms inhaled via Equine Aeromask or Equine Haler every 6 hours. (Beard 2008)
  c) For adjunctive treatment of foals with severe bronchospasm: 2–3 micrograms/kg via aerosol q6-8h. (Rush, BR 2007)

SMALL MAMMALS:
  a) As a bronchodilator in rats: one puff into nebulization chamber twice daily. (Monks & Cowan 2009)

Monitoring
Clinical efficacy

Client Information
If using the aerosol metered dose inhalers, do not use after 200 inhalations (puffs) even if there appears to be medication remaining; active ingredient cannot be assured; do not shake the HFA canister before using

This medication is not for treating an acute asthma attack, it is for maintenance treatment

Chemistry/Synonyms
Ipratropium bromide occurs as a white or almost white crystalline powder. It is soluble in water and slightly soluble in alcohol. The pH of a 1% solution is between 5 and 7.5.

Ipratropium bromide may also be known as Sch-1000; many trade names are available including Atrovent®.

Storage/stability
The solution for inhalation should be stored at room temperature and protected from light. Keep in foil pouch until time of use. The metered dose inhalers should be
The solution for inhalation should be stored at room temperature and protected from light. Keep in foil pouch until time of use. The metered dose inhalers should be stored at room temperature.

**Compatibility/Compounding Considerations**
The solution for nebulization may be mixed with albuterol or metaproterenol if used within one hour.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**
- Ipratropium Bromide Solution for Inhalation: 0.02% (500 micrograms/vial) preservative free in 25 & 60 unit-dose vials (2.5 mL “nebs”); generic (Dey); (Rx)
- Ipratropium Bromide Aerosol for Inhalation: each actuation delivers 17 micrograms in 12.9 grams metered dose inhaler w/mouthpiece (approx 200 inhalations); Atrovent® HFA (B1); (Rx)

Nasal sprays are available, and in combination with albuterol as nebs: DuoNeb® (Dey) and as a metered dose inhaler, Combivent® (B1).

**References**

**IRBESARTAN**

(いrb-eh-sar-tan) Avapro®

**ANGIOTENSIN-II RECEPTOR BLOCKER (ARB)**

**Prescriber Highlights**

- ARB that may be useful in treating dogs with hypertension secondary to renal insufficiency
- Very limited experience in veterinary medicine
- Not safe during pregnancy

---

**Uses/Indications**

Although experience in veterinary medicine is minimal irbesartan may be useful in treating canine hypertension associated with renal insufficiency. It possibly is effective in treating heart failure when dogs are unable to tolerate ACE inhibitors, but documentation for this use is lacking. One study, using very high irbesartan dosages (60 mg/kg PO twice daily) in dogs with subacute mitral regurgitation, demonstrated no improvement in left ventricular function or prevention of left ventricular remodeling (Perry *et al.* 2002).

**Pharmacology/Actions**

Irbesartan is an angiotensin-II receptor blocker (ARB). By selectively blocking the AT1 receptor, aldosterone synthesis and secretion is reduced causing vasodilation and decreased potassium and increased sodium excretion. While plasma concentrations of renin and angiotensin-II are increased, this does not counteract the blood pressure lowering effects of irbesartan. Irbesartan does not interfere with substance P or bradykinin responses. Irbesartan does not need to be converted to an active metabolite as does the ARB, losartan (*Cozar®*). Dogs, unlike humans, reportedly do not covert losartan to the active metabolite.

**Pharmacokinetics**

After single 30 mg/kg oral doses in dogs with experimentally induced renal hypertension, irbesartan peak levels occurred between 3–4 hours later and elimination half-life was approximately 9 hours. After 30 mg/kg doses PO once daily for 8 days, the elimination half-life was approximately 21 hours (Huang *et al.* 2005).

In humans, absorption is rapid and bioavailability ranges from 60–80%. Peak levels occur in about 1.5–2 hours. Bioavailability is not altered by the presence of food. The drug is 90% bound to plasma proteins and crosses the blood-brain barrier and placenta in small quantities. Irbesartan is metabolized in the liver via glucuronidation and oxidation; metabolites are not active. Both metabolites and unchanged drug are eliminated primarily in the feces and to a lesser extent, in urine. Terminal elimination half-life ranges from 11–15 hours. Dosages do not need to be adjusted in patients with renal dysfunction.

**Contraindications/Precautions/Warnings**

Patients who are volume or sodium depleted should have these corrected before starting therapy. Do not use in hypotensive patients. In humans, the drug is contraindicated in patients hypersensitive to it. It should not be used during pregnancy (see Reproductive Safety).

**Adverse Effects**

An adverse effect profile for dogs is not known due to limited use of this medication. In humans, the most commonly reported adverse effects include diarrhea, dyspepsia, fatigue, and orthostatic dizziness/hypotension.

**Reproductive/Nursing Safety**

Irbesartan is not safe to use during pregnancy. Studies in pregnant rats given high doses demonstrated a variety of fetal abnormalities (renal pelvic cavitation, hydroureter, absence of renal papilla). Smaller doses in rabbits caused increased maternal death and spontaneous abortion. In humans, the drug is considered teratogenic, particularly during the 2nd and 3rd trimesters. During this time, the FDA categorizes irbesartan as category D for use during pregnancy (*There is evidence...*)
human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) If pregnancy is detected in patients receiving irbesartan, the drug should be discontinued as soon as possible.

Because small amounts of irbesartan have been detected in rat milk, and there is significant concern about the safety of the drug in neonates, the manufacturer recommends that it not be used in nursing women.

Overdosage/Acute Toxicity
Rats and mice survived acute oral overdoses in excess of 2000 mg/kg. Likely effects seen in an overdose situation include hypotension and either bradycardia or tachycardia; treatment is supportive. Contact an animal poison control center for further information.

Drug Interactions
In humans or veterinary patients, no clinically significant drug interactions have been reported. Because of the drug’s pharmacologic actions, use caution with other drugs that can reduce blood pressure.

Laboratory Considerations
- No specific concerns were noted

Doses
- **DOGS:**
  - a) As an alternative to ACE inhibitors for treatment of hypertension associated with renal insufficiency: 5 mg/kg PO q12–24 hours. (Brown 2004)

Monitoring
- Blood pressure, heart rate
- Serum electrolytes, BUN, creatinine
- Adverse Effects: possibly GI (diarrhea), somnolence/activity changes

Client Information
- Clients should understand that veterinary experience with this medication is limited and that the adverse effect profile is not well known; anything unusual should be reported to the veterinarian
- May be given with food or on an empty stomach

Chemistry/Synonyms
Irbesartan is a nonpeptide angiotensin-II antagonist and occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol.

Irbesartan may also be known as: BMS 186295, SR 47346, Irbesartanum, Aprovel®, Arbit®, Avalide®, Avapro®, Cavapro®, Coapreval®, Ecard®, Ibsan®, Irban®, Irbes®, Iretensa®, Irovel®, Irvell®, Isart®, and Karvea®.

Storage/Stability
Irbesartan tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance.

**HUMAN-LABELED PRODUCTS:**
- Irbesartan Tablets: 75 mg, 150 mg, & 300 mg; Avapro® (Bristol-Meyers Squibb); (Rx)
- Irbesartan 150 mg with Hydrochlorothiazide 12.5 mg Tablets, Irbesartan 300 mg with Hydrochlorothiazide 12.5 mg or 25 mg Tablets; Avalide®; (Bristol-Myers Squibb); (Rx)

References

---

**IRON DEXTRAN**
*(eye-urn dex-tran)*

**INJECTABLE HEMATINIC**

**Prescriber Highlights**

- Injectable hematinic
- Contraindications: Known hypersensitivity to iron dextran, or with any anemia other than iron deficiency anemia; acute renal infections, in conjunction with oral iron supplements
- Adverse Effects: Prostration & muscular weakness, anaphylactoid reactions
High dosages may cause increased incidences of teratogenicity & embryotoxicity

Pigs born of vitamin E/selenium-deficient sows may demonstrate nausea, vomiting, & sudden death within 1 hour of injection

IM use in pigs after 4 weeks of age may cause muscle tissue staining

Uses/Indications
Iron dextran is used in the treatment and prophylaxis of iron deficiency anemias, primarily in neonatal food-producing animals.

Pharmacology/Actions
Iron is necessary for myoglobin and hemoglobin in the transport and utilization of oxygen. While neither stimulating erythropoiesis nor correcting hemoglobin abnormalities not caused by iron deficiency, iron administration does correct both physical signs and decreased hemoglobin levels secondary to iron deficiency. Ionized iron is a component in the enzymes cytochrome oxidase, succinic dehydrogenase, and xanthine oxidase.

Pharmacokinetics
After IM injection, iron dextran is slowly absorbed primarily via the lymphatic system. About 60% of the drug is absorbed within 3 days of injection and up to 90% of the dose is absorbed after 1–3 weeks. The remaining drug may be absorbed slowly over several months.

After absorption, the reticuloendothelial cells of the liver, spleen, and bone marrow gradually clear the drug from plasma. The iron is cleaved from the dextran component and the dextran is then metabolized or excreted. The iron is immediately bound to protein elements to form hemosiderin, ferritin or transferrin. Iron crosses the placenta, but in what form is unknown. Only traces of iron are excreted in milk.

Iron is not readily eliminated from the body. Iron liberated by the destruction of hemoglobin is reused by the body and only small amounts are lost by the body via hair and nail growth, normal skin desquamation, and GI tract sloughing. Accumulation can result with repeated dosing as only trace amounts of iron are eliminated in the feces, bile, or urine.

Contraindications/Precautions/Warnings
Iron dextran is contraindicated in patients with known hypersensitivity to it or with any anemia other than iron deficiency anemia. It is not to be used in patients with acute renal infections, and should not be used in conjunction with oral iron supplements.

Adverse Effects
The manufacturers of iron dextran injection for use in pigs state that occasionally pigs may react after injection with iron dextran, characterized by prostration and muscular weakness. Rarely, death may result from an anaphylactoid reaction. Iron dextran used in pigs born of vitamin E/selenium-deficient sows may demonstrate nausea, vomiting, and sudden death within 1 hour of injection. Iron dextran injected IM in pigs after 4 weeks of age may cause muscle tissue staining.

Large SC doses have been associated with the development of sarcomas in laboratory animals (rabbits, mice, rats, and hamsters).

Reproductive/Nursing Safety
High dosages may cause increased incidences of teratogenicity and embryotoxicity. Use only when clearly necessary at recommended doses in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Traces of unmetabolized iron dextran are excreted in milk.

Overdosage/Acute Toxicity
Depending on the size of the dose, inadvertent overdose injections may require chelation therapy. For more information, refer to the Ferrous Sulfate monograph for information on using deferoxamine and other treatments for iron toxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving iron and may be of significance in veterinary patients:

CHLORAMPHENICOL: Because chloramphenicol may delay the response to iron administration, avoid using chloramphenicol in patients with iron deficiency anemia

Laboratory Considerations

- Large doses of injectable iron may discolor the serum brown which can cause falsely elevated serum bilirubin values and falsely decreased serum calcium values.
- After large doses of iron dextran, serum iron values may not be meaningful for up to 3 weeks.

Doses

DOGS:
- a) For iron deficiency anemia: Iron dextran 10–20 mg/kg once, followed by oral therapy with ferrous sulfate (see ferrous sulfate monograph) (Weiser 1989)

CATS:
- a) For prevention of transient neonatal iron deficiency anemia: 50 mg iron dextran injection at 18 days of age (Weiser 1989)
- b) For adjunctive therapy with erythropoietin treatment: 10 mg/kg IM every 3–4 weeks. (Grauer 2008)
- c) For adjunctive therapy with erythropoietin treatment in cats who cannot tolerate oral iron therapy: 50 mg IM q3–4 weeks (Hoskins 2005)

FERRETS:
- a) 10 mg/kg IM once weekly (Williams 2000)

SWINE:
- a) For prevention of iron deficiency anemia in baby pigs (2–4 days of age): Administer an initial intramuscular injection of 100 mg of elemental iron to each
animal at 2 to 4 days of age. Dosage may be repeated in 14 to 21 days. (Label directions; Ferrextran-100®—Fort Dodge)

**BIRDS:**
For iron deficiency anemia or following hemorrhage:

a) 10 mg/kg IM; repeat in 7–10 days if PCV fails to return to normal (Clubb 1986)
b) 10 mg/kg IM; repeat weekly (McDonald 1989)

**Monitoring**
- If indicated: CBC, RBC indices
- Adverse reactions

**Client Information**
- In pigs, inject IM in the back of the ham

**Chemistry/Synonyms**
Iron dextran is a complex of ferric oxyhydroxide and low molecular weight partially hydrolyzed dextran derivative. The commercially available injection occurs as a dark brown, slightly viscous liquid that is completely miscible with water or normal saline and has a pH of 5.2–6.5.

Iron dextran may also be known as: iron–dextran complex, Cosmofer®, DexFerrum®, Dexiron®, Driken®, Fercayl®, Ferrocel®, Ferroin®, Ferrum Hausmann®, Fexiron®, Imferdex®, Imferon®, InFeD®, and Infufer®.

**Storage/stability**
Iron dextran injection should be stored at room temperature (15–30°C); avoid freezing.

**Compatibility/Compounding Considerations**
Iron dextran injection is reportedly physically **incompatible** when mixed with oxytetracycline HCl and sulfadiazine sodium.

**Dosage Forms/Regulatory Status/Withdrawal Times**

**VETERINARY-LABELLED PRODUCTS:**
Iron Dextran Injection: 100 mg of elemental iron/mL and 200 mg of elemental iron/mL in 100 mL vials; various manufacturers and trade names; (OTC). FDA-approved for use in swine. No slaughter withdrawal time required.

**HUMAN-LABELLED PRODUCTS:**
Iron Dextran Injection: 50 mg of elemental iron/mL (as dextran) in 1 mL & 2 mL single-dose vials; InFeD® (Watson); DexFerrum® (American Regent); (Rx)

**ISOFLUPREDONE ACETATE**
(eye-so-flu-preh-dohn) Predex 2X®

**Injectable Glucocorticoid**

For topical or otic use of isoflupredone, see the Topical Dermatological Agents, and Otic Appendixes

**Prescriber Highlights**

- Injectable glucocorticoid labeled for use in cattle, horses & swine for antiinflammatory & immunosuppressive effects
- Less likely to cause early parturition than dexamethasone or betamethasone, but avoid use in pregnancy
- May have mineralocorticoid effects in horses & cattle; hypokalemia has been noted

**Uses/Indications**
Isoflupredone acetate is a potent glucocorticoid and like other glucocorticoids can be used for its antiinflammatory or immunosuppressive effects. Labeled indications for isoflupredone include: adjunctive treatment of bovine ketosis, alleviating pain and lameness associated with musculoskeletal conditions, acute hypersensitivity reactions, adjunctive treatment of overwhelming infections with severe toxicity, shock, supportive therapy in the treatment of stress conditions (e.g., surgery), dystocia, retained placenta, inflammatory ocular conditions, snakebite and parturient paresis.

A study evaluating the effects of isoflupredone (20 mg IM) with or without insulin (ultralente 100 Units) on energy metabolism, milk production and overall health in dairy cows during the early lactation phase showed that isoflupredone with or without insulin “offered no metabolic, production, or reproductive benefits in lactating dairy cattle.” (Seifi et al. 2007)

In horses, isoflupredone has been used parenterally to reduce inflammation associated with recurrent airway obstruction (RAO, “heaves,” COPD).

While the drug could be used in small animals, it is recommended to use other glucocorticoid agents instead, where there has been more experience and other FDA-approved products for dogs and cats are available.
Pharmacology/Actions
Isoflupredone’s antiinflammatory potency is approximately 17 times that of hydrocortisone (cortisol). The label states that the glucocorticoid activity of isoflupredone is 50 times that of hydrocortisone and 10 times that of prednisolone as measured by liver glycogen deposition in rats. Isoflupredone reportedly has some mineralocorticoid effects, and can cause hypokalemia.

For more information on the pharmacologic actions associated with glucocorticoids, see the *Glucocorticoid Agents, General Information* monograph.

Pharmacokinetics
No specific pharmacokinetic values were located. The manufacturer states that gluconeogenic activity persists for 48 hours after dosing in cattle.

Contraindications/Precautions/Warnings
Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Because of their ulcerogenic potential, glucocorticoids should be used with extreme caution in patients with active GI ulcers or those susceptible to them. Use cautiously in patients with diabetes mellitus.

Because it can cause hypokalemia, it should not be used in downer cows or animals susceptible to the effects of hypokalemia.

Chronic use in young, growing animals must be undertaken cautiously, as decreased growth may occur.

Not to be used in calves to be processed into veal.

See Reproductive Safety for information on use during pregnancy.

Adverse Effects
Adverse effects are generally associated with long-term administration of glucocorticoids, particularly if given at higher dosages; these effects generally are manifested as signs of hyperadrenocorticism. Recent research has indicated, however, that even single doses administered to dairy cattle can cause hypokalemia. Potential adverse effects include: reduced milk production, hypokalemia, delayed wound healing, GI ulceration, increased infection rates, diabetes mellitus exacerbation/hyperglycemia, pancreatitis, hepatopathy, renal dysfunction, osteoporosis, laminitis (horses), hypothyroidism, and hyperlipidemia. When administered to young, growing animals, glucocorticoids can retard growth.

Reproductive/Nursing Safety
Avoid using isoflupredone during pregnancy. Glucocorticoids can induce abortion or early parturition in the later stages of pregnancy; most commonly seen in ruminants. While isoflupredone appears to have a much lower abortifacient potential (like hydrocortisone, prednisolone, & triamcinolone) than steroids such as dexamethasone, betamethasone or flumethasone; it may induce premature parturition with retained placenta and its use should generally be avoided during the later stages of pregnancy.

Glucocorticoids used during the first trimester have been linked to a variety of teratogenic effects in dogs and laboratory animals.

Glucocorticoid administration may reduce milk production. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

Overdosage/Acute Toxicity
A single overdose of isoflupredone is unlikely to cause harmful effects. Should clinical signs require intervention, use supportive treatment.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to the Adverse Effects section for more information.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving isoflupredone or other glucocorticoids and may be of significance in veterinary patients:

- **DIGITALIS GLYCOSIDES** (digoxin): Increased chance of digitalis toxicity may occur should hypokalemia develop; diligent monitoring of potassium and digitalis glycoside levels is recommended
- **POTASSIUM-DEPLETING DIURETICS** (furosemide, thiazides): Administered concomitantly with glucocorticoids may cause hypokalemia
- **SALICYLATES**: Glucocorticoids may reduce salicylate blood levels
- **ULCEROGENIC DRUGS** (e.g., NSAIDs): With glucocorticoids may increase the risk of gastrointestinal ulceration
- **VACCINES, TOXOIDS, BACTERINS**: A diminished immune response may occur after vaccine, toxoid, or bacterin administration; patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented

Laboratory Considerations
- Glucocorticoids may increase **serum cholesterol** and **serum and urine glucose** levels
- Isoflupredone may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T3 & T4** values; thyroid gland atrophy has been reported after chronic glucocorticoid administration
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- Glucocorticoids may cause false-negative results of the **nitroblue tetrazolium test** for systemic bacterial infections.

Doses

**CATTLE:**

a) For labeled systemic indications: 10–20 mg (total dose) IM, according to the size of the animal and severity of the condition. The dose may be repeated in 12 to 24 hours if indicated. (Label information; *Predef 2X®—Pharmacia & Upjohn*)

**HORSES**: (Note: RCI Class 4)

a) For labeled systemic indications: 5–20 mg (total dose) IM repeated as necessary. For intrasynovial administration: 5–20 mg or more depending on the size of the joint cavity. (Label information; *Predef 2X®—Pharmacia & Upjohn*)
b) For intraarticular administration: 4–20 mg; has a short to medium duration of action. (Goodrich 2006)
c) For treatment of “heaves” (RAO): 10–14 mg (total dose) IM once daily for a horse weighing between 450–500 kg. (Lavoie 2003)
d) For treatment of recurrent airway obstruction (RAO): 0.03 mg/kg IM once daily. Patients were treated for 14 days and developed significant decreases in serum potassium. (Picandet et al. 2003)

**SWINE:**

a) For labeled systemic indications: 5 mg (total dose) IM for a 300 lb. animal. Adjust dose proportionally for a smaller or larger animal. (Label information; Predef 2X®—Pharmacia & Upjohn)

**Monitoring**

- Single injections may not require monitoring beyond observation of the patient for efficacy and adverse effects, but consider evaluating serum potassium
- Ongoing usage requires enhanced monitoring including: renal and liver function, CBC, blood glucose and serum electrolytes
- ACTH stimulation tests may be indicated to determine extent of HPA axis suppression
- Consider thyroid hormone monitoring if use is prolonged or patient exhibits signs associated with thyroid hormone deficiency

**Client Information**

- If used in dairy cattle, warn producer that milk production may be affected
- If owners are to administer the medication, caution them to only administer as the veterinarian directs

**Chemistry/Synonyms**

Isoflupredone acetate is a fluorinated synthetic corticosteroid with a molecular weight of 420.5. The commercial injection is in an aqueous suspension that also contains sodium citrate, polyethylene glycol 3350, and povidone.

Isoflupredone acetate may also be known as: U-6013, 9alpha-fluoroprednisolone acetate, and Predef 2x®.

**Storage/Stability**

The injection should be stored at controlled room temperature 20°–25°C.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Isoflupredone acetate 2 mg/mL aqueous suspension for injection in 10 mL and 100 mL vials; Predef 2x® (Pfizer); (Rx). In the USA, Predef 2x® is FDA-approved for use in cattle, horses and swine.

Meat withdrawal time is 7 days; it is not to be used in calves to be processed for veal. There is no milk withdrawal time for isoflupredone in the USA, but in Canada a 72-hour withdrawal time is specified.

Isoflupredone is also found in some topical and otic products. For more information see the Dermatological Agents, Topical and Otic Appendixes.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

**HUMAN-LABELLED PRODUCTS:** None

**References**

---

**ISOFLURANE**

*(eye-soe-flu-rah-nee)* Isoflo®, Iso-Thesia®

**GENERAL ANESTHETIC, INHALANT**

**Prescriber Highlights**

- **Inhalant general anesthetic**
- **Contraindications:** History or predilection towards malignant hyperthermia
- **Caution with increased CSF or head injury, or myasthenia gravis**
- **Adverse Effects:** Dose related hypotension, respiratory depression, & GI effects (nausea, vomiting, ileus); cardiodepression generally is minimal at doses causing surgical planes of anesthesia. Arrhythmias are rare.
- **May be fetotoxic**
- **Drug interactions**

**Uses/Indications**

- Inhalation therapy for non-dermatologic inflammatory or neoplastic conditions, and to induce and maintain surgical anesthesia. Also used in veterinary medicine as an induction agent for general anesthesia.

**Dosage Form/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

- Isoflo® (Pfizer) (Rx) (isoflurane) in the USA, Canada and Japan 0.015–0.1% (1.5–10.0%/v/v) in oxygen.
- Iso-Thesia® (Pfizer) (isoflurane) in the USA, Canada, United Kingdom and Australia 0.015–0.1% (1.5–10.0%/v/v) in oxygen.
As halothane is no longer available, isoflurane is now the primary inhalant anesthetic used in veterinary medicine. When compared with older anesthetics such as halothane or methoxyflurane, isoflurane has less myocardial depressant and catecholamine sensitizing effects, and it can be used safely in patients with hepatic or renal disease. The newer inhalant anesthetics, sevoflurane (ability to change depth of anesthesia faster; not as respiratory irritating; mask inductions possible) and desflurane (very fast onset, faster recoveries) have some advantages over isoflurane, but are more expensive.

**Pharmacology/Actions**

While the precise mechanism that inhalant anesthetics exert their general anesthetic effects is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Some key pharmacologic effects noted with isoflurane include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression, hypotension, vasodilatation, myocardial depression (less so than with halothane), and muscular relaxation.

Minimal Alveolar Concentration (MAC; %) in oxygen reported for isoflurane in various species: Dog = 1.5; Cat = 1.2; Horse = 1.31; Human = 1.2. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

**Pharmacokinetics**

Isoflurane is rapidly absorbed from the alveoli. It is rapidly distributed into the CNS and crosses the placenta. The vast majority of the drug is eliminated via the lungs; only about 0.17% is metabolized in liver and only very small amounts of inorganic fluoride is formed.

**Contraindications/Precautions/Warnings**

Isoflurane is contraindicated in patients with a history or predilection towards malignant hyperthermia. It should be used with caution (benefits vs. risks) in patients with increased CSF or head injury, or myasthenia gravis.

Because of its respiratory depressant effects, intermittent positive pressure ventilation may be required to achieve anesthesia, particularly in horses; overdose risks are increased, however.

Both isoflurane and desflurane can be irritating to the respiratory system and are not recommended for mask induction (Clarke 2008).

**Adverse Effects**

Hypotension (secondary to vasodilation, not cardiodepression) may occur and is considered to be dose related. Hypotension usually responds to fluids, but profound hypotension may require the use of vasopressors.

- Dose-dependent respiratory depression, and GI effects (nausea, vomiting, ileus) have been reported. While cardiodepression generally is minimal at doses causing surgical planes of anesthesia, it may occur. Arrhythmias have rarely been reported.

**Reproductive/Nursing Safety**

Some animal studies have indicated that isoflurane may be fetotoxic. Use during pregnancy with caution. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving isoflurane and may be of significance in veterinary patients:

- **AMINOGYCOSIDES**: Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur.
- **ACE INHIBITORS OR OTHER HYPOTENSIVE AGENTS**: Concomitant use may increase risks for hypotension. Enalapril caused significant decreases in systolic blood pressure in cats and dogs undergoing isoflurane anesthesia (Ishikawa, Uechi & Ishikawa 2007), (Ishikawa, Uechi & Hori 2007)
- **LINCOSAMIDES**: Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur.
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS**: Additive neuromuscular blockade may occur.
- **SUCINYLCHOLINE**: With inhalation anesthetics, may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia.
- **SYMPATHOMIMETICS (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.):** While isoflurane sensitizes the myocardium to the effects of sympathomimetics less so than halothane, arrhythmias may still result. If these drugs are needed, they should be used with caution and in significantly reduced dosages with intensive monitoring.

**Doses**

- **DOGS/CATS:**
  - (Note: Concentrations are dependent upon fresh gas flow rate; the lower the flow rate, the higher the concentration required.)
  - a) 5% induction; 1.5—2.5% maintenance (Papich 1992)
  - b) 0.5—3%, inhaled (Hubbell 1994)

- **FERRETS/SMALL MAMMALS:**
  - a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: Using a non-rebreathing system: Induction: 2–3%, maintenance: 0.25–2% (Anderson 1994); (Adamcak & Otten 2000)
  - b) Ferrets: After premed with medetomidine at 50–100 micrograms/kg. Atropine at 0.05 mg/kg SC is used to counteract hypersalivation and bradycardia. Starting isoflurane at 1–2% will be less irritating to the ferret and cause less of a struggle. Use a non-rebreathing system. Consider intubation in procedures lasting longer than 30 minutes. For post-op pain either butorphanol at 0.1 mg/kg SC or buprenorphine at 0.02 mg/kg SC. (Johnson 2006)

- **REPTILES:**
  - a) Give 5% isoflurane and oxygen in a clear plastic bag or induction chamber. Fill chamber with gas and seal. Induction time may take 30–60 minutes, but can be shortened to 15–30 minutes with increased depth of anesthesia if animal is injected with 10–20 mg/kg of ketamine (SC or IM). Patient should be kept warm by placing on a water blanket. Surgical anesthesia can be determined by the loss of righting reflex. After induction, use either a mask, ET tube, or leave head in chamber. Maintenance levels are 3–5% (if isoflurane used alone). If apnea occurs during or after anesthesia, discontinue gas anesthetic and apply gentle manual ventilation 2–4 times per minute with small doses of doxapram IV. Normal respiration generally resumes in 3–5 minutes. Righting reflex generally recovers in an
Isoniazid inhibits the synthesis of mycolic acids, a component of mycobacterial cell walls; its exact mechanism is not well understood. It is most active against antmycobacterial agents to treat active disease.

In addition, INH has a narrow therapeutic index and toxicity is a concern (see Adverse Effects).

Isoniazid (INH) is sometimes used for chemoprophylaxis in small animals in households having a human with tuberculosis. It potentially can be used in combination with other antimycobacterial drugs to treat infections of M. bovis or M. tuberculosis in small animals, Lisorane, AErrane®, Forene®, Forenium®, Forthane®, Isoflo®, Isoflor®, Isofor®, Isoforine®, Isosol®, Isothane®, Iso-Thesia®, Lisorane®, Sofloran®, Tensocold®, Terrell® and Zuflax®.

Storage/stability

Isoflurane should be stored at room temperature; it is relatively unaffected by exposure to light, but should be stored in a tight, light-resistant container. Isoflurane does not attack aluminum, brass, tin, iron, or copper.

References

Gillespie, D. (1994). Respiratory and ventilatory status. Cardiac rate/rhythm; blood pressure (particularly with "at risk" patients

Isoniazid (INH) (eye-so-nye-ah-zid) Isonicotinic acid hydrazide

ANTIMYCOBACTERIAL

Prescriber Highlights

- Antimycobacterial that may be used for chemoprophylaxis of M. bovis or M. tuberculosis in small animals
- Treating active infections is controversial because of potential public health risks associated with the infections
- Hepatotoxicity & neurotoxicity possible; narrow therapeutic index

Uses/Indications

Isoniazid (INH) is sometimes used for chemoprophylaxis in small animals in households having a human with tuberculosis. It potentially can be used in combination with other antimycobacterial drugs to treat infections of M. bovis or M. tuberculosis in dogs or cats. But because of the public health risks, particularly in the face of increased populations of immunocompromised people, treatment of mycobacterial (M. bovis, M. tuberculosis) infections in domestic or captive animals is controversial.

In addition, INH has a narrow therapeutic index and toxicity is a concern (see Adverse Effects).

In humans, isoniazid (INH) is routinely used alone to treat latent tuberculosis infections (positive tuberculosis skin test) and in combination with other antimycobacterial agents to treat active disease.

Pharmacology/Actions

Isoniazid inhibits the synthesis of mycolic acids, a component of mycobacterial cell walls; its exact mechanism is not well understood. It is most active against antmycobacterial drugs.
Isoniazid inhibits the synthesis of mycolic acids, a component of mycobacterial cell walls; its exact mechanism is not well understood. It is most active against mycobacteria that are actively dividing and affects both extracellular and intracellular mycobacteria.

Isoniazid is only active against *M. tuberculosis*, *M. bovis* and some strains of *M. kansasii*. In humans, resistance develops rapidly if used alone against active clinical disease, but not when used for prophylactic treatment.

### Pharmacokinetics

No information was located on the pharmacokinetics of INH in dogs or cats. In humans, isoniazid is rapidly absorbed after oral administration; food can decrease absorption somewhat and INH may undergo significant first pass metabolism. The drug is highly distributed in the body and crosses into the CSF and caseous material. It is distributed into milk and crosses the placenta. It is only slightly (10%) bound to plasma proteins. In humans, the drug is initially primarily acetylated in the liver. The N-acetylated form is then further biotransformed to isonicotinic acid and monoaecetylhydrazine. Monoacetylhydrazine is thought to play a role in the drug’s hepatic toxicity. As dogs, like some humans, lack N-acetyltransferase, increased potential for INH toxicity may occur in this species. Elimination half-life in fast acetylators (humans) is 0.5–1.6 hours and 2–5 hours in slow acetylators. Patients with acute or chronic liver disease may have substantially longer half-lives (2X). The drug is mostly eliminated in the urine as inactive metabolites.

### Contraindications/Precautions/Warnings

Isoniazid is contraindicated in patients with acute liver disease or those that developed hepatopathy while taking the medication in the past. It should be used with caution in patients with decreased hepatic function or severe renal disease.

### Adverse Effects

The primary adverse effects associated with INH is hepatotoxicity with increased serum liver enzymes. Additional adverse effects reported in dogs include CNS stimulation, peripheral neuropathy and thrombocytopenia. Ataxia, seizures, salivation, diarrhea, vomiting and arrhythmias have been reported after overdoses in dogs. Adverse effects reported in cats include hepatotoxicity and peripheral neuritis. In humans, urticaria, hepatotoxicity and peripheral neuropathy are commonly reported; rarely, blood dyscrasias, SLE, and seizures have been reported.

### Reproductive/Nursing Safety

Isoniazid crosses the placenta and has been found to be embryocidal in some laboratory species, but teratogenic effects have not been detected in mice, rabbits, or rats. In humans, the FDA categorizes isoniazid as category C for use during pregnancy. Ingested levels via milk are not high enough to serve as prophylaxis for tuberculosis in nursing infants.

### Overdosage/Acute Toxicity

Overdosage of INH can be very serious. In dogs, the reported LD50 is 50 mg/kg; serious toxicity can occur with as little as one 300 mg tablet ingested. Ataxia, seizures, myocardial necrosis, metabolic acidosis, rhabdomyolysis, salivation, diarrhea, vomiting, and arrhythmias have been reported after overdoses in dogs. It is strongly recommended to contact an animal poison control center in the event of any inadvertent ingestion. Treatment may include enterogastric lavage, activated charcoal and drugs such as diazepam or phenobarbital to control seizures. Fluids and acidemia may need correction.

Pyridoxine (Vitamin B-6) has been suggested to be administered intravenously (preferably over 30–60 minutes) on a mg per mg of INH-ingested basis. It is available commercially as a 100 mg/mL 1 mL vial, but it may be difficult to obtain in an emergency situation. A local human hospital may stock it.

### Drug Interactions

Drug interactions have not been reported with isoniazid in animals. The following drug interactions have either been reported or are theoretical in humans receiving INH and may be of significance in veterinary patients:

- **ALFENTANIL**: Prolonged alfentanil duration of action
- **ANTACIDS (especially those containing aluminum)**: Decreased INH absorption
- **BENZODIAZEPINES**: INH may reduce benzodiazepine metabolism
- **CORTICOSTEROIDS**: May reduce INH efficacy
- **KETOCONAZOLE**: INH may reduce ketoconazole serum concentrations
- **OTHER HEPATOTOXIC DRUGS (e.g., acetaminophen, itraconazole, fluconazole, methimazole, ketoconazole, phenothiazines, sulfonamides, estrogens, etc.): increased risk of hepatotoxicity
- **OTHER NEUROTOXIC DRUGS**: Increased risk of neurotoxicity
- **PYRIDOXINE**: INH may antagonize or increase the excretion of pyridoxine, increased pyridoxine may be required; increased peripheral neuritis may occur secondary to pyridoxine/INH interaction
- **PHENYTOIN**: INH may inhibit metabolism and increase risks for phenytoin toxicity
- **RIFAMPIN**: Increased risk for hepatotoxicity
- **THEOPHYLLINE**: Increased risk of theophylline toxicity
- **FOOD INTERACTIONS** in humans: *cheese* (Swiss, Cheshire, etc.) or *fish* (Tuna, Skipjack, Sardinella): INH may interfere with metabolism of tyramine and histamine found in fish and cheese

### Laboratory Considerations

- **INH** may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict’s Solution, *Clinitest®*); tests utilizing glucose oxidase (*Tes-Tape®, Clinitest®*) are not affected

### Doses

**DOGS:**

- For *M. tuberculosis* chemoprophylaxis: 10 mg/kg PO once daily. Drug can be hepatotoxic and dose is extrapolated from human data. Treatment of *M. tuberculosis* can be started with an initial loading dose of double the maintenance dose administered over 7 days, followed by maintenance dosing.

**PHENYTOIN**

 Increased risk for phenytoin toxicity
a) For *M. tuberculosis* chemoprophylaxis: 10 mg/kg PO once daily. Drug can be hepatotoxic and dose is extrapolated from human data. Treatment of *M. tuberculosis* or *M. bovis* infections in dogs and cats is not recommended. (Greene & Gunn-Moore 2006)

**CATS:**

a) As a second-line treatment (reserved for resistant infections) for feline TB: 10–20 mg/kg PO once daily. (Gunn-Moore 2008)

**Monitoring**

- Baseline and periodic physical exam, including clinical efficacy and adverse effect queries
- Baseline and periodic: CBC, liver function, renal function

**Client Information**

- Best to administer on an empty stomach
- If this medication is to be effective, it must be given regularly as directed
- If a dose is missed, do not double the next dose
- Store well out of reach of children or pets; overdoses can be very serious
- Contact veterinarian if any of the following occur: vomiting, decreased appetite/weight loss, diarrhea or loose stools, changes in behavior or activity, yellowing of whites of eyes or mucous membranes, or difficulty running or going up/down stairs

**Chemistry/Synonyms**

Isoniazid occurs as colorless, or white, odorless crystals. It is freely soluble in water and sparingly soluble in alcohol. It is recommended not to use sugars such as glucose, fructose or sucrose in compounded oral solutions, as a condensation product can be formed that can impair absorption.

Isoniazid may also be known as: INH, INAH, isonicotinic acid hydrazide, isonicotinylhydrazide, isonicotinylhydrazine, or tubazid. INH is available throughout the world in many trade names, some of the more commonly used names include *Isotamine®, Laniazid®, or Nydrazid®*. **Caution:** *Isopyrin®* is one isoniazid trade name that in some countries contains ramifenazone and not isoniazid.

**Storage/Stability**

Isoniazid tablets should be stored at temperatures below 40°C, preferably between 15–30°C, in well-closed, light-resistant containers. The oral syrup should be stored at temperatures below 40°C, preferably between 15–30°C, in well-closed, light-resistant containers protected from freezing. The injection should be stored at temperatures below 40°C, preferably between 15–30°C; protected from light and freezing. At low temperatures, crystals may form in the injectable solution; crystals should redissolve upon warming to room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

---

**ISOPROTERENOL HCL**

(eye-so-proe-te-er-e-nole) *Isuprel®*

**BETA-ADRENERGIC AGONIST**

**Prescriber Highlights**

- Non-specific beta agonist used rarely for acute bronchial constriction, cardiac arrhythmias (complete AV block), & as adjunctive therapy in shock or heart failure
- Contraindications: Tachycardias or AV block caused by cardiac glycoside intoxication, ventricular arrhythmias that do not require increased inotropic activity
- Caution: Coronary insufficiency, hyperthyroidism, renal disease, hypertension, or diabetes; not a substitute for adequate fluid replacement in shock
- Adverse Effects: Tachycardia, anxiety, tremors, excitability, headache, weakness, & vomiting; more arrhythmogenic than dopamine or dobutamine
- Short duration of activity (including adverse effects)
Isoproterenol is a synthetic beta1- and beta2-adrenergic agonist that has no appreciable alpha activity at therapeutic doses. It is thought that isoproterenol’s adrenergic activity is a result of stimulating cyclic-AMP production. Its primary actions are increased inotropism and chronotropism, relaxation of bronchial smooth muscle, and peripheral vasodilatation. Isoproterenol may increase perfusion to skeletal muscle (at the expense of vital organs in shock). Isoproterenol will inhibit the antigen-mediated release of histamine and slow releasing substance of anaphylaxis (SRS-A).

Hemodynamic effects noted include decreased total peripheral resistance, increased cardiac output, increased venous return to the heart, and increased rate of discharge by cardiac pacemakers.

Pharmacokinetics
Isoproterenol is rapidly inactivated by the GI tract and metabolized by the liver after oral administration. Sublingual administration is not reliably absorbed and effects may take up to 30 minutes to be seen. Intravenous administration results in immediate effects, but only persists for a few minutes after discontinuation.

It is unknown if isoproterenol is distributed into milk. The pharmacologic actions of isoproterenol are ended primarily through tissue uptake. Isoproterenol is metabolized in the liver and other tissues by catechol-O-methyltransferase (COMT) to a weakly active metabolite.

Contraindications/Precautions/Warnings
Isoproterenol is contraindicated in patients that have tachycardias or AV block caused by cardiac glycoside intoxication. It is also contraindicated in ventricular arrhythmias that do not require increased inotropic activity.

Use isoproterenol with caution in patients with coronary insufficiency, hyperthyroidism, renal disease, hypertension or diabetes. Isoproterenol is not a substitute for adequate fluid replacement in shock.

Adverse Effects
Isoproterenol can cause tachycardia, anxiety, tremors, excitability, headache, weakness, and vomiting. Because of isoproterenol’s short duration of action, adverse effects are usually transient and do not require cessation of therapy, but may require lowering the dose or infusion rate. Isoproterenol is considered more arrhythmogenic than either dopamine or dobutamine, so it is rarely used in the treatment of heart failure.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy. (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

No specific lactation safety information was found, however, as isoproterenol is rapidly deactivated in the gut, it is unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity
In addition to the signs listed in the Adverse Effects section, high doses may cause an initial hypertension, followed by hypotension as well as tachycardias and other arrhythmias. Besides halting or reducing the drug, treatment is considered to be supportive. Should tachycardias persist, a beta-blocker could be considered for treatment (if patient does not have a bronchospastic disease).

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving isoproterenol and may be of significance in veterinary patients:

- **ANESTHETICS, GENERAL:** An increased risk of arrhythmias developing can occur if isoproterenol is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.
- **BETA-BLOCKERS:** May antagonize isoproterenol’s cardiac, bronchodilating, and vasodilating effects by blocking the beta effects of isoproterenol. Beta-blockers may be administered to treat the tachycardia associated with isoproterenol use, but use with caution in patient’s with bronchospastic disease.
- **DIGOXIN:** An increased risk of arrhythmias may occur if isoproterenol is used concurrently with digitalis glycosides.
- **OXYTOCIC AGENTS:** Hypertension may result if isoproterenol is used with oxytocic agents.
- **SYMPATHOMIMETIC AGENTS, OTHER:** Isoproterenol should not be administered with other sympathomimetic agents (e.g., phenylpropanolamine) as increased toxicity may result.
- **THEOPHYLLINE:** Isoproterenol may increase the risk for theophylline toxicity.

Doses
Note: Because of the cardiotimatory properties of isoproterenol, its parenteral use in human medicine for the treatment of bronchospasm has been largely supplanted by other more beta2 specific drugs (e.g., terbutaline) and administration methods (nebulization). Use with care.

**DOGS:**

For sinoatrial arrest, sinus bradycardia, complete AV block:
- 0.4 mg in 250 mL of D5W drip slowly to effect; or Isuprel® Glossets 5–10 mg sublingually or rectally q 4–6h (Tilley & Miller 1986)
- 0.04–0.08 micrograms/kg/min IV infusion; or 0.1–0.2 mg IM, SC q4h; or 0.4 mg in 250 mL D5W IV slowly (Morgan 1988)
- As an alternative to atropine for the adjunctive treatment for bradycardia associated with calcium channel blocker overdose: Mix 0.4 mg in 250 mL of D5W and give via slow IV drip to effect. (Holder 2000)

**CATS:**
For sinoatrial arrest, sinus bradycardia, complete AV block:

a) 0.4 mg in 250 mL D5W drip slowly to effect (Tilley & Miller 1986)

**HORSES:** (Note: ARCI UCGFS Class 2 Drug)

For short-term bronchodilatation:

a) Dilute 0.2 mg in 50 mL of saline and administer 0.4 micrograms/kg as an IV infusion, monitor heart rate continuously and discontinue when heart rate doubles. Effects may only last for an hour. (Derksen 1987)

**Monitoring**
- Cardiac rate/rhythm
- Respiratory rate/auscultation during anaphylaxis
- Urine flow if possible
- Blood pressure, and blood gases if indicated and possible

**Client Information**
- Isoproterenol for injection should be used only by trained personnel in a setting where adequate monitoring can be performed.

**Chemistry/Synonyms**
Isoproterenol HCl is a synthetic beta-adrenergic agent that occurs as a white to practically white, crystalline powder that is freely soluble in water and sparingly soluble in alcohol. The pH of the commercially available injection is 3.5–4.5.

Isoproterenol HCl may also be known as: isoprenaline hydrochloride, isopropylarterenol hydrochloride, isopropynoradrenaline hydrochloride, Imuprel®, Isolin®, Isuprel®, Lenoprel®, Norisodrine Aerotrol®, Proterenal, Saventrine®, and Vapo-iso®.

**Storage/stability**
Store isoproterenol preparations in tight, light-resistant containers. It is stable indefinitely at room temperature. Isoproterenol salts will darken with time upon exposure to light, light, or heat. Sulfites or sulfur dioxide may be added to preparations as an antioxidant. Solutions may become pink or brownish-pink if exposed to air, alkalies, or metals. Do not use solutions that are discolored or contain a precipitate. If isoproterenol is mixed with other drugs or fluids that result in a solution with a pH greater than 6, it is recommended that it be used immediately.

**Compatibility/Compounding Considerations**
Isoproterenol for injection is reported to be physically compatible with all commonly used IV solutions (except 5% sodium bicarbonate), and the following drugs:
calcium chloride/glucose, cephalothin sodium, cimetidine HCl, dobutamine HCl, heparin sodium, magnesium sulfate, multivitamin infusion, netilmicin sulfate, oxytetracycline HCl, potassium chloride, succinylcholine chloride, tetracycline HCl, verapamil HCl, and vitamin B complex with C.

It is reported to be physically incompatible when mixed with: aminophylline or sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Isoproterenol HCl for Injection: 1:5000 solution (0.2 mg/mL) 5 mL & 10 mL vials; generic; (Rx)

**References**

**ISOSORBIDE DINITRATE**
**ISOSORBIDE MONONITRATE**

(eye-so-er-bide) Isordil®, Ismo®, Imdur®

**VASODILATOR**

**Prescriber Highlights**
- Limited clinical experience; but may have some utility in small animal medicine for adjunctive treatment of heart failure

**Uses/Indications**
Isosorbide mononitrate (ISMN) and dinitrate (ISDN) are organic nitrates potentially useful as preload reducing agents in treating heart failure in small animals, however, research and clinical experience demonstrating clinical efficacy are lacking in dogs or cats. Limited research indicates that dogs may require much higher dosages of isosorbide to achieve therapeutic effects than do humans.

In humans, isosorbide nitrates are used for treating or preventing angina, treating esophageal spasm, and as an adjunctive treatment in CHF.

**Pharmacology/Actions**
Monitoring

Organic nitrates (e.g., isosorbide nitrates, nitroglycerin) share a similar pharmacologic profile. They relax vascular smooth muscle causing vasodilation, predominantly on the venous side, but somewhat on arteries/arterioles as well. The mechanism of action is related to their conversion to free radical nitric oxide. Nitric acid is thought to activate guanylate cyclase, thus increasing cyclic GMP and eventually leading to dephosphorylation of light chain myosin, causing vasodilation. In humans, nitrates reduce myocardial oxygen demand, but the exact mechanism for this effect is not well understood. Nitrates functionally antagonize the effects of acetylcholine, norepinephrine and histamine. Additionally, nitrates relax all smooth muscle including biliary (including biliary ducts, sphincter of Oddi), bronchial, GI (including the esophagus), ureteral and uterine.

Serum concentrations of isosorbide mononitrate above 100 ng/mL minimum concentration of the drug are believed required for hemodynamic effects in dogs and humans. However, a study (Adin et al. 2001) in both normal dogs and those with CHF, demonstrated no hemodynamic effects (blood pressure, heart rate, PCV, thoracic blood volume percentage, abdominal blood volume percentage) at doses that yielded peak levels as high as 2,352 ± 701 ng/mL.

In a study (Nagasawa et al. 2003) performed in dogs with experimentally induced mitral regurgitation, oral dosages of a sustained-release isosorbide dinitrate product at 8 mg/kg and above resulted in significant decreases in preload and afterload with increased cardiac output. Effects were sustained for at least 10 hours after dosing.

Pharmacokinetics
In dogs, isosorbide mononitrate oral bioavailability is approximately 70% after oral administration. Oral doses with standard tablets above 2 mg/kg yield peak plasma levels above 100 ng/mL, which is believed to be the minimum concentration of the drug required for hemodynamic effects in dogs and humans. Elimination half-life in dogs with standard tablets is about 1.5 hours. Dogs (24–31kg BW) given 60 mg sustained-release tablets (Imdur®) had peak plasma levels of approximately 550 ng/mL 3 hours after dosing. No pharmacokinetic information was located for cats.

Limited information on isosorbide dinitrate pharmacokinetics in small animals is available; it is reported that pharmacokinetics are similar in dogs and humans. In humans, both isosorbide dinitrate and mononitrate are well absorbed after oral administration. Food may delay the rate, but not the extent, of absorption. Isosorbide dinitrate undergoes extensive first-pass metabolism primarily to isosorbide mononitrate. Isosorbide mononitrate is metabolized primarily in the liver, but does not undergo first pass metabolism. Metabolites do not appear to have pharmacologic activity and are principally excreted in the urine.

Contraindications/Precautions/Warnings
Isosorbide nitrates should not be used in patients in shock or used alone in treating heart failure. Use with extreme caution in patients with low blood pressure or hypovolemia.

Adverse Effects
As there is limited experience in using these drugs in animals an adverse effect profile is not well known.

In humans, the most common adverse effects are headache and postural hypotension. Tachycardia, restlessness or gastrointestinal effects are not uncommon. There have been rare cases of patients who are hypersensitive to organic nitrates.

Reproductive/Nursing Safety
isosorbide nitrates are probably safe to use at therapeutic dosages during pregnancy. Dose-related increases in embryotoxicity occurred in rabbits given isosorbide dinitrate at 35–150X human dosages and there were some effects noted in rats (litter size, pup survival, prolonged gestation/parturition) given 125X doses of isosorbide mononitrate. Isosorbide mononitrate administered to rats and rabbits at 250 mg/kg/day (75X human dose) demonstrated no untoward effects. In humans, the FDA categorizes isosorbide nitrates as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown if isosorbide nitrates enter milk. Safe use during lactation cannot be guaranteed, but it is unlikely these drugs would pose significant risk to nursing offspring.

Overdosage/Acute Toxicity
isosorbide mononitrate caused significant lethality in rats and mice at dosages of 2000 mg/kg and 3000 mg/kg, respectively. The primary concerns with an overdosage of isosorbide nitrates would be venous pooling, decreased cardiac output, and hypotension. Treatment is basically supportive; drug therapies with agents such as epinephrine are not recommended. Increasing central fluid volume may be useful but in patients with CHF, must be used with extreme caution.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving isosorbide and may be of significance in veterinary patients:

- **ANTIHYPterensive Drugs:** Possible additive hypotensive effects
- **Phenothiazines:** Possible additive hypotensive effects
- **SelectivE Phosphodiesterase Inhibitors (E.g., Sildenafil):** Profound hypotension (use is contraindicated)

Laboratory Considerations

- **Serum cholesterol** levels may be falsely decreased by nitrates when using the Zlatkis-Zak color reaction method

Doses

- **DOGS/CATS:**
  a) Cats: For adjunctive treatment of heart failure associated with thyroid storm: Isosorbide dinitrate at 0.5–2 mg/kg PO q8–12h. Start at lowest level and titrate upward. (Ward 2006)
  b) Dogs/Cats: Efficacy is unknown, but isosorbide dinitrate at 0.5–2 mg/kg PO twice daily or isosorbide mononitrate at 0.25–2 mg/kg PO twice daily are occasionally used for refractory heart failure or in combination with hydralazine or amlodipine in patients unable to tolerate ACE inhibitors. It is unknown if nitrate-free periods are required to prevent nitrate tolerance. (Bulmer & Sisson 2005)

Monitoring

- **Clinical efficacy**
Client Information

- Inform clients of the limited experience in veterinary medicine with this medication
- May be given with or without meals

Chemistry/Synonyms

To minimize the risk for explosion, dry isosorbide dinitrate is mixed with lactose, mannitol or other inert excipients. To further stabilize the mixture, up to 1% ammonium phosphate or other suitable stabilizer can be used. The resultant dry mixture contains approximately 25% isosorbide dinitrate and is called diluted isosorbide dinitrate. It is an ivory-white, odorless powder that is very slightly soluble in water and sparingly soluble in alcohol.

Undiluted isosorbide mononitrate occurs as a white, crystalline powder that is freely soluble in water or alcohol. It is diluted with lactose or another suitable excipient to stabilize the powder and permit safe handling.

Isosorbide dinitrate may also be known as: ISD, ISDN, EV-151, or sorbide nitrate, Dilatrate-SR®, Isochron®, Isordil® and Titradose®; many international trade name products are available.

Isosorbide mononitrate may also be known as: AHR-4698, BM-22145, IS-5-MN, or isosorbide-5-mononitrate, lmndur®, Ismo®, and Monoket®; many international trade name products are available.

Storage/Stability

Isosorbide dinitrate oral tablets, chewable tablets, extended-release tablets, and sublingual tablets should be stored in well-closed containers, below 40°C and preferably between 15°–30°C. Heat and moisture accelerates loss of potency.

Isosorbide mononitrate tablets should be stored in tight containers, below 40°C and preferably between 15°–30°C. Isosorbide mononitrate extended-release tablets should be stored in tight containers, between 2°–30°C. Heat and moisture accelerates loss of potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

HUMAN-LABELED PRODUCTS:

Isosorbide Dinitrate Oral Tablets: 5 mg, 10 mg, 20 mg, 30 mg, & 40 mg; generic, Isordil Titradose® (Wyeth); (Rx)
Isosorbide Dinitrate Sublingual Oral Tablets: 2.5 mg, & 5 mg; generic; (Rx)
Isosorbide Dinitrate Extended-Release Oral Tablets: 40 mg; Isochron® (Forest), generic; (Corepharma); (Rx)
Isosorbide Mononitrate Tablets: 10 mg, & 20 mg; generic, Monoket® (Schwarz Pharma); (Rx)
Isosorbide Mononitrate Extended-Release Tablets: 30 mg, 60 mg, & 120 mg; generic, lmndur® (Key); (Rx)

References

ISOTRETINOIN
(eye-so-tret-i-noyn) Accutane®

RETINOID

Prescriber Highlights

- Synthetic retinoid that may be useful in treatment a variety of dermatology diseases associated with epithelial cell proliferation & differentiation
- Cautions (risk vs. benefit): Serum hypertriglyceridemia, hypersensitivity to drug; known teratogen
- Adverse Effects: Most common adverse effect seen in dogs is keratoconjunctivitis sicca (KCS); apparently not a problem in cats. Other potential adverse effects in small animals include: GI effects (anorexia, vomiting, abdominal distention), CNS effects (lassitude, hyperactivity, collapse), pruritus, erythema of feet & mucocutaneous junctions, polydipsia, swollen tongue
- Obtaining the medication for veterinary patients may be difficult
- Pregnant women should avoid contact with medication

Uses/Indications

Isotretinoin may be useful in treating a variety of dermatologic-related conditions, including canine lamellar ichthyosis, cutaneous T-cell lymphoma, intracutaneous cornifying epitheliomas, multiple epidermal inclusion cysts, comedo syndrome in Schnauzers, and sebaceous adenitis seen in standard poodles.

Because of the concerns of teratogenic effects in humans, availability to veterinarians may be restricted by the manufacturers and drug distributors; obtaining the medication for veterinary patients may be difficult.

Pharmacology/Actions
Pharmacology/Actions
A retinoid, isotretinoin’s major pharmacologic effects appear to be regulation of epithelial cell proliferation and differentiation. It affects monocyte and lymphocyte function, which can cause changes in cellular immune responses. The effects on skin include reduction of sebaceous gland size and activity, thereby reducing sebum production. It also has anti-keratinization and antiinflammatory activity and may indirectly reduce bacterial populations in sebaceous pores.

Pharmacokinetics
Isotretinoin is rapidly absorbed from the gut once the capsule disintegrates and the drug is dispersed in the GI contents. This may require up to 2 hours after dosing. Animal studies have shown that only about 25% of a dose reaches the systemic circulation, but food or milk in the gut may increase this amount. Isotretinoin is distributed into many tissues, but is not stored in the liver (unlike vitamin A). It crosses the placenta and is highly bound to plasma proteins. It is unknown if it enters milk. Isotretinoin is metabolized in the liver and is excreted in the urine and feces. In humans, terminal half-life is about 10–20 hours.

Contraindications/Precautions/Warnings
Isotretinoin should only be used when the potential benefits outweigh the risks when the following conditions exist: hypertriglyceridemia, severe renal or hepatic disease, or sensitivity to isotretinoin.

Isotretinoin is a known teratogen. Major anomalies have been reported in children of women taking the medication and it is not advised to use the medication in households where pregnant women are present.

Adverse Effects
There appears to be a low incidence of adverse effects, particularly in dogs. The most common adverse effect seen in dogs is keratoconjunctivitis sicca (KCS). This apparently is not a problem in cats. Other potential adverse effects include: GI effects (anorexia, vomiting, diarrhea, abdominal distention), CNS effects (lassitude, hyperactivity, behavioral changes, collapse), stiffness of limbs, puritus, exfoliative dermatitis, erythema of feet and mucocutaneous junctions/cheilitis, polydipsia, and swollen tongue.

Incidence of adverse effects may be higher in cats. Effects reported include: blepharospasm, periocular crusting, erythema, diarrhea and, especially, weight loss secondary to anorexia. If cats develop adverse effects, the time between doses may be prolonged (e.g., every other week give every other day) to reduce the total dose given.

Reproductive/Nursing Safety
Isotretinoin is a known teratogen. Major anomalies have been reported in children of women taking the medication. It is absolutely contraindicated in pregnant veterinary patients as well. Isotretinoin also appears to inhibit spermatogenesis. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

It is not known whether this drug is excreted in breast milk. At this time, it is not recommended for use in nursing mothers.

Overdosage/Acute Toxicity
There were 147 exposures to isotretinoin reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 140 were dogs with 5 showing clinical signs and the remaining 7 reported cases were cats showing no clinical signs. Common findings in dogs included hypersalivation. Because of the drug’s potential adverse effects, gut emptying should be considered with acute overdoses when warranted.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving isotretinoin and may be of significance in veterinary patients:

- **VITAMIN A or OTHER RETINOIDS:** Isotretinoin used with other retinoids (etretinate, tretinoin, or vitamin A) may cause additive toxic effects.
- **CYCLOSPORINE:** Isotretinoin may increase cyclosporine levels
- **TETRACYCLINES:** Use with tetracyclines may increase the potential for the occurrence of pseudotumor cerebri (cerebral edema and increased CSF pressure).

Laboratory Considerations
- Increases in serum triglyceride and cholesterol levels may be noted which can be associated with corneal lipid deposits
- Platelets may be increased
- ALT (SGOT), AST (SGPT), and LDH levels may be increased

Doses

- **DOGS:**
  a) For sebaceous adenitis when more conservative treatments have failed: 1 mg/kg PO q12h for one month; if improvement is noted reduce dose to 1 mg/kg PO once daily; long-term goal is to treat with either 1 mg/kg PO every other day or 0.5 mg/kg once daily (Rosser 1992)
  b) For sebaceous adenitis: 1–3 mg/kg PO once a day to twice daily (Bloom 2006)
  c) For treatment of Schnauzer comedo syndrome: 1 mg/kg once daily or divided q12h PO;
  d) For sebaceous adenitis in poodles; granulomatous sebaceous adenitis in viszlas: 1–2 mg/kg once daily or divided q12h PO;
  e) For epidermolysis bullosa, cutaneous lymphoma, cutaneous lymphoma: 2 mg/kg once daily or divided q12h PO (Power & Ihrke 1995)
  f) For Schnauzer comedo syndrome, sebaceous adenitis in poodles, ichthyosis, keratoconjunctivitis, epidermolysis bullosa, and sebaceous gland hyperplasia and adenoma: 1–3 mg/kg q12–24h PO (Kwochka 2003)
  e) For cutaneous lymphosarcoma: Isotretinoin at 3–4 mg/kg PO daily. Prednisone (1 mg/kg/day) may be useful to alleviate pruritus. Lomustine at 50 mg/m2 q21–30 days may be effective (see lomustine monograph for more information) (White 2005)

- **CATS:**
  a) 5 mg/kg PO once daily (Hall & Campbell 1994)
a) 5 mg/kg PO once daily (Hall & Campbell 1994)
b) 10 mg per cat once daily PO (Power & Ihrke 1995)
c) 1–3 mg/kg q12–24h PO (Kwochka 2003)

For epitheliotrophic lymphoma, cutaneus lymphoma:
a) 10 mg/cat once daily PO (Power & Ihrke 1995)

Monitoring
See Lab Considerations and Adverse Effects.

Efficacy
- Liver function tests (baseline and if signs appear)
- Dogs: Schirmer Tear tests (monthly—especially in older dogs)
- Cats: Weight

Client Information
- Isotretinoin should not be handled by pregnant females and use in households with pregnant women present is ill advised. Veterinarians must take the personal responsibility to educate clients of the potential risk of ingestion by pregnant females.
- Milk or high fat foods will increase the absorption of isotretinoin. To reduce variability of absorption, either have clients consistently give with meals or not.
- Avoid prolonged or excessive exposure to sunlight as UV light effects can be enhanced.
- Long-term therapy can be quite expensive.

Chemistry/Synonyms
A synthetic retinoid, isotretinoin occurs as a yellow-orange to orange, crystalline powder. It is insoluble in both water and alcohol. Commercially, it is available in soft gelatin capsules as a suspension in soybean oil.

Isotretinoin may also be known as: isotretinoinum, 13-cis-retinoic acid, Ro-4-3780, Accurate®, Accutane®, Accutin®, Amnesteem®, Claravis®, Curatane®, Isocane®, Isohexal®, Isotrex®, Liderma®, Nimegen®, Oratane®, Procuta®, Roaccutan®, Roacutane®, Sotret®, Stiefotrex®, and Tretin®.

Storage/Stability
Capsules should be stored at room temperature in tight, light resistant containers. The drug is photosensitive and will degrade with light exposure. Expiration dates of 2 years are assigned after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
- Isotretinoin Oral Capsules: 10 mg, 20 mg, 30 mg & 40 mg (regular & soft gel); Claravis® (Teva); Amnesteem® (Mylan); Sotret® (Ranbaxy); (Rx)

Note: Because of the concerns of teratogenic effects in humans, availability to veterinarians may be restricted by the manufacturers and drug distributors; obtaining the medication for veterinary patients may be difficult.

References

ISOXSUPRINE HCL
(eye-ox-suh-prine) Vasodilan®

Prescriber Highlights

- Peripheral vasodilator that may have some efficacy in treatment of navicular disease in horses; efficacy in doubt when used orally
- May be beneficial for Raynaud’s-like syndrome in dogs
- Contraindications: Immediately post-partum or in the presence of arterial bleeding
- Adverse Effects: After injection, CNS stimulation (uneasiness, hyperexcitability, nose-rubbing) or sweating. Adverse effects are unlikely after oral administration.

Uses/Indications
Isoxsuprline is used in veterinary medicine principally for the treatment of navicular disease in horses; however, recent studies have shown disappointing efficacy when used orally. It has been used in humans for the treatment of cerebral vascular insufficiency, dysmenorrhea, and premature labor, but efficacies are unproven for these indications.

There have been anecdotal reports of isoxsuprine being helpful for treating dogs with a Raynaud’s-like syndrome (periodic digital cyanosis, onychogryphosis) (Carlotti 2002) and to improve microcirculation in birds.
Pharmacology/Actions
Isoxsuprine causes direct vascular smooth muscle relaxation primarily in skeletal muscle. While it stimulates beta-adrenergic receptors it is believed that this action is not required for vasodilation to occur. In horses with navicular disease, isoxsuprine will raise distal limb temperatures significantly. Isoxsuprine will relax uterine smooth muscle and may have positive inotropic and chronotropic effects on the heart. At high doses, isoxsuprine can decrease blood viscosity and reduce platelet aggregation. Isoxsuprine does not appear to possess significant analgesia properties in horses (Lizarraga et al. 2004).

Pharmacokinetics
In humans, isoxsuprine is almost completely absorbed from the GI tract, but in one study that looked at the cardiovascular and pharmacokinetic effects of isoxsuprine in horses (Matthews 1986), bioavailability was low after oral administration, probably due to a high first-pass effect. After oral dosing of 0.6 mg/kg, the drug was non-detectable in plasma and no cardiac changes were detected. This study did not evaluate cardiovascular effects in horses with navicular disease, nor did it attempt to measure changes in distal limb blood flow. After IV administration in horses, the elimination half-life is between 2.5–3 hours.

Contraindications/Precautions/Warnings
Isoxsuprine should not be administered to animals immediately post-partum or in the presence of arterial bleeding.

Adverse Effects
After parenteral administration, horses may show signs of CNS stimulation (uneasiness, hyperexcitability, nose-rubbing) or sweating. Adverse effects are unlikely after oral administration, but hypotension, tachycardia, and GI effects are possible.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

No specific lactation safety information was found.

Overdosage/Acute Toxicity
Serious toxicity is unlikely in horses after an inadvertent oral overdose, but signs listed in the Adverse Effects section could be seen. Treat signs if necessary. CNS hyperexcitability could be treated with diazepam, and hypotension with fluids.

Drug Interactions
No clinically significant drug interactions have been reported for this agent.

Laboratory Considerations
■ None were noted

Doses
■ HORSES: (Note: ARCI UCGFS Class 4 Drug)
For treatment of orthopedic conditions, such as navicular disease:
  a) For long break-over if therapeutic shoeing does not correct: Initially, 1.2 mg/kg PO q8h for 3 weeks. The dose is decreased as soundness improves, to 1.2 mg/kg PO once daily for 6 weeks, then every other day until heel first landing occurs. Phenylbutazone is added if lameness is greater than grade II on a scale of I–V, or until recheck occurs.
  To increase the circulation to the podotrochlea: 0.6–1.2 mg/kg twice daily until sound, then decreased to once daily for 2 weeks then further decreased to every other day. The drug is classified as a “blocking” agent by the AHSA. (Turner 1999)
  b) 0.6–2 mg/kg PO q12h (Brumbaugh et al. 1999)
   As a tocolytic agent:
  a) 0.4–0.6 mg/kg IM or PO twice daily. Efficacy is unproven and oral bioavailability appears highly variable. (Wilkins 2004)

■ DOGS:
For treatment of “Raynaud-like” disease:
  a) 1 mg/kg/day PO (Carlotti 2002),

Monitoring
■ Clinical efficacy
■ Adverse effects (tachycardia, GI disturbances, CNS stimulation)

Client Information
■ To be maximally effective, doses must be given routinely as directed.
■ Tablets may be crushed and made into a slurry, suspension, or paste by adding corn syrup, cherry syrup, etc., just before administration.

Chemistry/Synonyms
A peripheral vasodilating agent, isoxsuprine occurs as an odorless, bitter-tasting, white, crystalline powder with a melting point of about 200°C. It is slightly soluble in water and sparingly soluble in alcohol.

Isoxsuprine HCl may also be known as: Caa-40, isoxsuprini hydrochloridum, phenoxyisopropynorsuprifen, Dilum®, Duvadilan®, Fadaespasmol®, Fenam®, Inibina®, Isodilan®, Isoten®, Uterine®, Vadosilan®, Vasodilan®, Vasolan®, Vadosuprina Ilfi®, Voxsuprine®, and Xuprin®.

Storage/Stability
Tablets should be stored in tight containers at room temperature (15–30°C).
Itraconazole should not be used in patients hypersensitive to it or other azole antifungal agents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Isoxsuprine HCI Tablets: 10 mg & 20 mg; Vasodilan® (Mead Johnson); Voxsuprine® (Major); generic; (Rx)

References

VET-LABELED PRODUCTS:

Tablets should be stored in tight containers at room temperature (15–30°C).

Itraconazole is metabolized by the liver to many different metabolites, including to hydroxyitraconazole, which is active. In humans, itraconazole's serum half-life ranges from 21–64 hours. Elimination may be a saturable process. Because of its long half-life, itraconazole does not reach steady state plasma levels for at least 6 days after starting therapy. If loading doses are given, levels will approach those of steady-state sooner.

Itraconazole absorption is highly dependent on gastric pH and presence of food. When given on an empty stomach, bioavailability may only be 50% or less; with food, it may approach 100%. In cats, the oral solution is more bioavailable and probably has fewer GI effects. The commercially available capsules are specially formulated to increase oral bioavailability. Compounding capsules from bulk powders may not yield a dosage form that is absorbed. The commercially available liquid preparation possesses adequate oral bioavailability in dogs and other species. The oral solution appears to be much better absorbed than capsules in horses.

Itraconazole absorption is highly dependent on gastric pH and presence of food. When given on an empty stomach, bioavailability may only be 50% or less; with food, it may approach 100%. In cats, the oral solution is more bioavailable and probably has fewer GI effects. The commercially available capsules are specially formulated to increase oral bioavailability. Compounding capsules from bulk powders may not yield a dosage form that is absorbed. The commercially available liquid preparation possesses adequate oral bioavailability in dogs and other species. The oral solution appears to be much better absorbed than capsules in horses.

Itraconazole is metabolized by the liver to many different metabolites, including to hydroxyitraconazole, which is active. In humans, itraconazole’s serum half-life ranges from 21–64 hours. Elimination may be a saturable process. Because of its long half-life, itraconazole does not reach steady state plasma levels for at least 6 days after starting therapy. If loading doses are given, levels will approach those of steady-state sooner.

Contraindications/Precautions/Warnings

Itraconazole should not be used in patients hypersensitive to it or other azole antifungal agents.
Use itraconazole in patients with hepatic impairment or achlorhydria (or hypochlorhydria) only when the potential benefits outweigh the risks. Itraconazole may have a negative inotropic effect; use with caution in animals with reduced cardiac function.

African grey Parrots appear to be extremely sensitive to itraconazole and can develop anorexia and depression. Other antifungals or reduced dosage of itraconazole are recommended for use in this species.

Compounding capsules from bulk powders may not yield a dosage form that is absorbed.

### Adverse Effects

In dogs, anorexia is the most common adverse effect seen, especially at higher dosages, but hepatic toxicity appears to be the most significant adverse effect. Approximately 10% of dogs receiving 10 mg/kg/day and 5% of dogs receiving 5 mg/kg/day developed hepatic toxicosis serious enough to discontinue treatment (at least temporarily). Hepatic injury is determined by an increased ALT activity. Anorexia is often the symptomatic marker for toxicity and usually occurs in the second month of treatment. Some dogs (7%) given itraconazole at the higher dosage rate (10 mg/kg/day) may develop ulcerative skin lesions/vasculitis and limb edema that may require dosage reduction. These generally resolve following drug discontinuation. Rarely, serious erythema multiforme or toxic epidermal necrolysis reactions have been noted.

In cats, adverse effects appear to be dose related. GI effects (anorexia, weight loss, vomiting), hepatotoxicity (increased ALT, jaundice) and depression have been noted. Should adverse effects occur and ALT is elevated, the drug should be discontinued. Increased liver enzymes in the absence of other signs do not necessarily mandate dosage reduction or drug discontinuation. Once ALT levels return to normal and other adverse effects have diminished, if necessary, the drug may be restarted at a lower dosage or use longer dosing intervals with intense monitoring.

### Reproductive/Nursing Safety

In laboratory animals, itraconazole has caused dose-related maternotoxicity, fetotoxicity and teratogenicity at high dosages (5–20 times labeled). As safety has not been established, use only when the benefits outweigh the potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Itraconazole enters maternal milk; significance is unknown.

### Overdosage/Acute Toxicity

There is very limited information on the acute toxicity of itraconazole. Giving oral antacids may help reduce absorption. If a large overdose occurs, consider gut emptying and give supportive therapy as required. Itraconazole is not removed by dialysis.

In chronic toxicity studies, dogs receiving 40 mg/kg PO daily for 3 months demonstrated no overt toxicity.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving itraconazole and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Lab animal studies have shown that itraconazole used concomitantly with amphotericin B may be antagonistic against Aspergillus or Candida; the clinical importance of these findings is not yet clear.

- **ANTACIDS**: May reduce oral absorption of itraconazole; administer itraconazole at least 1 hour before or 2 hours after antacids.

- **BENZODIAZEPINES** (alprazolam, diazepam, midazolam, triazolam): Itraconazole may increase levels.

- **BUSPIRONE**: Plasma concentrations may be elevated.

- **BUSULFAN**: Itraconazole may increase levels.

- **CALCIUM-CHANNEL BLOCKING AGENTS** (amlodipine, verapamil): Itraconazole may increase levels.

- **CISAPRIDE**: Itraconazole may increased cisapride levels and possibility for toxicity; use together contraindicated in humans.

- **CLOMIPRAMINE**: Itraconazole may decrease metabolism and increase clomipramine levels.

- **CORTICOSTEROIDS**: Itraconazole may inhibit the metabolism of corticosteroids; potential for increased adverse effects.

- **CYCLOPHOSPHAMIDE**: Itraconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity.

- **CYCLOSPORINE**: Increased cyclosporine levels.

- **DIGOXIN**: Itraconazole may increase digoxin levels; use together considered contraindicated in humans.

- **FENTANYL/ALFENTANIL**: Itraconazole may increase fentanyl or alfentanil levels.

- **H2-BLOCKERS** (ranitidine, famotidine, etc.): Increased gastric pH may reduce itraconazole absorption.

- **IVERMECTIN**: Itraconazole may increase risk for neurotoxicity.

- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May increase itraconazole concentrations.

- **PHENOBARBITAL/PHENYTOIN**: May decrease itraconazole levels.

- **PROTON-PUMP INHIBITORS** (omeprazole, etc.): Increased gastric pH may reduce itraconazole absorption.

- **QUINIDINE**: Increased risk for quinidine toxicity.

- **RIFAMPIN**: May decrease itraconazole levels; itraconazole may increase rifampin levels.

- **SULFONYLUREA ANTIDIABETIC AGENTS** (e.g., glipizide, glyburide): Itraconazole may increase levels; hypoglycemia possible.

- **Vincristine/Vinblastine**: Itraconazole may inhibit vinca alkaloid metabolism and increase levels.

- **WARFARIN**: Itraconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants.

### Laboratory Considerations

- Itraconazole may cause hypokalemia or increases in liver function tests in a small percentage of patients.
Doses

**DOGS:**

For systemic mycoses:

a) For Malassezia dermatitis: 5 mg/kg PO once daily for 3 weeks. (Fair evidence supports recommendation) (Negre et al. 2009)
b) Pulse therapy for Malassezia dermatitis: 5 mg/kg for 2 consecutive days per week for 3 weeks (Foil 2003a)
c) For dermatophytosis: 5 mg/kg PO once daily. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)
d) For dermatophytosis: 5 mg/kg PO once daily on an every other week schedule. Treatment is generally continued for three “pulses” of one week on, one week off. Toxicity problems are rare with this protocol. (DeBoer 2006)
e) For Blastomycesis: 5 mg/kg PO once daily for at least 30 days after all signs of disease have resolved (treatment must persist for at least 60–90 days). Give with food. (Davidson & Mathews 2000)
f) For Histoplasmosis: 10 mg/kg daily PO; given with food; if dog has intestinal histoplasmosis, treat with amphotericin B (0.5 mg/kg IV over 3–4 hours in D5W every other day) initially. Usually after six doses of amphotericin B, may switch to itraconazole. Total treatment times (amphotericin B and itraconazole) should be for at least 30 days after all signs of disease have resolved (treatment must persist for at least 90 days). (Legendre & Toal 2000)
g) For Blastomycesis: 5 mg/kg PO once a day or divided twice a day. Continue for 2–3 months or until active disease is not apparent. A loading dose of 10 mg/kg PO once a day (or divided twice a day) for the first three days may reduce the “lag” phase of effectiveness.

For coccidiomycosis: 5–10 mg/kg PO once daily; may need to treat for 6–12 months (Taboada 2000)
h) For sporotrichosis: 5–10 mg/kg PO once daily for 30 days beyond complete resolution of detectable lesions.

For pythiosis or legionellosis (after lesion resection): 10 mg/kg PO once daily (with terbinafine at 5–10 mg/kg PO q24h) for at least 2 months after surgery.

For zygomycosis (after aggressive surgical resection): 5–10 mg/kg PO q24h. For non-resectable lesions, either itraconazole for 3–6 months or amphotericin B lipid complex. Recurrence is possible with either surgical or medical therapy. (Grooters 2005)
i) For idiopathic lymphoplasmacytic (chronic) rhinitis (LPR): 5 mg/kg PO q12h for a minimum of 3-6 months has shown dramatic beneficial improvement in some dogs.

For nasal aspergillosis: 5 mg/kg PO q12h for 3-6 months may cure up to 60–70% of dogs with aspergillosis, although some studies have shown only marginal efficacy. (Kuehn 2010)

j) For coccidioidomycosis: 5–10 mg/kg PO q24h or 5 mg/kg PO q12h. (Graupmann-Kuzma et al. 2008)

**CATS:**

For susceptible systemic mycoses:

a) For Histoplasmosis: 10 mg/kg daily PO; given with food
For Cryptococcosis: 50–100 mg per cat per day PO for many months. Mean treatment time is 8.5 months. If response inadequate, may add flucytosine (at 100–125 mg/kg divided into three doses per day). (Legendre & Toal 2000)
b) For Blastomycosis: 10 mg/kg PO once a day or divided twice a day. Continue for 2–3 months or until active disease is not apparent (Note: cats usually require longer treatment than dogs)

For Histoplasmosis: 10 mg/kg once daily or divided twice daily PO; at least 2–4 months of treatment required
For coccidiomycosis: 5–10 mg/kg PO once daily; may need to treat for 6–12 months (Taboada 2000)
c) For sporotrichosis: 5–10 mg/kg once daily for 30 days beyond complete resolution of detectable lesions. (Grooters 2005)
d) For Cryptococcosis: For mild to moderate disease where cats are eating and do not have CNS involvement: Cats weighing 3.5 kg or less receive 50 mg PO once daily or 100 mg PO every other day; medium to large cats get 100 mg PO once daily. Give with food; may be mixed with tasty food treat. Monitor ALT; itraconazole hepatotoxicity is reversible upon discontinuation of the drug and it can usually be restarted safely at 50% of the original dose. Continue treatment until cat appears completely normal; generally takes 3–12 months. Then obtain serum sample to determine decline in antigen titer. A 4–5 fold reduction suggests successful therapy. Then restart therapy (possibly at a reduced dose) or change to ketoconazole (50 mg/day) until antigen level declines to zero. (Malik 2006)
e) For coccidioidomycosis: 25–50 mg (total dose) per cat q12-24h (Note: reference lists dosing frequency as q12-14h, but it is believed that this is a typo—Plumb). (Graupmann-Kuzma et al. 2008)

For generalized dermatophytosis:

a) Caused by *Microsporum canis*: 5 mg/kg PO once daily preferably between meals for 7 days on, 7 days off; repeat 3 times. Cats must be treated during weeks 1, 3 and 5 left untreated during weeks 2 and 4. In cases where a positive culture is obtained 4 weeks after the end of administration, the treatment should be repeated once at the same dosage regimen. In such cases where the cat is also immunosuppressed, treatment should be repeated and the underlying disease addressed. (Label Information—Intrafungol®; Janssen. U.K.)
b) 5 mg/kg PO twice daily or 10 mg/kg with food. Give until culture is negative 2 times at two week intervals; generally 3–5 weeks. Open capsule and measure out calculated portion; give in butter or adlib. Can be stored in the freezer.
Pulse therapy: 5 mg/kg PO for 2 consecutive days per week, increasing interval gradually is useful in the management of dermatophytosis in longhaired cats and in cats in a heavily contaminated environment.

For dermatophyte granuloma (TOC): 10 mg/kg PO once daily for weeks to months, at least one month beyond clinical resolution and until brush culture is negative x 2. (Foil 2003b)

c) For dermatophytosis: 5 mg/kg PO once daily on an every other week schedule. Treatment is generally continued for three “pulses” of one week on, one week off. Toxicity problems are rare with this protocol. (DeBoer 2006)

**RABBITS, RODENTS, SMALL MAMMALS:**

a) **Mice:** For blastomycosis: 50–150 mg/kg q24h; **Rats:** For vaginal candidiasis: 2.5–10 mg/kg q24h; **Guinea pigs:** 5 mg/kg q24h for systemic candidiasis (Adamcak & Otten 2000)
a) For guttural pouch mycosis, mycotic rhinitis or osteomyelitis: Using the oral solution at 5 mg/kg PO q24h should be sufficient for treatment. (Davis 2007)

**BIRDS:**

b) Ratties: 6–10 mg/kg PO once daily; if neuro signs develop reduce dose or discontinue (Jenson 1998)

c) For aspergillosis: 5–10 mg/kg PO once daily in Amazon parrots; 2.5–5 mg/kg PO once daily in African grey parrots. (Oglesbee 2009)

**Monitoring**

- Clinical Efficacy
- With long-term therapy, routine liver function tests are recommended (monthly ALT)
- Appetite
- Physical assessment for ulcerative skin lesions in dogs

**Client Information**

- Compliance with treatment recommendations must be stressed
- Have clients report any potential adverse effects
- Give capsules with food. Preferably, give oral solution on an empty stomach in mammals.
- For cats and small dogs, capsules can be opened and the appropriate dose measured proportionally. Pellets from within the capsule can be added to a food the animal will readily eat (cheese, butter, etc.).
- Do not give with any other medications without veterinarian’s approval

**Chemistry/Synonyms**

Itraconazole may also be known as: itraconazolum, oriconazole, R-51211, or Sporanox®; many other trade names are available.

**Storage/stability**

Itraconazole capsules should be stored between 15–25°C and protected from light and moisture.

**Compatibility/Compounding Considerations**

Compounding capsules or solutions from bulk chemicals or powders likely will not yield dosage forms that are absorbed. The oral bioavailability and solubility of itraconazole is dependent upon complexation with cyclodextran molecules, a technology used in the brand (Sporanox®) and generic commercially produced human drug products for itraconazole, but not in compounded dosage forms. A recent study (Smith et al. 2010) demonstrated that itraconazole compounded from the bulk chemical produces inferior blood levels in Black-footed penguins compared to FDA-approved itraconazole products. Inferior blood levels of itraconazole may contribute to treatment failure and fatality if compounded itraconazole is utilized in life-threatening infections such as blastomycosis or pythiosis. Unless itraconazole dosage forms are formulated from FDA-approved dosage forms, it is recommended **not to use compounded** itraconazole products unless prepared from commercial capsules or documented bioavailability and stability data are provided.

**Compounded preparation stability:** Two methods of preparing a stable (not necessarily bioavailable) itraconazole oral suspension prepared from commercially available capsules have been published. 1) Triturating twenty-four (24) itraconazole 100 mg capsules with 5 mL ethanol 95%, allowing to stand 3–4 minutes, grinding to paste and then bringing to a final volume of 60 mL with simple syrup yields a 40 mg/mL oral suspension that retains >95% potency for 35 days stored at 4°C and protected from light (Jacobson et al. 1995). 2) Triturating forty (40) itraconazole 100 mg capsules with 15 mL of ethanol 95%, allowing to stand 3–4 minutes, grinding to paste, adding 100 mL of Ora-Plus® and bringing to volume of 200 mL Ora-Sweet® yields a 20 mg/mL itraconazole suspension (Abdel-Rahmen & Nahata 1998). Solutions of itraconazole have a pH of 2.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None in the USA.

In several countries, itraconazole oral liquid 10 mg/mL in 52 mL bottles with dosing syringe; *Intrafungol*® (Janssen); (Rx). Labeled for use in cats (in the UK).

**HUMAN-LABELLED PRODUCTS:**

Itraconazole Capsules: 100 mg; *Sporanox*® (Janssen); (Rx)

Itraconazole Oral Solution: 10 mg/mL in 150 mL; *Sporanox*® (Ortho Biotech); (Rx)

IVERMECTIN
(eye-ver-mek-tin) Heartgard®, Ivomec®
ANTIPARASITIC

Prescriber Highlights

- Prototype avermectin drug used in variety of species as an antiparasiticide
- Contraindications: Label specific due to lack of safety data (foals, puppies, etc.) or public health safety (lactating dairy animals)
- Caution in breeds susceptible to ABCB1-1Δ (formerly MDR1-allele) mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, “white feet”); at higher risk for CNS toxicity
- Adverse Effects: Horses: Swelling & pruritus at the ventral mid-line can be seen approximately 24 hours after ivermectin administration due to a hypersensitivity reaction to dead *Onchocerca* spp. microfilaria. Dogs: May exhibit a shock-like reaction when ivermectin is used as a microfilaricide, presumably due to a reaction associated with the dying microfilaria. Cattle: Ivermectin can induce serious adverse effects by killing the larva when they are in vital areas; may also cause discomfort or transient swelling at the injection site. Mice & rats: May cause neurologic toxicity at doses slightly more than usually prescribed. Birds: Death, lethargy, or anorexia may be seen. Orange-cheeked Waxbill Finches & budgerigars may be more sensitive to ivermectin than other species.

Uses/Indications

Ivermectin is FDA-approved in horses for the control of: large strongyles (adult) (*Strongylus vulgaris, S. edentatus, S. equinus, Triodontophorus* spp.), small strongyles, pinworms (adults and 4th stage larva), ascarids (adults), hairworms (adults), large-mouth stomach worms (adults), neck threadworms (microfilaria), bots (oral and gastric stages), lungworms (adults and 4th stage larva), intestinal threadworms (adults), and summer sores (cutaneous 3rd stage larva) secondary to *Hebronema* or *Draschia* spp.

In cattle, ivermectin is FDA-approved for use in the control of gastrointestinal roundworms (adults and 4th stage larva), lungworms (adults and 4th stage larva), cattle grubs (parasitic stages), sucking lice, and mites (scabies). For a listing of individual species covered, refer to the product information.

In swine, ivermectin is FDA-approved for use to treat GI roundworms, lungworms, lice, and mange mites. For a listing of individual species covered, refer to the product information.

In reindeer, ivermectin is FDA-approved for use in the control of warbles.

In American Bison, ivermectin is FDA-approved for use in the control of grubs.

In dogs and cats, ivermectin is FDA-approved only for use as a preventative for heartworm. It has also been used as a microfilaricide, slow-kill adulticide, ectoparasiticide, and endoparasiticide. At the time of writing (2010) there is considerable interest in using ivermectin or another macrocyclic lactone with doxycycline for several months prior to melarsomine adulticide therapy in dogs. Ivermectin can kill *D. immitis* larval stages 3 & 4, kill microfilaria, and reduce the lifespan of adult heartworms. Doxycycline treatment can potentially reduce adult worm populations by eliminating *Wolbachia*, a bacterium associated with *D. immitis*. The American Heartworm Society has stated; “… it is beneficial to administer a macrocyclic lactone for up to three months prior to administration of melarsomine, when the clinical presentation does not demand immediate intervention” and “Doxycycline administered at 10 mg/kg twice daily for four weeks has been shown to eliminate over 90% of the *Wolbachia* organisms and the levels remain low for three to four months.” (American-Heartworm-Society 2010)

Pharmacology/Actions

Ivermectin enhances the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, ivermectin causes paralysis of the parasite and eventual death. As liver flukes and tapeworms do not use GABA as a peripheral nerve transmitter, ivermectin is ineffective against these parasites.

Pharmacokinetics

In simple-stomached animals, ivermectin is up to 95% absorbed after oral administration. Ruminants only absorb ¼–⅓ of a dose due to inactivation of the drug in the rumen. While there is greater bioavailability after SC administration, absorption after oral dosing is more rapid than SC. It has been reported that ivermectin’s bioavailability is lower in cats than in dogs, necessitating a higher dosage for prophylaxis of heartworm in this species.

Ivermectin is well distributed to most tissues, but does not readily penetrate into the CSF, thereby minimizing its toxicity. Collie-breed dogs with a specific gene defect allow more ivermectin into the CNS than other breeds/species.

Ivermectin has a long terminal half-life in most species (see below). It is metabolized in the liver via oxidative pathways and is primarily excreted in the feces. Less than 5% of the drug (as parent compound or metabolites) is excreted in the urine.

Pharmacokinetic parameters of ivermectin have been reported for various species:

- **Cattle**: Volume of distribution = 0.45–2.4 L/kg; elimination half-life = 2–3 days; total body clearance = 0.79 L/kg/day.
- **Dogs**: Bioavailability = 0.95; volume of distribution = 2.4 L/kg; elimination half-life = 2 days.
- **Swine**: Volume of distribution = 4 L/kg; elimination half-life = 0.5 days.
- **Sheep**: Bioavailability = 1 (intra-abomasal), 0.25 (intra-ruminal); volume of distribution = 4.6 L/kg; elimination half-life = 2–7 days.

Contraindications/Precautions/Warnings

The manufacturer recommends that ivermectin not be used in foals less than 4 months old, as safety of the drug in animals this young has not been firmly established. However, foals less than 30 days of age have tolerated doses as high as 1 mg/kg without signs of toxicity.

Ivermectin is not recommended for use in puppies less than 6 weeks old. After receiving heartworm prophylaxis doses, the manufacturer recommends observing Collie-type breeds for at least 8 hours after administration. Most clinicians feel that ivermectin should not be used in breeds susceptible (Collies, Shelties, Australian shepherds, etc.) to the ABCB1-1Δ (formerly MDR1-allele) mutation at the doses specified for treating microfilaria or other parasites unless the patient has been tested...
Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ivermectin and may be of significance in veterinary patients:
**BENZODIAZEPINES:** Effects may be potentiated by ivermectin; use together not advised in humans.

**KETAMINE:** It has been recommended not to use ivermectin in reptiles within 10 days of ketamine (Bays 2009).

**SPINOSAD** (Comfortis®): It has been recommended not to use with the high extra-label doses of ivermectin (Kuhl 2009).

Caution is advised if using other drugs that can inhibit **p-glycoprotein**. Those dogs at risk for **ABCB1-1Δ** (formerly **MDR1** allele) mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc., “white feet”) should probably not receive ivermectin with the following drugs, unless tested “normal” at least one reference states that ivermectin should never be used with ketoconazole in dogs (Waisglass 2009). Drugs and drug classes involved include:

- **AMIODARONE**
- **CARVEDILOL**
- **CLARITHROMYCIN**
- **CYCLOSPORINE**
- **DILTIAZEM**
- **ERYTHROMYCIN**
- **ITRACONAZOLE**
- **KETOCONAZOLE**
- **QUINIDINE**
- **SPIRONOLACTONE**
- **TAMOXIFEN**
- **VERAPAMIL**

**Laboratory Considerations**

When used at microfilaricide dosages, ivermectin may yield false-negative results in animals with occult heartworm infection.

**Doses**

**DOGS:**

**Note:** When used for prophylaxis or treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information.

As a preventative for heartworm:

- a) 6–12 micrograms/kg PO once monthly (Knight 2000)
- b) Minimum dosage of 6 micrograms/kg (0.006 mg/kg) PO per month. (Package insert; Heartgard30®—Merial)

As a microfilaricide:

- a) When used to kill third, fourth, and young fifth stage larvae for prophylaxis or to kill these larval stages prior to adulticide therapy along with microfilariae, ivermectin is dosed at 6–12 micro-grams/kg PO once a month. When only used to kill circulating microfilariae, ivermectin can be administered at 6 micrograms/kg (the FDA-approved prophylactic dose) or at a dose of 50 micrograms/kg (approximately 10 times the prophylactic dose). Microfilariae numbers decrease gradually to, or close to, zero within several months at the lower dose. The chance of adverse reactions with this approach is minimal. The higher dose results in a rapid kill that is associated with more adverse effects. (Kittleson 2006)

As an adulticide or pre-adulticide for heartworm:

- a) In combination with doxycycline as an adulticide for *D. immitis*: In this study, doxycycline was administered at 10 mg/kg PO once daily for 30 days along with ivermectin/pyrantel pamoate with the ivermectin dose at 6–14 micrograms/kg PO once every 15 days for 6 months. 100% (total of 11 dogs) were negative for circulating microfilaria by day 90. 74% of dogs were negative for circulating antigens at day 300 (4-months post ivermectin). (Grandi et al. 2010)

- b) For generalized demodicosis: **Note:** Do not consider use in **ABCB1-1Δ** (formerly **MDR1-allele** mutation susceptible breeds unless tested “normal/normal” for mutation (www.vetmed.wsu.edu). If normal/normal, drug reaction is very unlikely. Start at low dosage and increase:
  - Day 1: 100 micrograms/kg PO q24h,
  - Day 4: 200 micrograms/kg PO q24h,
  - Day 7: 300 micrograms/kg; continue to increase by 100 micro-grams/kg every 3rd day until reach target dose of 600 micrograms/kg PO daily and continue treatment 1–2 months after 2 negative skin scrapes. Treatment usually requires 10–33 weeks. (Hillier 2006)

- b) For demodectic: Start at a trial dose of 0.05 mg/kg (50 micrograms/kg) day 1. Then increase the dose to 0.12 mg/kg for the next week (this was the “test dose” that we used to use, as sensitive Collies generally react at this dose). If all is well, go up to 0.2 mg/kg for the next 3 days, and then increase the dose weekly by 0.1 mg/kg until you reach 0.6 mg/kg. Advise the owner to discontinue immediately if there is evidence of ivermectin toxicosis (especially lethargy, ataxia, mydriasis and gastrointestinal signs). If there is no reaction at a lower, but therapeutic, dose (above 0.3 mg/kg), author usually will try again at that lower dose but on an alternate day treatment schedule. Continue treatment for 2 months past negative scrapings (3-7 months of treatment). (Waisglass 2009)

- c) As scabicide: 300–400 micrograms/kg PO or SC once weekly for weeks. If using the 1% injection, 1 mL = 10,000 micrograms. Beware in sensitive breeds (e.g., Collies, etc.; “white feet, don’t treat”). Check heartworm status prior to treatment. Adverse effects are rare outside of sensitive breeds. (Foil 2003)

As an endoparasiticide:

- a) For treatment of parasitic lung disease (*Capillaria* spp.): 0.2 mg/kg PO once (Bauer 1988)
- b) For *Oslerus osleri*: 0.4 mg/kg SC once (Reinemeyer 1995)
- c) For *Eucoleus boehmi*: 0.2 mg/kg PO once (Reinemeyer 1995)
- d) For *Pneumonyssoides caninum*: 0.2 mg/kg SC once (Reinemeyer 1995)
**CATS:**

Note: When used for prophylaxis or treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information

As a preventative for heartworm:

a) Minimum effective dosage: 0.024 mg/kg (24 micrograms/kg) PO every 30–45 days (Note: also controls hookworms at this dosage) (Knight 1995)

For *Aelurostrongylus abstrusus*:

a) 0.4 mg/kg SC once (Reinemeyer 1995); (Hawkins 2000)

**FERRETS:**

a) For prevention of heartworm disease: 0.02 mg/kg PO monthly (Hoeffer 2000)

b) To treat heartworm disease using the very slow protocol: 50 micrograms PO once a month. (Hernandez-Divers 2007)

**RABBITS/RODENTS/SMALL MAMMALS:**

a) **Rabbits:** For *Sarcoptes scabiei, Notoedres cati*: 0.3–0.4 mg/kg SC, repeat in 14 days.

For ear mites (*Psoroptes*): 0.2–0.44 mg/kg PO, SC repeat in 8–18 days (Ivey & Morrisey 2000)

b) **Rabbits:** For treatment of ear mites: 200 micrograms/kg SC and repeated in two weeks. All rabbits in colony should be treated and cages cleaned and disinfected. (Burke 1999)

c) **Rodents and lagomorphs:** For treatment of sarcoptoid and some fur mites: 200–250 micrograms/kg SC. Cages should be thoroughly cleaned and disinfected. (Burke 1999)

d) **Mice, Rats, Gerbils, Guinea pigs, Chinchillas:** 200 micrograms/kg SC or PO every 7 days for 3 weeks Hamsters: 200–500 micrograms/kg SC or PO every 14 days for 3 weeks (Adamcak & Otten 2000)

e) **Guinea pigs** for *Trixacerus caviae* mites: 500 micrograms/kg SC, repeated at 14 and 28 days. (Johnson 2006)

**CATTLE:**

For susceptible parasites:

a) 200 micrograms/kg SC. Doses greater than 10 mL should be given at two separate sites. (Paul 1986)

b) For psoroptic mange: 200 mg/kg IM (Note: Reference was written before approval of the SC labeled bovine product); isolate from other cattle for at least 5 days after treatment. (Mullowney 1986)

c) 200 micrograms/kg (0.2 mg/kg) SC under the loose skin in front of or behind the shoulder (Product Information; Ivomec® Inj. for Cattle 1%—MSD)

**HORSES:**

For susceptible parasites:

a) 200 micrograms/kg (0.2 mg/kg) PO using oral paste or oral liquid (Product Information; Eqvalan®—MSD)

b) 0.2 mg/kg PO; 0.2 mg/kg PO at 4 day intervals for lice and mange (Robinson 1987)

c) As a larvicidal for arterial stages of *S. vulgaris*: 0.2 mg/kg once (Herd 1987)

**SWINE:**

For susceptible parasites:

a) 300 micrograms/kg (0.3 mg/kg) SC in the neck immediately behind the ear (Product Information; Ivomec® Inj. for Swine 1%—MSD)

b) For general control of endo- and ectoparasites in potbellied pigs: 300 micro-grams/kg SC or IM once for internal parasites and repeated in 10–14 days for external parasites (only partially effective against whipworms—see fenbendazole) (Braun 1995)

**SHEEP/GOATS:**

For susceptible parasites:

a) 200 micrograms/kg for nasal bot infection (Bennett 1986)

b) 200 micrograms/kg SC for one dose (goats also) (Upson 1988)

c) For adjunctive treatment of meningeal worm (*Parelaphostrongylus tenuis*): To prevent further migration: Ivermectin at 0.3 mg/kg SC once daily for 5 days with fenbendazole (50 mg/kg PO once daily for 5 days). (Edmondson 2009)

**CAMELIDS:**

For susceptible parasites:

a) New world camels: 0.2 mg/kg PO or SC for one dose (Cheney & Allen 1989)

b) For GI helminths in new world camels: 0.2 mg/kg PO once. (Wolff 2009)

c) For adjunctive treatment of meningeal worm (*Parelaphostrongylus tenuis*): To prevent further migration: Fenbendazole at 50 mg/kg PO once daily for 5 days and ivermectin at 0.3 mg/kg SC once daily for 5 days. Camels very susceptible to GI ulcers; give prophylaxis or treat with omeprazole or ranitidine. (Edmondson 2009)

**BIRDS:**

For susceptible parasites:

a) For ascarids, Capillaria and other intestinal worms, *Knemidocoptes pilae* (scaly face and leg mites): Dilute to a 2 mg/mL concentration. After diluting product, use immediately.

Most birds: Inject 220 micrograms/kg IM;

**Amazons:** 0.1 mg IM;

**Macaws:** 0.2 mg IM;

**Cats:** 0.2 mg IM
Macaws: 0.2 mg IM.

Finches: 0.02 mg (Stunkard 1984)

b) For ascarids, coccidia and other intestinal nematodes, Oxysipura, gapeworms, *Knemidocoptes pilae* (scaly face and leg mites): Dilute bovine preparation (10 mg/mL) 1:4 with propylene glycol.

For most species: 200 micrograms/kg IM or orally; repeat in 10–14 days.

Budgerigars: 0.01 mL of diluted product (see above) IM or PO (Clubb 1986)

c) 200 micrograms/kg (0.2 mg/kg) SC; dilute using propylene glycol. (Sikarskie 1986)

d) Ratites: 200 micrograms/kg PO, IM or SC. Has efficacy against *Chandlerella quiscalii* in emus. (Jenson 1998)

**REPTILES:**

For most nematodes, ectoparasites:

a) *Lizards, snakes, and alligators*: 0.2 mg/kg (200 micrograms/kg) IM, SC, or PO once; repeat in 2 weeks. A third treatment can be given if still positive after the second treatment. **Note:** Ivermectin is toxic to cheloniens, indigo snakes, skinks (de la Navarre 2003; Gauvin 1993)

**Monitoring**

- Clinical efficacy
- Adverse effects/toxicity (see Adverse Effects and Overdosage Sections)

**Client Information**

- When using large animal products the manufacturer recommends not eating or smoking and to wash hands after use. Avoid contact with eyes.
- Dispose of unused products and containers by incineration or in approved-landfills. Ivermectin may adversely affect fish or other water-borne organisms if disposed in water.
- Contact veterinarian if any treated animal exhibits signs of toxicity (see Adverse effects and Overdosage sections above).

**Chemistry/Synonyms**

An avermectin anthelmintic, ivermectin occurs as an off-white to yellowish powder. It is very poorly soluble in water (4 micrograms/mL), but is soluble in propylene glycol, polyethylene glycol, and vegetable oils.

Ivermectin may also be known as MK 933, Ivermectine, Ivermectinum or Ivermectina; many trade names are available.

**Storage/Stability**

Ivermectin is photolabile in solution; protect from light. Unless otherwise specified by the manufacturer, store ivermectin products at room temperature (15–30°C).

Ivermectin 1% oral solution (equine tube wormer product) is stable at 1:20 and 1:40 dilutions with water for 72 hours when stored in a tight container, at room temperature, and protected from light.

**Dosage Forms/Regulatory Status**

**VETERINARY FDA-APPROVED PRODUCTS:**

**Note:** As ivermectin is no longer patent protected in the USA, there are a variety of “generic” products available with many trade names. The following may not be a complete listing.

**Ivermectin for Injection:** 10 mg/mL (1%) in 50 mL, 200 mL and 500 mL packs; *Ivomec*® (Merial); (OTC); FDA-approved for use in swine. Slaughter withdrawal (at labeled doses) = 18 days.

**Ivermectin for Injection:** 10 mg/mL (1%) in 50 mL, 200 mL, 500 mL bottles; *Ivomec*® 1% *Injection for Cattle and Swine* (Merial), *Double Impact*® (AgriLabs); *Ultramectrin*® Injection (RXV); (OTC). FDA-approved for use in cattle (not female dairy cattle of breeding age) and swine. Slaughter (when used as labeled): cattle = 35 days, swine = 18 days, reindeer = 56 days, bison = 56 days. No milk withdrawal time has been established.

**Ivermectin for Injection:** 2.7 mg/mL (0.27%) in 200 mL bottles; *Ivomec*® 0.27% *Injection for Feeder and Grower Pigs* (Merial); (OTC). FDA-approved for use in swine. Slaughter (when used as labeled) = 18 days

**Ivermectin Oral Paste:** 1.87% (18.7 mg/gram) in 6.08 gram syringes; *Equinecritin* Paste 1.87% (Farnam), *Eqvalan*® Paste 1.87% (Merial), *Rotectin*® 1 Paste 1.87% (Farnam), *Zimectrin*® Paste (Farnam); (OTC). FDA-approved for use in horses (not intended for food purposes).

**Oral Paste:** containing 1.87% ivermectin and 14.03% of praziquantel in oral syringes (sufficient to treat one 1320 lb horse); *Equimax®*(Pfizer); (OTC). FDA-approved for use in horse or ponies not intended for food purposes.

**Oral Paste:** containing 1.55% ivermectin and 7.75% of praziquantel in oral syringses; *Zimecterin Gold®*(Merial); (OTC). FDA-approved for use in horse or ponies not intended for food purposes.

**Ivermectin Liquid:** 1% (10 mg/mL) in 50 mL and 100 mL btsls (for tube administration; **not** for injection); *Amtech Phoenectrin*® Liquid for Horses (Phoenix Scientific), *Eqvalan*® Liquid (Merial), *Ivercide*® Liquid for Horses (Phoenix Pharmaceutical); (RX). FDA-approved for use in horses (not intended for food purposes).

**Ivermectin Chewable Tablets:** 55 micrograms or 165 micrograms in cartons of 6 in 10 cartons per tray. *Heartgard® for Cats* (Merial); (RX) FDA-approved for use in cats.

**Ivermectin Oral Solution:** 0.08% in 960 mL and 4,800 mL containers; *Ivomec® Sheep Drench* (Merial); (OTC); FDA-approved for use in sheep. Slaughter withdrawal time = 11 days.

**Ivermectin Bolus:** 1.72 gram; *Ivomec® SR Bolus* (Merial); (OTC). FDA-approved for use in cattle (not female dairy cattle of breeding age). Slaughter withdrawal time = 180 days. No milk withdrawal time has been established.
Kaolin/pectin is thought to possess adsorbent and protective qualities. Presumably, bacteria and toxins are adsorbed in the gut and the coating action of the suspension.

**Pharmacology/Actions**

**References**

Ivermectin Tablets: 3 mg and 6 mg; Ivermectin/Pyrantel Oral Tablets: 68 micro-grams/57 mg, 136 micrograms/114 mg, 272 micrograms/228 mg; Heartgard® Plus Chewables (Merial); Tri-Heart® Plus Chewable Tablets (Schering): (Rx). FDA-approved for use in dogs.

Fenbendazole 454 mg, Ivermectin 27 mcg, & Praziquantel 23 mg (2.16g small chews) Chewable Tablets; Panacur Plus® Soft Chews (Intervet): (Rx). FDA-approved for use in adult dogs.

Fenbendazole 1.134 g, Ivermectin 68 mcg, & Praziquantel 57 mg (5.4g large chews) Chewable Tablet; Panacur Plus® Soft Chews (Intervet): (Rx). FDA-approved for use in adult dogs.

An otic product Acarexx® is also available.

**HUMAN-LABELED PRODUCTS:**

Ivermectin Tablets: 3 mg and 6 mg; Stromectol® (Merk); (Rx)

**References**

Bovine Mange.

Kaolin/pectin is thought to possess adsorbent and protective qualities. Presumably, bacteria and toxins are adsorbed in the gut and the coating action of the suspension may protect inflamed GI mucosa. The pectin component, by forming galacturonic acid, has been demonstrated to decrease pH in the intestinal lumen.

In one study in children with acute nonspecific diarrhea, stool fluidity was decreased, but stool frequency, water content, and weight remained unchanged. No studies documenting the clinical efficacy of this combination in either human or veterinary species were located.

**Pharmacokinetics**

Neither kaolin nor pectin are absorbed after oral administration. Up to 90% of the pectin administered may be decomposed in the gut.

**Contraindications/Precautions/Warnings**

There are no absolute contraindications to kaolin/pectin therapy, but it should not be relied on to control severe diarrheas. Kaolin/pectin should not replace adequate fluid/electrolyte monitoring or replacement therapy in severe or chronic diarrheas.

**Adverse Effects**

At usual doses, kaolin/pectin generally has no adverse effects. Constipation may occur, but is usually transient and associated with high dosages. High doses in debilitated, or in very old or young patients may rarely cause fecal impaction. In rats, kaolin/pectin has been demonstrated to increase fecal sodium loss in diarrhea.

In humans, kaolin/pectin is recommended for use only under the direct supervision of a physician, in patients less than 3 years of age or for longer than 48 hours.

**Reproductive/Nursing Safety**

Adsorbent (only) anti-diarrheal products should be safe to use during pregnancy and lactation. The addition of other active ingredients (e.g., as opiates) may alter this recommendation.

**Overdosage/Acute Toxicity**

Overdosage is unlikely to cause any serious effects, but constipation requiring treatment may occur.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving kaolin/pectin and may be of significance in veterinary patients:

- **DIGOXIN**: Some evidence exists that kaolin/pectin may impair the oral absorption of digoxin. Separate doses by at least two hours.
- **LINCOMYCIN**: Kaolin/pectin may inhibit the oral absorption of lincomycin. If both drugs are to be used, administer kaolin/pectin at least 2 hours before or 3–4 hours after the lincomycin dose.

**Doses**

- **DOGS**:
  - For diarrhea: a) 1–2 mL/kg PO q2–6h (Kirk 1986)
  - For enterotoxins secondary to garbage ingestion:
    - a) 2–5 mL/kg PO q1–6 hours (Coppock & Mostrom 1986)
    - b) 10–15 grams of kaolin/kg PO four times daily (Grauer & Hjelle 1988)

- **CATS**:
  - a) 1–2 mL/kg PO q2–6h (Kirk 1986)

- **FERRETS**:
  - a) 1–2 mL/kg PO 3–4 times daily (Williams 2000)

- **RABBITS/RODENTS/SMALL MAMMALS**:
  - a) Guinea pigs: 0.2 mL PO 3–4 times a day (Adamcak & Otten 2000)

- **CATTLE**:
  - a) Adult: 4–10 fl. oz. PO; Calves: 2–3 fl. oz PO; repeat every 2–4 hours or as indicated until condition improves. If no improvement in 48 hours additional treatment is indicated. (Label Directions; Kao-Forte®—Vet-A-Mix)
  - b) 1 oz. per 8 kg body weight PO 3–4 times a day (Clark & Becht 1987)
  - c) Foals: 3–4 oz PO q6–8h (authors believe that bismuth subsalicylate is superior) (Martens & Scrutchfield 1982)

- **SWINE**:
  - a) ½–2 fl. oz PO; repeat every 2–4 hours or as indicated until condition improves. If no improvement in 48 hours additional treatment is indicated. (Label Directions; Kao-Forte®—Vet-A-Mix)

- **SHEEP**:
  - a) 3–4 oz PO q2–3h (McConnell & Hughey 1987)

- **BIRDS**:
  - a) Canary or parakeet: 1 drop PO twice daily; or 1 and ½ dropperful placed in ⅔ oz. drinking water.
    - Medium-sized birds: 0.5 mL PO
Monitoring
- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea

Client Information
- Shake well before using
- If diarrhea persists, or if animal appears listless or develops a high fever, contact veterinarian

Chemistry/Synonyms
Kaolin is a naturally occurring hydrated aluminum silicate that is powdered and refined for pharmaceutical use. Kaolin is a white/light, odorless, almost tasteless powder that is practically insoluble in water.

Pectin is a carbohydrate polymer consisting primarily of partially methoxylated polygalacturonic acids. Pectin is a course or fine, yellowish-white, almost odorless powder with a mucilaginous flavor. It is obtained from the inner rind of citrus fruits or from apple pomace. One gram of pectin is soluble in 20 mL of water and forms a viscous, colloidal solution.

In the United States, the two compounds generally are used together in an oral suspension formulation in most propriety products.

Kaolin may also be known as: bolus alba, E559, weisser ton, Childrens Diarrhoea Mixture®, Entrocalm®, Kao-Pect®, Kao-Pect®, Kao-Pront®, Kaogel®; many multi-ingredient trade names are available.

Storage/Stability
Kaolin/pectin should be stored in airtight containers; protect from freezing.

Compatibility/Compounding Considerations
It is physically incompatible when mixed with alkalis, heavy metals, salicylic acid, tannic acid, or strong alcohol.

Dosage Forms/Regulatory Status
There are a variety of kaolin/pectin products available without prescription. Several products are labeled for veterinary use; their approval status is not known. Many products that formerly contained kaolin (e.g., Kapectate®) no longer contain any kaolin. In the USA, Kapectate® now contains bismuth subsalicylate as its active ingredient. In Canada, Kapectate® reportedly contains attapulgite.

VETERINARY-LABELED PRODUCTS:
Kaolin Pectin 90 gr kaolin/2 grams pectin per fluid oz. in 1 quart and 1 gallon containers. generic, (Bimeda, Durvet), Kao-Pect® (AgriLabs), Kao-Pect® (Phoenix Pharmaceutical), Kapectolin (Aspen, Butler); (OTC). Products may be labeled for use in horses, cattle, dogs and cats.

Kaolin Pectin 90 grams kaolin/4 grams pectin per fl oz. in 1 gallon containers. Kaolin Pectin Suspension (Vedco); (OTC)

HUMAN-LABELED PRODUCTS:
Kaolin, Pectin Antidiarrheal Suspension: 90 grams kaolin, 2 grams pectin/30 mL in 180 mL and 360 mL, pt and UD 30 mL; Kapectolin (various); generic; (OTC)

KETAMINE HCL
(kre-ta-men) Ketaset®, Ketaflo®, Vetalar®

DISASSOCIATIVE GENERAL ANESTHETIC; NMDA-RECEPTOR ANTAGONIST

Prescriber Highlights
- Dissociative general anesthetic; also inhibits NMDA-receptors so may be adjunctively useful to control pain
- Contraindications: Prior hypersensitivity reactions; animals to be used for human consumption, alone for general anesthesia, increased CSF pressure/head trauma
- Relative contraindications: Significant blood loss, malignant hyperthermia, increased intra-ocular pressure or open globe injuries; procedures involving the pharynx, larynx, or trachea
- Caution: Significant hypertension, heart failure, & arterial aneurysms, hepatic or renal insufficiency, seizure disorders
- Adverse Effects: Hypertension, hypersalivation, respiratory depression, hyperthermia, emesis, vocalization, erratic & prolonged recovery, dyspnea, spas tic jerking movements, seizures, muscular tremors, hypertonicity, opisthotonos, & cardiac arrest; pain after IM injection may occur
- Cats’ eyes remain open after ketamine: protect
Uses/Indications
Ketamine has been FDA-approved for use in humans, sub-human primates, and cats, although it has been used in many other species (see Dosage section). The FDA-approved indications for cats include, “for restraint, or as the sole anesthetic agent for diagnostic, or minor, brief, surgical procedures that do not require skeletal muscle relaxation … and in subhuman primates for restraint.” (Package Insert; Ketaset®—Bristol).

Ketamine can inhibit NMDA receptors in the CNS and can decrease “wind-up” effect. There is increasing interest in using it to prevent exaggerated pain associated with surgery or chronic pain states in animals.

Pharmacology/Actions
Ketamine is a rapid acting general anesthetic that has significant analgesic activity and a relative lack of cardiopulmonary depressant effects in healthy animals. It is thought to induce both anesthesia and amnesia by functionally disrupting the CNS through over stimulating the CNS or inducing a cataleptic state. Ketamine inhibits GABA, and may block serotonin, norepinephrine, and dopamine in the CNS. The thalamocortical system is depressed while the limbic system is activated. It induces anesthetic stages I and II, but not stage III. In cats, it causes a slight hypothermic effect as body temperatures decrease on average by 1.6°C after therapeutic doses.

Effects on muscle tone are described as being variable, but ketamine generally either causes no changes in muscle tone or increased tone. Ketamine does not abrogate the pinnal and pedal reflexes, nor the photic, corneal, laryngeal or pharyngeal reflexes.

Ketamine’s effects on the cardiovascular system include increased cardiac output, heart rate, mean aortic pressure, pulmonary artery pressure, and central venous pressure. Its effects on total peripheral resistance are described as being variable. Cardiovascular effects are secondary to increased sympathetic tone; ketamine has negative inotropic effects if the sympathetic system is blocked.

Ketamine can cause apneustic breathing (rapid breaths followed by breath-holding). It does not cause significant respiratory depression at usual doses, but at higher doses it can cause respiratory rates to decrease. Ketamine can cause bronchodilation and in humans with asthma, ketamine causes decreased airway resistance.

Pharmacokinetics
After IM injection in the cat, peak levels occur in approximately 10 minutes. Administration of a ketamine spray sublingually to cats appears to be absorbed enough to have pharmacologic action (Issabaglool 2008). Ketamine is distributed into all body tissues rapidly, with highest levels found in the brain, liver, lung, and fat. Plasma protein binding is approximately 50% in the horse, 53% in the dogs, and 37–53% in the cat.

In most species, ketamine is metabolized in the liver principally by demethylation and hydroxylation and these metabolites, along with unchanged ketamine, are eliminated in the urine. One active metabolite, nor-ketamine, has a half-life of 10-30% of the activity of the parent compound. In cats, ketamine is almost exclusively excreted unchanged in the urine. Ketamine will induce hepatic microsomal enzymes, but there appears to be little clinical significance associated with this effect. The elimination half-life in the cat, calf, and horse is approximately 1 hour, in humans it is 2–3 hours. Like the thiobarbiturates, the redistribution of ketamine out of the CNS is more of a factor in determining duration of anesthesia than is the elimination half-life.

By increasing the dose, the duration of anesthesia will increase, but not the intensity.

Contraindications/Precautions/Warnings
Ketamine is contraindicated in patients who have exhibited prior hypersensitivity reactions to it and animals to be used for human consumption. Use in patients with significant hypertension, heart failure, and arterial aneurysms could be hazardous. The manufacturer warns against its use in patients with hepatic or renal insufficiency but in humans with renal insufficiency, the duration of action is not prolonged. Because ketamine does not provide good muscle relaxation, it is contraindicated when used alone for major surgery.

Ketamine can cause increases in CSF pressure and it should not be used in cases with elevated pressures or when head trauma has occurred. Because of its supposed epileptogenic potential, it should generally not be used (unless very cautiously) in animals with preexisting seizure disorders. As myelography can induce seizures, ketamine should be used cautiously in animals undergoing this procedure.

Ketamine is considered to be relatively contraindicated when increased intra-ocular pressure or open globe injuries exist, and for procedures involving the pharynx, larynx, or trachea. Animals that have lost significant amounts of blood, may require significantly reduced ketamine dosages.

While ketamine has been used safely in humans with malignant hyperthermia, its use in animals susceptible to this condition is controversial.

Ketamine can increase heart rate, increase blood pressure and myocardial oxygen consumption; its use should be avoided in cats with hypertrophic cardiomyopathy (HCM) or in other patients where an increase in heart rate, blood pressure and myocardial oxygen consumption can be detrimental (e.g., unstable shock or congestive heart failure). Its effects on respiratory function can be enhanced in patients with unstable cardiopulmonary function. Because of ketamine’s tendencies to increase sympathetic tone (increased norepinephrine release), it should be used with caution in animals where increased sympathetic tone concurrently exists (e.g., pheochromocytoma, hyperthyroidism). Hyperthyroid human patients (and those receiving exogenous thyroid replacement) may be susceptible to developing severe hypertension and tachycardia when given ketamine. The veterinary significance of this potential problem is unknown.

Cats’ eyes remain open after receiving ketamine, and should be protected from injury plus an ophthalmic lubricant (e.g., Lacri-Lube®) should be applied to prevent excessive drying of the cornea.

Because ketamine is excreted almost exclusively via renal mechanisms, it should be used with caution in cats with reduced renal function.

To minimize the incidences of emergence reactions, it is recommended to minimize exposure to handling or loud noises during the recovery period. The monitoring of vital signs should still be performed during the recovery phase, however.

Because ketamine can increase blood pressure, careful control of post-surgical hemorrhage (e.g., declawing) should be managed. It is not essential to withhold food or water prior to surgery, but in elective procedures, it is recommended to withhold food for 6 hours prior to surgery.

Adverse Effects
In species where the drug is FDA-approved, the following adverse reactions are listed by the manufacturer: “respiratory depression … following high doses, emesis, vocalization, erratic and prolonged recovery, dyspnea, spastic jerking movements, convulsions, muscular tremors, hypertonicity, opisthotonos and cardiac arrest. In the cat, myoclonic jerking and/or tonic/clonic convulsions can be controlled by ultrashort-acting barbiturates or acarpemazine. These latter drugs must be given intravenously, cautiously, and slowly, to effect (approximately 1/4 to ¼ the normal dose may be required)” (Package Insert; Ketaset®—Fort Dodge)

• Minimize exposure to handling or loud noises during the recovery period, but monitor adequately
• Drug interactions
Seizures have been reported to occur in up to 20% of cats that receive ketamine at therapeutic dosages. Diazepam is suggested if treatment is necessary. It has been reported to rarely cause a variety of other CNS effects (mild CNS effects to blindness and death). Ketamine has been documented to cause hyperthermia in cats; low doses of acepromazine (0.01–0.02 mg/kg IV) may alleviate. Anecdotal reports of ketamine causing acute, CHF in cats with mild to moderate heart disease have been reported.

Pain after IM injection may occur.

To reduce the incidence of hypersalivation and other autonomic signs, atropine or glycopyrrolate is often administered.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

No specific lactation information was found.

**Overdosage/Acute Toxicity**

Ketamine is considered to have a wide therapeutic index (approximately 5 times greater when compared to pentobarbital). When given too rapidly or in excessive doses, significant respiratory depression may occur. Treatment using mechanically assisted respiratory support is recommended versus the use of analeptic agents. In cats, yohimbine with 4-aminopyridine has been suggested for use as a partial antagonist.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketamine and may be of significance in veterinary patients:

- **CHLORPHENICOL (parenteral):** May prolong the anesthetic actions of ketamine
- **CNS DEPRESSANTS:** Narcotics, barbiturates, or diazepam may prolong the recovery time after ketamine anesthesia
- **HALOTHANE:** When used with halothane, ketamine recovery rates may be prolonged and the cardiac stimulatory effects of ketamine may be inhibited; close monitoring of cardiac status is recommended when using ketamine with halothane
- **IVERMECTIN:** It has been recommended not to use ivermectin in reptiles within 10 days of ketamine (Bays 2009)
- **NEUROMUSCULAR BLOCKERS (e.g., succinylcholine and tubocurarine):** May cause enhanced or prolonged respiratory depression
- **THYROID HORMONES:** When given concomitantly with ketamine, thyroid hormones have induced hypertension and tachycardia in humans; beta-blockers (e.g., propranolol) may be of benefit in treating these effects

**Doses**

**Note:** Ketamine is used in many different combinations with other agents. The following are representative, but not necessarily inclusive; it is suggested to refer to a recent veterinary anesthesia reference for more information.

**DOGS:**

As an adjunct to anesthesia:

a) For use in combination with an opioid and ketamine (so-called “doggie magic”) to provide anesthesia and pain management (Note: reference has dosing tables for conversion of patient weight to various micrograms/m2 doses of dexmedetomidine; opioid concentrations used in the reference are: Butorphanol 10 mg/mL, Hydromorphone 2 mg/mL, Morphine 15 mg/mL, & Buprenorphine 0.3 mg/mL. Ketamine concentration is 100 mg/mL. As these drugs may be available in other concentrations, only use those products with the above concentrations if using this protocol):

- For geriatric dogs, dogs with renal or liver dysfunction as a premed prior to propofol or face mask induction, followed by maintenance on isoflurane or sevoflurane: dexmedetomidine at 62.5 micrograms/m2. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.
- For slightly heavier sedation in ASA class II or II dogs requiring sedation for radiographic procedures: Dexmedetomidine at 125 micrograms/m2. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.
- For dogs undergoing minor surgery, Penn hip or OFA-types of radiographic procedures that require significant muscle relaxation: Dexmedetomidine at 250 micrograms/m2. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.
- To induce a surgical plane of anesthesia for OHE, castration, or other abdominal surgery: Dexmedetomidine at 375 micrograms/m2. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV. Provides rapid immobilization; lateral recumbency in 5-8 minutes. Dogs can be intubated and maintained on oxygen. Supplemental low doses of isoflurane (0.5%) or sevoflurane (1%) can be used.
- For immobilizing extremely fractious dogs and wolf-hybrid dogs: Dexmedetomidine at 500 micrograms/m2. Combine with equal volumes of one of the opioids noted above and ketamine. Administer IM. This dose is rarely required.
- To reverse above, atipamezole IM at the same volume as the dexmedetomidine. (Ko 2009)

As an NMDA antagonist for adjunctive pain control:

a) 0.1–1 mg/kg PO, IM or SC q4–6h for mild to moderate pain in conjunction with opioids. (Nieves 2002)

b) For intraoperative use: If anesthesia was induced with a drug other than ketamine, give a loading dose of 0.5 mg/kg IV, then an infusion of 10–20 micrograms/kg/minute. A CRI of 2–10 micrograms/kg/minute can be used post-op. (Hellyer 2006)

c) In combination with opioids or lidocaine: 0.5 mg/kg IV loading bolus followed by 10 micrograms/kg/min CRI during surgery and 2 micrograms/kg/min for 24 hrs following surgery. (Shaffran 2009)

**CATS:**

Most clinicians recommend giving atropine or glycopyrrolate before use to decrease hypersalivation.

a) 11 mg/kg IM for restraint; 22–33 mg/kg for diagnostic or minor surgical procedures not requiring skeletal muscle relaxation (Package Insert; Ketaset®—Bristol)
b) For use in combination with an opioid and ketamine (so-called “kitty magic”, “DKT” or “Triple Combination”) to provide sedation and analgesia (Note: Opioid concentrations used in the reference are: Butorphanol 10 mg/mL, Hydromorphone 2 mg/mL, Morphine 15 mg/mL, & Buprenorphine 0.3 mg/mL. Ketamine concentration is 100 mg/mL. Dexmedetomidine concentration is 0.5 mg/mL. As these drugs may be available in other concentrations, only use those products with the above concentrations if using this protocol.):

For the chart below: MILD = For sedation or as a premed prior to propofol or face mask induction; MODERATE = For castration or minor surgical procedures; PROFOUND = Invasive surgical procedures including OHE and declaws. Cats can be reversed immediately with an equal volume (of the dexmedetomidine dose) of atipamezole.

(Ko 2009)

c) In combination as an immobilizing agent: For cats requiring more sedation when insufficient sedation from opioid, higher doses of medetomidine, and midazolam: butorphanol 0.2 mg/kg; medetomidine 0.015–0.02 mg/kg; midazolam 0.05–0.2 mg/kg; ketamine 1–5 mg/kg; all are given IM. For painful procedures consider adding buprenorphine at 0.02–0.04 mg/kg or substituting butorphanol or buprenorphine with either morphine 0.5 mg/kg or hydromorphone 0.1 mg/kg. More information available from: www.vsag.org.

For highly aggressive cats, 1 mL of ketamine can be sprayed into the open mouth or directed into the cat’s mouth using a feline urethral catheter through the cage bars. The drug should be sprayed quickly so the cat does not chew and swallow the catheter. (Moffat 2008)

As an NMDA antagonist for adjunctive pain control:

a) 0.1–1 mg/kg IM or SC q4–6h for mild to moderate pain in conjunction with opioids. (Nieves 2002)

b) For intraoperative use: If anesthesia was induced with a drug other than ketamine, give a loading dose of 0.5 mg/kg IV, then an infusion of 10–20 micrograms/kg/minute. A CRI of 2–10 micrograms/kg/minute can be used post-op. (Hellyer 2006)

c) In combination with opioids or lidocaine: 0.5 mg/kg IV loading bolus followed by 10 micrograms/kg/min CRI during surgery and 2 micrograms/kg/min for 24 hrs following surgery.

Using the MLK (morphine/lidocaine/ketamine) mixture: To a 500 mL bag of LRS add 10 mg morphine sulfate, 120 mg lidocaine, and 100 mg ketamine. Infuse at a rate of 10 mL/kg/hr (will provide morphine at 0.2 mg/kg/hr, lidocaine 40 micrograms/kg/minute, and ketamine 2 mg/kg/hr). Can add dexmedetomidine if needed. (Shaffran 2009)

RABBITS/RODENTS/SMALL MAMMALS:

For chemical restraint:

a) Mice: Alone: 50–100 mg/kg IM or IP, 50 mg/kg IV;
   In combination with diazepam: Ketamine 200 mg/kg with Diazepam 5 mg/kg IM or IP;
   In combination with xylazine: Ketamine 100 mg/kg with Xylazine 5–15 mg/kg IM or IP (Burke 1999)

b) Rats: Alone: 50–100 mg/kg IM or IP, 40–50 mg/kg IV;
   In combination with diazepam: Ketamine 40–60 mg/kg with Diazepam 5–10 mg/kg IP;
   In combination with xylazine: Ketamine 40–75 mg/kg with Xylazine 5–12 mg/kg IM or IP (Burke 1999)

c) Hamsters/Gerbils: 100 mg/kg IM;
   In combination with diazepam: Ketamine 50 mg/kg with Diazepam 5 mg/kg IM;
   In combination with xylazine: Not recommended (Burke 1999)

d) Guinea pig: Alone: 10–30 mg/kg IM;
   In combination with diazepam: Ketamine 60–100 mg/kg with Diazepam 5–8 mg/kg IM;
   In combination with xylazine: Ketamine 85 mg/kg with Xylazine 12–13 mg/kg IM (Burke 1999)

e) Rabbits: Alone: 20–60 mg/kg IM or IV;
   In combination with diazepam: Ketamine 60–80 mg/kg with Diazepam 5–10 mg/kg IM;
   In combination with xylazine: Ketamine 10 mg/kg with Xylazine 3 mg/kg IV (Burke 1999)

f) Rabbits: Alone: 20–50 mg/kg IM or 15–20 mg/kg IV
   In combination with diazepam for induction: Diazepam 5–10 mg/kg IM give ketamine 30 minutes after diazepam at 20–40 mg/kg IM or Diazepam 0.2–0.5 mg/kg and Ketamine 10–15 mg/kg (to effect) IV;
   In combination with diazepam for anesthesia without inhalants: Diazepam 5–10 mg/kg IM plus ketamine 60–80 mg/kg IM 30 minutes later;
   In combination with xylazine: Not recommended for pet rabbits (Ivey & Morrissey 2000)

g) Injectable anesthesia: Rodents: midazolam (5 mg/kg) + ketamine (100 mg/kg) + buprenorphine (0.05 mg/kg) IP.
   Rabbits: Midazolam (0.05 mg/kg) + buprenorphine (0.03 mg/kg) + ketamine (10 mg/kg) IM. (Bennett 2009)

FERRETS:

a) For injectable anesthesia: Butorphanol 0.1 mg/kg, Ketamine 5 mg/kg, medetomidine 80 micrograms/kg. Combine in one syringe and give IM. May need to supplement with isoflurane (0.5–1.5%) for abdominal surgery. (Finkler 1999)

CATTLE:

a) Premedicate with atropine and xylazine, then ketamine 2 mg/kg IV bolus (Thurmon & Benson 1986)
For use of ketamine in zoo, exotic and wildlife medicine refer to specific references, including:

**ZOO, EXOTIC, WILDLIFE SPECIES:**

- **BIRDS:**
  - Weighing greater than 250 g. Xylazine is not recommended to be used in debilitated birds because of its cardiodepressant effects.
  - In combination with xylazine: Ketamine 10–30 mg/kg IM; Xylazine 2–6 mg/kg IM; birds less than 250 grams require a higher dosage (per kg).
  - Reversal of all dosages with atipamezole is 4–5 times the medetomidine dose (Heard 1999)

- **REPTILES:**
  - Medetomidine 40–80 micrograms/kg with ketamine 4–8 mg/kg IV or IM. Wait 30–40 minutes for peak effect;
  - Diazepam (0.03 mg/kg IV). Mix the diazepam with the

- **SWINE:**
  - Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine.
  - This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes, or Dizepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes, or 4) Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)

- **SWINE:**
  - Redose xylazine: up to half the original dose, or Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes, or Dizepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes, or 4) Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)

- **GOATS:**
  - Give atropine, then ketamine at 11 mg/kg IM. To prolong anesthesia and increase analgesia give additional ketamine 2–4 mg/kg IV. Local anesthetics injected at the surgical site (e.g., 2% lidocaine) may enhance analgesia. (Thurmon & Benson 1986)
  - Ketamine (22 mg/kg) combined with acepromazine (1.1 mg/kg) IM (Swindle 1985)
  - As an anesthetic: butorphanol 0.07–0.1 mg/kg; ketamine 0.2–0.3 mg/kg IV or butorphanol 0.05–0.1 mg/kg; ketamine 0.2–0.5 mg/kg; xylazine 0.2–0.5 mg/kg IM (Woff 2009)
  - For procedural pain (e.g., castrations) when recumbency (up to 30 minutes) is desired: Alpacas: butorphanol 0.046 mg/kg; xylazine 0.46 mg/kg; ketamine 4.6 mg/kg. Llamas: butorphanol 0.037 mg/kg; xylazine 0.37 mg/kg; ketamine 3.7 mg/kg. All drugs are combined in one syringe and given IM. May administer 50% of original dose of ketamine and xylazine during anesthesia to prolong effect up to 15 minutes.

- **SHEEP:**
  - Give atropine, then ketamine at 11 mg/kg IM. To prolong anesthesia and increase analgesia give additional ketamine 2–4 mg/kg IV. Local anesthetics injected at the surgical site (e.g., 2% lidocaine) may enhance analgesia. (Thurmon & Benson 1986)
  - Give atropine, then ketamine at 11 mg/kg IM. To prolong anesthesia and increase analgesia give additional ketamine 2–4 mg/kg IV. Local anesthetics injected at the surgical site (e.g., 2% lidocaine) may enhance analgesia. (Thurmon & Benson 1986)

- **CAMELIDS (llamas and alpacas):**
  - Give atropine, then ketamine at 11 mg/kg IM. To prolong anesthesia and increase analgesia give additional ketamine 2–4 mg/kg IV. Local anesthetics injected at the surgical site (e.g., 2% lidocaine) may enhance analgesia. (Thurmon & Benson 1986)

- **REPTILES:**
  - Medetomidine 100–150 micrograms/kg with ketamine 5–10 mg/kg IV or IM;
  - Medetomidine 150–300 micrograms/kg with ketamine 10–20 mg/kg IV or IM;
  - Medetomidine 40 micrograms/kg with ketamine 4 mg/kg IV or IM

  - Medetomidine 100–150 micrograms/kg with ketamine 5–10 mg/kg IV or IM;
  - Medetomidine 150–300 micrograms/kg with ketamine 10–20 mg/kg IV or IM;
  - Medetomidine 40 micrograms/kg with ketamine 4 mg/kg IV or IM

- **BIRDS:**
  - Birds weighing:
    - <100 grams (canaries, finches, budgies): 0.1–0.2 mg/gm IM;
    - 250–500 grams (parrots, pigeons): 0.05–0.1 mg/gm IM;
    - 500 grams–3 kg (chickens, owls, hawks): 0.02–0.1 mg/gm IM;
    - >3 kg (ducks, geese, swans): 0.02–0.05 mg/gm IM (Booth 1988)

  - In combination with xylazine: Ketamine 10–30 mg/kg IM; Xylazine 2–6 mg/kg IM; birds less than 250 grams require a higher dosage (per kg) than birds weighing greater than 250 g. Xylazine is not recommended to be used in debilitated birds because of its cardiodepressant effects.

  - In combination with diazepam: Ketamine 10–50 mg/kg IM; Diazepam 0.5–2 mg/kg IM or IV; doses can be halved for IV use.

  - In combination with acepromazine: Ketamine 25–50 mg/kg IM; Acepromazine 0.5–1 mg/kg IM (Wheler 1993)
For use of ketamine in zoo, exotic and wildlife medicine refer to specific references, including:
c) Restraint and Handling of Wild and Domestic Animals. Fowler, M (ed), Iowa State University Press, 1995
e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

Monitoring
- Level of anesthesia/analgiesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Monitor eyes to prevent drying or injury;
- Body temperature

Client Information
- Should only be administered by individuals familiar with its use.

Chemistry/Synonyms
A congener of phencyclidine, ketamine HCl occurs as white, crystalline powder. It has a melting point of 258–261°C, a characteristic odor, and will precipitate as the free base at high pH. One gram is soluble in 5 mL of water, and 14 mL of alcohol. The pH of the commercially-available injections are between 3.5–5.5.

Ketamine HCl may also be known as: CI-581, CL-369, CN-52372-2, ketamini hydrochloridum, Amtech®, Brevinaze®, Calypsol®, Cost®, Inducmin®, Keto®, Keta-HameIn®, Ketaject®, Ketalin®, Ketanex®, Ketaset®, Ketasthesia®, Keta-thetic®, Ketava®, Ketina®, Ketmin®, Ketolar®, Velaron®, VetaKer®, and Vetalar®.

Storage/Stability
Ketamine injection should be stored between 15–30°C (59–86°C) and protected from light. Solution may darken upon prolonged exposure to light which does not affect the drug’s potency. Do not use if precipitates appear.

Ketamine may be mixed with sterile water for injection, D5W, and normal saline for diluent purposes. Do not mix ketamine with barbiturates or diazepam in the same syringe or IV bag as precipitation may occur.

Compatibility/Compounding Considerations
Ketamine may be mixed with sterile water for injection, D5W, and normal saline for diluent purposes. Ketamine is physically compatible in the same syringe with xylazine ("KAX") supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored in the dark at room temperature.

Ketamine may be mixed with sterile water for injection, D5W, and normal saline for diluent purposes. Do not mix ketamine with barbiturates or diazepam in the same syringe or IV bag as precipitation may occur.

Solution may darken upon prolonged exposure to light which does not affect the drug’s potency. Do not use if precipitates appear.

A study (Taylor et al. 2009) evaluating the stability, sterility, pH, particulate formation and efficacy in laboratory rodents of compounded ketamine, acepromazine and xylazine (“KAX”) supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored in the dark at room temperature.

Information “on file” with the manufacturer states that dexmedetomidine 0.5 mg/mL solution for injection can be mixed with butorphanol 2 mg/mL or with ketamine 50 mg/mL solution, or with butorphanol 2 mg/mL solution and ketamine 50 mg/mL solution, in the same syringe and possesses no pharmacological risk.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Ketamine HCl for Injection: 100 mg/mL in 10 mL vials; Ketaset® (Phoenix Pharmaceutical), Ketaset® (Pfizer), Keta-thetic® (RXV), Vetalar® (BIVI), VetaKer® (Lloyd), generic; (Rx, C-III). FDA-approved for use in cats and sub-human primates. The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Ketamine HCl Injection: 10 mg/mL in 20 mL vials; 50 mg/mL in 10 mL vials & 100 mg/mL in 5 mL vials; Ketalar® (JHP); generic; (Rx, C-III). FDA-approved for use in cats and sub-human primates.

KETOCONAZOLE
(kee-toe-kahn-za-zole) Nizoral®
AZOLE ANTIFUNGAL

Prescriber Highlights

- Original imidazole oral antifungal used for systemic mycoses, including aspergillosis, cryptococcal meningitis, blastomycosis, & histoplasmosis; also used to reduce dose/costs of cyclosporine therapy and as an alternative treatment of hyperadrenocorticism in dogs.
- Contraindications: Known hypersensitivity; some believe ketoconazole is contraindicated in cats
- Caution: Hepatic disease or thrombocytopenia
- Potentially teratogenic & embryotoxic; weigh risks vs. benefits
- May cause infertility in male dogs by decreasing testosterone synthesis.
- Adverse Effects: GI (anorexia, vomiting, &/or diarrhea) most common & more prevalent in cats; hepatic toxicity, thrombocytopenia, reversible lightening of haircoat, transient dose-related suppressant effect on gonadal & adrenal steroid synthesis
- Long-term treatment may be required
- Many drug interactions

Uses/Indications

Because of its comparative lack of toxicity when compared to amphotericin B, oral administration, and relatively good efficacy, ketoconazole has been used to treat several fungal infections in dogs, cats, and other small species. Ketoconazole is often employed with amphotericin B to enhance the efficacy of ketoconazole, and by reducing the dose of amphotericin B, decreasing its risk of toxicity. See the Dosage section or Pharmacology section for specifics. Newer antifungal agents (fluconazole, itraconazole) have advantages over ketoconazole, primarily less toxicity and/or enhanced efficacy; however, ketoconazole can be significantly less expensive than the newer agents. Ketoconazole is considered by some to still be the drug of choice for treating histoplasmosis in dogs.

Use of ketoconazole in cats is controversial and some say it should never be used that species.

Ketoconazole is also used clinically for the medical treatment of hyperadrenocorticism in dogs. Ketoconazole appears to be a viable option, although it’s relatively expensive and less effective when compared with mitotane. However, it may be particularly useful for palliative therapy in dogs with large, malignant, or invasive tumors where surgery is not an option. Ketoconazole is also used frequently in dogs for stabilization prior to surgery. As it is a reversible inhibitor of steroidogenesis, it is usually not a viable option for long-term treatment.

Because it interferes with the metabolism of cyclosporine, ketoconazole has been used to reduce cyclosporine dosage and costs in dogs.

Pharmacology/Actions

At usual doses and serum concentrations, ketoconazole is fungistatic against susceptible fungi. At higher concentrations for prolonged periods of time or against very susceptible organisms, ketoconazole can be fungicidal. It is believed that ketoconazole increases cellular membrane permeability and causes secondary metabolic effects and growth inhibition. The exact mechanism for these effects has not been determined, but may be due to ketoconazole interfering with ergosterol synthesis.

The fungicidal action of ketoconazole may be due to a direct effect on cell membranes.

Ketoconazole has activity against most pathogenic fungi, including Blastomycetes, Coccidioides, Cryptococcus, Histoplasma, Microsporum, and Trichophyton. Higher levels are necessary to treat most strains of Aspergillus and Sporothrix. Resistance to ketoconazole has been documented for some strains of Candida albicans.

Ketoconazole has in vitro activity against Staphylococcus aureus and epidermidis, Nocardia, enterococci, and herpes simplex virus types 1 and 2. The clinical implications of this activity are unknown.

Via inhibition of 5-lipoxygenase, ketoconazole possesses some antiinflammatory activity. The drug can suppress the immune system, probably by suppressing T-lymphocytes proliferation.

Ketoconazole also has endocrine effects as steroid synthesis is directly inhibited by blocking several P-450 enzyme systems. Measurable reductions in testosterone or cortisol synthesis can occur at dosages used for antifungal therapy, but higher dosages are generally required to reduce levels of testosterone or cortisol to be clinically useful in the treatment of prostatic carcinoma or hyperadrenocorticism. Effects on mineralocorticoids are negligible.

Pharmacokinetics

Although it is reported that ketoconazole is well absorbed after oral administration, oral bioavailability of ketoconazole tablets in dogs is highly variable. One study (Baxter et al. 1986) in six normal dogs, found bioavailabilities ranging from 0.04–0.89 (4–89%) after 400 mg (19.5–25.2 mg/kg) was administered to fasted dogs. Peak serum concentrations occur between 1 and 4.25 hours after dosing and peak serum levels ranged from 1.1–45.6 micrograms/mL. This wide interpatient variation in six normal dogs, found bioavailabilities ranging from 0.04–0.89 (4–89%) after 400 mg (19.5–25.2 mg/kg) was administered to fasted dogs. Use of ketoconazole in cats is controversial and some say it should never be used that species.

Ketoconazole is metabolized extensively by the liver into several inactive metabolites. These metabolites are excreted primarily into the feces via the bile. About 13% of a given dose is excreted into the urine and only 2–4% of the drug is excreted unchanged in the urine. Half-life in dogs is about 1–6 hours (avg. 2.7 hours).
Ketoconazole is contraindicated in patients with known hypersensitivity to it. It should be used with caution in patients with hepatic disease or thrombocytopenia.

### Contraindications/Precautions/Warnings
Ketoconazole is contraindicated in patients with known hypersensitivity to it. It should be used with caution in patients with hepatic disease or thrombocytopenia.

### Adverse Effects
Gastrointestinal signs of anorexia, vomiting, and diarrhea are the most common adverse effects seen with ketoconazole therapy and are more prevalent in cats. Anorexia may be minimized by dividing the dose and/or giving it with meals. Appetite stimulants such as oxazepam or cyproheptadine may also be of benefit in cats.

Hepatic toxicity consisting of cholangihepatitis and increased liver enzymes has been reported with ketoconazole, and may be either idiosyncratic in nature or a dose-related phenomenon. Cats may be more prone to developing hepatoxicity than dogs. While liver enzymes should be monitored during therapy, an increase does not necessarily mandate dosage reduction or discontinuation unless concomitant anorexia, vomiting, diarrhea, or abdominal pain is present. Thrombocytopenia has also been reported with ketoconazole therapy, but is rarely encountered. A reversible lightening of haircoat may also occur in patients treated with ketoconazole.

Ketoconazole has a transient dose-related suppressant effect on gonadal and adrenal steroid synthesis. Doses as low as 10 mg/kg depressed serum testosterone levels in dogs within 3–4 hours after dosing, but levels returned to normal within 10 hours. Doses of 30 mg/kg/day have been demonstrated to suppress serum cortisol levels in dogs with hyperadrenocorticism (see Dosages section). Dogs undergoing high dose antifungal therapy may need additional glucocorticoid support during periods of acute stress.

### Reproductive/Nursing Safety
Ketoconazole is a known teratogen and embryotoxin in rats. There have been reports of mummified fetuses and stillbirths in dogs who have been treated. Ketoconazole should not be considered absolutely contraindicated in pregnant animals, however, as it is often used in potentially life-threatening infections. The benefits of therapy should be weighed against the potential risks. Ketoconazole may cause infertility in male dogs by decreasing testosterone synthesis. Testosterone production rebounds once the drug is discontinued.

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Ketoconazole is excreted in milk; use with caution in nursing dams.

### Overdosage/Acute Toxicity
No reports of acute toxicity associated with overdosage were located. The oral LD50 in dogs after oral administration is >500 mg/kg. Should an acute overdose occur, the manufacturer recommends employing supportive measures, including gastric lavage with sodium bicarbonate.

### Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving ketoconazole and may be of significance in veterinary patients:

- **ALCOHOL:** Ethanol may interact with ketoconazole and produce a disulfiram-like reaction (vomiting)
- **ANTACIDS:** May reduce oral absorption of ketoconazole; administer ketoconazole at least 1 hour before or 2 hours after
- **ANTIDEPRESSANTS, TRICYCLIC (amitriptyline, clomipramine):** Ketoconazole may reduce metabolism and increase adverse effects
- **BENZODIAZEPINES (MIDAZOLAM, TRIAZOLAM):** Ketoconazole may increase levels
- **BUSPIRONE:** Plasma concentrations may be elevated
- **BUSULFAN:** Ketoconazole may increase levels
- **CALCIUM-CHANNEL BLOCKING AGENTS (amlodipine, verapamil):** Ketoconazole may increase levels
- **CISAPRIDE:** Ketoconazole may increase cisapride levels and possibility for toxicity; use together contraindicated in humans
- **CORTICOSTEROIDS:** Ketoconazole may inhibit the metabolism of corticosteroids; potential for increased adverse effects
- **CYCLOPHOSPHAMIDE:** Ketoconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity
- **CYCLOSPORINE:** Increased cyclosporine levels
- **DIGOXIN:** Ketoconazole may increase digoxin levels
- **FENTANYL/ALFENTANIL:** Ketoconazole may increase fentanyl or alfentanil levels
- **H2-BLOCKERS (ranitidine, famotidine, etc.):** Increased gastric pH may reduce ketoconazole absorption
- **HEPATOTOXIC DRUGS, OTHER:** Because ketoconazole can cause hepatotoxicity, it should be used cautiously with other hepatotoxic agents
- **ISONIAZID:** May affect ketoconazole levels and concomitant use not recommended in humans
- **IVERMECTIN:** Ketoconazole may increase risk for neurotoxicity. At least one reference states that ivermectin should never be used with ketoconazole in dogs (Waisglass 2009).
- **MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin):** May increase ketoconazole concentrations
- **MITOTANE:** Mitotane and ketoconazole are not recommended for use together to treat hyperadrenocorticism as the adrenolytic effects of mitotane may be inhibited by ketoconazole’s inhibition of cytochrome P450 enzymes
- **PHENYTOIN:** May decrease ketoconazole levels and concomitant use not recommended in humans
- **PROPIONATE ANTI-ACID (omeprazole, etc.):** Increased gastric pH may reduce ketoconazole absorption
- **QUINIDINE:** Ketoconazole may increase quinidine levels
- **RIFAMPIN:** May decrease ketoconazole levels; ketoconazole may increase rifampin levels
- **SULFONYLUREA ANTIDIABETIC AGENTS (e.g., glyburide, glipizide):** Ketoconazole may increase levels; hypoglycemia possible
- **THALIAZINE:** May reduce oral absorption of ketoconazole; administer ketoconazole at least 1 hour before and 2 hours after
- **TETRAHYMENA ANTIBIOTICS (erythromycin, clindamycin):** May decrease ketoconazole levels
- **ZOLMESARTAN:** May affect ketoconazole levels and concomitant use not recommended in humans
**SULFONE/URCA ANTIDIABETIC AGENTS** (e.g., glipizide, glyburide): Ketoconazole may increase levels, hypoglycemia possible

**THEOPHYLLINE**: Ketoconazole may decrease serum theophylline concentrations in some patients; theophylline levels should be monitored

**VINCRISTINE/VINBLASTINE**: Ketoconazole may inhibit vinca alkaloid metabolism and increase levels

**WARFARIN**: Ketoconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants

**Laboratory Considerations**

Ketoconazole can reduce serum cortisol levels and affect adrenal function tests. After stopping ketoconazole, cortisol levels usually return to baseline within 24 hours.

**Doses**

*Note: Clinical antifungal effects may require 10–14 days of therapy*

**DOGS:**

For coccidioidomycosis:

a) For the systemic form of the disease: 5–10 mg/kg PO twice daily; For the CNS form: 15–20 mg/kg PO twice daily. Treatment should persist for a minimum of 3–6 months. Animals with bony lesions or relapses after discontinuing therapy, give lifelong therapy at 5 mg/kg PO every other day. (Macy 1989)
b) 10–30 mg/kg PO divided twice a day; most animals need to be treated for 6–12 months (Taboada 2000)

For blastomycosis:

a) 10 mg/kg PO twice daily (15–20 mg/kg PO twice daily if CNS involvement) for at least 3 months with amphotericin B: initially at 0.25–0.5 mg/kg every other day IV. If tolerated, increase dose to 1 mg/kg until 4–5 mg/kg total dose is administered. See amphotericin B monograph for more information. (Macy 1989)
b) Ketoconazole 20 mg/kg/day PO once daily or divided twice daily; 40 mg/kg divided twice daily for ocular or CNS involvement (for at least 2–3 months or until remission then start maintenance) with amphotericin B 0.15–0.5 mg/kg IV 3 times a week. When a total dose of amphotericin B reaches 4–6 mg/kg, start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or ketoconazole at 2.5–5 mg/kg PO once daily. If CNS/ocular involvement, use ketoconazole at 20–40 mg/kg PO divided twice daily (Greene, C.E. et al. 1984)

For histoplasmosis:

a) 10 mg/kg PO once a day or twice a day for at least 3 months. Treat at least 30 days after complete resolution of clinical disease. If patient relapses, retreat as above then put on maintenance 5 mg/kg PO every other day indefinitely. For acute cases: use with amphotericin B (see blastomycosis recommendation by same author above) (Macy 1988)
b) Ketoconazole 10–20 mg/kg/day PO once daily or divided twice daily (for at least 2–3 months or until remission then start maintenance) with amphotericin B at 0.15–0.5 mg/kg IV 3 times a week. When a total dose of amphotericin B reaches 2–4 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or at 2.5–5 mg/kg PO once daily (Greene, C.E. et al. 1984)

For aspergillosis:

a) 20 mg/kg PO for at least 6 weeks; may require long-term/maintenance therapy (Macy 1989)
b) For nasal aspergillosis: 10 mg/kg PO once daily (q24h) or 5 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. Itraconazole somewhat more effective. (Greene, C. et al. 2006)

For cryptococcosis:

a) Amphotericin B 0.15–0.4 mg/kg IV 3 times a week with flucytosine 150–175 mg/kg PO divided three to four times a day. When a total dose of amphotericin B reaches 4–6 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month with flucytosine at 10 mg/kg PO once daily or divided twice daily (Greene, C.E. et al. 1984)

For fungal myocarditis:

a) 10 mg/kg PO three times daily (Ogburn 1988)

For Candidiasis:

a) 10 mg/kg PO once daily (q24h) or 5 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. Itraconazole somewhat more effective. (Greene, C. et al. 2006)

For Sporotrichosis:

a) 15 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. (Greene, C. et al. 2006)

For Malassezia dermatitis:

a) For severe cases: Dosing of oral ketoconazole ranges from 5 mg/kg PO once daily to 10 mg/kg twice daily. Improvement (but usually not cure) should be noted in 2 weeks. If a low dose of ketoconazole is given and improvement is not noted in 2 weeks, a higher dose should be given before the diagnosis is reconsidered; administer until the clinical signs have abated and no organisms are seen on cytologic evaluations. (Merchant 2009b)
b) 5–10 mg/kg PO twice a day for 30 days. Often used with therapeutic shampoos containing selenium disulfide, miconazole, ketoconazole or chlorhexidine. Underlying conditions must be identified and remedied or condition will recur. (Noxon 1997)
c) 5–10 mg/kg PO daily for 10 days, then every other day for an additional 10 days. This regimen resolves the majority of cases, but some may need higher dosages. (Muse 2000)
d) Initial dose is 5 mg/kg twice daily for 21–30 days, may increase to 10 mg/kg PO twice daily if poor response. Absorption is enhanced when administered with food and is ideal in an acid environment. (McDonald 1999)
e) 2.5–10 mg/kg PO once daily (q24h) for 7–14 days; once a good response is seen taper every other day (q48h) and continue until a complete remission occurs. In the rare case when ketoconazole is ineffective or intolerance or toxicity is seen, itraconazole or fluconazole can be used. (Rosenkrantz 2006)

For treatment of hyperadrenocorticism:

a) Author usually uses mitotane therapy, but if animal fails to respond can try ketoconazole: Initiate therapy at 5–10 mg/kg PO twice daily. The patient is monitored as for mitotane—water consumption or first sign of side effects (vomiting, diarrhea or anorexia) which can be seen as a result of the drug or secondary to hypokalemia. An idiosyncratic hepatopathy can also be seen (rare?). If no side effects are seen or the patient was not PU/PD initially, then the medication...
b) Begin with a dose of 5 mg/kg q12h for 5–7 days and if there are no side effects (usually GI-related), increase dose to 10 mg/kg q12h for 10–14 days and perform ACTH stimulation test. Plasma cortisol levels should be between 0.7–1.8 micrograms/dL if ketoconazole is to be effective. Over 25% of cases do not respond to ketoconazole and many cases that do respond, require doses of between 15–20 mg/kg q12h. Because of unpredictable efficacy, high occurrence of adverse effects, twice daily dosing, and expense, ketoconazole usage for PDH has been limited. (Church 2004)

c) For palliative treatment of canine Cushing’s syndrome: 15 mg/kg PO q12h (Lorenz & Melendez 2002)

To reduce the dosage requirements of cyclosporine:

a) Ketoconazole at 5–10 mg/kg PO per day can be administered concurrently with cyclosporine; in these patients the cyclosporine dose can be reduced (approximately half) or possibly tapered sooner than in patients not receiving the combination. Addition of ketoconazole is particularly useful in allergic patients with concurrent Malassezia dermatitis or otitis. (Hnilica 2006)

b) To treat perianal fistula: ketoconazole 7.5 mg/kg PO twice daily; cyclosporine 0.5–0.75 mg PO twice daily. (O’Neill et al. 2001)

c) For atomic dermatitis: Cyclosporine at 5–7 mg/kg/day or less. Ideally should be given on an empty stomach, but if causes GI upset administration with food may help. In large dogs, administration of cyclosporine at 2.5 mg/kg/day with ketoconazole (5 mg/kg/day) may give good results and reduce expenses. (White 2007)

d) As an alternative immunosuppressive agent for refractory IMHA, especially those that are non-regenerative: Cyclosporine at 5–10 mg/kg PO divided twice daily to achieve plasma trough levels of >200 ng/mL. (Note: reference states >200 mg/mL, but it is believed this is a typo). Large breed dogs can be dosed concurrently with ketoconazole (10 mg/kg/day) to allow reduction of cyclosporine dose. (Macintire 2006)

CATS:

Note: Use of ketoconazole in cats is somewhat controversial and some clinicians recommend that it not be used in this species because of its toxic potential. Consider using itraconazole in its place.

a) For coccidioidomycosis: 10–30 mg/kg PO divided twice a day, most animals need to be treated for 6–12 months (Taboada 2000)

b) For coccidioidomycosis: 50 mg per cat PO once daily; or 25–75 mg per cat q12–48h. Treatment requires many months (9–12 on average) and should continue for 1 month beyond last detection of infection. (Greene, C. et al. 2006)

c) For blastomycosis: 10 mg/kg q12h PO (for at least 60 days) with amphotericin B: 0.25 mg/kg in 30 mL D5W IV over 15 minutes q48h. Continue amphotericin B therapy until a cumulative dose of 4 mg/kg is given or until BUN >50 mg/dL. If renal toxicity does not develop, may increase dose to 0.5 mg/kg of amphotericin B. (Legendre, A.M. 1989)

d) For cryptococcosis: 10 mg/kg twice daily. Very useful for this condition in cats, but at this dosage can produce anorexia and debility. (Legendre, A. 1995)

e) For aspergillosis: 10 mg/kg PO q12h (Legendre, A.M. 1989)

f) For dermatophytosis: Usually reserved for when griseofulvin ineffective or not tolerated. 10 mg/kg PO once daily with an acidic meal. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

g) For Sporotrichosis: 5–10 mg/kg PO q12–24h. Treatment requires many weeks (2–4 months on average) and should continue for 1 month beyond last detection of infection. (Greene, C. et al. 2006)

HORSES:

a) For susceptible yeasts and Aspergillus spp: Using the commercial oral solution (Note: Not marketed in the USA): 5 mg/kg PO once daily.

For Scopulariopsis pneumonia: Oral tablets may be administered via NG tube by mixing them with 0.2 Normal hydrochloric acid and dosed at 30 mg/kg q12h. (Stewart et al. 2008a; Stewart et al. 2008b)

RABBITS/RODENTS/SMALL MAMMALS:

a) Rabbits: 10–40 mg/kg per day PO for 14 days (Ivey & Morrisey 2000)

b) Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: For systemic mycoses/candidiasis: 10–40 mg/kg per day PO for 14 days (Adamcak & Otten 2000)

BIRDS:

For susceptible fungal infections:

a) For severe refractory candidiasis in Psittacines: 5–10 mg/kg as a gavage twice daily for 14 days. For local effect in crop dissolve ¼ tablet (50 mg) in 0.2 mL of 1 N hydrochloric acid and add 0.8 mL of water. Solution turns pale pink when dissolved. Add mixture to food for gavage.

To add to water for most species: 200 mg/L for 7–14 days. As drug is not water soluble at neutral pH, dissolve in acid prior to adding to water (see above).

To add to feed for most species: 10–20 mg/kg for 7–14 days. Add to favorite food or add to mash. (Clubb 1986)

b) 20–30 mg/kg PO twice daily (based on the kinetics determined in a single trial of Moluccan Cockatoos) (Flammer 2003)

c) Rattus: 5–10 mg/kg PO once daily (Jenson 1998)

REPTILES:

a) For susceptible infections: For most species: 15–30 mg/kg PO once daily for 2–4 weeks (Gauvin 1993)

b) For fungal shell diseases in turtles/tortoises: 25 mg/kg PO once a day for 2–4 weeks (Rosskopf 1986)

Monitoring

- Liver enzymes with chronic therapy (at least every 2 months; some clinicians say monthly)
- CBC with platelets
Ketoprofen potentially has many other uses in a variety of species and conditions. Ketoprofen is labeled for use in horses for the alleviation of inflammation and pain associated with musculoskeletal disorders. Like flunixin (and other NSAIDs), 

**References**

**HUMAN-LABELLED PRODUCTS:**

Ketoconazole Tablets: 200 mg (scored); generic; (Rx)

Topical forms are also available.

**Compatibility/Compounding Considerations**

**Compound preparation stability:** Ketocoza ne oral suspension compounded from the commercially available tablets has been published (Allen & Erickson 1996). The toxicity of twelve (12) ketoconazole 200 mg tablets with 60 mL of Ora Plus® and Ora-Sweet® yields a 20 mg/mL ketoconazole oral suspension that retains >95% potency for 60 days when stored at both 5°C and 25°C and protected from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None for systemic use.

**KETOCONAZOLE**

- Non steroidal antinflammatory agent used in horses, cats (short-term) & dogs
- Cautions: GI ulceration or bleeding, hypoproteinaemia, breeding animals (especially late in pregnancy), significant renal or hepatic impairment; may mask the signs of infection (inflammation, hyperpyrexia)
- Adverse Effects: Horses: Potentially, gastric mucosal damage & GI ulceration, renal crest necrosis, & mild hepatitis may occur. Dogs: Vomiting, anorexia, & GI ulcers
- Do not administer intra-arterially & avoid SC injections
- Drug-drug: drug-lab interactions

**KETOPROFEN**

(ket-oe-proe-fen) Keto fen®, Anafen®

**NON-STERoidal ANTIINFLAMMATory AGENT**

**Prescriber Highlights**

- Nonsteroidal antinflammatory agent used in horses, cats (short-term) & dogs
- Cautions: GI ulceration or bleeding, hypoproteinaemia, breeding animals (especially late in pregnancy), significant renal or hepatic impairment; may mask the signs of infection (inflammation, hyperpyrexia)
- Adverse Effects: Horses: Potentially, gastric mucosal damage & GI ulceration, renal crest necrosis, & mild hepatitis may occur. Dogs: Vomiting, anorexia, & GI ulcers
- Do not administer intra-arterially & avoid SC injections
- Drug-drug: drug-lab interactions

**Uses/Indications**

Ketoprofen is labeled for use in horses for the alleviation of inflammation and pain associated with musculoskeletal disorders. Like flunixin (and other NSAIDs), ketoprofen potentially has many other uses in a variety of species and conditions.
Some consider ketoprofen to be the NSAID of choice for use short-term for analgesia in cats. There are approved dosage forms for dogs and cats in Europe and Canada. In Canada, ketoprofen has labeled indications for use in dogs and cats for the alleviation of inflammation, lameness and pain due to osteoarthritis, hip dysplasia, disc disease, spondylosis, panosteitis, trauma, and related musculoskeletal diseases; for the management of post-surgical pain; and for the symptomatic treatment of fever. It is labeled to be used with appropriate antiinfective therapy when inflammation and/or fever are associated with a primary infectious process.

**Pharmacology/Actions**

Ketoprofen exhibits actions similar to that of other nonsteroidal antiinflammatory agents in that it possesses antipyretic, analgesic and antiinflammatory activity. Its purported mechanism of action is the inhibition of cyclooxygenase catalysis of arachidonic acid to prostaglandin precursors (endoperoxides), thereby inhibiting the synthesis of prostaglandins in tissues. Ketoprofen purportedly has inhibitory activity on lipoxygenase, whereas flunixin reportedly does not at therapeutic doses, but the evidence for this action is weak as in vitro studies have not confirmed lipoxygenase activity in studied species.

The S (+) enantiomer is associated with anti-prostaglandin activity and toxicity and the R (-) form analgesia without the GI effects.

**Pharmacokinetics**

In species studied (rats, dog, man), ketoprofen is rapidly and nearly completely absorbed after oral administration. The presence of food or milk decreases oral absorption. Oral absorption is poor in horses. It has been reported that when comparing IV vs. IM injections in horses, the areas under the curve are relatively equivalent. Volume of distribution is low in adult horses. Volume of distribution is reported to be higher in foals and doses may need to be higher (1.5X) with longer durations between doses in neonates (Wilcke et al. 1998). The drug enters synovial fluid and is highly bound to plasma proteins (99% in humans, and approximately 93% in horses). In horses, the manufacturer reports that the onset of activity is within 2 hours and peak effects 12 hours post dose.

Ketoprofen is eliminated via the kidneys both as a conjugated metabolite (primarily glucuronidation in dogs and horses) and unchanged drug. In cats, thioesterification is proposed as a major elimination mechanism. The elimination half-life in horses is about 1.5 hours and in adult cats it is approximately 1-1.5 hours. The S- form half-life in dogs is about 1.6 hours.

**Contraindications/Precautions/Warnings**

While the manufacturer states that there are no contraindications to the drug’s use (other than previous hypersensitivity to ketoprofen), it should be used only when the potential benefits outweigh the risks in cases where GI ulceration or bleeding is evident or in patients with significant renal or hepatic impairment. Ketoprofen may mask the clinical signs of infection (inflammation, hyperpyrexia). Because ketoprofen is highly protein bound, patients with hypoproteinemias may have increased levels of free drug, thereby increasing the risks for toxicity.

**Adverse Effects**

Ketoprofen appears to have low toxicity in horses and reports indicate that ketoprofen appears relatively safe to use in horses and may have a lower incidence of adverse effects than either phenylbutazone or flunixin. Potentially, gastric mucosal damage and GI ulceration, renal crest necrosis, and mild hepatitis may occur.

Do not administer intra-arterially and avoid SC injections. While not labeled for IM use in horses, it reportedly is effective and may only cause occasional inflammation at the injection site.

In dogs or cats, ketoprofen may cause vomiting, anorexia, and GI ulcers.

**Reproductive/Nursing Safety**

The manufacturer cautions against ketoprofen’s use in breeding horses because effects on fertility, pregnancy, or fetal health have not been established. However, rat and mice studies have not demonstrated increased teratogenicity or embryotoxicity. Rabbits receiving twice the human dose exhibited increased embryotoxicity, but not teratogenicity. Because non-steroidal antiinflammatory agents inhibit prostaglandin synthesis, adversely affecting neonatal cardiovascular systems (premature closure of patent ductus), ketoprofen should not be used late in pregnancy. Studies in male rats demonstrated no changes in fertility. In humans, the FDA categorizes this drug as category B for use during the first two trimesters of pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is presently unknown whether ketoprofen enters equine milk. Ketoprofen does enter canine milk; use with caution.

**Overdose/Acute Toxicity**

Humans have survived oral ingestions of up to 5 grams. The LD50 in dogs after oral ingestion has been reported to be 2000 mg/kg, but exposures as low as 0.44 mg/kg in dogs have caused GI ulcers. Cats have developed renal toxicity at doses as low as 0.7 mg/kg. Horses given ketoprofen at doses up to 11 mg/kg administered IV once daily for 15 days exhibited no signs of toxicity. Severely laminitis was observed in a horse given 33 mg/kg/day (15X over labeled dosage) for 5 days. Anorexia, depression, icterus, and abdominal swelling were noted in horses given 55 mg/kg/day (25X labeled dose) for 5 days. Upon necropsy, gastritis, nephritis, and hepatitits were diagnosed in this group.

There were 16 exposures to ketoprofen reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 9 were dogs with 2 showing clinical signs and the remaining 7 cases with 2 showing clinical signs. Common findings in dogs recorded included vomiting.

This medication is a NSAID. As with any NSAID, overdose can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis is warranted.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketoprofen and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES (gentamicin, amikacin, etc.):** Increased risk for nephrotoxicity
- **ANTICOAGULANTS (heparin, LMWH, warfarin):** Increased risk for bleeding possible
- **ASPIRIN:** When aspirin is used concurrently with ketoprofen, plasma levels of ketoprofen could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with ketoprofen cannot be recommended.
- **BISPHOSPHONATES (alendronate, etc.):** May increase risk for GI ulceration
- **CORTICOSTEROIDS:** Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **CYCLOSPORINE:** May increase risk for nephrotoxicity
- **CYCLOSPORINE:** May increase risk for nephrotoxicity
- **PARACETAMOL:** May increase risk for nephrotoxicity
**FLUCONAZOLE**: May increase NSAID levels

**FUROSEMIDE**: Ketoprofen may reduce the saluretic and diuretic effects of furosemide

**HIGHLY PROTEIN BOUND DRUGS** (e.g., phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, and the sulfonylurea antidiabetic agents): Because ketoprofen is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.

**METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.

**PROBENECID**: May cause a significant increase in serum levels and half-life of ketoprofen

**Laboratory Considerations**

Ketoprofen may cause:

- Falsely elevated blood glucose values when using the glucose oxidase and peroxidase method using ABTS as a chromogen;
- Falsely elevated serum bilirubin values when using DMSO as a reagent;
- Falsely elevated serum iron concentrations using the Ramsey method, or falsely decreased serum iron concentrations when using bathophenanthroline disulfonate as a reagent

**Doses**

**DOGS**:

As an antiinflammatory/analgesic:

a) Injection at a dose of 2 mg/kg (0.2 mL/kg) IM, IV or SC injection for one day, and continue with ketoprofen tablets PO at a lower maintenance dose of 1 mg/kg once a day for four more days. (Adapted from label information—Anafen®; Merial-Canada)
b) For post-operative pain control: 1–2 mg/kg IV, IM once daily for 2–3 days duration (Tranquilli 2003)
c) For post-operative pain control: 1–2 mg/kg IV, SC once daily for 3 days duration after surgery; or 1 mg/kg PO once daily for 5 days, after surgery (Hansen 2003)
d) For acute indications: 2 mg/kg SC, IM, IV once daily for up to 3 consecutive days. If preferred after one injection treatment may be followed on the next day with tablets at 1 mg/kg PO per day and continued on successive days for up to 4 days (i.e., up to 5 days in total). For chronic pain: 0.25 mg/kg PO once daily for up to 30 days. (Label Information Ketofen 1%; Ketofen® Tablets—Merial U.K.)

**CATS**:

As an antiinflammatory/analgesic:

a) Injection at a dose of 2 mg/kg (0.2 mL/kg) SC for one day, and continue with ketoprofen tablets PO at a lower maintenance dose of 1 mg/kg once a day for four more days. In severe cases, the parenteral loading dose of 2 mg/kg can be given for up to three consecutive days. (Label information; Anafen®—Merial-Canada)
b) 1 mg/kg PO or SC once daily for up to 5 days, or 2 mg/kg SC as a single injection. (Duncan et al. 2007)
c) For post-operative pain control: 1–2 mg/kg IV, SC once daily for 3 days duration after surgery; or 1 mg/kg PO once daily for 3 days, after surgery (Hansen 2003)
d) 2 mg/kg SC once daily for up to 3 consecutive days. If preferred after one injection treatment may be followed on the next day with tablets at 1 mg/kg and continued on successive days for up to 4 days (i.e., up to 5 days in total). (Label Information Ketofen® 1%; Ketofen® Tablets—Merial U.K.)

**FERRETS**:

a) As a post-operative analgesic: 1–2 mg/kg (route not indicted; suggest SC or IM as per cats—Plumb) q24h. (Lichtenberger 2008)

**RABBITS/RODENTS.SMALL MAMMALS**:

a) **Rabbits**: For chronic pain/antiinflammatory: 1 mg/kg IM q12–24h (Ivey & Morrisey 2000)
b) **Rats**: 5 mg/kg SC (Adamcak & Otten 2000)
c) **Rabbits**: 3 mg/kg IM, estimated duration of action 12-24 hours. (Flecknell 2008)

**HORSES**:

(Note: ARCI UCGFS Class 4 Drug)

a) For labeled indications: 2.2 mg/kg (1 mL/100 lbs) IV once daily for up to 5 days (Package insert; Ketofen®)
b) As an adjunctive treatment for laminitis: 2.2 mg/kg IV once daily (Brumbaugh et al. 1999)

**CATTLE**:

a) 3 mg/kg IV or deep IM once daily for up to 3 days; withdrawal times (U.K.) are meat: 4 days; milk: 0 days (Label information Comforion Vet®—Merial U.K.)
b) 3.3 mg/kg; duration of effect 24 hours; appropriate withdrawal times: 24 hours for milk; 7 days for meat. (Walz 2006)

**SWINE**:

a) 3 mg/kg IM once daily for up to 3 days; withdrawal times (U.K.) for meat: 4 days (Label information Comforion Vet®—Merial U.K.)

**BIRDS**:

As an antiinflammatory analgesic:

a) 2 mg/kg IM q8–24 hours (Clyde & Paul-Murphy 2000)
b) 2 mg/kg IM or SC q8-24h (Echols 2008)

**ZOO, EXOTIC, WILDLIFE SPECIES**:

For use of ketoprofen in zoo, exotic and wildlife medicine refer to specific references, including:

Monitoring

- Efficacy
- Adverse Effects (occasional liver or renal function tests are recommended with long-term therapy)

Chemistry/Synonyms

A propionic acid derivative nonsteroidal antiinflammatory agent (NSAID), ketoprofen occurs as an off-white to white, fine to granular powder. It is practically insoluble in water, but freely soluble in alcohol at 20°C. Ketoprofen has a pKa of 5.9 in a 3:1 methanol/water solution. Ketoprofen has both an S enantiomer and R enantiomer. The commercial product contains a racemic mixture of both. The S (+) enantiomer has greater antiinflammatory potency than the R (-) form.

Ketoprofen may also be known as ketoprofenum and RP-19583; many trade names are available.

Storage/Stability

Ketoprofen oral capsules should be stored at room temperature in tight, light resistant containers. The veterinary injection should be stored at room temperature. Compatibility studies with injectable ketoprofen and other compounds have apparently not been published.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Ketoprofen Injection: 100 mg/mL in 50 mL and 100 mL multi-dose vials; Ketofen® (Pfizer), generic (Phoenix), (Rx). FDA-approved for use in horses not intended for food.
- In Canada and the U.K., there are FDA-approved oral dosage forms (5, 10, 20 mg tablets) and an injectable form (10 mg/mL) for use in dogs and cats. Trade names include Anafen® and Ketofen®.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

- Ketoprofen Capsules: 50 mg & 75 mg; generic; (Rx)
- Ketoprofen Extended-Release Capsules: 100 mg, 150 mg and 200 mg; generic; (Rx)

References

KETOROLAC TROMETHAMINE

(kee-toe-role-ak) Toradol®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- NSAID used primarily for short-term analgesia
- Contraindications: Active GI ulcers or history of hypersensitivity to the drug
- Relatively contraindicated: Hematologic, renal, or hepatic disease
- Caution: History of gastric ulcers, heart failure
- Adverse Effects: GI ulcers & perforation, renal effects possible with chronic use; consider co-dosing with misoprostol/sucralfate in dogs to reduce chances of ulcers

Uses/Indications

Ketorolac is used primarily for its analgesic effects for short-term treatment of mild to moderate pain in dogs and rodents. The duration of analgesic effect in dogs is about 8–12 hours, but because of the availability of approved, safer NSAIDs for dogs, its use is questionable.

Pharmacology/Actions

Like other NSAIDs, ketorolac exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase with resultant impeding of prostaglandin synthesis. Ketorolac may exhibit a more potent analgesic effect than some other NSAIDs. It inhibits both COX-1 and COX-2 receptors.

Pharmacokinetics
After oral administration, ketorolac is rapidly absorbed; in dogs peak levels occur in about 50 minutes and oral bioavailability is about 50–75%.

Ketorolac is distributed marginally through the body. It does not appear to cross the blood-brain barrier and is highly bound to plasma proteins (99%). The volume of distribution in dogs is reported to be about 0.33–0.42 L/kg (similar in humans). The drug does cross the placenta.

Ketorolac is primarily metabolized via glucuronidation and hydroxylation. Both unchanged drug and metabolites are excreted mainly in the urine. Patients with diminished renal function will have longer elimination times than normal. In normal dogs, the elimination half-life is between 4–8 hours.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketorolac and may be of significance in veterinary patients:

- **ACE INHIBITORS:** Increased risk for nephrotoxicity
- **ALPRAZOLAM:** Hallucinations reported in some human patients taking with ketorolac
- **AMINOGYCOPLIDES (gentamicin, amikacin, etc.):** Increased risk for nephrotoxicity
- **ANTICOAGULANTS (heparin, LMWH, warfarin):** Increased risk for bleeding possible
- **ASPIRIN:** Increased likelihood of GI adverse effects (blood loss)
- **BISPHOSPHONATES (alendronate, etc.):** May increase risk for GI ulceration
- **CORTICOSTEROIDS:** Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **CYCLOSPORINE:** May increase risk for nephrotoxicity
- **FLUCONAZOLE:** May increase NSAID levels
- **FLUOXETINE:** Hallucinations reported in some human patients taking with ketorolac
- **Furosemide:** Ketorolac may reduce the saluretic and diuretic effects of furosemide
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **MUSCLE RELAXANTS, NONDEPOLARIZING:** Ketorolac may potentiate effects
- **PROBENECID:** May cause a significant increase in serum levels and half-life of ketorolac
- **Hallucinations reported in some human patients taking with ketorolac**
- **May cause a significant increase in serum levels and half-life of ketorolac**
- **May increase NSAID levels**
- **May increase risk for GI ulceration**
- **Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution**
- **Ketorolac may potentiate effects**
- **May cause a significant increase in serum levels and half-life of ketorolac**

**Doses**

- **DOGS:**
  - a) As an analgesic: 0.5 mg/kg IV three times daily or 0.3 mg/kg PO twice daily. Repeated doses have considerable potential for causing GI or renal toxicity. Treated dogs should receive misoprostol. (Dowling 2000)
  - b) As an analgesic: 0.3–0.5 mg/kg IV, IM q8–12h for one or two doses (Scherk 2003)

- **CATS:**
  - a) As an analgesic: 0.25 mg/kg IM q8–12h for one or two doses (Scherk 2003)

- **GOATS:**
  - a) As an analgesic: 0.3–0.7 mg/kg IV, IM, SC, PO three times daily (Resources 2000)

- **RABBITS/RODENTS/SMALL MAMMALS:**
  - a) As an analgesic: Mice: 0.7–10 mg/kg PO once daily. Rats: 3–5 mg/kg PO once to twice a day; 1 mg/kg IM once to twice a day (Huerkamp 2000)

**Monitoring**

- Analgesic/antiinflammatory efficacy
Client Information

- Notify veterinarian if signs of GI distress (anorexia, vomiting, diarrhea, black feces, or blood in stool) occur, or if the animal becomes depressed.

Chemistry/Synonyms

A carboxylic acid derivative nonsteroidal antiinflammatory agent, ketorolac tromethamine occurs as an off-white crystalline powder with a pKa of 3.54 (in water). More than 500 mg are soluble in one mL of water at room temperature. The commercially available injection is a clear, slightly yellow solution with a pH of 6.9–7.9. Sodium chloride is added to make the solution isotonic.

Ketorolac tromethamine may also be known as RS-37619-00-31-3; many trade names are available.

Storage/Stability

Both the tablets and injection should be stored at room temperature and protected from light. Protect the tablets from excessive humidity. The injection is stable for at least 48 hours in commonly used IV solutions.

Compatibility/Compounding Considerations

It is recommended to not mix the injection with other drugs in the same syringe.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Ketorolac Tromethamine Tablets: 10 mg; generic; (Rx)
Ketorolac Tromethamine Injection: 15 mg/mL & 30 mg/mL in 1 mL, 2 mL single-dose vials, & 10 mL multiple-dose vials; generic; (Rx)
A topical ophthalmic preparation is also available; see the ophthalmology section in the appendix for further information.

Lactated Ringer’s—see the appendix section on intravenous fluids

**LACTULOSE**

*(d-l-tyoo-lose)* Cephulac®

DISACCHARIDE LAXATIVE/AMMONIA REDUCER

Prescriber Highlights

- Disaccharide laxative & reducer of blood ammonia levels
- Adverse Effects: Flatulence, gastric distention, cramping, etc.; diarrhea & dehydration are signs of overdosage
- Cats dislike the taste of lactulose liquid & administration may be difficult; lactulose crystals (*Kristalose®*) mixed into cats’ food may be more accepted
- May alter insulin requirements in diabetics

Uses/Indications

The primary use of lactulose in veterinary medicine is to reduce ammonia blood levels in the prevention and treatment of hepatic encephalopathy (portal-systemic encephalopathy; PSE) in small animals and pet birds. It is also used as a laxative in small animals.

Pharmacology/Actions

Lactulose is a disaccharide (galactose/fructose) that is not hydrolyzable by mammalian and, probably, avian gut enzymes. Upon reaching the colon, lactulose is metabolized by the resident bacteria resulting in the formation of low molecular weight acids (lactic, formic, acetic) and CO2. These acids have a dual effect; they increase osmotic pressure drawing water into the bowel causing a laxative effect and also acidify colonic contents. The acidification causes ammonia NH3 (ammonia) to migrate from the blood into the colon where it is trapped as [NH4]⁺ (ammonium ion) and expelled with the feces.

Pharmacokinetics

In humans, less than 3% of an oral dose of lactulose in absorbed (in the small intestine). The absorbed drug is not metabolized and excreted unchanged in the urine within 24 hours.
Contraindications/Precautions/Warnings

Lactulose syrup contains some free lactose and galactose, and may alter the insulin requirements in diabetic patients. In patients with preexisting fluid and electrolyte imbalances, lactulose may exacerbate these conditions if it causes diarrhea; use cautiously.

Adverse Effects

Signs of flatulence, gastric distention, cramping, etc. are not uncommon early in therapy, but generally abate with time. Diarrhea and dehydration are signs of overdosage; dosage should be reduced.

Cats dislike the taste of lactulose syrup and administration may be difficult. Lactulose granules (crystals) have been more successfully administered after mixing into food.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category B for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether lactulose is excreted in milk, but it would be unexpected.

Overdosage/Acute Toxicity

Excessive doses may cause flatulence, diarrhea, cramping, and dehydration. Replace fluids and electrolytes if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lactulose and may be of significance in veterinary patients:

**ANTACIDS, ORAL:** Antacids (non-adsorbable) may reduce the colonic acidification effects (efficacy) of lactulose

**LAXATIVES, OTHER:** Do not use lactulose with other laxatives as the loose stools that are formed can be falsely attributed to the lactulose with resultant inadequate therapy for hepatic encephalopathy

**NEOMYCIN:** Theoretically, orally administered antibiotics (*e.g.*, neomycin) could eliminate the bacteria responsible for metabolizing lactulose, thereby reducing its efficacy. However, some data suggests that synergy may occur when lactulose is used with an oral antibiotic (*e.g.*, neomycin) for the treatment of hepatic encephalopathy; enhanced monitoring of lactulose efficacy is probably warranted in cases where an oral antibiotic is added to the therapy

Doses

**DOGS:**

If using the crystals for oral solution: one gram of the crystals is equivalent to 1.5 mL of the liquid.

For hepatic encephalopathy:

a) 15–30 mL PO four times a day; adjust the dosage to produce 2–3 soft stools per day (Cornelius & Bjorling 1989)

b) Give 5 mL per 2.5 lbs. of body weight divided three times a day, may increase as necessary to achieve 2–3 soft stools per day. If patient is in hepatic encephalopathy crisis, may give 20–60 mL via stomach tube every 4–6 hours or may give as an intermittent enema (diluted with water) to total 200–300 mL (300–450 grams). (Tams 2000)

c) 1–10 mL PO three times daily; adjust dose to give 3–4 soft stools per day; reduce dose if diarrhea develops. May also give via enema in treating severe hepatic encephalopathy. (Twedt 2005)

d) 0.5 mL/kg PO two to three times a day with dietary adjustments. (Favier 2009)

For constipation:

a) 1 mL per 4.5 kg of body weight PO q8h initially, then adjust as needed (Kirk 1986)

**CATS:**

If using the crystals for oral solution: one gram of the crystals is equivalent to 1.5 mL of the liquid. An anecdotal suggested dose for constipation in cats is ½ to ¾ of a teaspoonful twice daily.

For hepatic encephalopathy:

a) 0.25–1 mL PO; individualize dosage until semi-formed stools are produced (Center *et al.* 1986)

For constipation:

a) As an enema: 5–10 mL per cat; administered slowly with a well-lubricated 10-12 (french) rubber catheter or feeding tube. Orally: 0.5 mL/kg PO two to three times a day. (Washabau 2007)

b) For maintaining soft stools in cats with chronic constipation: 0.5 mL/kg PO two to three times daily. Dosage is adjusted to obtain the stool quality desired. (Carr 2009)

**BIRDS:**

For hepatic encephalopathy; to stimulate appetite, improve intestinal flora:

a) Cockatiel: 0.03 mL PO two to three times a day; *Amazon:* 0.1 mL PO two to three times a day. Reduce dosage if diarrhea develops. May be used for weeks. (Clubb 1986)

**REPTILES:**

As a laxative:

a) *Green Iguana:* 0.3 mL/kg PO q12h (Wilson 2002)

Monitoring

*Clinical efficacy (2–3 soft stools per day) when used for PSE*

*In long-term use (months) or in patients with preexisting fluid/electrolyte problems, serum electrolytes should be monitored.*
Limited information is available for dogs and cats but it appears that lanthanum is well tolerated. Vomiting has been reported in cats. Adverse Effects as there is an increased chance for oral absorption. There are no listed contraindications for lanthanum carbonate, but it should be used with caution in patients where the GI tract is not intact (Contraindications/Precautions/Warnings). Studies in dogs, mice, and rats have shown that lanthanum levels in tissues increase over time and can be several orders of magnitude higher than that found in the plasma. Highest tissue levels are found in the GI tract, bone, and liver. In rats, absorbed lanthanum is cleared primarily via biliary excretion into the feces. In humans, systemically available lanthanum is very highly bound to plasma proteins (>99%).

Following oral doses, lanthanum bioavailability is very low (less than 0.002%). In humans, systemically available lanthanum is very highly bound to plasma proteins (>99%). Studies in dogs, mice, and rats have shown that lanthanum levels in tissues increase over time and can be several orders of magnitude higher than that found in the plasma. Highest tissue levels are found in the GI tract, bone, and liver. In rats, absorbed lanthanum is cleared primarily via biliary excretion into the feces. In dogs, mean recovery of an oral dose of lanthanum averages 94%.

Contraindications/Precautions/Warnings
There are no listed contraindications for lanthanum carbonate, but it should be used with caution in patients where the GI tract is not intact (e.g., GI ulcers, colitis, etc.) as there is an increased chance for oral absorption.

Adverse Effects

- Oral administration of lanthanum carbonate may cause nausea, vomiting, and diarrhea in some patients. Contact veterinarian if signs worsen or less than 2–3 soft stools are produced per day.
- In long-term use (months) or in patients with preexisting fluid/electrolyte problems, serum electrolytes should be monitored.

Client Information

- Contact veterinarian if diarrhea develops.
- When lactulose is used for hepatic encephalopathy, contact veterinarian if signs worsen or less than 2–3 soft stools are produced per day.

Chemistry/Synonyms

A synthetic derivative of lactose, lactulose is a disaccharide containing one molecule of galactose and one molecule of fructose. It occurs as a white powder that is very slightly soluble in alcohol and very soluble in water. The commercially available solutions are viscous, sweet liquids with an adjusted pH of 3–7. One gram of the lactulose crystals for oral solution (Kristalose®) is equivalent to 1.5 mL of the liquid. Lactulose may also be known as lactulosum; many trade names are available.

Storage/Stability

Lactulose syrup should be stored in tight containers, preferably at room temperature; avoid freezing. If exposed to heat or light, darkening or cloudiness of the solution may occur, but apparently this does not affect drug potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lactulose Solution: 10 grams lactulose per 15 mL (<1.6 grams galactose, <1.2 grams lactose and ≤1.2 grams of other sugars) in 237 mL, 473 mL, 946 mL, 960 mL, 1893 mL, 1.89 L, 1.9 L, & UD 30 mL; Cephulac® (Hoechst-Marion Roussel); Constulose® and Enulose® (Alpharma); generic; (Rx)

Lactulose Crystals for Oral Solution: Lactulose (<0.3 grams galactose and lactose/10 g) in 10 grams and 20 grams; Kristalose® (Bertek); (Rx)

Lactulose Solution for oral or rectal use: 10 grams/15 mL in 473 mL & 1,892 mL; Generic® (Morton Grove Pharmaceuticals); (Rx)

References

Limited information is available for dogs and cats but it appears that lanthanum is well tolerated. Vomiting has been reported in cats.

Reproductive/Nursing Safety
It is likely that lanthanum is safe to use during pregnancy. For humans, the FDA has placed it in category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans. However, there does not appear to be a significant risk to offspring.)

Lanthanum should be safe to use in nursing dams.

Overdosage/Acute Toxicity
No specific information was located. It is likely that an acute overdose would be tolerated, with the chance that it might cause GI effects. Only supportive treatment should be required. In a poster presentation of a dose escalation study in cats, cats tolerated oral dosages up to 1 gram/kg, but vomited repeatedly after receiving 2 grams/kg (Schmidt & Spiecker-Hauser 2009).

Drug Interactions
Drug interactions with lanthanum carbonate have not been reported, but as it is a binding agent similar to aluminum, it seems prudent to separate by two hours dosing lanthanum and the following:

- ALLOPURINOL
- CHLOROQUINE
- CORTICOSTEROIDS
- DIGOXIN
- ETHAMBU TOL
- FLUOROQUINOLONES
- H-2 ANTAGONISTS (ranitidine, famotidine, etc.)
- IRON SALTS
- ISONIAZID
- PENCILLAMINE
- PHENOTHIAZINES
- TETRACYCLINES
- THYROID HORMONES

Laboratory Considerations
- No specific concerns

Doses

CATS:
As a phosphate binder:

a) Relatively little is known about use of sevelamer and lanthanum in dogs and cats; anecdotally they appear to be both safe and effective. Both have been used in cats at a dose of 200 mg (total dose) PO (on/in food) 2–3 times daily. (Sparkes 2006)

b) Using the proprietary product Renalzin®: The standard recommended dosage is 2 mLs (400 mg) applied in the cat’s food, once or twice daily depending on the cat’s feeding regimen. (Renalzin®—Bayer-UK)

Monitoring
- Serum phosphorous (and other electrolytes such as potassium, calcium, bicarbonate, chloride)

Client Information
- As the human dosing recommendations are to chew tablets and not to swallow whole tablets intact, crush and place on the animal’s food. If using a veterinary commercial product containing lanthanum carbonate, follow the administration directions.

Chemistry/Synonyms
Lanthanum is a chemical element with the symbol La and atomic number 57. When used pharmacologically, it is administered as lanthanum carbonate. Lanthanum carbonate may also be known as: Bay-78-1887, and by the trade names Lantharenol®, Renalzin®, and Fosrenol®.

Storage/Stability
Store tablets at room temperature (25°C, 77°F); excursions are permitted to 15°–30°C (59°–86°F). Protect from moisture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in USA
A lanthanum carbonate (octa-hydrate), kaolin, and vitamin E labeled product (Renalzin®) for use in cats is available in several countries (not USA or Canada at time of writing). It does not appear to be a licensed product, but is a food additive/supplement in those countries. Confirmed concentrations of the ingredients were not found, but it has been reported that 1 mL contains 200 mg of lanthanum carbonate. Available as a pump gel/paste in 50 mL and 150 mL pump containers; Renalzin® (Bayer)
HUMAN-LABELED PRODUCTS:
Lanthanum Carbonate Oral Chewable Tablet 500 mg, 750 mg, & 1,000 mg; Foxrenol® (Rexar); (Rx)

References

LAXATIVES, HYPEROSMOTIC
MAGNESIUM SALTS
PEG 3350 PRODUCTS
SORBITOL
GoLYTELY®, Epsom Salts, Glauber’s Salt
LAXATIVES
Prescriber Highlights

- Saline/hyperosmotic agents for constipation, bowel “cleansing”, & to increase elimination of GI toxins
- Contraindications: PEG 3350 solutions are contraindicated in patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon (humans). Saline cathartics should be used with extreme caution in patients with renal insufficiency, pre-existing water-balance or electrolyte abnormalities, or cardiac disease.
- Adverse Effects: Cramping, nausea possible. Electrolyte disturbances possible, particularly with repeated use
- If magnesium salts used chronically: Hypermagnesemia (muscle weakness, ECG changes & CNS effects)

Uses/Indications
The hyperosmotic laxatives are used for their cathartic action to relieve constipation. They are also used to reduce intestinal transit time thereby reducing the absorption of orally ingested toxicants. Commonly, or historically used hyperosmotic laxatives include: magnesium sulfate, magnesium oxide (milk of magnesia), sodium sulfate, sorbitol, and polyethylene glycol 3350 products.

Pharmacology/Actions
Although unproven, it is commonly believed that the hyperosmotic effect of the poorly absorbed magnesium cation causes water retention, stimulates stretch receptors and enhances peristalsis in the small intestine and colon. Recent data, however, suggests that magnesium ions may directly decrease transit times and increase cholecystokinin release.
Sorbitol is a non-absorbable sugar alcohol that acts as an osmotic laxative.
Polyethylene glycol (PEG) 3350 is a non-absorbable compound that when used alone (MiraLax®, etc.) acts as an osmotic laxative agent. When used as a bowel cleansing solution (Colyte®, GoLytel®, etc.), additional electrolytes are added to help prevent electrolyte imbalances from occurring. Sodium sulfate is the primary sodium source so sodium absorption is minimized. Other electrolytes (bicarbonate potassium and chloride) are also added so that no net change occurs with either absorption or secretion of electrolytes or water in the gut.

Pharmacokinetics
When magnesium salts are administered, up to 30% of the magnesium dose of magnesium can be absorbed.
Generally, the onset of action of saline cathartics (characterized by a loose, watery stool) occurs in 3–12 hours after dosing in monogastric animals and within 18 hours in ruminants. Depending on dose and additional fluid consumed, polyethylene glycol (PEG) and sorbitol laxatives can have an effect within one hour of dosing.

Contraindications/Precautions/Warnings
Saline cathartics are contraindicated in dehydrated patients or for long-term use. Sodium containing laxatives are contraindicated in patients with congestive heart failure or congenital megacolon. In humans, PEG 3350 and sorbitol solutions are contraindicated in patients with GI obstruction, gastric retention, bowel perforation, toxic colitis, or megacolon. Saline cathartics should be used with extreme caution in patients with renal insufficiency, pre-existing water-balance or electrolyte abnormalities, or cardiac disease.

Adverse Effects
Except for possible cramping and nausea, adverse effects in otherwise healthy patients generally occur only with the saline cathartics with chronic use or overdoses.
When magnesium salts are used, hypermagnesemia manifested by muscle weakness, ECG changes and CNS effects can occur.
Sorbitol may cause vomiting, dehydration, secondary hypernatremia, abdominal cramping or pain, and possible hypotension.
In one small study (N=6) in cats where PEG 3350 with electrolytes (e.g., CoLyte®) was given long-term (powder in food and dose titrated to produce soft, but formed stools), one cat sporadically vomited after dosing, mild erythrocytosis was noted in one cat, and 3 cats developed mild hyperkalemia. The authors concluded that PEG 3350 was a safe and palatable oral laxative in cats for long-term use; potential side effects include hyperkalemia and subclinical dehydration (Tam et al. 2010). In humans, polyethylene glycol 3350 has rarely caused hyponatremia secondary to syndrome of inappropriate vasopressin release (SIADH).

Reproductive/Nursing Safety
It is not known whether PEG or magnesium is excreted in human milk. For nursing women, it is recommended to refrain from its use; if that is not possible, the risk to the nursing infant should be weighed against the mother’s need for PEG or magnesium.
Doses

**DOGS:**

Magnesium hydroxide (Milk of Magnesia) as a cathartic:
- a) 5–10 mL (Davis, L.E. 1985)
- b) 1–20 mL PO (Rossoff 1974)

Magnesium sulfate:
- a) 5–25 grams PO (Davis, L.E. 1985)
- b) 2–60 grams PO (Rossoff 1974)

Sorbitol (70%):
- a) As a cathartic with activated charcoal in intoxications: If activated charcoal does not contain a pre-existing cathartic (for the first dose administered), one can potentially add in sorbitol (70% solution) for a one dose dosing at: 1–2 mL/kg, PO, given within 60 minutes of toxin ingestion. (Lee 2010)

Polyethylene Glycol-Electrolyte Solution:
- a) For colonic cleansing prior to colonoscopy using Go-Lytely®: Keep animal from food for 24–36 hours. On the evening prior to a morning colonoscopy (or the morning for an afternoon colonoscopy), give 60 mL/kg via orogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia. (Leib 2003), (Leib 2006)
- b) For colonic cleansing prior to colonoscopy using Go-Lytely®: 12–18 hours prior to colonoscopy give 25 mL/kg via orogastric tube three to five times, one hour apart. Give enema shortly after last Go-Lytely® dose and one to two hours prior to endoscopy procedure. (Richter 2003)
- c) For colonic cleansing prior to colonoscopy using Go-Lytely®: Withhold food for 18–24 hours. Give two doses of 20 mL/kg Go-Lytely® 4–6 hours apart the afternoon before an AM endoscopy. The morning of procedure, a warm-water enema is administered. (Jergens 2003)
- d) For mechanical bowel cleansing prior to (antibiotics and) colonic surgery: Go-Lytely® (or similar osmotic cathartic): 50–75 mL/kg by stomach tube or NE tube the evening prior to surgery. (Trepanier 2003)

**CATS:**

Magnesium hydroxide (Milk of Magnesia) as a cathartic:
- a) 2–6 mL (Davis, L.E. 1985)
- b) 1–5 mL PO (Rossoff 1974)

Magnesium sulfate:
- a) 2–5 grams PO (Davis, L.E. 1985), (Rossoff 1974)

Sorbitol (70%):
- a) As a cathartic with activated charcoal in intoxications: If activated charcoal does not contain a pre-existing cathartic (for the first dose administered), one can potentially add in sorbitol (70% solution) for a one dose dosing at: 1–2 mL/kg, PO, given within 60 minutes of toxin ingestion. (Lee 2010)

Polyethylene Glycol-Electrolyte Solution:
- a) As a laxative: ¼th to ½ teaspoonful twice daily in food. (Scherk 2010)

Polyethylene Glycol-Electrolyte Solution:
- a) For colonic cleansing prior to colonoscopy using Go-Lytely®: Keep animal from food for 24–36 hours. On the evening prior to a morning colonoscopy (or the morning for an afternoon colonoscopy), give 60 mL/kg via nasogastric tube. Repeat in 2 hours. A warm water enema should follow each dose and a third enema given prior to anesthesia. Metoclopramide (0.2 mg/kg SC 15–20 minutes before the first Go-Lytely® dose is given to reduce vomiting. (Leib 2003), (Leib 2006)

**HORSES:**

Magnesium hydroxide (Milk of Magnesia) as a cathartic:
- a) 2–6 mL (Davis, L.E. 1985)
- b) 1–5 mL PO (Rossoff 1974)

Magnesium sulfate:
- a) 2–5 grams PO (Davis, L.E. 1985), (Rossoff 1974)

Sorbitol (70%):
- a) As a cathartic with activated charcoal in intoxications: If activated charcoal does not contain a pre-existing cathartic (for the first dose administered), one can potentially add in sorbitol (70% solution) for a one dose dosing at: 1–2 mL/kg, PO, given within 60 minutes of toxin ingestion. (Lee 2010)

Polyethylene Glycol-Electrolyte Solution:
- a) As a cathartic for plant intoxications: Activated charcoal (AC) slurry dosage range of 1–5 grams/kg (~1 gram of activated charcoal per 5 mL of water). Multi-dose activated charcoal is beneficial for a number of plant intoxications, including oleander. Administration of a cathartic mixed in the AC slurry helps to hasten elimination of contents from the gastrointestinal tract. Commonly used cathartics include sodium sulfate (Glauber’s salts), magnesium sulfate (Epsom salts), and sorbitol. Sodium or magnesium sulfate can be administered at 250–500 mg/kg mixed in the AC slurry. Sorbitol (70%), also mixed in the AC slurry, can be administered at 3 mL/kg. There is little need to administer a cathartic if significant diarrhea is already present. (Puschner 2010)

Magnesium sulfate (Epsom salt):
a) 0.2 grams/kg diluted in 4 L of warm water administered via nasogastric tube. Administer only to well-hydrated animals (ideally in conjunction with IV fluid therapy). Do not treat longer than 3 days or there is an increased risk of enteritis or magnesium toxicity occurring. (Clark & Becht 1987)
b) As a laxative: 1 gram/kg PO every 1–2 days; in colic delay treatment until rehydrated (Moore 1999)
c) To reduce absorption of toxicants and GI transit time: 500 grams (as a 20% solution) PO. If mineral oil has been used initially, give saline cathartic 30–45 minutes after mineral oil. (Oehme 1987)
d) For cecal impactions: 1 gram/kg dissolved in water given via NG tube. Give with a balanced electrolyte solution IV to stimulate secretion into the dehydrated ingesta. (White 2005)

CATTLE:
a) Sodium sulfate (as a cathartic) 500–750 grams PO as a 6% solution via stomach tube (Davis, L. 1993) Note: When used in food animals, FARAD states that this salt is rapidly excreted and not considered a residue concern in animal tissues; therefore, a 24 hour preslaughter withdrawal interval (WDI) would be sufficient. (Haskell et al. 2005)
b) See the reference by Puschner in the horse section above.
MgSO4 (as a cathartic):
a) 0.5–1 kg/500 kg orally (Whitlock 1986)
b) 1–2 grams/kg PO (Howard 1993)
MgO:
a) 0.5–1 kg/500 kg orally (Whitlock 1986)

SHEEP & GOATS:
a) Sodium sulfate (as a cathartic) 60 grams PO as a 6% solution via stomach tube (Davis, L. 1993)

SWINE:
a) Magnesium sulfate (as a cathartic): 1–2 grams/kg PO (Howard 1993)
b) Sodium sulfate (as a cathartic): 30–60 grams PO as a 6% solution via stomach tube (Davis, L. 1993)

BIRDS:
Magnesium sulfate:
a) To act as a cathartic and reduce lead absorption: 0.5–1 gram/kg PO as a 5% solution in drinking water (McDonald 1986)

Monitoring
- Fluid and electrolyte status in susceptible patients, high doses, or chronic use
- Clinical efficacy

Client Information
- Do not give dosages greater than, or for periods longer than those recommended by veterinarian
- Contact veterinarian if patient begins vomiting

Chemistry/Synonyms
Magnesium cation containing solutions of magnesium citrate, magnesium hydroxide, or magnesium sulfate act as saline laxatives. Magnesium citrate solutions contain 4.71 mEq of magnesium per 5 mL. Magnesium hydroxide contains 34.3 mEq of magnesium per gram and milk of magnesia contains 13.66 mEq per 5 mL. One gram of magnesium sulfate (Epsom salt) contains approximately 8.1 mEq of magnesium.

Sodium sulfate (hexahydrate form) occurs as large, colorless, odorless, crystals or white crystalline powder. It will effloresce in dry air and partially dissolve in its own water of crystallization at about 33°C. 1 gram is soluble in about 2.5 mL of water. Sodium sulfate may also be known as E514, Glauber’s Salt, natrii sulphas, natrium sulfatatum, or natrium sulfuricum.

Polyethylene glycol 3350 is a non-absorbable compound that acts as an osmotic agent.

Storage/Stability
Magnesium citrate solutions should be stored at 2–30°C. Store milk of magnesia at temperatures less than 35°C, but do not freeze. PEG 3350 reconstituted (from powder by the pharmacy, client, clinic, etc.) solutions should be kept refrigerated and used within 24 hours.

Dosage Forms/Regulatory Status
Saline cathartic products have apparently not been formally FDA-approved for use in domestic animals. They are available without prescription (OTC).

VETERINARY-LABELED PRODUCTS: None located
HUMAN-LABELED PRODUCTS:
Saline/Hyperosmotic Laxatives (not an inclusive list):
Milk of Magnesia:
- Milk of Magnesia Concentrated® (Roxane)
- Phillips® Milk of Magnesia Concentrated (Bayer); generic; (OTC)
Milk of Magnesia Concentrated® (Bayer); generic; (OTC)
Milk of Magnesia Concentrated® (Bayer); generic; (OTC)
Milk of Magnesia Concentrated® (Bayer); generic; (OTC)

Magnesium Sulfate (Epsom Salt) Granules: in 120 g, 1lb and 4lbs; generic; (OTC)
Sodium sulfate (hexahydrate) is available from chemical supply houses.

Sorbitol 70% in pints; generic; (OTC). Sorbitol is also included in several activated charcoal products.

Polyethylene Glycol 3350 Powder for solution:
MiraLax® (Plough); GlycoLax® (K-U); ClearLax® (Perrigo); Dulcolax Balance® (BI); generic. Available in either pre-measured 17 gram packets or bulk powder and are OTC.
Polylethylene Glycol 3350 and Electrolyte Solutions (Rx):

**OCL** Solution (Abbott); (Rx) Oral Solution in 1500 mL: 146 mg sodium chloride, 168 mg sodium bicarbonate, 1.29 grams sodium sulfate decahydrate, 75 mg potassium chloride, 6 grams PEG-3350.

**CoLyte** (Schwartz Pharma); (Rx); 1 gallon of Powder for Oral Solution in bottles: 227.1 grams PEG 3350, 5.53 grams sodium chloride, 6.36 grams sodium bicarbonate, 21.5 grams sodium sulfate, 2.82 grams potassium chloride; 4L of solution: 240 grams PEG 3350, 22.72 grams sodium sulfate, 6.72 grams sodium bicarbonate, 5.84 grams NaCl, 2.98 grams KCL

**GoLYTELY** (Barntree Labs); (Rx); Powder for Oral Solution in jugs: 5.86 grams sodium chloride, 6.74 grams sodium bicarbonate, 22.74 grams sodium sulfate, 2.97 grams potassium chloride, 236 grams PEG 3350; Packets: 227.1 grams PEG 3350, 21.5 grams sodium sulfate, 6.36 grams sodium bicarbonate, 5.53 grams NaCl, 2.82 grams KCL

**NuLytely** (Barntree Labs); **TriLyte** (Schwarz Pharma); (Rx); Powder for Reconstitution in 4 L jugs: 420 grams PEG 3350, 5.72 grams sodium bicarbonate, 11.2 grams NaCl, 1.48 grams KCL

**MoviPrep** (Satix); (Rx); Powder for Reconstitution in pouches: 100 grams PEG 3350, 7.5 grams sodium sulfate, 2.691 grams NaCl, 1.015 grams KCl.

**LEFLUNOMIDE** (le-floo-noh-myde) Arava®

**IMMUNOMODULATING AGENT**

**Prescriber Highlights**

- Immunomodulating drug that may be useful in dogs for treating a variety of immune-mediated conditions such as IMHA, systemic & cutaneous reactive histiocytosis, granulomatous meningoencephalitis, etc.; can be used as part of transplant rejection protocols in dogs. Has been used with methotrexate to treat rheumatoid arthritis in cats.
- Appears well-tolerated in dogs and cats, but numbers treated are low
- Teratogenic (Category X)
- Active metabolite can persist in body for years
- Treatment can be very expensive, but prices dropping secondary to generic availability

---

**Uses/Indications**

Leflunomide is an immunomodulating drug that may be useful in dogs for treating a variety of immune-related conditions such as IMHA, systemic and cutaneous reactive histiocytosis, granulomatous meningoencephalitis, etc; it can be used as part of transplant rejection protocols in dogs. Leflunomide has been used with methotrexate to treat rheumatoid arthritis in cats.

**Pharmacology/Actions**

Leflunomide inhibits autoimmune T-cell proliferation and autoantibody production by B cells. Leflunomide acts almost exclusively via its active metabolite A77 1726 (M1). This metabolite reversibly inhibits the mitochondrial enzyme dihydroorotate dehydrogenase thereby preventing the formation of ribonucleotide uridine monophosphate (rUMP). This causes decreased DNA and RNA synthesis, inhibition of cell proliferation, and G1 cell cycle arrest.

**Pharmacokinetics**

Specific information on the pharmacokinetics of leflunomide in dogs and cats was not located, but it has been reported that the conversion to a toxic metabolite is slower in cats than in dogs. Leflunomide is rapidly converted to A77 1726 (active metabolite; M1) in the GI mucosa and liver. Peak levels of A77 1726 occur between 6–12 hours after an oral dose. The presence of food in the gut does not appear to affect oral bioavailability. A77 1726 Is highly bound to albumin (>99%). A77 1726 is further degraded in the liver as glucuronides and an oxalinic acid compound which are excreted in the urine and bile. Half-life is about 15 days, but the metabolite (A77 1726) can be detectable in patients up to 2 years after it is discontinued.

**Contraindications/Precautions/Warnings**

Leflunomide is contraindicated during pregnancy and in patients hypersensitive to it. It should be used with extreme caution in patients with immunodeficiency and in patients with significant renal impairment.
Adverse Effects
Leflunomide appears to be well tolerated by dogs. Adverse effects reported include decreased appetite, lethargy, vomiting, lymphopenia, and anemia.

In humans, gastrointestinal effects (diarrhea, nausea), alopecia and rash are most commonly reported. Serious adverse effects that have been reported include hematologic toxicity, dermatologic effects (TEN, Stevens-Johnson, etc.), and hepatotoxicity.

Reproductive/Nursing Safety
Leflunomide should not be used during pregnancy. A variety of teratogenic effects in laboratory animals have been detailed at doses used clinically. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

It is not known whether leflunomide is excreted in milk; it is suggested to use milk replacer if the dam is receiving the drug.

Overdosage/Acute Toxicity
Acute toxicologic studies in mice and rats have demonstrated that the minimally toxic dose is 200 mg/kg and 100 mg/kg, respectively. Cholestyramine or activated charcoal are recommended to accelerate elimination. Contact an animal poison control center for more information.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving leflunomide and may be of significance in veterinary patients:
- **CHARCOAL, ACTIVATED:** Can increase elimination and decrease A77 1726 drug concentrations; may be used when more rapid elimination is desirable
- **CHOLESTYRAMINE:** Can increase elimination and decrease A77 1726 drug concentrations; may be used when more rapid elimination is desirable
- **HEPATOTOXIC AGENTS, OTHER:** Increased risk for toxicity
- **METHOTREXATE:** Increased risk for toxicity
- **PHENYTOIN:** Leflunomide can increase phenytoin levels
- **RIFAMPIN:** Can increase A77 1726 peak levels
- **VACCINES, LIVE VIRUS:** Live virus vaccines should be used with caution, if at all, during leflunomide therapy
- **WARFARIN:** Leflunomide may increase INR

Doses

**DOGS:**
- a) As an immunosuppressive as part of a protocol (with cyclosporine) following organ transplant: Leflunomide 4–6 mg/kg PO q24h and then to maintain trough plasma levels of 20 micrograms/mL. (Sykes 2007)
- b) As an adjunctive immunosuppressive for immune-mediated hemolytic anemia: 4 mg/kg PO q24h. (Chabanne 2006)
- c) For treatment of systemic and cutaneous reactive histiocytosis: 2–4 mg/kg PO once daily to attain trough levels of 20 micrograms/mL. (Foil 2003)
- d) For treatment of Evans’ Syndrome in a diabetic dog (from a case report): In combination with human intravenous immunoglobulin (hIVIg), leflunomide was initiated at a dosage of 2 mg/kg PO q12h (based on the nontoxic dosage of 4 mg/kg per day used in studies of the canine renal transplantation model). Leflunomide dosage was decreased by 25% every 4 weeks for the first 4 months in order to achieve a trough level of approximately 20 micrograms/mL (leflunomide trough levels were based on studies of the canine renal transplantation model); then the dosage was decreased every 8 weeks until discontinuation after 10 months of therapy. (Bianco & Hardy 2009)

**CATS:**
- a) For rheumatoid arthritis: Initially, leflunomide at 10 mg (total dose) PO once daily and methotrexate at 2.5 mg (total dose) PO three times on one day per week. When significant improvement occurs, reduce doses of leflunomide to 10 mg PO twice weekly and methotrexate to 2.5 mg PO once weekly. (Bennett 2005)

Monitoring
- Adverse effects (CBC, liver enzymes)
- Trough levels of A771 1726 (20 micro-grams/mL is target)

Client Information
- Relatively experimental when used in veterinary patients; contact veterinarian if any unusual effects are noted
- Treatment can be very expensive

Chemistry/Synonyms
Leflunomide has a melting point of 165–166°C. It is poorly soluble in water (21 mg/L).
Leflunomide may also be known as HWA 486, RS 34821, or SU 101; a common trade name is Arava®.

Storage/Stability
Leflunomide tablets should be stored at room temperature (15–30°C) and protected from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Leflunomide Tablets: 10 mg & 20 mg; Arava® (Hoechst Marion Roussel); generic; (Rx)
LEUCOVORIN CALCIUM
(loo-koe-vor-in) Folic Acid, Citrovorum Factor
ORAL OR INJECTABLE FOLIC ACID DERIVATIVE

Prescriber Highlights

- Primarily used in veterinary medicine to help reverse neurotoxicity or hematologic toxicity associated with dihydrofolate reductase inhibitors (e.g., pyrimethamine, trimethoprim, or ormetoprim)
- Leucovorin does not require conversion by dihydrofolate reductase for it to be active

Uses/Indications
Leucovorin calcium is the calcium salt of folinic acid and is used as an antidote for toxicity from folic acid antagonists (e.g., methotrexate, pyrimethamine, trimethoprim, ormetoprim). It is used routinely in human medicine as a rescue agent for high-dose methotrexate chemotherapy, but the drug is rarely used for this in veterinary medicine. More commonly, it is used in dogs, cats or horses to help reverse or prevent hematologic toxicity associated with pyrimethamine, trimethoprim, or ormetoprim.

Pharmacology/Actions
Reduced folates act as coenzymes in the synthesis of purine and pyrimidine nucleotides that are necessary for DNA synthesis. Folates are also required for maintenance of normal erythropoiesis.

Leucovorin is a reduced form of folic acid that does not require dihydrofolate reductase conversion, as does folic acid, for it to become biologically active. It is further converted to active reduced forms, of which 5-methyltetrahydrofolate (5-methyl THF) is predominantly responsible for its activity. Although, leucovorin is a mixture of diastereoisomers, only the (-)-L-isomer (citrovorum factor) becomes biologically active.

Leucovorin inhibits thymidylate synthase by stabilizing the binding of fluorodeoxyuridylic acid to the enzyme. This can potentiate the activity, but also the toxicity of fluorouracil (5-FU).

Pharmacokinetics
There is limited information available on the pharmacokinetics of leucovorin in animals. In dogs, the elimination half-life of the L-isomer (active) of leucovorin is about 50 minutes. It is extensively metabolized and then excreted into the urine. The D-form (not biologically active) elimination half-life is about 2.5 hours. Apparent volume of distribution for both forms is about 0.6 L/kg.

In humans, oral bioavailability of leucovorin is reduced as dosage is increased above 25 mg. A 25 mg dose in an adult has a bioavailability of 97%, while 50 mg and 100 mg doses have bioavailabilities of 75% and 37%, respectively. IM bioavailability is similar to IV. Oral doses of 25 mg yield peak levels of leucovorin in about an hour and peaks of the active reduced folates occur between 1.7 and 2.4 hours after dosing. After intravenous administration, peak total reduced folate levels occur in about 10 minutes. About 50% of oral body stores of reduced folates are found in the liver. Elimination occurs in the urine, primarily as 10-formyl-THF or 5,10-methyl-THF. Elimination half-life is approximately 5–6 hours for total reduced folates.

Contraindications/Precautions/Warnings
Leucovorin is contraindicated only when known intolerance to the drug is documented. In humans, cobalamin (B-12) levels may be reduced with megaloblastic anemias and folic acid therapy may mask the signs associated with it.

Use with extreme caution in patients receiving systemic fluorouracil (see Drug Interactions).

Because of its calcium content, large intravenous doses should be given slowly and not bolused.

Reproductive/Nursing Safety
Leucovorin reproductive studies have not been performed nor is it known if it enters milk, however, it is likely safe to administer during pregnancy or nursing.

Adverse Effects
Adverse effects have not been noted when leucovorin has been used in animals. In humans, gastrointestinal effects can be seen when the drug is given orally and, very rarely, seizures or hypersensitivity reactions may occur.

Overdosage/Acute Toxicity
Except in situations where drug interactions are possible, an inadvertent overdose is unlikely to be of concern.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving leucovorin and may be of significance in veterinary patients:

- **BARBITURATES, PRIMIDONE, PHENYTOIN**: Large doses of leucovorin may reduce the antiseizure efficacy of these agents
- **FLUOROURACIL**: Leucovorin may increase both the antineoplastic efficacy and toxicity of 5-FU
- **TRIMETHOPRIM, ORMETOPRIM, PYRIMETHAMINE** (drugs that inhibit dihydrofolate reductase): Leucovorin may reduce efficacy somewhat, however, protozoa cannot utilize leucovorin
Leucovorin calcium occurs as a yellowish-white or yellow, odorless powder. It is very soluble in water and practically insoluble in alcohol. It is a mixture of diastereoisomers of 5-formyl tetrahydrofolic acid.

Leucovorin calcium may also be known as: folinic acid, citrovorum factor, 5-formyl tetrahydrofolate, citrovorin, folidan, folinic, FTHF, NSC-3590, calcium folinate, calcifolin, calfonat, or folinic acid calcium salt; many international trade names are available.

Storage/Stability
Leucovorin calcium tablets should be stored below 40°C, preferably between 15–30°C in a well-closed container; protect from light.

Leucovorin solution for injection should be stored refrigerated between 2°–8°C; protect from light.

Leucovorin Powder for reconstitution and injection should be stored below 40°C, preferably between 15–30°C; protect from light.

Compatibility/Compounding Considerations
The powder for injection is reconstituted by adding 5 or 10 mL of bacteriostatic water for injection or sterile water for injection. As bacteriostatic water for injection contains benzyl alcohol, it is not recommended in neonates or very small animals. If reconstituting with sterile water for injection, the resulting solution should be administered immediately; solutions made with bacteriostatic water for injection are stable up to 7 days.

Intravenous solutions containing leucovorin calcium in Ringer’s lactate, Ringer’s, or 0.9% sodium chloride are stable up to 24 hours at room temperature.

Leucovorin calcium is not compatible with solutions containing fluorouracil.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

**Note:** Strengths listed are in terms of leucovorin base.

- Leucovorin Calcium Oral Tablets: 5 mg, 15 mg, & 25 mg; generic; (Rx)
- Leucovorin Calcium Injection Solution: 10 mg/mL in 5 mg single dose vials; generic; (Rx)
- Leucovorin Calcium Powder for Injection: 50 mg, 100 mg, 200 mg & 350 mg in vials; generic; (Rx)

**LEUPROLIDE**

(loe-proe-lide) Lupron®

---
Hormonal Agonist

Prescriber Highlights

- For medical treatment of adrenal associated endocrinopathy in ferrets, & to treat inappropriate egg laying in captive birds
- Depot form must not be confused with once a day injectable, doses below are for depot (IM suspension)
- Teratogenic, contraindicated in pregnancy
- Extremely costly (especially for ferrets); may be obtained in smaller aliquots from compounding pharmacies
- Lab considerations

Uses/Indications
The primary uses for leuprolide at present are for the medical treatment of adrenal associated endocrinopathy in ferrets, and to treat inappropriate egg laying in captive cockatiels. In ferrets, it may be more effective in treating clinical signs associated with adrenal hyperplasia or adenomas than with adenocarcinomas.

Pharmacology/Actions
Leuprolide is a luteinizing hormone-releasing hormone agonist. Via negative feedback, leuprolide inhibits the release of luteinizing hormone and follicle stimulating hormone from the pituitary. Both estrogen and androgen levels are decreased in the serum.

Pharmacokinetics
No veterinary data was located. The depot forms appear to have sustained effects in birds and ferrets.

Contraindications/Precautions/Warnings
Contraindicated in pregnancy.

Adverse Effects
In ferrets, adverse effects reported include pain/irritation at injection site, dyspnea, and lethargy. Tachyphylaxis (higher dosages required over time to obtain same effect) has been reported when using leuprolide in ferrets.

Little information is available on the adverse effect profile of leuprolide birds. At this point, it appears safe at the recommended doses.

Reproductive/Nursing Safety
Leuprolide is considered contraindicated in pregnancy. Major fetal abnormalities may result. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

- It is not known whether leuprolide is excreted in milk; use with caution.

Overdosage/Acute Toxicity
Because of its expense and method of dosing, it is unlikely an acute overdose would occur. Studies in lab animals at dosages of up to 5 grams/kg IM produced no untoward effects.

Drug Interactions
No documented adverse drug interactions with leuprolide were located.

Laboratory Considerations
- Diagnostic tests measuring pituitary gonadotrophic and gonadal functions may be misleading during, and for several months after discontinuing therapy

Doses

**Ferrets:**
- For treatment of adrenal associated endocrinopathy:
  a) Leuprolide acetate (Lupron Depot 30 day formulation): 100 micrograms/kg IM for females, 200 micrograms/kg IM for males q30 days has been proven effective in ferrets for management of the disease.
  b) Leuprolide acetate (Lupron Depot 3 month formulation): 1 mg (total dose) IM every 60-75 days (length of control in intact ferrets in Spring; may be useful for annual Dec/Feb suppression).
  c) Leuprolide acetate (Lupron Depot 4 month formulation): 2 mg (total dose) IM every 70-80 days (anecdotal time before signs reappear; may be useful for annual Dec/Feb suppression. (Johnson-Delaney 2009)
  d) Using the 30 day depot form: If ferret weighs less than 1 kg: 100 micrograms IM q30 days. If weighs >1 kg: 200 micrograms IM q30 days. Generally, the drug is diluted from its original concentration to negate the muscle necrosis problem that has been reported. The diluted form appears to remain active after being stored in the freezer for a year. (Murray 2002) (Note: The manufacturer states that the depot form is not to be frozen and no studies are known that support the stability of the depot activity when frozen and thawed—Plumb)
  e) Using the one month depot form: 100–250 micrograms/kg IM every 4 weeks until signs resolve, then every 4–8 weeks as needed, lifelong. Larger ferrets may require the higher dosage range. (Johnson 2006)

**Birds:**
- For inappropriate egg laying in Cockatiels if management changes, such as conversion to a pelleted diet, decreasing photoperiod, and reducing ‘mate’
Leuprolide may also be known as: leuprolin, leuprelinum, abbott-43818, leuprolide acetate, TAP-144, Carcini®, Daronda®, Eligard®, Elityran®, Enantone®, Enantone-Gyr®, Ginecrin®, Lectram®, Leuplin®, Lucrin®, Lupride®, Lupron®, Procrin®, Prostap®, Reliser®, Trenantone®, Uno-Enantone®, and Viadur®.

Compatibility/Compounding Considerations
The issue whether the solution containing microspheres (depot forms) can be frozen for later use is somewhat controversial as some have frozen the solution and state that it is still effective. However, the manufacturer states that the depot form is not to be frozen as the microspheres are destroyed and no studies are known that support the stability of the depot activity when frozen and thawed. Some compounding pharmacies may divide the lyophilized powder into individual dosages in vials. If it is decided to freeze the solution, most recommend putting individual aliquots into tuberculin syringes before freezing; do not re-freeze once thawed.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Leuprolide Acetate Injection: 5 mg/mL in 2.8 mL multi-dose vials; Lupron® & Lupron® for Pediatric Use (TAP Pharm); generic; (Rx)

Leuprolide Acetate Injection: 22.5 mg in single-use kits with a 2-syringe mixing system and needle; 30 mg & 45 mg in single-use kit with 2-syringe mixing system and syringe containing Atrigel®; Eligard® (Sanofi-Synthelabo); (Rx)

Leuprolide Powder for Injection: lyophilized 7.5 mg in single-use kits with a 2-syringe mixing system and needle; Eligard® (Sanofi-Synthelabo); (Rx)

Leuprolide Acetate Microspheres for Injection, lyophilized and preservative free with mannitol: 3.75 mg, 7.5 mg, 11.25 mg (regular—30 day & 3 month), 15 mg, 22.5 mg (3 month), & 30 mg (4 month) in single dose kits and pre-filled dual-chamber syringes; Lupron® Depot and Lupron® Depot-Ped and Lupron® Depot-3 or -4 Month (TAP Pharm); (Rx)

References

Client Information

Monitoring

■ Clinical effects Birds: decreased egg-laying; Ferrets: decreases in vulvar swelling, pruritus, undesirable sexual behaviors, aggression, and increased hair regrowth

Chemistry/Synonyms

A synthetic nonapeptide analog of GnRH (gonadotropin releasing hormone, gonadorelin, luteinizing hormone-releasing hormone), leuprolide acetate occurs as a white to off-white powder. In water more than 250 mg are soluble in one mL.

Leuprolide may also be known as: leuproprelin, leuprorelinum, abbott-43818, leuprolide acetate, TAP-144, Carcini®, Daronda®, Eligard®, Elityran®, Enantone®, Enantone-Gyr®, Ginecrin®, Lectram®, Leuplin®, Lucrin®, Lupride®, Lupron®, Procrin®, Prostap®, Reliser®, Trenantone®, Uno-Enantone®, and Viadur®.

Storage/Stability

The injection should be stored below room temperature (<78°F); do not freeze and protect from light (store in carton until use). The depot form may be stored at room temperature. After reconstituting the suspension is stable for 24 hours, but as it contains no preservative it is recommended for immediate use.

Compatibility/Compounding Considerations
The issue whether the solution containing microspheres (depot forms) can be frozen for later use is somewhat controversial as some have frozen the solution and state that it is still effective. However, the manufacturer states that the depot form is not to be frozen as the microspheres are destroyed and no studies are known that support

References

Uses/Indications

Depending on the product licensed, levamisole is indicated for the treatment of many nematodes in cattle, sheep and goats, swine, poultry. In sheep and cattle, levamisole has relatively good activity against abomasal nematodes, small intestinal nematodes (not particularly good against Strongyloides spp.), large intestinal nematodes (not Trichuris spp.), and lungworms. Adult forms of species that are usually covered by levamisole, include: Haemonchus spp., Trichostrongylus spp., Osteragia spp., Cooperia spp., Nematodirus spp., Bunostomum spp., Oesophagostomum spp., Chabertia spp., and Dictyocaulus viviparus. Levamisole is less effective against the immature forms of these parasites, and is generally ineffective in cattle (but not sheep) against arrested larval forms. Resistance of parasites to levamisole is a growing concern.

In swine, levamisole is indicated for the treatment of Ascaris suum, Oesophagostomum spp., Strongyloides, Stephanurus, and Metastrongylus.

Levamisole has been used in dogs as a microfilaricide to treat Dirofilaria immitis infection in the past, but is rarely used today. It has also garnered some interest as an immunostimulant in the adjunctive therapy of various neoplasms.

Because of its narrow margin for safety and limited efficacy against many equine parasites, levamisole is not generally used in horses as an antiparasitic agent. It has been tried as an immune stimulant, however.

Pharmacology/Actions

Levamisole stimulates the parasympathetic and sympathetic ganglia in susceptible worms. At higher levels, levamisole interferes with nematode carbohydrate metabolism by blocking fumarate reduction and succinate oxidation. The net effect is a paralyzing effect on the worm that is then expelled alive. Levamisole’s effects are considered to be nicotinic in action.

Levamisole’s mechanism of action for its immunostimulating effects is not well understood. It is believed it restores cell-mediated immune function in peripheral T-lymphocytes and stimulates phagocytosis by monocytes. Its immune stimulating effects appear to be more pronounced in animals that are immune-compromised.

Pharmacokinetics

Levamisole is absorbed from the gut after oral dosing and through the skin after dermal application, although bioavailabilities are variable. It is reportedly distributed throughout the body. Levamisole is primarily metabolized with less than 6% excreted unchanged in the urine. Plasma elimination half-lives have been determined for several veterinary species: Cattle, 4–6 hours; Dogs, 1.8–4 hours; and Swine, 3.5–6.8 hours. Metabolites are excreted in both the urine (primarily) and feces.

Contraindications/Precautions/Warnings

Levamisole is contraindicated in lactating animals (not approved). It should be used cautiously, if at all, in animals that are severely debilitated, or significant renal or hepatic impairment.

Use cautiously or, preferably, delay use in cattle that are stressed due to vaccination, dehorning, or castration.

Levamisole is not indicated for use as a dirofilarial adulticide.

Avoid, if possible, administering levamisole intramuscularly to birds.

One reference states that levamisole is contraindicated in cats with FIV or FIP and likely ineffective in cats with FeLV (Hartmann 2009).

Adverse Effects

Adverse effects that may be seen in cattle can include muzzle foaming or hypersalivation, excitement or trembling, lip-licking and head shaking. These effects are generally noted with higher than recommended doses or if levamisole is used concomitantly with organophosphates. Signs generally subside within 2 hours. When injecting into cattle, swelling may occur at the injection site. This will usually abate in 7–14 days, but may be objectionable in animals that are close to slaughter.

In sheep, levamisole may cause a transient excitability in some animals after dosing. In goats, levamisole may cause depression, hyperesthesia, and salivation. Injecting levamisole SC in goats apparently causes a stinging sensation.

In swine, levamisole may cause salivation or muzzle foaming. Swine infected with lungworms may develop coughing or vomiting.

Adverse effects that may be seen in dogs include GI disturbances (usually vomiting, diarrhea), neurotoxicity (panting, shaking, agitation or other behavioral changes), immune-mediated anemia, agranulocytosis, dyspnea, pulmonary edema, immune-mediated skin eruptions (erythroedema, erythema multiforme, toxic epidermal necrolysis), and lethargy.

Adverse effects seen in cats include hypersalivation, excitement, mydriasis, and vomiting.

Reproductive/Nursing Safety

There is little information available regarding the safety of this drug in pregnant animals. Levamisole has been implicated in causing abortion in goats. Although levamisole is considered relatively safe to use in large animals that are pregnant, use only if the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In separate systems evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Levamisole is excreted in cows’ milk; use with caution in nursing dams.

Overdosage/Toxicity

Signs of levamisole toxicity often mimic those of organophosphate toxicity. Signs may include hypersalivation, hyperesthesia and irritability, clonic seizures, CNS depression, dyspnea, defecation, urination, and collapse. These effects are best treated by supportive means as animals generally recover within hours of dosing. Acute levamisole overdosage can result in death due to respiratory failure. Should respiratory failure occur, artificial ventilation with oxygen should be instituted until recovery occurs. Cardiac arrhythmias may also be seen. If the ingestion was oral, emptying the gut and/or administering charcoal with cathartics may be indicated.

Levamisole is considered to be more dangerous when administered parenterally than when given orally or topically. Intravenous administration is particularly hazardous, and is never recommended.

In pet birds (cockatoos, budgerigars, Mynah birds, parrots, etc.), 40 mg/kg has been reported as a toxic dose when administered SC. IM injections may cause more severe toxicity. Depression, ataxia, leg and wing paralysis, mydriasis, regurgitation, and death may be seen after a toxic dose in birds.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving levamisole and may be of significance in veterinary patients.
The following drug interactions have either been reported or are theoretical in humans or animals receiving levamisole and may be of significance in veterinary patients:

- **ASPIRIN**: Levamisole may increase salicylate levels
- **CHLORAMPHENICOL**: Fatalities have been reported after concomitant levamisole and chloramphenicol administration; avoid using these agents together
- **CHOLINESTERASE-INHIBITING DRUGS** *(e.g., organophosphates, neostigmine)*: Could theoretically enhance the toxic effects of levamisole; use together with caution
- **NICOTINE-LIKE COMPOUNDS** *(e.g., pyrantel, morantel, diethylcarbamazine)*: Could theoretically enhance the toxic effects of levamisole; use together with caution.
- **WARFARIN**: Increased risk for bleeding

**Doses**

- **DOGS**:
  - As an immune stimulant:
    a) For recurrent cutaneous infections: 2.2 mg/kg PO every other day, with appropriate antimicrobial therapy *(Rosenkrantz 1989)*
    b) 0.5–2 mg/kg PO 3 times a week *(Kirk 1989)*
    c) For adjunctive therapy in dogs with chronic pyoderma: 0.5–1.5 mg/kg PO 2–3 times a week *(efficacy not established)* *(Lorenz 1984)*
    d) For adjunctive therapy in dogs with chronic pyoderma: 2.2 mg/kg PO every other day *(may only be efficacious in 10% of cases)* *(Ihrke 1986)*
  - As an alternative treatment for SLE:
    a) 3–7 mg/kg PO every other day for 4 months; alone or in combination with corticosteroids *(Marks & Henry 2000)*
  - As a microfilaricide *(Note: Rarely recommended today)*:
    a) 11 mg/kg PO for 6–12 days. Examine for microfilaria within 7–10 days and at weekly intervals until eliminated or treatment is halted. Retching and vomiting are common. Avoid giving on an empty stomach or immediately after drinking water. A “conditioning” dose of 5 mg/kg PO once a day may be necessary. Stop therapy if abnormal behavior or ataxia develops. *(Knight 1989)*
    
    For treatment of *Angiostrongylus vasorum*:
    a) 7.5 mg/kg (route not specified) for two consecutive days, followed by 10 mg/kg for 2 days; if the infection is not cleared, the regimen is repeated. *(Bowman 2006)*
  - For the treatment of lungworms:
    a) For *Crenosoma vulpis*: 8 mg/kg once *(Todd et al. 1985)*
    b) For *Capillaria*: 7–12 mg/kg once daily PO for 3–7 days
    c) For *Filaroides osleri*: 7–12 mg/kg once daily PO for 20–45 days *(Roudebush 1985)*
    d) 7.5 mg/kg PO twice daily or 25 mg/kg PO every other day for 10 days *(Bauer 1988)*
    
    For *Capillaria aerophila*:
    a) 10 mg/kg PO once daily for 5 days; repeat in 9 days *(Reinemeyer 1995)*

- **CATS**: For the treatment of lungworms:
  a) 20–40 mg/kg PO every other day for 5–6 treatments *(Kirk 1989)*
  b) For *Aelurostrongylus abstrusus*: 100 mg PO daily every other day for 5 treatments; give atropine *(0.5 mg SC, 15 minutes before administering)*; or 15 mg/kg PO every other day for 3 treatments, then 3 days later: 30 mg/kg PO, then 2 days later: 60 mg/kg.

  For *Capillaria aerophila*:
  a) 4.4 mg/kg SC for 2 days, then 8.8 mg/kg once 2 weeks later; or 5 mg/kg PO once daily for 5 days, followed by 9 days of no therapy, repeat twice *(Todd et al. 1985)*
  
  c) 25 mg/kg every other day for 10–14 days *(Roudebush 1985)*
  d) For *Capillaria aerophila*: 10 mg/kg PO once daily for 5 days; repeat in 9 days *(Reinemeyer 1995)*

- **RABBITS/RODENTS/SMALL MAMMALS**: For nematodes: 12.5–20 mg/kg PO (for gastric nematodes) or SC (for extragastric nematodes) *(Ivey & Morrisey 2000)*

- **HORSES**:
  - As an immunostimulant:
    a) Dosages have ranged from 2.5 mg/kg injected at 7 day intervals, and 2.2 mg/kg PO every 24 hours for 3 days, then off for 4 days for a period of 4–6 weeks. Anecdotal reports of beneficial effects in the treatment of nasal viral papillomas, COPD, and EPM have been suggested. *(Bentz 2006)*
    b) As adjunctive therapy for EPM: 1–2 mg/kg per day PO *(MacKay 2008)*

- **CATTLE**:
  - For treatment of susceptible nematodes (also refer to specific label directions for FDA-approved products):
    a) For removal of mature and immature *Dictyocaulus viviparus*: 5.5–11 mg/kg PO, either given in feed or as a drench or oral bolus. May also be administered SC. *(Bennett 1986)*
at 3.3–8 mg/kg. (Bennett 1986)
b) 7.5 mg/kg PO (Brander et al. 1982)

**CAMELIDS:**
For treatment of susceptible nematodes:

a) **Llamas:** 5–8 mg/kg IM, or PO (Fowler 1989)
b) **Llamas:** 5–8 mg/kg PO or SC for 1 day (Cheney & Allen 1989)

**SWINE:**
For treatment of susceptible nematodes (refer to specific label directions for FDA-approved products):
a) For removal of mature and immature Metastrongylus: 8 mg/kg PO in feed or water (Bennett 1986)

**SHEEP & GOATS:**
For treatment of susceptible nematodes (also refer to specific label directions for FDA-approved products):
a) For removal of mature and immature *Dictyocaulus vivapurus*: 8 mg/kg PO (Bennett 1986)
b) 7.5 mg/kg PO (Brander et al. 1982)

**BIRDS:**
a) Using 13.65% injectable:
For intestinal nematodes: 5–15 mL/gallon of drinking water for 1–3 days; repeat in 10 days. If birds refuse to drink, withhold water prior to treating. For gavage in Australian Parakeets (or desert species that refuse to drink water): 15 mg/kg; repeat in 10 days
For parenteral use: 4–8 mg/kg IM or SC; repeat in 10–14 days. May cause vomiting, ataxia, or death. Do not use in debilitated birds. For immunostimulation: 0.3 mL/gallon of water for several weeks
As a parenteral immunostimulant: 2 mg/kg IM or SC. 3 doses at 14 day intervals (Clubb 1986)
b) As a nebulized immunostimulant: 1 mL (of 13.65% levamisole phosphate) in 15 mL saline (Spink 1986)
c) For Capillaria infections: 15–30 mg/kg orally as a single bolus or through a crop tube; or 2.25 mg/gallon of drinking water for 4–5 days. Repeat treatment in 10–14 days. (Flammer 1986)
d) Poultry: 18–36 mg/kg, PO (Brander et al. 1982)
e) **Ratites:** For *Libyastrongylus douglassi*: Give 30 mg/kg PO or IM at one month of age, then once a month for 7 treatments, then 4 times yearly (Jenson 1998)

**REPTILES:**
a) As an anthelmintic:
For nematodes: 5–10 mg/kg PO; repeat in two weeks followed by a fecal exam 14 days after the second dose. If positive, a third dose is given. Acanthocephalans, or Pentastomes: as above, but may also be given SC or ICe. (de la Navarre 2003)

**Monitoring**
- Clinical efficacy
- Adverse effects/toxicity observation

**Client Information**
- Levamisole is not FDA-approved for use in dairy animals of breeding age.
- Follow directions on the product label unless otherwise directed by veterinarian. Animals that are severely parasitized or in conditions with constant helminth exposure should be retreated 2–4 weeks after initial treatment.
- Do not administer injectable products IV.
- Report serious adverse effects to veterinarian.

**Chemistry/Synonyms**
The levo-isomer of dl-tetramisole, levamisole has a greater safety margin than does the racemic mixture. It is available commercially in two salts, a phosphate and a hydrochloride. Levamisole hydrochloride occurs as a white to pale cream colored, odorless or nearly odorless, crystalline powder. One gram is soluble in 2 mL of water.

Levamisole HCl may also be known as: cloridrato de levamizol, ICI-59623, levamisoli hydrochloridum, NSC-177023, R-12564, RP-20605, l-tetramisole hydrochloride, *Amtech®*, *Ascaridil®*, *Decaris®,* *Ergamisol®,* *Immunol®,* *Ketrax®,* *Levasole®,* *Meglum®,* *Prohibit®,* *Solaskil®,* *Vermisol®,* and *Vizole®.

**Storage/Stability**
Levamisole hydrochloride products should be stored at room temperature (15–30°C), unless otherwise instructed by the manufacturer; avoid temperatures greater than 40°C. Levamisole phosphate injection should be stored at temperatures at or below 21°C (70°F); refrigeration is recommended and freezing should be avoided.

**Compatibility/Compounding Considerations**
Compounded preparation stability: Levamisole oral solution compounded from the commercially available tablets and active pharmaceutical ingredient powder has been published (Chiadmi et al. 2005). Triturating 2500 mg (2.5 grams) of levamisole hydrochloride powder with 100 mL sterile water yields a 25 mg/mL levamisole hydrochloride oral solution that retains >97% potency for 90 days when stored at both 4°C and 25°C and protected from light.

**Dosage Forms/Regulatory Status/Withdrawal Times**
In cattle, sheep, and swine a level of 0.1 ppm has been established for negligible residues in edible tissues.

**VETERINARY-LABELED PRODUCTS:**
- **Note:** marketing status of these products is not known; it has been reported that levamisole is “getting harder to find.”
- Levamisole Phosphate Injection: 136.5 mg/mL (13.65%) in 500 mL vials. Levamisole Injectable (AgriLabs), *Levasole® Injectable Solution 13.65%* (Schering
LEVETIRACETAM
(lee-ve-tair-a-se-tam) Keppra®
ANTICONVULSANT

Prescriber Highlights

✦ In dogs, may be useful as a third drug adjunct for refractory canine epilepsy or when either phenobarbital or bromides are not tolerated. Dogs may become refractory to therapy with time.

✦ In cats, probably a second-line drug when phenobarbital alone does not control seizures, but can be tried as sole therapy when phenobarbital is not tolerated.

✦ Appears to be well tolerated; adverse effects (may be transient) include sedation in dogs, and lethargy and decreased appetite in cats.

✦ Phenobarbital may cause significant drug interaction with levetiracetam in dogs.

✦ Dosage frequency (three times daily) problematic.

✦ Cost has been an issue, but costs decreasing with availability of generics.

Uses/Indications

Levetiracetam may be useful as a third antiseizure medication in dogs that are not well controlled with phenobarbital and bromides or when either bromides or phenobarbital are not tolerated. Some evidence suggests that in dogs suffering from phenobarbital liver toxicity, the addition of levetiracetam will allow reduction of their phenobarbital dosage without increasing seizure frequency. Recent reports in dogs of reduced efficacy with time (“honeymoon effect”) and that phenobarbital can significantly affect levetiracetam pharmacokinetics in dogs is concerning.

Levetiracetam may also be useful as add-on therapy in cats when phenobarbital does not control seizures. It can be tried as sole therapy when phenobarbital is not tolerated.

Pharmacology/Actions

The exact mechanism for levetiracetam’s antiseizure activity is not well understood. It may selectively prevent hypersynchronization of epileptiform burst-firing and propagation of seizure activity. It does not affect normal neuronal excitability.

Pharmacokinetics
In dogs and cats levetiracetam is well absorbed after oral dosing and peak levels occur in about 2 hours. In dogs, levetiracetam elimination half-life is about 2-5 hours and volume of distribution is about 0.9 L/kg. In cats, levetiracetam half-life is around 3 hours, but there can be wide inter-patient variation.

In humans, levetiracetam is rapidly, and nearly completely, absorbed after oral administration. Peak levels occur about one hour after dosing. Presence of food in the gut delays the rate, but not the extent of drug absorbed and it can be administered without regard to feeding status. Less than 10% of the drug is bound to plasma proteins. While not extensively metabolized, the drug’s acetamide group is enzymatically hydrolyzed to the carboxylic acid metabolite that is apparently not active. Hepatic CYP P450 isoenzymes are not involved. Half-life in humans is about 7 hours; about 66% of a given dose is excreted unchanged via renal mechanisms, primarily glomerular filtration and active tubular secretion. Clearance can be significantly reduced in patients with impaired renal function.

### Contraindications/Precautions/Warnings
Levetiracetam is contraindicated in patients who have previously exhibited hypersensitivity to it or any of its components. It should be used with caution in patients with renal impairment; dosage amounts or dosing frequency changes should be considered. In humans, renal elimination of levetiracetam correlates with creatinine clearance.

### Adverse Effects
Levetiracetam appears to be very well tolerated in dogs and cats. Most common adverse effects reported include sedation in dogs and reduced appetite and lethargy in cats. These effects may be transient. Changes in behavior, and gastrointestinal effects could occur.

In humans, it is recommended to withdraw the drug slowly to prevent “withdrawal” seizures.

### Reproductive/Nursing Safety
In pregnant dogs or cats, levetiracetam should be used with caution. In humans, the FDA categorizes levetiracetam as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). At high dosages, levetiracetam has caused increased embryofetal mortality in rabbits and rats. At dosages equivalent to the maximum human therapeutic dose, levetiracetam caused minor skeletal abnormalities and retarded offspring growth in rats.

Levetiracetam is excreted into maternal milk and its safety in nursing offspring is unknown. Use with caution in nursing patients.

### Overdose/Acute Toxicity
Levetiracetam is a relatively safe agent. Dogs given 1200 mg/kg/day (approximately 20 times therapeutic dosage) developed only salivation and vomiting. Human patients given 6000 mg/kg during drug testing developed only drowsiness. Other effects noted in human overdoses (doses not specified) after the drug was released include depressed levels of consciousness, agitation, aggression and respiratory depression. Treatment is basically supportive; the drug can be removed with hemodialysis. In the circumstance of a significant overdose in animals, contact an animal poison control center for further recommendations.

### Drug Interactions
- **NSAIDS:** In humans, naproxen and ketorolac have been implicated with increasing the risk for seizures in patients with epilepsy. Veterinary significance is not clear.
- **PHENOBARBITAL:** In dogs, ongoing (21 days in the study) phenobarbital use significantly increased levetiracetam clearance and reduced half-life (from 3.43 hrs without phenobarbital to 1.73 hrs after 21 days of phenobarbital); dosage adjustments may be required. (Moore et al. 2009)

### Laboratory Considerations
- No specific laboratory interactions or considerations noted.

### Doses
- **DOGS:**
  a) As an add-on treatment for epilepsy in dogs refractory to phenobarbital and bromides: 20 mg/kg PO every 8 hours (Munana, K 2004), (Munana, KR 2010)
  b) As an add-on treatment for epilepsy in dogs refractory to phenobarbital and/or bromides: 7.1–23.8 mg/kg PO every 8 hours (Steinberg & Faissler 2004)
  c) 10–20 mg/kg PO q8h (Dickinson 2007)
  d) Initially, 20 mg/kg PO q8h. May increase dose in 20 mg/kg increments until efficacy achieved, side effects become apparent, or the drug becomes cost prohibitive. (Dewey, C. 2005)
  e) 20 mg/kg PO q8h; may also be given as an IV bolus (20 mg/kg). (Fletcher 2009)
  f) From a single-dose pharmacokinetic study: In normal dogs, a 60 mg/kg IV bolus dose of levetiracetam is well tolerated and achieves plasma drug concentrations within or above the therapeutic range reported for humans for at least 8 hours after administration. (Dewey, C.W. et al. 2008)
  g) For status epilepticus: Initially, lorazepam at 0.2 mg/kg IV once, followed by a bolus IV loading dose of levetiracetam at 60 mg/kg. (Podell 2009)

- **CATS:**
  a) As an add-on to phenobarbital treatment for epilepsy: Initially, 20 mg/kg PO three times daily; slowly increase to effect (Pearce 2006)
  b) As an adjunct to phenobarbital in suspected idiopathic epilepsy: Initially, 20 mg/kg PO three times daily. Monitor as below. If ineffective, increase dose in 20 mg/kg increments. (Bailey & Dewey 2009)

### Monitoring
- The therapeutic range for animals has not been specifically determined, but it is thought that it is similar to humans, 5–45 micrograms/mL. Monitoring is recommended approximately one week after starting levetiracetam and then every 6-12 months. Because the drug appears to be very safe, therapeutic drug monitoring is used primarily to adjust dosage (Bailey & Dewey 2009).
- Veterinarians should have the owner keep a record of seizure activity to document efficacy and report any potential levetiracetam-associated adverse effects.
- Routine CBC, basic metabolic panel every 6 months

### Client Information
- Clients should understand that limited experience has occurred with levetiracetam in dogs and cats. Although it appears to be well tolerated, information on its safety and efficacy profile is still being generated.
Chemistry/Synonyms
A pyrrolidine-derivative antiepileptic agent, levetiracetam occurs as an odorless, bitter-tasting, white to off-white crystalline powder. It is very soluble in water and soluble in ethanol. It is a chiral molecule with one asymmetric carbon atom. Levetiracetam is not related chemically to other antiseizure medications. Levetiracetam may also be known as: S-Etriacetam, UCB-22059, UCB-L059, and Keppra®.

Storage/Stability
Levetiracetam tablets or oral solution should be stored at 25°C (77°F); excursions permitted to 15–30°C (59–86°F).

Dosage Forms/Regulatory Status
VETERINARY-LABELLED PRODUCTS: None
HUMAN-LABELLED PRODUCTS:
Levetiracetam Oral Tablets (film-coated, scored): 250 mg, 500 mg, 750 mg & 1000 mg; Keppra® (UCB); generic; (Rx)
Levetiracetam Extended-Release Oral Tablets: 500 mg & 750 mg; Keppra XR® (UCB); (Rx)
Levetiracetam Oral Solution: 100 mg/mL in 473 mL, 480 mL & 500 mL; Keppra® (UCB); generic; (Rx)
Levetiracetam Concentrate for Injection: 100 mg/mL in 5 mL single-use vials; Keppra® (UCB); (Rx)

References

LEVOTHYROXINE SODIUM
(lee-voie-thye-rox-een) Soloxine®, Synthroid®
THYROID HORMONE
Prescriber Highlights

- Thyroid hormone for hypothyroidism in all species
- Contraindications: Acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency
- Caution: Concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or elderly patients
- Adverse Effects: Only associated with OD’s (tachycardia, polyphagia, PU/PD, excitability, nervousness, & excessive panting); some cats may appear apathetic
- Drug-drug; drug-lab interactions

Uses/Indications
Levothyroxine sodium is indicated for the treatment of hypothyroidism in all species.

Pharmacology/Actions
Thyroid hormones affect the rate of many physiologic processes including: fat, protein, and carbohydrate metabolism, increasing protein synthesis, increasing gluconeogenesis, and promoting mobilization and utilization of glycogen stores. Thyroid hormones also increase oxygen consumption, body temperature, heart rate and cardiac output, blood volume, enzyme system activity, and growth and maturity. Thyroid hormone is particularly important for adequate development of the central nervous system. While the exact mechanisms how thyroid hormones exert their effects are not fully understood, it is known that thyroid hormones (primarily triiodothyronine) act at the cellular level.

In humans, triiodothyronine (T3) is the primary hormone responsible for activity. Approximately 80% of T3 found in the peripheral tissues is derived from thyroxine (T4) which is the principle hormone released by the thyroid.

Pharmacokinetics
In dogs, peak plasma concentrations after oral dosing reportedly occur 4–12 hours after administration and the serum half-life is approximately 12–16 hours. There is wide variability from animal to animal, however.

Contraindications/Precautions/Warnings
Levothyroxine (and other replacement thyroid hormones) are contraindicated in patients with acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency. It should be used with caution, and at a lower initial dosage, in patients with concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or in those who are aged.

Adverse Effects
- The current dosage frequency recommendation (q8h) may be difficult to adhere to, but the drug may not be effective if not followed.
Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category A for use during pregnancy (Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Minimal amounts of thyroid hormones are excreted in milk and should not affect nursing offspring.

Overdosage/Acute Toxicity

Chronic overdosage will produce signs of hyperthyroidism, including tachycardia, polyphagia, PU/PD, excitability, nervousness and excessive panting. Dosage should be reduced and/or temporarily withheld until signs subside. Some (10%) cats may exhibit signs of “apathetic” (listlessness, anorexia, etc.) hyperthyroidism.

A single acute overdose in small animals is less likely to cause severe thyrotoxicosis than with chronic overdosage. Vomiting, diarrhea, hyperactivity to lethargy, hypertension, tachycardia, tachypnea, dyspnea, and abnormal pupillary light reflexes may be noted in dogs and cats. In dogs, clinical signs may appear within 1–9 hours after ingestion. If ingestion occurred within 2 hours, treatment to reduce absorption of drug should be accomplished using standard protocols (emetics, cathartics, charcoal) unless contraindicated by the patient’s condition. Treatment is supportive and symptomatic. Oxygen, artificial ventilation, cardiac glycosides, beta-blockers (e.g., propranolol), fluids, dextrose, and antipyretic agents have all been suggested for use if necessary; contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving levothyroxine and may be of significance in veterinary patients:

- **AMIODARONE**: May decrease the metabolism of T4 to T3
- **ANTACIDS, ORAL**: May reduce levothyroxine absorption; separate doses by 4 hours
- **ANTIDEPRESSANTS, TRICYCLIC/TETRACYCLIC**: Increased risk for CNS stimulation and cardiac arrhythmias
- **ANTIDIABETIC AGENTS (insulin, oral agents)**: Levothyroxine may increase requirements for insulin or oral agents
- **CHOLESTYRAMINE**: May reduce levothyroxine absorption; separate doses by 4 hours
- **CORTICOSTEROIDS (high dose)**: Decreased conversion of T4 to T3
- **DIGOXIN**: Potential for reduced digoxin levels
- **FERROUS SULFATE**: May reduce levothyroxine absorption; separate doses by 4 hours
- **HIGH FIBER DIET**: May reduce levothyroxine absorption
- **KETAMINE**: May cause tachycardia and hypertension
- **PHENOBARBITAL**: Possible increased metabolism of thyroxine; dosage adjustments may be needed
- **PROPYLETHIOURACIL**: Decreased conversion of T4 to T3
- **RIFAMPIN**: Possible increased metabolism of thyroxine; dosage adjustments may be needed
- **SERTRALINE**: May increase levothyroxine requirements
- **SUCRALFATE**: May reduce levothyroxine absorption; separate doses by 4 hours
- **SYMPATHOMIMETIC AGENTS (epinephrine, norepinephrine, etc.)**: Levothyroxine can potentiate effects
- **WARFARIN**: Thyroid hormones increase the catabolism of vitamin K-dependent clotting factors that may increase the anticoagulation effects in patients on warfarin

Laboratory Considerations

- **Renal Function Tests**: Hypothyroid dogs can have decreased GFR (creatinine clearance); restoration to a euthyroid state can increase GFR and reduce serum creatinine levels

The following drugs may have effects on thyroid function tests; evaluate results accordingly:

- **Effects on serum T4**: aminogluthethimide*, anabolic steroids/androgens*, antithyroid drugs (PTU, methimazole)*, asparaginase*, barbiturates*, corticosteroids*, danazol*, diazepam*, estrogens† (Note: estrogens may have no effect on canine T3 or T4 concentrations), fluorouracil†, heparin†, insulin†, lithium carbonate†, mitotane (o,p-DDD)*, nitroprusside†, phenytoin†, propranolol†, salicylates (large doses)*, sulphonamides*, and sulfonyleureas.*
- **Effects on serum T3**: antithyroid drugs (PTU, methimazole)*, barbiturates*, corticosteroids*, estrogens†, fluorouracil†, heparin†, lithium carbonate*, phenytoin†, propranolol†, salicylates (large doses)*, sulphonamides*, and thioureas†.
- **Effects on T3 uptake resin**: anabolic steroids/androgens†, antithyroid drugs (PTU, methimazole)*, asparaginase*, corticosteroids†, danazol†, estrogens†, fluorouracil†, heparin†, lithium carbonate†, phenytoin†, propranolol†, salicylates (large doses)*, sulfonamides*, and thioureas†.
- **Effects on serum TSH**: aminogluthethimide*, antithyroid drugs (PTU, methimazole)*, corticosteroids*, danazol*, lithium carbonate†, and sulphonamides†.
- **Effects on Free Thyroxine Index (FTI)**: antithyroid drugs (PTU, methimazole)*, barbiturates*, corticosteroids*, heparin†, lithium carbonate*, and phenytoin†.

**Doses**

For hypothyroidism:

- a) Use a trade name product. Initially give 20 micrograms/kg (0.02 mg/kg) body weight PO twice daily with a maximum dose of 0.8 mg twice daily. Four to eight weeks later evaluate clinical response and draw a T4 level 4–6 hours post dosing.

If positive clinical response and 1) low normal T4: increase dose and recheck in 4 weeks; 2) high normal to slightly higher than normal T4: no change in dosing and recheck in 6 months; 3) 40% or more greater than high normal: decrease dose or consider once a day therapy and recheck in 4 weeks (if once a day dosing
Levothyroxine sodium preparations should be stored at room temperature in tight, light-resistant containers. The injectable product should be reconstituted immediately upon opening the vial. The injectable product contains levothyroxine sodium, which is the levo isomer of thyroxine that is the primary secretion of the thyroid gland. It occurs as an odorless, light yellow to buff-colored, tasteless, hygroscopic powder that is very slightly soluble in water and slightly soluble in alcohol. The commercially available powders for injection also contain mannitol.

Levothyroxine sodium may also be known as: T4, T4 thyroxine sodium, levothyroxin natrium, levothyroxinum natricum, 3,5,3',5'-tetra-iodo-L-thyronine sodium, thyroxine sodium, L-thyroxine sodium, thyroxinum natricum, tirossina, and tiroxina sodica; many trade names are available. 100 micrograms of levothyroxine is approximately equivalent to 65 mg (1 grain) of desiccated thyroid.

Levothyroxine sodium is the levo isomer of thyroxine that is the primary secretion of the thyroid gland. It occurs as an odorless, light yellow to buff-colored, tasteless, hygroscopic powder that is very slightly soluble in water and slightly soluble in alcohol. The commercially available powders for injection also contain mannitol.

Prepared synthetically for commercial use, levothyroxine sodium is the levo isomer of thyroxine that is the primary secretion of the thyroid gland. It occurs as an odorless, light yellow to buff-colored, tasteless, hygroscopic powder that is very slightly soluble in water and slightly soluble in alcohol. The commercially available powders for injection also contain mannitol.

Storage/Stability
- Levothyroxine sodium preparations should be stored at room temperature in tight, light-resistant containers. The injectable product should be reconstituted immediately upon opening the vial.
- The injectable product contains levothyroxine sodium, which is the levo isomer of thyroxine that is the primary secretion of the thyroid gland. It occurs as an odorless, light yellow to buff-colored, tasteless, hygroscopic powder that is very slightly soluble in water and slightly soluble in alcohol. The commercially available powders for injection also contain mannitol.
Levothyroxine sodium preparations should be stored at room temperature in tight, light-resistant containers. The injectable product should be reconstituted immediately before use; unused injection should be discarded after reconstituting. Do not mix levothyroxine sodium injection with other drugs or IV fluids.

Levothyroxine sodium is reportedly unstable in aqueous solutions. If using a commercial liquid preparation, it is suggested to obtain validated stability data for the product.

**Dosage Forms/Regulatory Status**

All levothyroxine products require a prescription, but are not necessarily FDA-approved. There have been bioavailability differences between products reported. It is recommended to use a reputable product and not to change brands indiscriminately.

**VETERINARY-LABELLED PRODUCTS:**

Levothyroxine Sodium Tablets: 0.1 mg, 0.2 mg, 0.3 mg, 0.4 mg, 0.5 mg, 0.6 mg, 0.7 mg, 0.8 mg, (1 mg Soloxide®); Levosyn® (V.E.T.); Soloxine® (Vet-Tabs® (Vet-A-Mix); Thyro-Tabs®; Thyroxin® (Vedco); Thyroxine Tablets® (Butler); Thyrozone® (Phoenix Pharmaceutical); Thyrokare Tablets® (Neoegen); generic; (Rx). Labeled for use in dogs.

Levothyroxine Sodium Tablets Chewable (Veterinary): 0.1 mg, 0.2 mg, 0.3 mg, 0.4 mg, 0.5 mg, 0.6 mg, 0.7 mg, 0.8 mg; Canine Thyroid Chewable Tablets® (Pala-Tech); Nutrived® T-4 Chewable Tablets (Vedco); Heska Thyromed® Chewable Tablets (Heska); (Rx). Labeled for use in dogs.

Levothyroxine Oral Solution: 1 mg/mL in 30 mL bottles: Leventa® Oral Solution (Vet-Tabs); (Rx) Labeled for use in dogs.

Levothyroxine Sodium Powder (Veterinary): 0.22% (1 gram of T4 in 454 grams of powder): One level teaspoonful contains 12 mg of T4. Available in 1 lb. and 10 lb. containers; Equine Thyroid Supplement® (Pala-Tech); Thyroxine Powder® (Phoenix Pharmaceutical); Levoxine® Powder (First Priority); Thyro-R® (Lloyd); Throxine-L® Powder (Butter); Equi-Phar Thyroxin Powder® (Vedco); Thyrokare® Powder (Neoegen); (Rx). Labeled for use in horses.

**HUMAN-LABELLED PRODUCTS:**

Levothyroxine Sodium Tablets: 0.025 mg (25 micrograms), 0.05 mg (50 micrograms), 0.075 mg (75 micrograms), 0.088 mg (88 micrograms), 0.1 mg (100 micrograms), 0.112 mg (12 micrograms), 0.125 mg (125 micrograms), 0.137 mg (137 micrograms), 0.15 mg (150 micrograms), 0.175 mg (175 micrograms), 0.2 mg (200 micrograms) & 0.3 mg (300 mcg); Synthroid® (Abbott); Levothroid® (Forest); Lev oxy® (Jones Pharma); Thyro-Tabs® (Lloyd); Unitroid®; generic; (Rx)

Levothyroxine Sodium Liquid-filled Oral Capsules: 13 micrograms (0.013 mg), 25 micrograms (0.025 mg), 50 micrograms (0.05 mg), 75 micrograms (0.075 mg), 88 micrograms (0.088 mg), 100 micrograms (0.112 mg), 125 micrograms (0.125 mg), 137 micrograms (0.137 mg) & 150 micrograms (0.15 mg) in blister 56s; Tiosint® (Akrimax); (Rx)

Levothyroxine Powder for Injection lyophilized: 200 micrograms (0.2 mg) & 500 micrograms (0.5 mg) in 10 mL vials; generic; (Rx)

References

**LIDOCAINE HCL (SYSTEMIC)**

(Ly-doe-kane) Xylocaine®

**ANTIARRHYTHMIC/LOCAL ANESTHETIC**

**Prescriber Highlights**

- Local anesthetic & antiarrhythmic agent; may be useful to prevent post-operative ileus, reperfusion injury in horses
- Low dose IV constant-rate and intermittent or constant regional infusions been found useful to treat hyperalgesia and neuropathic pain induced by trauma or surgical procedures
- Contraindications: Known hypersensitivity to the amide-class local anesthetics, severe degree of SA, AV, or intraventricular heart block (if not being artificially paced), or Adams-Stokes syndrome
- Caution: Cats appear more sensitive to cardiodepressant and CNS effects of lidocaine; use with caution in patients with liver disease, congestive heart failure, shock, hypovolemia, severe respiratory depression, marked hypoxia, bradycardia, or incomplete heart block having VPC’s, unless the heart rate is first accelerated
- Patients susceptible to malignant hyperthermia should receive intensified monitoring
- Adverse Effects: Most common adverse effects reported are dose related (serum level) & mild. CNS signs include drowsiness, depression, ataxia, muscle tremors, etc.; nausea & vomiting (usually transient). Adverse cardiac effects usually only at high plasma concentrations in most species, but cats are susceptible.
- When an IV bolus is given too rapidly, hypotension may occur

- **DO NOT use the product containing epinephrine intravenously**
- **Drug interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving lidocaine and may be of significance in veterinary patients:

**Drug Interactions**

pentobarbital) should be avoided. Should circulatory depression occur, treat with fluids, pressor agents and, if necessary, begin CPR.

That is required for minor signs. Seizures or excitement may be treated with diazepam, or a short or ultrashort acting barbiturate. Longer acting barbiturates (if not being artificially paced), or Adams-Stokes syndrome. The use of lidocaine in patients with Wolff-Parkinson-White (WPW) syndrome is controversial. Some cats tend to be more sensitive to lidocaine’s analgesic effects but are likely via several mechanisms, including reducing ectopic activity of damaged afferent neurons.

Lidocaine apparently has some enhancing effects on intestinal motility in patients with postoperative ileus. The mechanism for this effect is not well understood, but probably involves more than just blocking increased sympathetic tone.

Lidocaine has been shown to be a scavenger of reactive oxygen species (ROS) and lipid peroxidation.

**Pharmacology/Actions**

Lidocaine is not effective orally as it has a high first-pass effect. If very high oral doses are given, toxic signs occur (due to active metabolites?) before therapeutic levels can be reached. Following a therapeutic IV bolus dose, the onset of action is generally within 2 minutes and has duration of action of 10–20 minutes. If a constant infusion is begun without an initial IV bolus, it may take up to an hour for therapeutic levels to be reached. IM injections may be given every 1.5 hours in the dog, but because monitoring and adjusting dosages are difficult, it should be reserved for cases where IV infusions are not possible.

After injection, the drug is rapidly redistributed from the plasma into highly perfused organs (kidney, liver, lungs, heart) and distributed widely throughout body tissues. It has a high affinity for fat and adipose tissue and is bound to plasma proteins, primarily alpha-1-acid glycoprotein. It has been reported that lidocaine binding to this protein is highly variable and concentration dependent in the dog and may be higher in dogs with inflammatory disease. Lidocaine is distributed into milk. The apparent volume of distribution (Vd) has been reported to be 4.5 L/kg in the dog.

Lidocaine is rapidly metabolized in the liver to active metabolites (MEGX and GX). The terminal half-life of lidocaine in humans is 1.5–2 hours and has been reported to be 0.9 hours in the dog. The half-lives of lidocaine and MEGX may be prolonged in patients with cardiac failure or hepatic disease. Less than 10% of a parenteral dose is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Cats tend to be more sensitive to the CNS and cardiodepressant effects of lidocaine; use with caution. Cats with concurrent illnesses or under general anesthesia may be particularly sensitive to lidocaine’s effects.

Lidocaine is contraindicated in patients with known hypersensitivity to the amide-class local anesthetics, a severe degree of SA, AV or intraventricular heart block (if not being artificially paced), or Adams-Stokes syndrome. The use of lidocaine in patients with Wolff-Parkinson-White (WPW) syndrome is controversial. Some manufacturers state its use is contraindicated, but several physicians have used the drug in people.

Lidocaine should be used with caution in patients with liver disease, congestive heart failure, shock, hypovolemia, severe respiratory depression, or marked hypoxia. It should also be used with caution in patients with bradycardia or incomplete heart block having VPC’s, unless the heart rate is first accelerated. Patients susceptible to developing malignant hyperthermia should receive lidocaine with intensified monitoring.

When preparing lidocaine for intravenous injection, be certain of the concentration and do not use products containing epinephrine.

**Adverse Effects**

At usual doses and if the serum level remains within the proposed therapeutic range (1–5 micrograms/mL), serious adverse reactions are quite rare. The most common adverse effects reported are dose related (serum level) and mild. CNS signs include drowsiness, depression, ataxia, muscle tremors, etc. Nausea and vomiting may occur, but are usually transient. Adverse cardiac effects generally only occur at high plasma concentrations and are usually associated with PR and QRS interval prolongation and QT interval shortening. Lidocaine may increase ventricular rates if used in patients with atrial fibrillation. If an IV bolus is given too rapidly, hypotension may occur.

Reproductive/Nursing Safety

In horses, lidocaine may be useful to prevent post-operative ileus and reperfusion injury. Lidocaine infusions perioperatively have been shown to reduce MAC requirements in dogs, horses and cats. In dogs and horses, this may be of benefit, but in cats, additive cardiodepression has been shown.

Overdosage/Acute Toxicity

In dogs, if serum levels of >8 micrograms/mL are attained, toxicity may result. Signs may include ataxia, nystagmus, depression, seizures, bradycardia, hypotension and, at very high levels, circulatory collapse. Because lidocaine is rapidly metabolized, cessation of therapy or reduction in infusion rates with monitoring may be all that is required for minor signs. Seizures or excitement may be treated with diazepam, or a short or ultrashort acting barbiturate. Longer acting barbiturates (e.g., pentobarbital) should be avoided. Should circulatory depression occur, treat with fluids, pressor agents and, if necessary, begin CPR.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lidocaine and may be of significance in veterinary patients:

**ANESTHETICS, GAS:** Lidocaine infusions perioperatively have been shown to reduce MAC requirements in dogs, horses and cats. In dogs and horses, this may be of benefit, but in cats, additive cardiodepression has been shown.
be of benefit, but in cats, additive cardiodepression has been shown.

**ANTIARRHYTHMICS, OTHER (e.g., procainamide, quinidine, propranolol, phenytoin):** When administered with lidocaine may cause additive or antagonistic cardiac effects and toxicity may be enhanced.

**CIMETIDINE:** Lidocaine levels or effects may be increased.

**FUROSEMIDE (or other drugs that can cause hypokalemia):** Hypokalemia may reduce the antiarrhythmic effects of lidocaine.

**PHENOBARBITAL, PHENYTOIN:** May increase lidocaine metabolism; decrease levels.

**SUCCINYLCHOLINE:** Large doses of lidocaine may prolong succinylcholine-induced apnea.

### Laboratory Considerations

- Lidocaine may cause increased creatine kinase levels (CK).

### Doses

**DOGS:**

As an antiarrhythmic agent:

a) For immediate treatment of ventricular tachycardia in dogs, lidocaine is the drug of choice. For sustained VT, use lidocaine at 2–4 mg/kg bolus given over a minute and repeat up to 8 mg/kg (total dose over 10 minutes). If successful, perform constant rate infusion (CRI) of lidocaine at 40–80 micrograms/kg/min. (Schwartz 2009)

b) For rapid conversion of life-threatening, incessant, unstable ventricular tachycardia: Initial IV bolus of 1–2 mg/kg preferably over 30 seconds to judge response, higher doses may be required but rarely need to give 4 mg/kg. Once effectiveness determined, begin constant rate infusion at 25–80 micrograms/kg/minute. Adjust dose to attain efficacy but without side effects. To prevent adverse effects total dose should not exceed 8 mg/kg over approximately one hour. Alternatively may give lidocaine at 4 mg/kg IM, but not if shock is present. Effects generally are seen in 10–15 minutes, and persist for about 90 minutes. (Moise 2000)

c) For ventricular arrhythmias: Initial dosage of 2–8 mg/kg IV slowly is given to effect while monitoring ECG; then following by a CRI of 25–75 micrograms/kg/minute starting at a high dose and tapering down when possible. (Macintire 2006)

As an analgesic agent:

a) CRI: 2–4 mg/kg/hour. **Note:** also see the “recipe” for combination with morphine, ketamine and medetomidine in the Compatibility/Compounding Considerations section below. (Hansen 2008)

b) Using the MLK (morphine/lidocaine/ketamine) mixture: To a 500 mL bag of LRS add 10 mg morphine sulfate, 120 mg lidocaine, and 100 mg ketamine. Infuse at a rate of 10 mL/kg/hr (will provide morphine at 0.2 mg/kg/hr, lidocaine 40 micrograms/kg/minute, and ketamine 2 mg/kg/hr). Can add dexmedetomidine if needed. (Shaffran 2009)

c) 1–4 mg/kg IV bolus, followed by a CRI of 1–5 mg/kg/hr depending on severity of pain. (Dyson 2008)

d) Initial bolus of 2 mg/kg IV given over 2–3 minutes, then a CRI of 50–100 micro-grams/kg/minute starting at a high dose and tapering down when possible. (Grint 2008)

As an epidural:

a) 4–5 mg/kg epidurally. Onset of action <10 minutes; duration 1.5 hours. Can be combined with alpha2 agonists or opioids. Adding epinephrine prolongs duration of action. (Valverde 2008)

**CATS:**

**Caution:** Cats are reportedly very sensitive to the CNS effects of lidocaine and can develop cardiodepression. There are several sources that state that lidocaine should not be used in cats as an injectable analgesic. If lidocaine is to be used, monitor carefully.

As an antiarrhythmic:

a) Initially, IV bolus of 0.25–0.5 mg/kg given slowly; can repeat at 0.15–0.25 mg/kg in 5–20 minutes; if effective, 10–20 micro-grams/kg/minute (0.01–0.02 mg/kg/min) as a constant rate IV infusion (Ware 2000)

b) 0.25–0.5 mg/kg slow IV, with the possibility of repeating up to twice more if needed. If diluting for accurate dosing, use an insulin/tuberculin syringe. May be used as first-line therapy, or after propranolol, if it was ineffective. (Cote 2004)

As an epidural:

a) 4–5 mg/kg epidurally. Onset of action <10 minutes; duration 1.5 hours. Can be combined with alpha2 agonists or opioids. Adding epinephrine prolongs duration of action. (Valverde 2008)

**HORSES:** **(Note: ARCI UCGFS Class 2 Drug)**

For ventricular tachyarrhythmias:

a) Initially IV bolus of 1–1.5 mg/kg. Will generally distinguish between ventricular tachyarrhythmias (effective) and supraventricular tachyarrhythmias (no effect). To maintain effect, a constant IV infusion will be required. (Hilwig 1987)

b) 0.25–0.5 mg/kg IV (slowly) every 5–10 minutes up to a total dose of 1.5 mg/kg (Mogg 1999)

For postoperative ileus:

a) Initially, IV bolus of 1.3 mg/kg followed by a IV infusion of 0.05 mg/kg/minute for 24 hours (Malone et al. 1999)(Valverde 2008)

For colic patients:

a) Lidocaine has anti-endotoxic, analgesic and anti-ileus properties. Can be dosed as an initial IV bolus at 1.4 mg/kg, then as a CRI at 0.03–0.05 mg/kg/min (1.8–3 mg/kg/hr). (Hallowell 2008)
Premixed with D5W for IV infusion in concentrations of 2 mg/mL, 4 mg/mL, and 5 mg/mL, injections with epinephrine, topical liquids, patches, ointment, cream, syringes & cartridges (with or without laryngotracheal cannula); 10 mL & 20 mL

Lidocaine Hydrochloride Injection: 0.5%, 1%, 1.5%, 2% & 4% in 5 mL, 10 mL, 20 mL, 30 mL & 50 mL single- & multi-dose vials, 2 mL & 5 mL amps, 5 mL syringes & cartridges (with or without laryngotracehal cannula); 10 mL & 20 mL PolyAmp DuoFit & 1.8 mL cartridges; Xylocaine® & Xylocaine MPF® (AstraZeneca); generic; (Rx)

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

Lidocaine HCl for Injection: 2% (20 mg/mL) in 100 mL & 250 mL multi-use vials; (contains preservatives); generic; (Rx)

Compatibility/Compounding Considerations
Lidocaine is physically compatible with: aminophylline, bretylium tosylate, calcium chloride/glucose, atropine, cananbicinilin disodium, chloramphenicol sodium succinate, chlorothiazide sodium, cinetidine HCl, dexamethasone sodium phosphate, dexmedetomidine, digoxin, diphenhydramine HCl, dobutamine HCl, ephedrine sulfate, erythromycin lactobionate, fentanyl, glycopyrrolate, heparin sodium, hydrocortisone sodium succinate, hydroxyzine HCl, ketamine, insulin (regular), mephentamine sulfate, metaraminol bitartrate, methicillin sodium, metoclopramide HCl, morphine sulfate, nitrofurantoin sodium, oxytetracycline HCl, penicillin G potassium, pentobarbital sodium, phenylephrine HCl, potassium chloride, procainamide HCl, prochlorperazine edisylate, promazine HCl, sodium bicarbonate, sodium lactate, tetracaine HCl, verapamil HCl, and Vitamin B-Complex with C.

Lidocaine may not be compatible when mixed with ampicillin sodium, cefazolin sodium, methohexital sodium, or phenytoin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

To prepare IV infusion solution using the veterinary 2% solution add 1 gram (50 mL of 2% solution to 1 liter of D5W or other compatible solution, this will give an approximate concentration of 1 mg/mL (1000 micro-grams/mL). When using a mini-drip (60 drops/mL) IV set, each drop will contain approximately 17 micrograms. In small dogs and cats, a less concentrated solution may be used for greater dosage accuracy. When preparing solutions be certain that you are not using the lidocaine product that contains epinephrine.

A combination intravenous infusion for analgesia and sedation in vigorous postoperative patients (dogs, NOT cats) that require sedation to sleep the night after surgery is described (Hansen 2008): For this technique, plan on adding the drugs to a bag of fluids for which the administration rate will not change, which usually means a lower fluid administration rate to provide a constant rate of drug delivery. For example, to calculate a drug plan for a 20-kg dog that is to receive morphine, lidocaine, ketamine, and medetomidine for the first 8 to 24 hours postoperatively, drug doses to consider might include:

- Morphine: 0.1 mg/kg/hr x 20 kg = 2 mg/hr
- Lidocaine: 2.5 mg/kg/hr x 20 kg = 50 mg/hr
- Ketamine: 0.1 mg/kg/hr x 20 kg = 2 mg/hr
- Medetomidine: 2 micrograms/kg/hr x 20 kg = 40 micrograms/hr (Note: This is not the dose for dexmedetomidine)

The maintenance fluid administration rate for a dog this size lying quietly in a cage is roughly 800 mL/day or 33 mL/hr. Therefore, a 1-L bag contains approximately 30 hour’s worth of treatment, and to a 1-L bag one must add:

- Morphine: 2 mg/hr x 30 hours = 60 mg = 4 mL (if using 15 mg/mL morphine)
- Lidocaine: 50 mg/hr x 30 hours = 1500 mg = 75 mL (if using 20 mg/mL lidocaine)
- Ketamine: 2 mg/hr x 30 hours = 60 mg = 0.6 mL (if using 100 mg/mL ketamine)
- Medetomidine: 40 micrograms/hr x 30 hours = 1200 micrograms = 1.2 mL (if using 1000 micro-grams/mL medetomidine)

If the drugs are added to a 1-L bag of fluid, the final volume is greater than a liter—in this case 1081 mL. Therefore, 81 mL should be removed from the bag before addition of the medications.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:**

There are injectable lidocaine products labeled for use in veterinary medicine (dogs, cats, horses, and cattle) as an anesthetic, but it is not FDA-approved for use as an antiarrhythmic agent. Information regarding its use in food-producing species is conflicting; when using a food animal it is suggested to contact FARAD (see appendix).

Lidocaine HCl for Injection: 2% (20 mg/mL) in 100 mL & 250 mL multi-use vials; (contains preservatives); generic; (Rx)

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**

Lidocaine Hydrochloride Injection: 0.5%, 1%, 1.5%, 2% & 4% in 5 mL, 10 mL, 20 mL, 30 mL & 50 mL single- & multi-dose vials, 2 mL & 5 mL amps, 5 mL syringes & cartridges (with or without laryngotracheal cannula); 10 mL & 20 mL PolyAmp DuoFit & 1.8 mL cartridges; Xylocaine® & Xylocaine MPF® (AstraZeneca); generic; (Rx)

Lidocaine Hydrochloride with Dextrose Injection: 1.5% with 7.5% dextrose & 5% with 7.5% dextrose in 2 mL amps & single-dose amps; Xylocaine MPF® (APP Pharmaceutical); generic; (Abbott); (Rx)

Premixed with D5W for IV infusion in concentrations of 2 mg/mL, 4 mg/mL, and 5 mg/mg, injections with epinephrine, topical liquids, patches, ointment, cream, lotion, gel, spray, & jelly available.

References

LINCOSAMIDE ANTIMICROBIAL

Prescriber Highlights

- Lincosamide antibiotic similar to clindamycin; broad spectrum against many anaerobes, gram-positive aerobic cocci, Toxoplasma, etc.
- Contraindications: Horses, Rodents, Ruminants, Lagomorphs; Hypersensitivity to lincosamides
- Caution: Liver or renal dysfunction; consider reducing dosage if severe
- Adverse Effects: Gastroenteritis, pain at injection site if given IM; rapid IV administration can cause hypotension & cardiopulmonary arrest
- Distributed into milk; may cause diarrhea in nursing animals
- Drug interactions

Uses/Indications

Lincomycin has dosage forms FDA-approved for use in dogs, cats, swine, and in combination with other agents for chickens. Because clindamycin is generally better absorbed, more active, and probably less toxic, it has largely supplanted the use of lincomycin for oral and injectable therapy in small animals, but some clinicians believe that clindamycin does not offer enough clinically significant improvements over lincomycin to justify its higher cost. For further information, refer to the Pharmacology or Doses sections.

Pharmacology/Actions

The lincosamide antibiotics lincomycin and clindamycin, share mechanisms of action and have similar spectrums of activity although lincomycin is usually less active against susceptible organisms. Complete cross-resistance occurs between the two drugs; at least partial cross-resistance occurs between the lincosamides and erythromycin. They may act as bacteriostatic or bactericidal agents, depending on the concentration of the drug at the infection site and the susceptibility of the organism. The lincosamides are believed to act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation.

Most aerobic gram-positive cocci are susceptible to the lincosamides (Strep. faecalis is not), including staphylococcus and streptococci. Other organisms that are generally susceptible include: Corynebacterium diphtheriae, Nocardia asteroides, Erysipelothrix, and Mycoplasma spp. Anaerobic bacteria that may be susceptible to the lincosamides include: Clostridium perfringens. C. tetani (not C. difficile), Bacteroides (including many strains of B. fragilis), Fusobacterium, Peptostreptococcus, Actinomyces, and Peptococcus.

Pharmacokinetics

The pharmacokinetics of lincomycin have not apparently been extensively studied in veterinary species. Unless otherwise noted, the following information applies to humans. The drug is rapidly absorbed from the gut, but only about 30–40% of the total dose is absorbed. Food both decreases the extent and the rate of absorption. Peak serum levels are attained about 2–4 hour after oral dosing. IM administration gives peak levels about double those reached after oral dosing, and peak at about 30 minutes post injection.

Lincomycin is partially metabolized in the liver. Unchanged drug and metabolites are excreted in the urine, feces and bile. Half-lives can be prolonged in patients with renal or hepatic dysfunction. The elimination half-life of lincomycin is reportedly 3–4 hours in small animals.

Contraindications/Precautions/Warnings

Although there have been case reports of parenteral administration of lincosamides to horses, cattle and sheep, the lincosamides are considered contraindicated for use in rabbits, hamsters, guinea pigs, horses, and ruminants because of serious gastrointestinal effects that may occur, including death.

Lincomycin is contraindicated in patients with known hypersensitivity to it or having a preexisting monilial infection.

Lincomycin is generally not recommended for use in neonatal animals because of its effects on gut flora.

Adverse Effects

Adverse effects reported in dogs and cats include gastroenteritis (emesis, loose stools, and infrequently bloody diarrhea in dogs). IM injections reportedly cause pain at the injection site. Rapid intravenous administration can cause hypotension and cardiopulmonary arrest.

Swine may develop gastrointestinal disturbances while receiving the medication.

Reproductive/Nursing Safety

Lincomycin crosses the placenta and cord blood concentrations are approximately 25% of those found in maternal serum. Safe use during pregnancy has not been established, but neither has the drug been implicated in causing teratogenic effects.

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no...
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Because lincomycin is distributed into milk, nursing animals of mothers given lincomycin may develop diarrhea.

Overdosage/Acute Toxicity
There is little information available regarding overdoses of this drug. In dogs, oral doses of up to 300 mg/kg/day for up to one year or parenterally at 60 mg/kg/day apparently did not result in toxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving lincomycin and may be of significance in veterinary patients:

- **CYCLOSPORINE:** Lincomycin may reduce levels
- **ERYTHROMYCIN:** In vitro antagonism when used with lincomycin; concomitant use should probably be avoided
- **KAOLIN:** Kaolin (found in several over-the-counter antidiarrheal preparations) has been shown to reduce the absorption of lincomycin by up to 90% if both are given concurrently; if both drugs are necessary, separate doses by at least 2 hours
- **NEUROMUSCULAR BLOCKING AGENTS (e.g., pancuronium):** Lincomycin possesses intrinsic neuromuscular blocking activity and should be used cautiously with other neuromuscular blocking agents

Laboratory Considerations
- Slight increases in liver function tests (AST, ALT, Alk. Phosph.) may occur. There is apparently not any clinical significance associated with these increases.

Doses
- **DOGS:**
  a) For skin and soft tissue infections: 15.4 mg/kg PO q8h or 22 mg/kg PO q12h. Treatment for superficial pyoderma 21–42 days; for deep, resistant pyoderma 56 days;
  b) For systemic infections: 22 mg/kg IM, SC, or IV (must be diluted and given as a slow drip infusion) q24h or 11 mg/kg IM or SC q12h for 12 days or less.
  c) For bacteremia, sepsis: 11–22 mg/kg IV q8h for 12 days or less. (Greene et al. 2006)
  d) For pyoderma: 40–50 mg/kg/day PO divided into two or three doses per day. (Carlotti 2008)
  e) For superficial pyodermas: 20 mg/kg PO q12h (White 2007)
  f) For pyoderma: 22 mg/kg PO twice daily; good for first time pyodermas. (Logas 2005)
- **CATS:**
  a) For skin and soft tissue infections: 11 mg/kg IM q12h or 22 mg/kg IM q24h. Treatment for 12 days or less;
  b) For systemic infections: 15 mg/kg PO q8h or 22 mg/kg PO q12h. Treatment for 12 days or less. (Greene et al. 2006)
- **FERRETS:**
  a) 10–15 mg/kg PO three times daily; 10 mg/kg IM twice daily (Williams 2000)
- **SWINE:**
  a) For mycoplasmal (M. hyopneumoniae) pneumonia: Fed at 200 grams per ton of feed for 21 days or 11 mg/kg IM once daily (Amass 1999)
  b) 11 mg/kg IM once daily for 3–7 days; or added to drinking water at a rate of 250 mg/gallon (average of 8.36 mg/kg/day) (Label directions; Lincocin®—Upjohn)

Monitoring
- Clinical efficacy
- Adverse effects; particularly severe diarrheas

Client Information
- Clients should be instructed to report the incidence of severe, protracted, or bloody diarrhea to the veterinarian.

Chemistry/Synonyms
An antibiotic obtained from cultures of *Streptomyces lincolnensis*, lincomycin is available commercially as the monohydrate hydrochloride. It occurs as a white to off-white, crystalline powder that is freely soluble in water. The powder may have a faint odor and has a pKa of 7.6. The commercially available injection has a pH of 3–5.5 and occurs as a clear to slightly yellow solution.

Lincomycin may also be as: U-10149, NSC-70731, Anbycin®, Fradicina®, Fredcina®, Linco®, Lincocin®, LincoMed®, Lincomix®, Linco-Ped®, Lincon® and Macrolin®.

Storage/Stability
Lincomycin capsules, tablets and soluble powder should be stored at room temperature (15–30°C) in tight containers. Lincomycin injectable products should be stored under refrigeration (2–8°C) and protected from freezing.
Lincomycin capsules, tablets and soluble powder should be stored at room temperature (15–30°C) in tight containers. Lincomycin injectable products should be stored at room temperature; avoid freezing.

Drugs that are reportedly physically incompatible when mixed with lincomycin, data conflicts, or compatibility is concentration and/or time dependent include: ampicillin sodium, carbenicillin disodium, methicillin sodium, and phenytoin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
- Lincomycin Oral Tablets: 100 mg, 200 mg, 500 mg; Lincocin® (Pfizer); (Rx). FDA-approved for use in dogs and cats.
- Lincomycin Oral Solution: 50 mg/mL in 20 mL dropper bottles; Lincocin® Aquadrops (Pfizer); (Rx). FDA-approved for use in dogs and cats.
- Lincomycin Sterile Injection: 100 mg/mL in 20 mL vials; Lincocin® (Pfizer); (Rx). FDA-approved for use in dogs and cats.
- Lincomycin Sterile Injection: 25 mg/mL, 100 mg/mL & 300 mg/mL in 100 mL vials; FDA-approved for use in swine. Slaughter withdrawal (when used as labeled) = 48 hours. Lincocin® Sterile Solution (Pfizer); Lincomix® Injectable (Pfizer); generic; (OTC)

There are also several lincomycin combination feed/water additive products for use in swine and/or poultry.

HUMAN-LABELED PRODUCTS:
- Lincomycin Injection: 300 mg (as hydrochloride)/mL in 2 mL & 10 mL vials; Lincocin® (Upjohn), (Rx)

References

LIOTHYRONINE SODIUM
(lye-oh-thy-roe-neen) Cytomel®, Triostat®
THYROID HORMONE

Prescriber Highlights

- Form of T3 (active thyroid hormone) used for hypothyroidism particularly in animals unresponsive to T4
- Shorter duration of effect than levothyroxine
- Contraindications: Acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency
- Caution: Concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or elderly
- Adverse Effects: Only associated with OD’s (tachycardia, polyphagia, PU/PD, excitability, nervousness, & excessive panting); some cats may appear apathetic
- Drug-drug; drug-lab interactions

Uses/Indications

Because of its shorter duration of action, liothyronine is generally not considered the drug of first choice in treating hypothyroidism. Infrequently, animals not responding to levothyroxine may respond to liothyronine. Liothyronine is not recommended for initial therapy because only serum T3 concentrations are normalized while T4 levels remain low.

Pharmacology/Actions

Thyroid hormones affect the rate of many physiologic processes including: fat, protein, and carbohydrate metabolism, increasing protein synthesis, increasing gluconeogenesis, and promoting mobilization and utilization of glycogen stores. Thyroid hormones also increase oxygen consumption, body temperature, heart rate and cardiac output, blood volume, enzyme system activity, and growth and maturity. Thyroid hormone is particularly important for adequate development of the central nervous system. While the exact mechanisms how thyroid hormones exert their effects are not well understood, it is known that thyroid hormones (primarily triiodothyronine) act at the cellular level.

In humans, triiodothyronine (T3) is the primary hormone responsible for activity. Approximately 80% of T3 found in the peripheral tissues is derived from thyroxine (T4) which is the principle hormone released by the thyroid.

Pharmacokinetics

In dogs, peak plasma levels of liothyronine occur 2–5 hours after oral dosing. The plasma half-life is approximately 5–6 hours. In contrast to levothyroxine, it is believed that liothyronine is nearly completely absorbed by dogs and absorption is not as affected by stomach contents, intestinal flora changes, etc.

Contraindications/Precautions/Warnings
Chemistry/Synonyms

Doses

Laboratory Considerations The following drugs may have effects on thyroid function tests; evaluate results accordingly:

- **Effects on serum T4**: aminoglutethimide↓, anabolic steroids androgens↓, antithyroid drugs (PTU, methimazole)↓, asparaginase↓, barbiturates↓, corticosteroids↓, danazol↓, diazepam↓, estrogens↑ (Note: estrogens may have no effect on canine T3 or T4 concentrations), fluorouracil↑, heparin↓, lithium carbonate↓, mitotane (o,p-DDD)↓, nitroprusside↓, phenylbutazone↓, phenytoin↓, propranolol↓, salicylates (large doses)↓, sulfonamides↓, and sulfonylureas↓.

- **Effects on serum T3**: antithyroid drugs (PTU, methimazole)↑, barbiturates↑, corticosteroids↑, estrogens↑, fluorouracil↑, heparin↑, lithium carbonate↑, phenytoin↑, propranolol↑, salicylates (large doses)↑, sulfonamides↑, and thiazides↑.

- **Effects on T3 uptake resin**: anabolic steroids androgens↑, antithyroid drugs (PTU, methimazole)↑, asparaginase↑, corticosteroids↑, danazol↑, estrogens↑, fluorouracil↑, heparin↑, lithium carbonate↑, phenytoin↑, phenylbutazone↑, and salicylates (large doses)↑.

- **Effects on serum TSH**: aminoglutethimide↑, antithyroid drugs (PTU, methimazole)↑, corticosteroids↓, danazol↑, lithium carbonate↑, and sulfonamides↑.

- **Effects on Free Thyroxine Index (FTI)**: antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, heparin↑, lithium carbonate↓, and phenylbutazone↓.

Doses

- **DOGS**: For hypothyroidism:
  a) Initially, 4–6 micrograms/kg PO q8h. Some dogs may require less frequent dosing (Nelson 1989)
  b) Initial starting dose is 4–6 micrograms/kg PO q8h. Liothyronine is only indicated in those few situations when T4 supplementation has failed to achieve a response in a dog with confirmed hypothyroidism, perhaps due to impaired GI T4 absorption. Dogs receiving T3 supplementation may be more susceptible to iatrogenic thyrotoxicosis since serum T4 concentrations are important in the feedback regulation of the hypothalamic-pituitary-thyroid axis. Combination products that contain both T3 and T4 should be avoided for similar reasons. (Scott-Moncrieff, J. & Guptill-Yoran 2000)(Scott-Moncrieff, J.C. 2009)

- **CATS**: For hypothyroidism:
  a) Initially, 4.4 micrograms/kg PO 2–3 times a day (Feldman & Nelson 1987)

Monitoring

- Similar to levothyroxine, but T4 levels will remain low. When monitoring T3 levels, draw serum just prior to dosing and again 2–4 hours after administering the drug.

Client Information

- Clients should be instructed in the importance of compliance with therapy as prescribed
- Also, review the signs that can be seen with too much thyroid supplementation

Adverse Effects

When administered at an appropriate dose to patients requiring thyroid hormone replacement, there should not be any adverse effects associated with therapy. For adverse effects associated with overdosage, see below.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category A for use during pregnancy (Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Minimal amounts of thyroid hormones are excreted in milk and should not adversely affect nursing offspring.

Overdosage/Acute Toxicity

Chronic overdosage will produce signs of hyperthyroidism, including tachycardia, polyphagia, PU/PD, excitability, nervousness, and excessive panting. Dosage should be reduced and/or temporarily withheld until signs subside. Some (10%) cats may exhibit signs of “apathetic” (listlessness, anorexia, etc.) hyperthyroidism. Chronic overdosage will produce signs of hyperthyroidism, including tachycardia, polyphagia, PU/PD, excitability, nervousness, and excessive panting. Dosage should be reduced and/or temporarily withheld until signs subside. Some (10%) cats may exhibit signs of “apathetic” (listlessness, anorexia, etc.) hyperthyroidism.

Acute massive overdosage can produce signs resembling thyroid storm. After oral ingestion, treatment to reduce absorption of drug should be accomplished using standard protocols (emetics or gastric lavage, cathartics, charcoal) unless contraindicated by the patient’s condition. Treatment is supportive and symptomatic. Oxygen, artificial ventilation, cardiac glycosides, beta-blockers (e.g., propranolol), fluids, dextrose, and antipyretic agents have all been suggested for use if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving liothyronine and may be of significance in veterinary patients:

- **ANTIDEPRESSANTS, TRICYCLIC/TETRACYCLIC**: Increased risk for CNS stimulation and cardiac arrhythmias
- **ANTIDIABETIC AGENTS (insulin, oral agents)**: Levothyroxine may increase requirements for insulin or oral agents
- **CHOLESTYRAMINE**: May reduce liothyronine absorption; separate doses by 4 hours
- **DIGOXIN**: Potential for reduced digoxin levels
- **KETAMINE**: May cause tachycardia and hypertension
- **SYMPATHOMIMETIC AGENTS (epinephrine, norepinephrine, etc.)**: Levothyroxine can potentiate effects
- **WARFARIN**: Thyroid hormones increase the catabolism of vitamin K-dependent clotting factors that may increase the anticoagulation effects in patients on warfarin

Laboratory Considerations The following drugs may have effects on thyroid function tests; evaluate results accordingly:

- **Effects on serum T4**: aminoglutethimide↓, anabolic steroids androgens↓, antithyroid drugs (PTU, methimazole)↓, asparaginase↓, barbiturates↓, corticosteroids↓, danazol↓, diazepam↓, estrogens↑ (Note: estrogens may have no effect on canine T3 or T4 concentrations), fluorouracil↑, heparin↓, lithium carbonate↓, mitotane (o,p-DDD)↓, nitroprusside↓, phenylbutazone↓, phenytoin↓, propranolol↓, salicylates (large doses)↓, sulfonamides↓, and sulfonylureas↓.

- **Effects on serum T3**: antithyroid drugs (PTU, methimazole)↑, barbiturates↑, corticosteroids↑, estrogens↑, fluorouracil↑, heparin↑, lithium carbonate↑, phenytoin↑, propranolol↑, salicylates (large doses)↑, sulfonamides↑, and thiazides↑.

- **Effects on T3 uptake resin**: anabolic steroids androgens↑, antithyroid drugs (PTU, methimazole)↑, asparaginase↑, corticosteroids↑, danazol↑, estrogens↑, fluorouracil↑, heparin↑, lithium carbonate↑, phenytoin↑, phenylbutazone↑, and salicylates (large doses)↑.

- **Effects on serum TSH**: aminoglutethimide↑, antithyroid drugs (PTU, methimazole)↑, corticosteroids↓, danazol↑, lithium carbonate↑, and sulfonamides↑.

- **Effects on Free Thyroxine Index (FTI)**: antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, heparin↑, lithium carbonate↓, and phenylbutazone↓.

Monitoring

- Similar to levothyroxine, but T4 levels will remain low. When monitoring T3 levels, draw serum just prior to dosing and again 2–4 hours after administering the drug.

Client Information

- Clients should be instructed in the importance of compliance with therapy as prescribed
- Also, review the signs that can be seen with too much thyroid supplementation
Lisinopril is contraindicated in patients who have demonstrated hypersensitivity to the ACE inhibitors. It should be used with caution and close supervision in patients

Contraindications/Precautions/Warnings

Pharmacology/Actions

The principle uses of lisinopril in veterinary medicine at present are as a vasodilator in the treatment of heart failure or hypertension. Recent studies have demonstrated

Uses/Indications

The principle uses of lisinopril in veterinary medicine at present are as a vasodilator in the treatment of heart failure or hypertension. Recent studies have demonstrated that ACE inhibitors, particularly when used in conjunction with furosemide, do improve the quality of life in dogs with heart failure. It is not clear, however, whether it has any significant effect on survival times. Lisinopril may also be of benefit in treating the effects associated with valvular heart disease (mitral regurgitation) and left to right shunts. It is being explored as adjunctive treatment in chronic renal failure and in protein losing nephropathies.

Lisinopril may have advantages over other ACE inhibitors in that it may be dosed once daily and less expensive. Disadvantages are that it is only available in

May be less expensive than other ACE inhibitors & probably can be dosed once daily

Not as much information available or experience as enalapril or benazepril in dogs or cats

Caution: Renal insufficiency (doses may need to be reduced), patients with hyponatremia, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE)

Adverse Effects: GI distress (anorexia, vomiting, diarrhea); Potentially: weakness, hypotension, renal dysfunction, & hyperkalemia

Uses/Indications

The principle uses of lisinopril in veterinary medicine at present are as a vasodilator in the treatment of heart failure or hypertension. Recent studies have demonstrated that ACE inhibitors, particularly when used in conjunction with furosemide, do improve the quality of life in dogs with heart failure. It is not clear, however, whether it has any significant effect on survival times. Lisinopril may also be of benefit in treating the effects associated with valvular heart disease (mitral regurgitation) and left to right shunts. It is being explored as adjunctive treatment in chronic renal failure and in protein losing nephropathies.

Lisinopril may have advantages over other ACE inhibitors in that it may be dosed once daily and less expensive. Disadvantages are that it is only available in human labeled dosage forms and there is much less published information on its use (efficacy, safety, dosing) in veterinary species.

Pharmacology/Actions

Unlike enalapril, lisinopril does not need to be converted in the liver to an active metabolite. Lisinopril prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for lisinopril than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased. Lisinopril has a higher affinity for ACE than either enalaprilat or captopril.

The cardiovascular effects of lisinopril in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure, no change or decrease in heart rate, and increased cardiac index and output, stroke volume, and exercise tolerance. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Pharmacokinetics

In dogs, lisinopril’s bioavailability ranges from 25–50% with peak levels occurring about 4 hours after dosing. Lisinopril is distributed poorly into the CNS. It is unknown if it is distributed into maternal milk, but it does cross the placenta. Half-lives are increased in patients with renal failure or severe CHF. Duration of action in dogs has been described as being 24 hours, but effects tend to drop off with time.

Contraindications/Precautions/Warnings

The cardiovascular effects of lisinopril in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure, no change or decrease in heart rate, and increased cardiac index and output, stroke volume, and exercise tolerance. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Lisinopril may have advantages over other ACE inhibitors in that it may be dosed once daily and less expensive. Disadvantages are that it is only available in human labeled dosage forms and there is much less published information on its use (efficacy, safety, dosing) in veterinary species.
Lisinopril is contraindicated in patients who have demonstrated hypersensitivity to the ACE inhibitors. It should be used with caution and close supervision in patients with renal insufficiency and doses may need to be reduced.

Lisinopril should be used with caution in patients with hyponatremia or sodium depletion, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE). Patients with severe CHF should be monitored very closely upon initiation of therapy.

### Adverse Effects

Lisinopril's adverse effect profile in dogs is reportedly similar to other ACE inhibitors, principally GI distress (anorexia, vomiting, diarrhea). Potentially, cough, weakness, hypotension, renal dysfunction, and hyperkalemia could occur. Because it lacks a sulfhydryl group (unlike captopril), there is less likelihood that immune-mediated reactions will occur, but rashes, neutropenia, and agranulocytosis have been reported in humans.

### Reproductive/Nursing Safety

Lisinopril crosses the placenta. High doses in rodents have caused decreased fetal weights and increases in fetal and maternal death rates; teratogenic effects have not been reported.

Current recommendations for humans are to discontinue ACE inhibitors as soon as pregnancy is detected. In humans, the FDA categorizes this drug as category C for use during the first trimester of pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans or there are no animal reproduction studies and no adequate studies in humans.) In humans, the FDA categorizes this drug as category D for use during the second and third trimesters of pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

It is not known whether lisinopril is excreted in milk; use with caution.

### Overdosage/Acute Toxicity

There were 688 exposures to lisinopril reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 654 were dogs with 58 showing clinical signs, 31 were cats with 2 showing clinical signs, and the remaining cases were 3 birds with 1 showing clinical signs. Common findings in dogs recorded in decreasing frequency included hypotension, lethargy, vomiting, and tachycardia.

The ASPCA Animal Poison Control Center (APCC) has over 3500 lisinopril exposure cases in its files, mostly involving dogs, but some birds and cats. The lowest dosage documented to cause hypotension in dogs is 27 mg/kg. Generally dosages below 20 mg/kg cause mild signs only, most commonly vomiting and lethargy. Higher dosages warrant decontamination. Only a single cat out of 218 cats developed hypotension at a dosage of 4.9 mg/kg. In birds, only mild somnolence occurred at 41 mg/kg.

In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug’s long duration of action, prolonged monitoring and treatment may be required. Recent overdoses should be managed using gut-emptying protocols when warranted.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lisinopril and may be of significance in veterinary patients:

- **ANTIDIABETIC AGENTS** (insulin, oral agents): Possible increased risk for hypoglycemia; enhanced monitoring recommended
- **DIURETICS** (e.g., furosemide, hydrochlorothiazide): Potential for increased hypotensive effects; some veterinary clinicians recommend reducing furosemide doses (by 25–50%) when adding ACE-inhibitors to therapy in CHF
- **DIURETICS, POTASSIUM-Sparing (e.g., spironolactone, triamterene)**: Increased hyperkalemic effects, enhanced monitoring of serum potassium recommended
- **HYPOTENSIVE AGENTS, OTHER**: Potential for increased hypotensive effect
- **LITHIUM**: Increased serum lithium levels possible; increased monitoring required
- **NSAIDS**: May reduce the anti-hypertensive or positive hemodynamic effects of enalapril; may increase risk for reduced renal function
- **POTASSIUM SUPPLEMENTS**: Increased risk for hyperkalemia

### Laboratory Considerations

- ACE inhibitors may cause a reversible decrease in localization and excretion of **iodohippurate sodium** $^{123}$I/$^{131}$I, or **Technetium Tc$^{99}$** pententate renal imaging in the affected kidney in patients with renal artery stenosis, which may lead to confusion in test interpretation.

### Doses

**DOGS:**

- For adjunctive treatment of heart failure:
  - a) 0.5 mg/kg PO q12–24 hours (Ware & Keene 2000)
  - b) 0.5 mg/kg PO q24h (Fuentes 2003)
  - c) 0.25–0.5 mg/kg PO once daily (q24h); highest recommended doses should be used unless not tolerated by patient. (Rishniw 2008)

**CATS:**

- For adjunctive treatment of heart failure:
  - a) 0.25–0.5 mg/kg PO once daily (Fox 2000)

### Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential, periodic
- Blood pressure (if treating hypertension or signs associated with hypotension arise)
Client Information

- Do not abruptly stop or reduce therapy without veterinarian’s guidance
- Contact veterinarian if vomiting or diarrhea persist or are severe or if animal’s condition deteriorates.

Chemistry/Synonyms

An oral angiotensin-converting enzyme inhibitor (ACE inhibitor) lisinopril is directly active and not a prodrug like enalapril. It occurs as a white crystalline powder. One mg is soluble in 10 mL of water; 70 mL of methanol. It is practically insoluble in alcohol, chloroform, or ether.

Lisinopril may also be known as: L-154826, lisinoprilum, and MK-521; many trade names are available.

Storage/Stability

Store lisinopril tablets at room temperature in tight containers, unless otherwise directed by manufacturer.

Compatibility/Compounding Considerations

**Compounded preparation stability:** Lisinopril oral suspension compounded from the commercially available tablets has been published (Nahata & Morosco 2004). Triturating ten (10) lisinopril 10 mg tablets with 50 mL of Ora Plus® and qs ad to 100 mL with Ora Sweet® yields a 1 mg/mL lisinopril oral suspension that retains >95% potency for 91 days when stored at 4°C and protected from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**

Lisinopril Oral Tablets: 2.5 mg, 5 mg, 10 mg, 20 mg, 30 mg & 40 mg; Prinivil® (Merck); Zestril® (AstraZeneca); generic; (Rx)

Also available are fixed dose combinations of lisinopril with hydrochlorothiazide.

References

---

**LOMUSTINE (CCNU)**

*(loe-muss-teen) CeeNu®*

**Prescriber Highlights**

- Antineoplastic usually used for CNS neoplasms, mast cell tumors, histiocytic sarcomas or as a rescue agent for lymphoma
- Cautions (risk vs. benefit): Anemia, bone marrow depression, pulmonary function impairment, current infection, impaired renal function, sensitivity to lomustine, or patients that have received previous chemotherapy or radiotherapy
- Adverse Effects: GI effects (anorexia, vomiting, diarrhea), stomatitis, alopecia, corneal de-epithelization, & rarely, renal toxicity, hepatotoxicity, & pulmonary infiltrates or fibrosis. Most serious: bone marrow depression (anemia, thrombocytopenia, leukopenia); nadirs in dogs generally occur about 1–3 weeks after treatment
- Teratogenic

---

**Uses/Indications**

Lomustine may be useful in the adjunctive treatment of CNS neoplasms, lymphomas, and mast cell tumors in dogs and cats.

**Pharmacology/Actions**

While lomustine’s mechanism of action is not totally understood, it is believed it acts as an alkylating agent; however, other mechanisms such as carbamylation and cellular protein modification may be involved; net effects are DNA and RNA synthesis inhibition. Lomustine is cell cycle-phase nonspecific.

**Pharmacokinetics**

Lomustine is absorbed rapidly and extensively from the GI tract and some absorption occurs after topical administration. Lomustine or its active metabolites are widely distributed in the body. While lomustine is not detected in the CSF, its active metabolites are detected in substantial concentrations. Lomustine is metabolized extensively in the liver to both active and inactive metabolites that are then eliminated primarily in the urine. Lomustine half-life in humans is very short (about 15 minutes), but its biologic activity is significantly longer due to the longer elimination times of active metabolites.

**Contraindications/Precautions/Warnings**

Lomustine should be used only when its potential benefits outweigh its risks with the following conditions: anemia, bone marrow depression, pulmonary function impairment, current infection, impaired renal function, sensitivity to lomustine, or patients who have received previous chemotherapy or radiotherapy.
Adverse Effects
The most serious adverse effects are bone marrow depression (anemia, thrombocytopenia, leukopenia) and hepatotoxicity. CBC nadirs in dogs generally occur about 1–6 weeks after treatment has begun. In dogs, lomustine may cause delayed, cumulative dose-related, chronic, irreversible hepatotoxicity (Kristal et al. 2004). There are some anecdotal reports of SAMe and silymarin being successfully used to treat or prevent lomustine hepatotoxicity. Other potential adverse effects include GI effects (anorexia, vomiting, diarrhea), stomatitis, alopecia, corneal de-epithelization and rarely, renal toxicity, and pulmonary infiltrates or fibrosis. Cross-resistance may occur between lomustine and carmustine.

Reproductive/Nursing Safety
Lomustine is a teratogen in lab animals. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Lomustine can suppress gonadal function. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Lomustine and its metabolites have been detected in maternal milk. Nursing puppies should receive milk replacer when the bitch is receiving lomustine.

Overdosage/Acute Toxicity
No specific information was located. Because of the potential toxicity of the drug, overdoses should be treated aggressively with gut emptying protocols employed when possible. For further information, refer to an animal poison control center.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving lomustine and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSIVE DRUGS, OTHER (e.g., azathioprine, cyclophosphamide, corticosteroids):** Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS, OTHER (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine):** The principal concern with lomustine is with its concurrent use with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.
- **VACCINES, LIVE VIRUS:** Live virus vaccines should be used with caution, if at all, during lomustine therapy.

Doses
**NOTE:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS/CATS:**

The following is a usual dose or dose range for this drug and should be used only as a general guide: Depending on the indication and protocol, lomustine is usually dosed in dogs from 50–90 mg/m2 (NOT mg/kg) every 2–6 weeks and in cats at 60 mg/m2 every 6 weeks or as a single 10 mg dose every 3 weeks.

Monitoring
- CBC with platelets one week after dosing and prior to next dose; if platelets less than 200,000/mc1; stop therapy until thrombocytopenia is resolved
- Liver function tests; initially before starting treatment and then every 3–4 months

Client Information
- Lomustine or its metabolites can be detected in the urine up to 24 hours after a dose. If urine must be cleaned up, use appropriate protection to avoid skin contact.
- Liver and bone marrow toxicity are possible; contact veterinarian immediately if patient develops an infection, runs a fever, bleeds, has yellowing of the whites of the eyes, has persistent vomiting or becomes ill.

Chemistry/Synonyms
A nitrosourea derivative alkylating agent, lomustine occurs as a yellow powder that is practically insoluble in water and soluble in alcohol.

Lomustine may also be known as: CCNU, lomustinum, NSC-79037, RB-1509, Belustine®, CCNU®, CeeNu®, CINU®, Citosta®, Lomeblastin®, Lucostin®, Lucostine®, and Prava®.

Storage/Stability
Store capsules in well-closed containers at room temperature. Expiration dates of two years are assigned after manufacture.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Lomustine Capsules: 10 mg, 40 mg & 100 mg with mannitol; CeeNu® (Bristol Labs Oncology); (Rx)

References

Prescriber Highlights

- Synthetic opiate GI motility modifier used for symptomatic treatment of diarrhea, primarily in dogs
- Contraindications: Dogs with ABCB1-1Δ (MDR1) mutation. Known hypersensitivity to narcotic analgesics, diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract
- Caution: Respiratory disease, hepatic encephalopathy, hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), head injuries, or increased intracranial pressure, & acute abdominal conditions (e.g., colic), & in geriatric or severely debilitated patients; avoid use in untested dogs of breeds (“white-feet”) susceptible to MDR1 mutation
- Adverse Effects: Dogs: Constipation, bloat, & sedation. Potential for: paralytic ileus, toxic megacolon, pancreatitis, & CNS effects. Cats: Use is controversial, may exhibit excitatory behavior.
- Dose very carefully in small dogs and cats

Uses/Indications
Loperamide is used as a GI motility modifier in small animals. Some have found that loperamide is useful for treating or helping to reduce chemotherapy-induced (e.g., toceranib) diarrhea in dogs (London 2010), (Vail 2009). Use in cats is controversial and many clinicians do not recommend using in cats.

Pharmacology/Actions
Among their other actions, opiates inhibit GI motility and excessive GI propulsion. They also decrease intestinal secretion induced by cholera toxin, prostaglandin E2 and diarrheas caused by factors in which calcium is the second messenger (non-cyclic AMP/GMP mediated). Opiates may also enhance mucosal absorption.

Pharmacokinetics
In humans, loperamide’s half-life is about 11 hours. It is unknown if the drug enters milk or crosses the placenta. In dogs, loperamide reportedly has a faster onset of action and longer duration of action than diphenoxylate, but clinical studies confirming this appear to be lacking. In dogs, loperamide’s half-life is about 11 hours. It is unknown if the drug enters milk or crosses the placenta.

Contraindications/Precautions/Warnings
All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency, (Addison’s), and in geriatric or severely debilitated patients.

Contraindications should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions (e.g., colic), as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation). Opiate antidiarrheals should be used with extreme caution in patients with hepatic disease with CNS clinical signs of hepatic encephalopathy. Hepatic coma may result.

Many clinicians recommend not using diphenoxylate or loperamide in dogs weighing less than 10 kg, but this is probably a result of the potency of the tablet or capsule forms of the drugs. Dosage titration using the liquid forms of these agents should allow their safe use in dogs when indicated.

Because loperamide is potentially a neurotoxic substrate of P-glycoprotein, it is contraindicated in dogs tested positive for the ABCB1-1Δ (MDR1) mutation. Alternative antidiarrheals should be considered in untested dogs of herding breeds (e.g., Collies, Shelties, Australian shepherds, etc.) that may have the gene mutation.

Adverse Effects
In dogs, constipation, bloat, and sedation are the most likely adverse reactions encountered when usual doses are used. Potentially, paralytic ileus, toxic megacolon, pancreatitis, and CNS effects could be seen.

Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

Reproductive/Nursing Safety
In humans, the FDA categorizes loperamide as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known whether loperamide is excreted in maternal milk. Safety during nursing has not been established.

Overdosage/Acute Toxicity
In dog toxicity studies, doses of 1.25–5 mg/kg/day produced vomiting, depression, severe salivation, and weight loss. Breeds with a defective MDR-1 gene are more sensitive to CNS depression with loperamide than other breeds and have shown signs at 0.06 mg/kg per the APCC database.

There were 376 exposures to loperamide reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 358 were dogs with 231 showing clinical signs and 14 cats with 1 showing clinical signs. The remaining cases were 4 birds with 1 showing clinical signs. Common findings in dogs recorded in decreasing frequency included diarrhea, vomiting, lethargy, anorexia, weakness, and hypersalivation.

Treatment should follow standard decontamination protocols, although the use of apomorphine for emesis should be avoided since it can have additive CNSA or respiratory depressant effects. Naloxone may be used to treat severe depression; higher than usual doses may be required.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving loperamide and may be of significance in veterinary patients:

**AMIODARONE:** By inhibiting P-gp may increase loperamide plasma concentrations
CARVEDILOL: By inhibiting P-gp may increase loperamide plasma concentrations
ERYTHROMYCIN: By inhibiting P-gp may increase loperamide plasma concentrations
KETOCONAZOLE, ITRACONAZOLE: By inhibiting P-gp may increase loperamide plasma concentrations
QUINIDINE: By inhibiting P-gp may increase loperamide plasma concentrations
TAMOXIFEN: By inhibiting P-gp may increase loperamide plasma concentrations
VERAPAMIL: By inhibiting P-gp may increase loperamide plasma concentrations

Laboratory Considerations
- Plasma amylase and lipase values may be increased for up to 24 hours following administration of opiates.

Doses

**DOGS:**
As an antidiarrheal:

**Note:** Collies and related breeds (MDR1 mutation) may be overly sensitive to loperamide

a) 0.08 mg/kg, PO three times daily (DeNovo 1988; Washabau 2004)
b) 0.1–0.2 mg/kg PO q8–12h (Willard 2003)
c) 0.1 mg/kg PO three times a day; probably should not be given longer than 5 days and is potentially contraindicated when diarrhea is suspected to be caused by enteric infections (Hall & Simpson 2000)
d) As adjunctive treatment for diarrhea associated with chemotherapy: 0.08 mg/kg PO three times daily. (Vail 2009)
e) 0.08 mg/kg PO 3–4 times a day (Cote 2000)
f) 0.1–0.2 mg/kg PO q6–12h (Leib 2004)

**CATS:**

**Note:** Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

a) For Diarrhea: Using the suspension 0.04–0.06 mg/kg PO twice daily (Tams 1999)
b) 0.08–0.16 mg/kg PO q12h (Willard 2003)

**RABBITS, RODENTS, SMALL MAMMALS:**

- **Rabbits:** 0.1 mg/kg in 1 mL of water PO q8h for 3 days, then once daily for 2 days (Ivey & Morrisey 2000)
- **Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:** 0.1 mg/kg PO q8h for 3 days, then once daily for 2 days; give in 1 mL of water (Adamcak & Oten 2000)

Monitoring
- **Clinical efficacy**
- **Fluid and electrolyte status in severe diarrhea**
- **CNS effects if using high dosages**

Client Information
- If diarrhea persists or if animal appears listless or develops a high fever, contact veterinarian.

Chemistry/Synonyms
A synthetic piperidine-derivative antidiarrheal, loperamide occurs as a white to faintly yellow powder with a pKa of 8.6 that is soluble in alcohol and slightly soluble in water.

Loperamide may also be known as PJ 185, or R 18553; a common trade name is *Imodium*®.

Storage/Stability
Loperamide capsules or oral solution should be stored at room temperature in well-closed containers. It is recommended that the oral solution not be diluted with other solvents.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**
- Loperamide HCl Oral Liquid: 1 mg/5 mL (0.2 mg/mL), & 1 mg/7.5 mL in 60 mL, 90 mL, 118 mL and 120 mL; *Imodium® A-D* (McNeil-CPC); generic; (OTC)

References
Used/Indications
Lorazepam may be useful in treating status epilepticus in dogs and the adjunctive treatment of behavior disorders (fears, phobias, anxiety) in dogs and cats. Although, in veterinary medicine, when compared with diazepam, there is much less experience using lorazepam, it has some advantages. Lorazepam is not metabolized by the liver into active metabolites so it can be used more safely in patients with liver dysfunction, obese, or geriatric patients. It appears as effective as diazepam, may have longer anticonvulsant duration of action (not proven in dogs), and can be easier to administer (intranasal, IM, sublingual/buccal).

In human medicine, lorazepam is now frequently used in place of diazepam for treating status epilepticus and anxiolytic indications. It is also used for treating cancer chemotherapy-induced nausea and emesis, alcohol withdrawal, and akathisia secondary to antipsychotic medications.

Pharmacology/Actions
Lorazepam and other benzodiazepines depress the subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS thus producing anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. Receptors are lacking in the white matter in all species studied.

Pharmacokinetics
In dogs, intravenous administration of 0.2 mg/kg gave peak levels of about 165 ng/mL and remained above 30 ng/mL (considered necessary for anticonvulsant activity in humans) for 60 minutes. After intranasal administration of 0.2 mg/kg to dogs (Mariani et al. 2003), peak levels of about 106 ng/mL were achieved; in 3/6 dogs studied, levels stayed above 30 ng/mL for 60 minutes. Levels reached 30 ng/mL between 3–9 minutes after intranasal administration. While elimination half-life has been reported as approximately 1 hour in dogs, concentrations in the brain may persist longer than in the serum as lorazepam has a high affinity for benzodiazepine receptors in the CNS. Rectal administration of lorazepam in dogs does not appear to yield serum concentrations high enough for efficacious treatment of status epilepticus due to a high first-pass effect. Lorazepam is converted into glucuronide forms in the liver in most species. These metabolites are not active. Primary elimination route is via the urine in dogs. In cats, elimination is approximately 50% in the urine (primarily as the glucuronide) and 50% in the feces.

In humans, absolute bioavailability is about 90% after oral administration and, unlike diazepam, it is relatively rapidly and completely absorbed after IM dosing. Sublingual administration has similar bioavailability as oral dosing, but serum levels peak sooner. Elimination half-life appears to be much longer in humans (12 hours) than in dogs (1 hour).

Contraindications/Precautions/Warnings
Lorazepam is contraindicated in patients known to be hypersensitive to benzodiazepines, or with severe respiratory insufficiency unless being mechanically ventilated.

When using for negative behaviors, withdraw the drug gradually or a rebound effect may occur. Physical dependency has been induced in dogs. If long-term regular usage has occurred, withdraw the drug gradually.

Injectable lorazepam must not be given intra-arterially; arteriospasm may occur resulting in necrosis.

Adverse Effects
In small animals, benzodiazepines can cause increased appetite, aggression, increased activity/excitement, and vocalization. With initiation of therapy, dosage increases, or at higher dosages, ataxia, somnolence and lethargy can occur.

Reproductive/Nursing Safety
For humans, lorazepam is designated by the FDA as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) However, studies in animals generally suggest that the drug is relatively safe for use during pregnancy at usual dosages. Except in one study in mice that were given approximately 400X the human dose producing offspring with an increased rate of cleft palate formation, animal studies have not shown significant increased rates of teratogenicity. If high doses are used just prior to delivery, “floppy infant” syndrome has been seen in humans.

Small amounts of lorazepam are distributed into milk, but it should be safe to use during nursing.

Overdose/Acute Toxicity
Overdoses of lorazepam are generally limited to CNS depression (confusion, lethargy, somnolence, decreased reflexes, etc.). Very large overdoses can cause ataxia, hypotension, coma, and death (very rare).

Treatment of acute orally-ingested toxicity consists of standard protocols for removing and/or binding the drug in the gut and supportive systemic measures. In patients with normal renal function, forced diuresis with intravenous fluids/electrolytes and mannitol may enhance excretion of lorazepam. The use of analeptic agents (CNS stimulants such as caffeine) is generally not recommended. Flumazenil may be considered for adjunctive treatment of serious overdoses of benzodiazepines, but its use does not replace proper supportive therapy. Flumazenil is not recommended in patients with seizure-disorders as it may induce seizures.

Prescriber Highlights
- Benzodiazepine that can be useful as an anxiolytic in dogs & cats or as an alternative to diazepam for treating status epilepticus
- Can be administered intranasally or IV for status epilepticus
- Adverse Effects (most likely): Increased appetite, activity or behavior changes (lethargy/somnolence to hyperexcitability/aggression)
**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving lorazepam and may be of significance in veterinary patients:

- **CNS DEPRESSANTS (e.g., opiates, barbiturates, sedatives, anticonvulsants):** Additive CNS effects
- **PROBENECID:** Decreased renal clearance of lorazepam
- **SCOPOLAMINE:** Increased CNS depression, irrational behavior
- **THEOPHYLLINE:** Decreased sedation from lorazepam
- **VALPROATE:** Increased lorazepam serum concentration

**Laboratory Considerations**

- No specific concerns noted

**Doses**

**DOGS:**

- For status epilepticus:
  - a) As an alternative to diazepam for status epilepticus: 0.2 mg/kg IV, IM or intranasal once. (Hopper 2006)
  - b) Lorazepam 0.2 mg/kg IV once, followed by a bolus IV loading dose of levetiracetam at 60 mg/kg. (Podell 2009)

- For behavior indications:
  - a) For fears, anxieties, phobias: 0.02–0.1 mg/kg PO once daily to three times a day; may be used on an as needed basis. (Landsberg 2005)
  - b) As an anxiolytic: 0.05–0.25 mg/kg PO q12–24h. (Virga 2005)
  - c) For fears/anxiety: 0.02–0.5 mg/kg PO q8h. The lowest dose and frequency that alleviate the fear should be used. (Crowell-Davis 2008)
  - d) For fears, anxieties, phobias, aversions: 0.02–0.5 mg/kg q8-24h; minimally sedating, may require 4 weeks to peak effect. (Sherman & Mills 2008)

**CATS:**

- a) For fears/anxiety: 0.03–0.08 mg/kg PO q12h. The lowest dose and frequency that alleviate the fear should be used. (Crowell-Davis 2008)
  - b) For fears, anxieties, phobias: 0.125 mg–0.25 mg total dose (¼–½ of a 0.5 mg tablet) once to twice a day; may be used on an as needed basis. (Landsberg 2005)
  - c) As an anxiolytic: 0.05–0.25 mg/kg PO q12–24h. (Virga 2005)

**Monitoring**

- No specific monitoring is required beyond clinical efficacy and adverse effects

**Client Information**

- This medication may increase appetite, diligent food restriction may be required
- May cause changes in activity levels and can cause either lethargy or increased activity/excitement
- Do not stop treatment abruptly without veterinarian’s guidance; animals receiving this medication on a regular basis for a prolonged period of time may develop withdrawal signs if not “weaned off” the drug
- Although liver toxicity has not yet been reported in animals receiving this medication, a drug (diazepam) similar to lorazepam has rarely caused liver toxicity in cats. If vomiting, lack of appetite, or yellowing of the whites of eyes or mucous membranes occur contact veterinarian immediately.
- Tablets are relatively tasteless and readily disintegrate in saliva. If pilling is difficult, place inside the patient’s cheek and follow in a minute or so with a small treat to facilitate swallowing of saliva/medication.

**Chemistry/Synonyms**

- Lorazepam occurs as a white or practically white, practically odorless powder. It is insoluble in water and sparingly soluble in alcohol.
  - Lorazepam may also be known as BRN-07599084, CB-8133, Ro-7-8408, Wy-4036, lorazepamum, anxiedin, azurogen, bonatranquan, delormetazepam, lorazin, lorazon, lenrin, norlormetazepam, novhepar, novolorazem, o-Chloroxazepam, sinestrin, Ativan®, and Lorazepam Intensol®; many international trade names are available.

**Storage/Stability**

- Lorazepam tablets should be stored in well-closed containers at room temperature (20–25°C). The oral solution and injection should be stored refrigerated (2–8°C) and protected from light.
  - The injection must be further diluted just prior before to intravenous injection with an equal volume of D5W, normal saline, or sterile water for injection. Do not shake the syringe vigorously, but gently invert repeatedly until the injection is diluted and completely mixed in solution. Do not use if solution is discolored or a precipitate forms. IV injections should be administered slowly, 2 mg over 2–5 minutes.
  - Although not part of the label information, lorazepam can be further diluted in D5W or NS for IV infusion. When used in this manner, lorazepam injection is most soluble in final concentrations from 0.1–0.2 mg/mL. For example, if using the 2 mg/mL injection, further dilution with 9 mL or 19 mL of D5W or NS would yield a final concentration of 0.2 or 0.1 mg/mL. The injection is very viscous; mix well before use. As precipitation/crystallization can occur, observe the solution before and during the infusion. D5W may be less prone to crystallization formation than is NS. Solutions for infusion mixed in this manner should be used within 12 hours of preparation.

**Compatibility/Compounding Considerations**

- Medications reported to be compatible (partial listing):
- **Syringe:** hydromorphone

**Compatibility Data**

- No specific compatibility concerns noted

**References**

Lufenuron (loo-fen-ur-on) Program®, Sentinel®

Chitin Synthesis Inhibitor

Prescriber Highlights

- Used for flea control in dogs & cats; potentially an antifungal agent
- Adverse Effects: None at recommended doses

Uses/Indications

Lufenuron is FDA-approved for use in dogs and cats 6 weeks of age and older for the control of flea populations. The combination product of lufenuron and milbemycin (Sentinel®) is indicated for use in puppies and dogs 4 weeks and older for prevention and control flea populations, prevention of heartworm disease, control of adult hookworms, and the removal and control of adult roundworms and whipworms.

In evaluating lufenuron as an ectoparasiticide, advantages include: convenient, can be administered orally, safe environmentally and to patient. Disadvantages: Treated animals must not come into contact with any untreated animal, must be given with food, no repellant activity, does not kill adult fleas of pupae, adult flea must feed on animal to ingest, no activity on ticks, lag period of several weeks to months (often 60-90 days), can be expensive in multi-pet households. One author (Irthke 2009) recommends lufenuron to be used with spot-ons or with newer oral products for long-term control, not for use as sole therapy unless very closed environment.

Lufenuron has been proposed as a potential treatment or preventative for *E. cuniculi* infections in rabbits, but no studies are available evaluating its use for this indication.

Lufenuron showed initial promise as a treatment for fungal infections, but the early enthusiasm has dampened considerably as efficacy appears doubtful.

Pharmacology/Actions

Lufenuron acts by inhibiting chitin synthesis, polymerization, and deposition in fleas, thereby preventing eggs from developing into adults. It is believed that lufenuron’s nonspecific effect on chitin synthesis is related to serine protease inhibition. Lufenuron’s mechanism of action, theoretically, would also have effect on fungi.

Lufenuron does not kill adult fleas.

Pharmacokinetics

Approximately 40% of an oral dose is absorbed with the remainder eliminated in the feces. To maximize oral absorption, the manufacturer recommends administering in conjunction with or immediately after (within 30 minutes) a full meal. The drug is absorbed in the small intestine and stored in lipose tissue that acts as depot reservoir to slowly redistribute the drug back into the circulation. While the drug concentrates in the milk of lactating animals, it apparently does not cause ill effects in nursing animals.

After cats receive the injectable product, 2–3 weeks are required before blood levels attain effective concentrations. Cats require a substantially higher oral dosage per kg than do dogs for equivalent efficacy. The drug is apparently not metabolized, but excreted unchanged into the bile and eliminated in the feces.

Contraindications/Precautions/Warnings

The cat labeled injectable product should not be used in dogs; severe local reactions are possible.

Adverse Effects

Adverse effects reported in dogs and cats after oral lufenuron include: vomiting, lethargy/depression, pruritus/urticaria, diarrhea, dyspnea, anorexia, and reddened skin.

The manufacturer reports that the adverse reaction rate is less than 5 animals in one million doses.

Reproductive/Nursing Safety

The manufacturer reports that the adverse reaction rate is less than 5 animals in one million doses.

After receiving the injectable product, a small lump at the injection site has been noted in some cats. A few weeks may be required for this to dissipate.
The oral lufenuron products are considered safe to use in pregnant, breeding, or lactating animals; safety of the injectable product in reproducing cats has not been formally established at this time.

**Overdosage/Acute Toxicity**
Growing puppies were dosed at levels up to 30X for 10 months without overt effect on growth or viability noted. Cats receiving oral dosages of up to 17X apparently were unaffected.

**Drug Interactions**
Limited data available; the manufacturer states that when used with a variety of adulticides, vaccines, antibiotics, anthelmintics, and steroids no adverse effects or interactions were noted in either dogs or cats.

**Doses**

---

**DOGS:**

a) For control of flea populations: See the label directions for *Program with Capstar* for using lufenuron with nitenpyram.

For control of fleas, heartworm prevention, hookworm, ascarid or whipworms: see the label directions for Lufenuron/Milbemycin with Nitenpyram (*Sentinel® and Capstar®*—Novartis)

b) For adjunctive therapy for dermatophytosis: 50–100 mg/kg PO once every 14 days for two treatments, then once a month until at least two negative fungal cultures are obtained (Mantousek 2003)

---

**CATS:**

a) For control of flea populations: See the label directions *Program* and *Program with Capstar* for using lufenuron with or without nitenpyram.

b) For adjunctive therapy for dermatophytosis: 50–100 mg/kg PO once every 14 days for two treatments, then once a month until at least two negative fungal cultures are obtained. (Mantousek 2003)

---

**RABBITS/RODENTS/SMALL MAMMALS:**

a) *Rabbits*: 30 mg/kg PO every month (Ivey & Morrisey 2000)

---

**Monitoring**

- **Efficacy**

**Client Information**

- **Must be used every 30 days to maximize efficacy.**

- **All animals in a household should be treated.**

- **Absorption of the drug is enhanced if given with a fatty meal. If animal vomits within 2 hours after dosing, the drug should be re-dosed. If a dose is missed, re-dose and then resume a monthly dosage regimen (dogs receiving the lufenuron/milbemycin product should be tested in 6 months or more for heartworm exposure with an antigen test).**

- **Do not split tablets.**

**Chemistry/Synonyms**

A benzoylphenylurea derivative, lufenuron is classified as an insect development inhibitor. The drug is lipophilic.

Lufenuron may also be known as CGA-184699, *Capstar®, Program®* and *Sentinel®*.

**Storage/Stability**

The commercially available tablets and suspension should be stored at room temperature (15–30°C). The manufacturer states that intermittent exposure or exposure less than 48 hours to temperatures outside of storage recommendations for the tablets or suspension should not affect potency. Lufenuron tablets are assigned a 4 year expiration date after manufacture; the suspension 3 years after manufacture; and *Sentinel®* tablets 3 years after manufacture. Opened pouches of the suspension are not recommended for storage or use for the following dosing cycle.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Lufenuron Oral Suspension: in six tube packs; 135 mg (for cats up to 10 lb,—orange), 270 mg (for cats 11–20 lb,—green), cats over 20 lbs are provided the appropriate combination of packs.; *Program® Suspension* (Novartis); (Rx). FDA-approved for use in cats and kittens (6 weeks of age or older).

Lufenuron 6 Month Injectable for Cats: 100 mg/mL in 10 syringe packages: 0.4 mL (40 mg) prefilled syringe (for cats up to 8.8 lb), 0.8 mL (80 mg) prefilled syringe (for cats 8.9–17.6 lb); *Program® 6 Month Injectable* (Novartis); (Rx). FDA-approved for use in cats and kittens 6 weeks of age or older.

Lufenuron Oral Flavor Tabs for Dogs and Cats: For dogs up to 10 lb: 45 mg; For dogs 11 to 20 lb: 90 mg; For dogs 21 to 45 lb: 204.9 mg; For dogs 46 to 90 lb: 409.8 mg; Dogs over 90 lbs receive the appropriate combination of lufenuron tablets; For cats up to 6 lbs. 90 mg; 7–15 lb: 204.9 mg; cats over 15 lb. receive the appropriate combination of lufenuron tablets *Program* and *Capstar® Flea Management System for Dogs* (Novartis); (OTC). FDA-approved for use in dogs, puppies, cats, & kittens (4 weeks of age or older).

Lufenuron and Nitenpyram Oral Tablets for Dogs: For dogs up to 10 lb: 45 mg Lufenuron, 11.4 mg nitenpyram; For dogs 11 to 20 lb: 90 mg lufenuron, 11.4 mg nitenpyram; For dogs 21 to 25 lb: 204.9 mg lufenuron, 11.4 mg nitenpyram; For dogs 26 to 45 lb: 204.9 mg lufenuron, 57 mg nitenpyram; For dogs 46 to 90 lb: 409.8 mg lufenuron, 57 mg nitenpyram; Dogs over 90 lbs receive the appropriate combination of Lufenuron tablets and 57 mg nitenpyram tablets; *Program® Flavor Tabs and Capstar® Flea Management System for Dogs* (Novartis); (OTC). FDA-approved for use in dogs and puppies (6 weeks of age or older).

Lufenuron and Nitenpyram Oral Tablets for Cats: For cats 2 to 6 lb: 90 mg lufenuron, 11.4 mg nitenpyram; For cats 7 to 15 lb: 204.9 mg lufenuron, 11.4 mg nitenpyram; For cats 16 to 25 lb: appropriate combination of tabs provided lufenuron, 11.4 mg nitenpyram; *Program® Flavor Tabs* (OTC); and *Capstar® Flea Management System for Cats* (Novartis); (OTC)

Milbemycin/Lufenuron Oral Tablets with Nitenpyram Oral Tablets for Dogs: For dogs 2 to 10 lb: 46 mg milbemycin/Lufenuron, 11.4 mg nitenpyram; for dogs 11 to...
**Milbemycin/Lufenuron Oral Tablets with Nitenpyram Oral Tablets for Dogs:**
- For dogs 2 to 10 lb: 46 mg milbemycin/Lufenuron, 11.4 mg nitenpyram.
- For dogs 11 to 25 lb: 115 mg milbemycin/Lufenuron, 57 mg nitenpyram.
- For dogs 26–50 lb: 230 mg milbemycin/Lufenuron, 57 mg nitenpyram.
- For dogs 51 to 100 lb: 460 mg milbemycin/Lufenuron, 57 mg nitenpyram.
- For dogs 100 to 125 lb: (appropriate number supplied) milbemycin/Lufenuron, 57 mg nitenpyram; *Sentinel® Flavor Tabs with Capstar®* (Novartis); (Rx). FDA-approved for use in dogs and puppies 4 weeks of age or older.

**Human-Approved Products:**
- None

**LYSINE**

**L-lysine**

*NUTRITIONAL AMINO ACID*

**Prescriber Highlights**
- Amino acid that may be effective in suppressing FHV-1 infections in cats; efficacy in doubt
- Adverse effects unlikely if mixed with food
- Long-term treatment required

**Uses/Indications**

Lysine may be effective in suppressing FHV-1 infections in cats. Three recently published studies (Drazenovich *et al.* 2009), (Maggs *et al.* 2007), (Rees & Lubinski 2008) however, have not shown lysine to be effective to prevent or reduce the recurrence of upper respiratory tract infections in shelter cats and in two of these studies, cats receiving lysine supplementation had increases in disease severity and detection of FHV-1 DNA.

**Pharmacology/Actions**

Lysine is an amino acid that is thought to compete with arginine for incorporation into many herpes viruses. As it is believed that arginine is required for producing infective viral particles, when lysine is incorporated, the virus becomes less infective.

**Pharmacokinetics**

No specific information was located.

**Contraindications/Precautions/Warnings**

No specific contraindications.

**Adverse Effects**

Adverse effects are unlikely when mixed with food. Patients (human) taking lysine have occasionally complained of abdominal pain and diarrhea; one patient developing tubulointerstitial nephritis has been reported.

**Reproductive/Nursing Safety**

Lysine showed no teratogenic effects when given to pregnant rats, although safety has not been established in other species.

**Overdosage/Acute Toxicity**

Significant toxicity is unlikely. Gastrointestinal effects (nausea, vomiting, diarrhea) may occur.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving lysine and may be of significance in veterinary patients:

- **ARGinine:** Arginine may negate the anti-herpesvirus effects of lysine
- **CALCIUM, ORAL:** Concomitant use with calcium supplements may increase calcium absorption from the gut and decrease calcium loss in the urine

**Laboratory Considerations**

- No specific concerns noted

**Doses**

**CATS:**
- To prevent or reduce recurrent feline herpesvirus ocular infections:
  - a) 500 mg PO twice daily for life (Glaze 2002)
  - b) 500 mg mixed with food daily (Nasisse 2002)
  - c) 250 mg PO twice daily (Powell 2002), (August 2007)
- As adjunctive therapy for feline herpesvirus dermatologic infections:
Monitoring

- No specific monitoring is required for lysine except those that would be required to monitor the herpes infection in the patient.

Client Information

- Lysine is easiest to administer by crushing tablets or emptying capsules and then mixing with food.
- Clients should understand that lysine does not cure the infection, but helps to control it (reduces the severity and frequency) and that lifetime therapy may be required.
- When purchasing, avoid products that contain propylene glycol.

Chemistry/Synonyms

An aliphatic amino acid, lysine has the chemical name L-2,6-diaminohexanoic acid and has a molecular weight of 146.2. It may be commercially available as the acetate or hydrochloride salts, or as the base.

Lysine may also be known as: L-lysine, L-Lysine Powder-Pure®, Lys, K, Enisyl®, Incremin®, and Viralys®.

Storage/Stability

Unless otherwise specified on the label, lysine should be stored at room temperature in tight containers.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:**

Note: There are many products containing lysine as one of many ingredients. The following products were located with veterinary labeling where lysine is the sole active ingredient:

- L-lysine Gel: 250 mg per 1.25 mL: Viralys® Gel (Vet Solutions); (OTC). Labeled for use in cats and kittens.
- L-lysine Powder: (in a palatable base) approximately 250 mg per rounded scoop: Viralys® Powder (Vet Solutions); (OTC). Labeled for use in cats and kittens.
- L-Lysine Powder Feed Additive: in 16 oz. jars and 5 lb. pails; L-Lysine Powder-Pure® (AHC); (OTC) Labeled for use in horses.

**HUMAN-LABELLED PRODUCTS:**

- L-Lysine Tablets & Capsules: 312 mg, 334 mg, 500 mg & 1000 mg; Enisyl® (Person & Covey); generic; (OTC)

Lysine is considered a nutrient in the USA, therefore, it is exempt from FDA approval requirements. There are many products available including tablets and capsules that usually range in strengths from 250 mg to 1000 mg. Combination products are also available.

Magnesium-containing Laxatives (Magnesium Sulfate; Magnesium Oxide)—see Laxatives, Hyperosmotic

---

**MAGNESIUM HYDROXIDE**

**MAGNESIUM/ALUMINUM ANTACIDS**

(mag-ne-zee-um hye-drok-sidy)

**ORAL ANTACID/LAXATIVE**

**Prescriber Highlights**

- Used as a gastric antacid for ulcers, etc., but use largely supplanted by newer agents
- In ruminants, can be useful to increase rumen pH; powder much more effective than boluses
- Magnesium salts contraindicated in patients with renal disease; in cattle, rumen pH should be measured before use
- Magnesium salts may cause diarrhea
- Chronic use may lead to electrolyte abnormalities
- Many potential drug interactions

---

**Uses/Indications**

Magnesium hydroxide in combination with aluminum salts have been used in veterinary medicine for the adjunctive treatment of esophagitis, gastric hyperacidity, peptic ulcer and gastritis. In foals and small animals, because of difficulty in administration, the frequent dosage that is often required, and availability of the histamine-
peptic ulcer and gastritis. In foals and small animals, because of difficulty in administration, the frequent dosing that is often required, and availability of the histamine-2 blocking agents (cimetidine, ranitidine, etc.), proton-pump inhibitors (e.g., omeprazole) and sucralfate, antacids have largely been relegated to adjunctive roles in therapy for these indications.

Magnesium hydroxide alone (milk of magnesia) is sometimes used as an oral laxative in small animals. In ruminants, magnesium hydroxide is used to increase rumen pH and as a laxative in the treatment of rumen overload syndrome (aka acute rumen engorgement, rumen acidosis, grain overload, engorgement toxemia, rumen impaction).

**Pharmacology/Actions**

Oral antacids used in veterinary medicine are generally relatively non-absorbable salts of aluminum, calcium or magnesium. Up to 20% of an oral dose of magnesium can be absorbed, however. Antacids decrease HCl concentrations in the GI. One gram of these compounds generally neutralizes 20–35 mEq of acid (*in vitro*).

Although the pH of the gastric fluid can rarely be brought to near-neutral conditions, at a pH of 3.3, 99% of all gastric acid is neutralized, thereby reducing gastric acid back-diffusion through the gastric mucosa and reducing the amount of acid presented to the duodenum. Pepsin proteolytic activity is reduced by raising the pH and can be minimized if the pH of the gastric contents can be increased to >4.

In cattle, orally administered magnesium hydroxide can act as a rumen alkalinizing agent and decrease rumen antimicrobial activity.

**Contraindications/Precautions/Warnings**

Magnesium-containing antacids are contraindicated in patients with renal disease. Some products have significant quantities of sodium or potassium and should be used cautiously in patients who should have these electrolytes restricted in their diet. Aluminum-containing antacids may inhibit gastric emptying; use cautiously in patients with gastric outlet obstruction.

Oral magnesium hydroxide should only be used clinically in ruminants with documented rumen acidosis and should not be used for treatment of other suspected rumen disorders or hypomagnesemia. (Smith & Correa 2004).

**Adverse Effects**

In monogastric animals, the most common side effects of antacid therapy are constipation with aluminum- and calcium-containing antacids, and diarrhea or frequent loose stools with magnesium containing antacids. Many products contain both aluminum and magnesium salts in the attempt to balance the constipating and laxative actions of the other.

If the patient is receiving a low phosphate diet, hypophosphatemia can develop if the patient chronically receives aluminum antacids. Magnesium-containing antacids can cause hypermagnesemia in patients with severe renal insufficiency.

In ruminants, alkalinization of the rumen may enhance the absorption of ammonia, histamine or other basic compounds.

**Reproductive/Nursing Safety**

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), these drugs are categorized as class: A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

**Overdosage/Acute Toxicity**

See the Adverse Effects section above. If necessary, GI and electrolyte imbalances that can occur with chronic or acute overdose should be treated symptomatically.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral magnesium hydroxide and may be of significance in veterinary patients:

- **QUINIDINE**: Increased absorption or pharmacologic effect may occur
- **SODIUM POLYSTYRENE SULFONATE** (*Kayexalate®*): Antacids may decrease the potassium lowering effectiveness of the drug and in patients in renal failure may cause metabolic alkalosis
- **SUSTAINED- or EXTENDED-RELEASE MEDICATIONS**: When magnesium hydroxide is used at laxative dosages, it may alter the absorption of these drugs by altering GI transit times
- **SYMPATHOMIMETIC AGENTS**: Increased absorption or pharmacologic effect may occur
  
  Oral magnesium salts can decrease the amount absorbed or the pharmacologic effect the drugs listed below; separate oral doses of oral magnesium salts and these drugs by two hours to help reduce this interaction.

  - **ALLOPURINOL**
  - **AZOLE ANTIFUNGALS** (*Ketoconazole, Itraconazole*)
  - **CHLOROQUINE**
  - **CORTICOSTEROIDS**
  - **DIGOXIN**
  - **ETHAMBUTOL**
  - **FLUOROQUINOLONES**
  - **H-2 ANTAGONISTS** (*Ranitidine, Famotidine*, etc.)
  - **IRON SALTS**
  - **ISONIAZID**
  - **PENICILLAMINE**
  - **PHENOTHIAZINES**
  - **TETRACYCLINES**
  - **THYROID HORMONES**

**Doses**

For adjunctive treatment of hypomagnesemia in dogs with GI disease and severe hypocalcemia:

**DOGS:**

a) Oral magnesium hydroxide (milk of magnesia) at 5–15 mL/per dog per 24 hours. If giving parenterally: magnesium (magnesium sulfate) at 1 mEq/kg/day. (Marks 2009)

For adjunctive therapy for gastric ulcers:

a) Aluminum hydroxide suspension or aluminum hydroxide/magnesium hydroxide suspension: 2–10 mL PO q2–4h (Hall & Twedt 1989)

As an antacid:

a) Magnesium hydroxide (Milk of Magnesia): 5–30 mL PO once to twice daily (Morgan 1988)

**CATS:**

As an antacid:

a) Magnesium hydroxide (Milk of Magnesia): 5–15 mL PO once to twice daily (Morgan 1988)

**CATTLE:**

For rumen overload syndrome:

a) For adult animals: Up to 1 gram/kg (MgOH) mixed in 2–3 gallons of warm water and given PO per tube. May repeat (use smaller doses) at 6–12 hour intervals. If the rumen has been evacuated, do not exceed 225 grams initially. Dehydration and systemic acidosis must be concomitantly corrected.

Calves: As above but use ⅛th–¼th the amount (Wass et al. 1986)

**HORSES:**

For adjunctive gastroduodenal ulcer therapy in foals:

a) Aluminum/magnesium hydroxide suspension: 15 mL 4 times a day (Clark & Becht 1987)

**SHEEP & GOATS:**

For rumen overload syndrome:

a) As above for cattle, but use ⅛th–¼th the amount (Wass et al. 1986)

**Monitoring**

- Monitoring parameters are dependent upon the indication for the product. Patients receiving high dose or chronic therapy should be monitored for electrolyte imbalances outlined above.

**Client Information**

- Oral magnesium hydroxide products are available without prescription (OTC); do not give on a regular basis without veterinary supervision

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

- Oral Boluses 17.9–27 grams of magnesium hydroxide (Note: products may also contain ginger, capsicum and methyl salicylate); Magnalax® (Aspen), Carmilax® (Pfizer), Polymag® (Butler), Rumen Bolus® (Durvet), Instamag® (Vedco), Magnalax® (Phoenix), Polyoxy®Il (Bimeda), Laxade® (AgriPharm); (OTC)

- Oral Powder, each pound of powder contains: 350–361 grams of magnesium hydroxide (Note: products may also contain ginger, capsicum and methyl salicylate); Carmilax Powder® (Pfizer), Magnalax® (Phoenix), Polyox® (Bimeda), Laxade® (AgriPharm); (OTC)

- Milk of Magnesia (Magnesium Hydroxide) 80 mg/mL in gallons; generic, (Neogen); (OTC)

**HUMAN-LABELED PRODUCTS:**

- The following is a list of some magnesium hydroxide products available, it is not meant to be all-inclusive.

  **Magnesium Hydroxide**
  - Tablets chewable: 311 mg & 400 mg; Phillips’ Chewable® (Bayer Consumer); Pedia-Lax® (Fleet); (OTC)
  - Liquid, Oral (also called Milk of Magnesia): 400 mg/5 mL in 129 mL, 355 mL, 360 mL, 780 mL, pt, gal and UD 15 mL & 30 mL; liquid concentrate: 800 mg/5 mL in 240 mL & 1,200 mg/5 mL in 400 mL; generic; (OTC)
  - Aluminum Hydroxide and Magnesium Hydroxide

Suspension (NOTE: There are too many products and concentrations to list in this reference; a representative product is Maalox® Suspension (Rorer) which contains 225 mg aluminum hydroxide and 200 mg magnesium hydroxide per 5 mL.

All aluminum and magnesium hydroxide preparations are OTC. Other dosage forms that are available commercially include: tablets, chewable tablets, and aerosol foam suspension.

**References**

Uses/Indications
Parenteral magnesium sulfate is used as a source of magnesium in magnesium deficient states (hypomagnesemia), for adjunctive therapy of malignant hyperthermia in swine, and also as an anticonvulsant. It may be of benefit in the treatment of refractory ventricular fibrillation.

Pharmacology/Actions
Magnesium is used as a cofactor in a variety of enzyme systems and plays a role in muscular excitement and neurochemical transmission.

Pharmacokinetics
IV magnesium results in immediate effects; IM administration may require about 1 hour for effect. Magnesium is about 30–35% bound to proteins and the remainder exists as free ions. It is excreted by the kidneys at a rate proportional to the serum concentration and glomerular filtration.

Contraindications/Precautions/Warnings
Parenteral magnesium is contraindicated in patients with myocardial damage or heart block. Magnesium should be given with caution to patients with impaired renal function. Patients receiving parenteral magnesium should be observed and monitored carefully to avoid hypermagnesemia.

Adverse Effects
Magnesium sulfate (parenteral) adverse effects are generally the result of magnesium overdosage and may include drowsiness or other CNS depressant effects, muscular weakness, bradycardia, hypotension, respiratory depression, and increased Q-T intervals on ECG. Very high magnesium levels may cause neuromuscular blocking activity and, eventually, cardiac arrest.

When using IV for hypomagnesemia, reduce potassium supplementation or hyperkalemia may result.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) The possibility of fetal harm appears remote; however, use only if clearly needed.

Magnesium is excreted in milk, but is unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity
See Adverse Effects above. Treatment of hypermagnesemia is dependent on the serum magnesium level and any associated clinical effects. Ventilatory support and administration of intravenous calcium [10–50 mg/kg IV; (Macintire 2003)] may be required for severe hypermagnesemia.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving parenteral magnesium sulfate or HCl and may be of significance in veterinary patients:
- **CALCIUM:** Concurrent use of calcium salts may negate the effects of parenteral magnesium
- **CNS DEPRESSANT DRUGS** (e.g., barbiturates, general anesthetics): Additive CNS depression may occur.
- **DIGOXIN:** Because serious conduction disturbances can occur, parenteral magnesium should be used with extreme caution with digitalis cardioglycosides
- **NEUROMUSCULAR BLOCKING AGENTS:** Excessive neuromuscular blockade possible

Doses
**Note:** Do not confuse mEq/mL and mg/mL concentrations and dosages; One gram of magnesium sulfate hexahydrate contains 8.1 mEq of magnesium. Magnesium chloride contains 9.25 mEq of magnesium per gram.

**DOGS/CATS:**
For hypomagnesemia:
a) Use magnesium sulfate as an IV CRI at 1 mEq/kg/24 hours; often seen in refractory hypokalemic patients (Reiser 2006)
b) For chronic hypomagnesemia (once parenteral repletion has occurred): Using oxide or hydroxide salts, 1–2 mEq/kg/day PO. Diarrhea may occur. (Fascetti 2003)
c) For hypomagnesemia associated with diabetic ketoacidosis in cats: Total magnesium concentrations of less than 1.5 mg/dL should be treated with magnesium sulfate as an IV CRI of 0.5–1 mEq/kg administered over 24 hours. (Waddell 2007)
d) For adjunctive treatment of hypomagnesemia in dogs with GI disease and severe hypocalcemia: Parenterally: magnesium (magnesium sulfate) at 1 mEq/kg/day. Oral treatment: magnesium hydroxide (milk of magnesia) at 5–15 mL/per dog per 24 hours. (Marks 2009)
e) For hypomagnesemia in cats: Mild hypomagnesemia may be treated by administering isotonic replacement crystalloid solutions that contain magnesium (Plasma-Lyte 148®). For severe hypomagnesemia (serum magnesium <1.2 mg/dL), an infusion of magnesium sulfate can be made by adding to 5% dextrose in water at an initial dose of 0.75–1 mEq/kg/day CRI for the first 24 hours, then reducing the dose by 50% for the next 3–5 days. (Kerl 2008)

For refractory ventricular arrhythmias:
a) Magnesium sulfate: 30 mg/kg slowly IV (Note: This converts to a dose of 0.243 mEq/kg—Plumb) (Macintire 2006)
b) If needed for life-threatening ventricular arrhythmias: 0.15–0.3 mEq/kg may be administered over 5–15 minutes. (Holland & Chastain 1995)

HORSES:
For hypomagnesemia:

a) Magnesium sulfate and magnesium chloride are the solutions of choice for intravenous administration. For oral treatment, magnesium oxide, magnesium carbonate and magnesium sulfate can be used. For magnesium sulfate, a dose of 100 mg/kg will provide 9.7 mg/kg of Mg++ while for magnesium chloride a dose of 100 mg/kg will provide 25.5 mg/kg of Mg++. This is critical as overdosing can be fatal. Excessive oral (nasogastric) supplementation with magnesium sulfate can act as a laxative and induce CNS depression. Recommended IV dose rates for magnesium sulfate in adult horses are 25–150 mg/kg/IV/day diluted in 0.9% NaCl, dextrose or polyionic isotonic solutions. Constant rate infusions (CRI) of magnesium sulfate at 100–150 mg/kg/day should meet the daily requirements of foals and adult horses. Magnesium sulfate is also used to treat ventricular arrhythmias, in particular quinidine intoxication (torsades de pointes), and should be considered in horses with refractory ileus and synchronous diaphragmatic flutter. Doses of 50–100 mg/kg over 30 minutes are considered safe. This is equivalent to 25–50 grams of magnesium sulfate for an adult horse. In foals with IV magnesium in the first hour, followed by a CRI of 25 mg/kg/hr has been proposed. This regime can be continued for several days, adjusting the dose based on serum magnesium concentrations. Oral supplementation with magnesium oxide, magnesium carbonate or magnesium sulfate should be considered in animals with chronic hypomagnesemia, malabsorption, renal disease, and exercise-associated hypomagnesemia. Recommended doses are 30–50 mg/kg/day for magnesium oxide, 60–80 mg/kg/day for magnesium carbonate, or 80–100 mg/kg/day for magnesium sulfate. These doses are safe for horses, particularly when compared to the cathartic doses of magnesium sulfate (0.5–1 gram/kg). (Toribio 2009)

For VTach:

a) 4 mg/kg IV boluses every 2 minutes or a 2 mg/kg/min IV infusion to a total dose of 50 mg/kg (Note: Do not use magnesium plus calcium containing solutions) (Mogg 1999)

For adjunctive treatment of perinatal asphyxia syndrome in foals:

a) Magnesium sulfate 50 mg/kg diluted to 1% and given IV over one hour, then decrease to 25 mg/kg/hr as a constant rate infusion for 24 hours (Vaala 2003)
b) As above in “a”; but after the first hour: 25 mg/kg/hr CRI for 1–3 days. (Bentz 2006)

RUMINANTS:

For hypomagnesemia (grass and other magnesium-related tetanies):

a) Cattle (presentation was specifically on beef cattle): A typical treatment to an adult cow has been slow intravenous administration (over at least 5 minutes) of 100 mL of the 25% Epsom salt solution, this provides 2.5 grams of magnesium (0.025 grams of magnesium/mL of solution). This solution is highly hypertonic (2028 mOsm/L). Hypomagnesemia is most commonly treated using commercially available combined calcium, magnesium, and phosphorous solutions, 500 mL of these solutions typically contain 1.6 to 2.7 grams of magnesium in the form of a borogluconate, chloride, or hypophosphite salt (the phosphorous in hypophosphate salt form is unavailable to ruminants and therefore worthless). Combined calcium and magnesium solutions are preferred for intravenous administration to 25% Epsom salt solution because ruminants with hypomagnesemia frequently have hypocalcemia, and hypercalcemia provides some protection against the toxic effects of hypermagnesemia. The maximum safe rate of administration of magnesium in cattle is 0.04 mL of 25% Epsom salt solution/kg body weight/minute. For a 500 kg beef cow with hypomagnesemia, this corresponds to a maximum safe rate of administration of 20 mL/minute. Subcutaneous administration can cause necrosis of the skin. Only combined solutions containing calcium and magnesium solutions should be given subcutaneously.

In a seizing, hypomagnesemic beef cow, rectal administration may be the only safe and practical way to administer magnesium. After evacuating the rectal contents, an enema containing 60 grams of Epsom Salts (magnesium sulfate heptahydrate) or magnesium chloride in 200 mL of water can be placed in the descending colon (NOT the rectum) and the tail held down for 5 minutes; this increases plasma magnesium concentrations within 10 minutes. Enema solutions can be prematurely evacuated, eliminating the chance for therapeutic success, and some degree of colonic mucosal injury is expected because of the high osmolarity of 30% solutions (approximately 2400 mOsm/L). (Constable 2008)

b) Cattle: 350 mL (250 mL of 25% calcium borogluconate and 100 mL of 10% of magnesium sulfate) by slow IV. If not a proprietary mixture, give calcium first. Relapses occur frequently after IV therapy, and 350 mL SC of magnesium sulfate 20% may give more sustained magnesium levels. Alternating calcium and magnesium may prevent adverse effects. Continue control measures for 4–7 days to prevent relapse. (Merrall & West 1986)
c) Sheep and Goats: 50–100 mL of above solution (calcium/magnesium). (Merrall & West 1986)

For whole milk tetany in calves 2–4 months of age:

a) Magnesium sulfate 10% 100 mL; followed by oral magnesium oxide at daily doses of 1 gram PO (0–5 weeks old), 2 grams PO (5–10 weeks old), and 3 grams PO (10–15 weeks old) (Merrall & West 1986)

SWINE:

For adjunctive therapy of malignant hyperthermia syndrome:

Note:

This converts to a dose of 0.243 mEq/kg—Plumb) (Macintire 2006)

Do not use magnesium plus calcium containing solutions)
There are many oral magnesium products in various dosage forms available.

**Magnesium Chloride Injection**: 20% (200 mg/mL; 1.97 mEq/mL) in 50 mL multi-dose vials; generic; (Rx)

4 mEq/mL) in 2 mL, 10 mL, 20 mL & 50 mL vials; generic; (Rx)

1,000 mL single-dose containers; generic; (Rx)

Veterinary-Labeled Products:

Dosage Forms/Regulatory Status

Dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Compatibility/Compounding Considerations**

Magnesium sulfate is reportedly physically compatible with the following intravenous solutions: dextrose 5%, LRS, and Normal saline. It is also compatible with calcium gluconate, cephalothin sodium, chloramphenicol sodium succinate, cisplatin, hydrocortisone sodium succinate, isoproterenol HCl, methyldopate HCl, metoclopramide HCl (in syringes), norepinephrine bitartrate, penicillin G potassium, potassium phosphate, and verapamil HCl. Additionally, at Y-sites: acyclovir sodium, amikacin sulfate, ampicillin sodium, carbamazepine sodium, cefamandole sodium, cefazolin sodium, cefoperazone sodium, cefuroxime sodium, cefotaxime sodium, cefoxitin sodium, cephaloridine sodium, cimetidine, chloramphenicol sodium succinate, cisplatin, hydrocortisone sodium succinate, isoproterenol HCl, methyldopate HCl, metoclopramide HCl, metronidazole (RTU), moxalactam sodium, nafcillin sodium, oxacillin sodium, piperacillin sodium, potassium chloride, tetracycline HCl, ticarcillin disodium, tobramycin sulfate, trimethoprim/sulfamethoxazole, vancomycin HCl, and vitamin B-complex with C.

Magnesium sulfate is reportedly physically incompatible when mixed with alkali hydroxides, alkali carbonates, salicylates and many metals, including the following solutions or drugs: fat emulsion 10%, calcium gluceptate, dobutamine HCl, polynyxin B sulfate, procaine HCl, and sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**Veterinary-Labeled Products:**

There are no parenteral magnesium-only products FDA-approved for veterinary medicine. There are, however, several proprietary magnesium-containing products available that may also include calcium, phosphorus, potassium, and/or dextrose; refer to the individual product’s labeling for specific dosage information. Trade names for these products include: Norcalciplus® (Pfizer); Cal-Dextro® Special, and #2 (Fort Dodge); and CMPK®; and Cal-Phos® #2 (Techamerica). They are legend (Rx) drugs.

**Human-Labeled Products:**

Magnesium Sulfate Injection, Solution in 5% Dextrose: 1% (10 mg/mL; 0.081 mEq/mL) in single-dose containers; 2% (20 mg/mL; 0.162 mEq/mL) in 500 mL & 1,000 mL single-dose containers; generic; (Rx)

Magnesium Sulfate Injection, solution: 4% (40 mg/mL; 0.325 mEq/mL) in 50 mL, 100 mL, 500 mL & 1,000 mL; 8% (80 mg/mL; 0.65 mEq/mL) in 50 mL; 50% (500 mg/mL; 4 mEq/mL) in 2 mL, 10 mL, 20 mL & 50 mL vials; generic; (Rx)

Magnesium Chloride Injection: 20% (200 mg/mL; 1.97 mEq/mL) in 50 mL multi-dose vials; generic; (Rx)

There are many oral magnesium products in various dosage forms available.

Halt treatment if progressive heart failure, pulmonary congestion, or progressive renal failure/damage develop

Contraindications: Anuria secondary to renal disease, severe dehydration, severe pulmonary congestion, or pulmonary edema

Halt treatment if progressive heart failure, pulmonary congestion, or progressive renal failure damage develop
Mannitol is a substance used to promote diuresis, reduce intraocular and intracranial pressures, and enhance urinary excretion of some toxins. It is used to manage conditions such as acute oliguric renal failure, reduce intraocular and intracerebral pressures, and enhance urinary excretion of some toxins. It is also used as an irrigating solution during transurethral prostatic resections.

**Pharmacology/Actions**
Mannitol is a substance used to promote diuresis, reduce intraocular and intracranial pressures, and enhance urinary excretion of some toxins. It is used to manage conditions such as acute oliguric renal failure, reduce intraocular and intracerebral pressures, and enhance urinary excretion of some toxins. It is also used as an irrigating solution during transurethral prostatic resections.

**Contraindications/Precautions/Warnings**
Mannitol is contraindicated in patients with anuria secondary to renal disease, severe dehydration, severe pulmonary congestion or pulmonary edema. In humans, mannitol is labeled as contraindicated in patients with intracranial bleeding (unless during craniotomy), but there does not appear to be any clinical evidence to support this contraindication.

- Use mannitol with caution when treating ethylene glycol toxicity or other hyperosmolar states as it can add to intravascular hyperosmolarity.
- When using for increased CSF pressure, an intact capillary membrane is required for efficacy. If this membrane is disrupted, mannitol can leak into the brain interstitium and increase cerebral edema.
- It has been reported that mannitol caused harmful effects when used in a feline model of acute spinal cord trauma.
- Mannitol therapy should be stopped if progressive heart failure, pulmonary congestion, progressive renal failure or damage (including increasing oliguria and azotemia) develops after mannitol therapy is instituted.
- Use with caution in hypovolemic patients as mannitol can enhance hypotension. Hypertonic saline may be a better choice to treat increased CSF pressure and increase intravascular volume in these patients.
- Mannitol is relatively contraindicated for treating secondary glaucomas, as it may cross the damaged “blood-aqueous barrier” and increase intraocular pressure (IOP).

**Adverse Effects**
Fluid and electrolyte imbalances are the most severe adverse effects generally encountered during mannitol therapy. Mannitol can promote hypernatremia. Adequate monitoring and support are imperative.

- When used for oliguric renal failure, the potential exists for volume overload should oliguria persist.
- Other adverse effects that may be encountered include GI (nausea, vomiting), cardiovascular (pulmonary edema, CHF, tachycardia), and CNS effects (dizziness, headache, etc.).

**Reproductive/Nursing Safety**
In humans, the FDA categorizes this drug as category C for use during pregnancy. It is not known whether this drug is excreted in milk, but it is unlikely that it would pose significant risk to nursing offspring.

**Overdosage/Acute Toxicity**
Inadvertent overdosage can cause excessive excretion of sodium, potassium, and chloride. If urine output is inadequate, water intoxication or pulmonary edema may occur. Treat by halting mannitol administration and monitoring and correcting electrolyte and fluid imbalances. Hemodialysis is effective in clearing mannitol.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving mannitol and may be of significance in veterinary patients:

- **LITHIUM:** Mannitol can increase the renal elimination of lithium
Mannitol can interfere with blood inorganic phosphorus concentrations and blood ethylene glycol determinations.

**Doses**

**DOGS/CATS:**

For treatment of oliguric renal failure:

a) After correcting fluid, electrolyte, acid/base balance and determining that the patient is not anuric: Mannitol (20–25% solution) 0.25–0.5 gram/kg IV over 5–10 minutes. If substantial diuresis occurs, may repeat q4–6 hours or administered as a constant infusion (8–10% solution) for first 12–24 hours of therapy. Mannitol has at least three theoretical advantages over furosemide: 1) it may enhance renal function by minimizing renal tubular cell swelling via its osmotic properties, 2) mannitol exerts its diuretic effects along the entire nephron and therefore may directly affect the proximal tubule, and 3) mannitol may expand the extracellular fluid volume. The major disadvantage of mannitol is the potential for vascular overload if oliguria persists. Therefore, mannitol should be avoided in overhydrated oliguric patients. (Polzin 2005; Polzin 2009)

b) After rehydration, but not fluid overloaded give mannitol at 0.25–0.5 gram/kg IV slowly over 5–10 minutes; repeat dose at 30–40 minute intervals up to 1.5 gram/kg total. Author prefers using furosemide for ARF. (Bersenas 2007)

c) In fluid replete animals: 0.5 gram/kg IV over 20–30 minutes; if significant diuresis is accomplished within 30 minutes, may administer as a CRI of 60–120 mg/kg/hr IV or as intermittent boluses repeated every 4–6 hours. Mannitol is contraindicated in patients who are still dehydrated, hypervolemic, or anuric. (Waddell 2007)

d) Mannitol (10–25%) is given to fluid replete animals as an initial slow bolus of 0.5 gram/kg IV over 20-30 minutes to promote diuresis. If significant diuresis is accomplished within 30 minutes, mannitol can then be started as a constant rate infusion (CRI) at 60–120 mg/kg/hour IV or as intermittent repeated boluses every 4–6 hours (as above). Mannitol is contraindicated in patients who are hypervolemic or have evidence of cardiac failure or pulmonary edema. Fluid balances must be carefully monitored to prevent dehydration and further renal compromise. (Silverstein 2009)

For adjunctive treatment of acute glaucoma:

a) Drug of first choice in the acute patient; 0.5–1 gram/kg IV given over 15–20 minutes; withhold water for 3–4 hours. IOP reduction begins in 20–30 minutes and has a 4–6 hour duration of effect. Efficacy reduced in patients with anterior uveitis. (Wilkie 2002)

b) If latanaprost (Xalatan®) has not affected pupil size and started to reduce IOP after one hour, give mannitol (20%) at 1–2 grams/kg IV over a period of 20 minutes and withhold water for 1–2 hours. Peak effect is about 90 minutes after administration. (Millichamp 2006)

c) Greatest value is in acute primary angle-closure glaucoma and pre-op in lens luxations. Give 1 gram/kg of mannitol 20% for injection IV over 20 min. May repeat in 4 hours if needed but chronic use is not advised. Should heat/filter (5 micron filters) to avoid giving crystals IV. Withhold water for several hours post-dose. Mannitol can lower IOP from 60-80 mm Hg to normal in 1–2 hours and keep IOP low for 12-24 hrs. Toxicity limits its use to eyes that have vision or the potential for vision. Side effects include headache, osmotic diuresis and worsening of dehydration, renal failure, or cardiovascular disease. Fatalities may occur with IV crystals and from pulmonary edema if given with methoxyflurane. Use with caution in uveitis or hyphema. (Miller 2009)

For adjunctive treatment of increased CSF pressure/cerebral edema:

a) 0.5–1.5 grams/kg IV over 10–20 minutes. Maximum effect occurs 10–20 minutes after administration and the effects last for 2–5 hours. May repeat every 6–8 hours based on clinical response and intracranial pressure monitoring. Do not use if patient hypovolemic. Monitor serum osmolality and electrolytes. (McDonnell 2004)

b) Mannitol should be administered as a bolus over a 15-minute period, rather than as an infusion in order to obtain the plasma expanding effect; its effect on decreasing brain edema takes approximately 15-30 minutes to establish and lasts between 2–5 hours. Administering doses of 0.25 gram/kg appear equally effective in lowering ICP as doses as large as 1 gram/kg, but may last a shorter time. Repeated administration of mannitol can cause an accompanying diuresis, which may result in volume contraction, intracerebral dehydration and the concomitant risk of hypotension and ischemia. It is therefore recommended that mannitol use be reserved for the critical patient (Glasgow coma score of < 8) or for the deteriorating patient. (Platt 2008)

c) 0.5–1.5 grams/kg intravenously over 10-20 minutes. Serum osmolality and electrolytes should be monitored with repeated mannitol use; osmolality should be maintained at or below 320 mOsm/L (to reduce the risk of renal failure due to renal vasoconstriction) and electrolytes should be kept within normal limits. Although monitoring measured (not calculated) osmolality and osmolar gap (the difference between measured and calculated osmolality) and avoiding large changes in either is recommended, a recent retrospective study of 95 human patients with head trauma showed that neither was correlated with the development of acute renal insufficiency. A useful guideline to prevent possible unwanted side effects of mannitol use is to limit administration of mannitol to three boluses in a 24-hr period. However, due to the conflicting evidence in the literature regarding the potential for patients to develop renal failure secondary to mannitol infusion, the authors recommend that mannitol be aggressively administered to patients with progressive neurologic signs that are responding to it. Since mannitol tends to crystallize at room temperature, it should be warmed to approximately 37°C (99°F) and administered through an in-line filter. (Dewey 2008)

d) Secondary to trauma: 0.5–1 gram/kg IV followed 20 minutes later by furosemide (1 mg/kg IV). Potential risk for worsening intracranial hemorrhage, but patients that are dying before your eyes can benefit from this aggressive therapy. (Mazzaferro 2007)

**CATTLE, SWINE, SHEEP, GOATS:**

For adjunctive treatment of cerebral edema:

a) 1–3 gram/kg IV (usually with steroids and/or DMSO) (Dill 1986)

As a diuretic for oliguric renal failure:

a) 1–2 gram/kg (5–10mL of 20% solution) IV after rehydration; monitor urine flow and fluid balance (Osweiler 1986)

**HORSES:**

a) 0.25–2 gram/kg as a 20% solution by slow IV infusion (Schulz 1986)

b) For increased intracranial pressure from traumatic brain injury (TBI): Intermittent IV bolus doses of 0.25–1 gram/kg. Mannitol produces immediate reduction of ICP by decreasing hematocrit and viscosity, improving CBF, and decreasing blood vessel diameter. Cerebral oxygenation improves because of improved red cell oxygen transport. These effects are best accomplished with rapid bolus administration rather than continuous administration. The patient must be monitored to
References
Veterinary oral fluoroquinolone antibiotic effective against a variety of pathogens

Not effective against anaerobes

Contraindications: Hypersensitivity to fluoroquinolones; Relatively contraindicated for young, growing animals due to cartilage abnormalities

Caution: Hepatic or renal insufficiency, seizure patients, or dehydration

Adverse Effects: GI distress; does not appear to cause ocular toxicity in cats

Drug interactions

Uses/Indications
Marbofloxacin is labeled for the treatment of susceptible bacterial infections in dogs and cats.

Pharmacology/Actions
Marbofloxacin is a bactericidal agent. The bactericidal activity of marbofloxacin is concentration dependent, with susceptible bacteria cell death occurring within 20–30 minutes of exposure. Like other fluoroquinolones, marbofloxacin has demonstrated a significant post-antibiotic effect for both gram − and + bacteria and is active in both stationary and growth phases of bacterial replication.

Its mechanism of action is not thoroughly understood, but it is believed to act by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), preventing DNA supercoiling and DNA synthesis.

Marbofloxacin has a similar spectrum of activity as the other veterinary commercially available agents. These agents have good activity against many gram-negative bacilli and cocci, including most species and strains of Pseudomonas aeruginosa, Klebsiella spp., E. coli, Enterobacter, Campylobacter, Shigella, Salmonella, Aeromonas, Haemophilus, Proteus, Yersinia, Serratia, and Vibrio species. Other organisms that are generally susceptible include Brucella spp., Chlamydia trachomatis, Staphylococci (including penicillinase-producing and methicillin-resistant strains), Mycoplasma, and Mycobacterium spp. (not the etiologic agent for Johne’s Disease).

The fluoroquinolones have variable activity against most streptococci and are not usually recommended to use for these infections. These drugs have weak activity against most anaerobes and are ineffective in treating anaerobic infections.

Resistance does occur by mutation, particularly with Pseudomonas aeruginosa, Klebsiella pneumonia, Acinetobacter, and Enterococci, but plasmid-mediated resistance is thought to occur only rarely.

Pharmacokinetics
In dogs, marbofloxacin is characterized as being rapidly absorbed after oral administration with a bioavailability of 94%. Peak plasma levels occur in about 1.5 hours. Protein binding is low and the apparent volume of distribution is 1.2–1.9 L/kg. Elimination half-life averages 9–12 hours. The drug is eliminated unchanged in the urine (40%) and bile/feces. Only about 15% of a dose is metabolized in the liver.

In cats, absorption after oral dosing is nearly complete and peak serum levels occur about 1–2 hours post-dose. Terminal elimination half-life is about 13 hours. Renal impairment does not significantly alter dosing requirements.

Contraindications/Precautions/Warnings
Like other quinolones, marbofloxacin is labeled as contraindicated in small and medium breed dogs up to 8 months of age, large breeds to 12 months old, and giant breeds to 18 months old. It is also labeled as contraindicated in cats under 12 months of age. Quinolones are also contraindicated in patients hypersensitive to them. Marbofloxacin can (rarely) cause CNS stimulation and should be used with caution in patients with seizure disorders.

The FDA has prohibited the use of this drug in food-producing animals.

Adverse Effects
With the exception of potential cartilage abnormalities in young animals (see Contraindications above), the adverse effect profile of marbofloxacin is usually limited to GI distress (vomiting, anorexia, soft stools, diarrhea) and decreased activity.

Other fluoroquinolones have, in rare incidences, caused elevated hepatic enzymes, ataxia, seizures, depression, lethargy, and nervousness in dogs. Hypersensitivity reactions or crystalluria could potentially occur.

It is not known if marbofloxacin can also cause the ocular toxicity that has been reported with high dose enrofloxacin in cats. While unlikely, FDA’s Adverse Drug Reaction database has received 14 reports (as of July 3, 2007) of blindness associated with marbofloxacin. Causal effect cannot be proven, but use higher dosages carefully.

Reproductive/Nursing Safety
Safety of marbofloxacin during pregnancy has not been established.

Overdosage/Acute Toxicity
It is unlikely an acute overdose of marbofloxacin would result in signs more serious than either anorexia or vomiting, but the adverse effects noted above could occur.

Dogs receiving 55 mg/kg per day for 12 days developed anorexia, vomiting, dehydration, tremors, red skin, facial swelling, lethargy, and weight loss.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving marbofloxacin or related fluoroquinolones and may be of significance in veterinary patients:

**ANTACIDS/DAIRY PRODUCTS:** Containing cations (Mg++, Al+++ , Ca++) may bind to marbofloxacin and prevent its absorption; separate doses of these products by at least 2 hours.
ANTIBIOTICS, OTHER (aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum): Synergism may occur, but is not predictable, against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although marbofloxacin has minimal activity against anaerobes, *in vitro* synergy has been reported when used with clindamycin against strains of Peptostreptococcus, Lactobacillus and *Bacteroides fragilis*.

CYCLOSPORINE: Fluoroquinolones may exacerbate the nephrotoxicity and reduce the metabolism of cyclosporine (used systemically)

FLUNIXIN: Has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown if marbofloxacin also causes this effect or if other NSAIDs interact with marbofloxacin in dogs

GLYBURIDE: Severe hypoglycemia possible

IRON, ZINC (oral): Decreased marbofloxacin absorption; separate doses by at least two hours

METHOTREXATE: Increased MTX levels possible with resultant toxicity

NITROFURANTOIN: May antagonize the antimicrobial activity of the fluoroquinolones and their concomitant use is not recommended

PHENYTOIN: Marbofloxacin may alter phenytoin levels

PROBENECID: Blocks tubular secretion of ciprofloxacin and may also increase the blood level and half-life of marbofloxacin

QUINIDINE: Increased risk for cardiotoxicity

SUCCRALFATE: May inhibit absorption of marbofloxacin; separate doses of these drugs by at least 2 hours

THEOPHYLLINE: Marbofloxacin may increase theophylline blood levels; this interaction is more likely with enrofloxacin than with marbofloxacin (Martin-Jimenez 2009)

WARFARIN: Potential for increased warfarin effects

**Laboratory Considerations**

In some human patients, the fluoroquinolones have caused increases in liver enzymes, BUN, and creatinine and decreases in hematocrit. The clinical relevance of these mild changes is not known at this time.

**Doses**

**DOGS:**
- a) For susceptible infections (urinary tract, skin and soft tissue): 2.75–5.5 mg/kg PO once daily. Give for 2–3 days beyond cessation of clinical signs (skin/soft tissue infections); and for at least 10 days (urinary tract). If no improvement noted after 5 days, reevaluate diagnosis. Maximum duration of treatment is 30 days. (Package insert; *Zeniquin*®—Pfizer)
- b) For susceptible *Pseudomonas* otitis in patients with otitis media, patients with severe proliferative chronic otitis externa, patients with ulcerative otitis externa, patients where inflammatory cells are seen cytologically (indicating deeper skin involvement) and in patients where owners cannot administer topical therapy or where a patient has had an adverse reaction to topically administered antimicrobial agents: Dose at the high end of the flexible dosing label (*Note*: high end = 5.5 mg/kg PO once daily). (Cole 2008)

**CATS:**
- a) For susceptible infections (urinary tract, skin and soft tissue): 2.75–5.5 mg/kg PO once daily. Give for 2–3 days beyond cessation of clinical signs (skin/soft tissue infections); and for at least 10 days (urinary tract). If no improvement noted after 5 days, reevaluate diagnosis. Maximum duration of treatment is 30 days. (Package insert; *Zeniquin*®—Pfizer)
- b) First-line treatment (pending definitive diagnosis) for feline tuberculosis (if decision is made to treat in cases of localized cutaneous infections) or non-tuberculous mycobacteria (NTM; not effective against MAC infection): 2 mg/kg PO once daily. (Gunn-Moore 2008)
- c) For hemoplasmosis: 2.75 mg/kg PO once daily (q24h). (Dowers 2009)

**REPTILES:**
- a) Study done in Ball pythons (*Python regius*): 10 mg/kg PO at least every 48 hours. Further studies required to determine effective doses and toxicity. (Coke *et al.* 2006)

**Monitoring**

- Clinical efficacy
- Adverse effects

**Client Information**

Give as the veterinarian prescribes; do not stop treating just because the animal appears well.

**Chemistry/Synonyms**

A synthetic fluoroquinolone antibiotic, marbofloxacin is soluble in water, but solubility decreases as pH increases. Marbofloxacin may also be known as Ro 9-1168, *Marbocyl*, or *Zeniquin*®.

**Storage/Stability**

Marbofloxacin tablets should be stored below 30°C.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Marbofloxacin Oral Tablets: 25 mg, 50 mg, 100 mg, 200 mg; *Zeniquin*® (Pfizer); (Rx). FDA-approved for use in dogs and cats. Must not be used in food animals.

**HUMAN-LABELED PRODUCTS:**

None
**Uses/Indications**

Maropitant citrate injectable solution is indicated for the prevention and treatment of acute vomiting in dogs; maropitant citrate tablets are indicated for the prevention of acute vomiting and the prevention of vomiting due to motion sickness in dogs. Both are also used extra-label in cats.

Maropitant has been effective to control vomiting secondary to a variety of stimuli, including cisplatin (chemotherapy)—induced vomiting, copper sulfate and apomorphine-induced vomiting, and ipecac induced vomiting.

**Pharmacology/Actions**

Maropitant is a neurokinin-1 (NK₁) receptor antagonist, which acts in the central nervous system by inhibiting Substance P, the key neurotransmitter involved in vomiting. Maropitant suppresses both peripheral & centrally mediated emesis. Maropitant has been shown to reduce the MAC requirements of sevoflurane and reduce visceral pain in dogs as NK-1 receptors are stimulated by substance P (Boscan et al. 2009). Maropitant does not affect gastric emptying times or intestinal transit times, but it can decrease small intestine contraction pressure patterns (McCord et al. 2009).

**Pharmacokinetics**

In dogs, maropitant is rapidly absorbed after oral (PO) & subcutaneous (SC) administration. Peak plasma concentrations (Tmax) occur in less than 1 hour following 1 mg/kg subcutaneous administration and less than 2 hours after oral administration of 2 or 8 mg/kg. After oral administration bioavailability is 24% (2 mg/kg) and 37% (8 mg/kg), suggesting first pass metabolism that becomes saturated at the higher dose. Feeding status does not affect bioavailability.

Maropitant follows non-linear pharmacokinetics (PK) at oral therapeutic doses but approximately linear PK at higher doses (20–50 mg/kg). Bioavailability is 91% following subcutaneous administration of 1 mg/kg. An accumulation ratio of 1.5 occurs after once daily use of maropitant for 5 consecutive days at 1 mg/kg SC or 2 mg/kg PO. Accumulation ratio is 2.18 after 2 consecutive days at 8 mg/kg PO daily.

Hepatic metabolism of maropitant involves two cytochrome P450 enzymes: CYP2D15 (low capacity, high affinity) and CYP 3A12 (high capacity, low affinity). The non-linear kinetics at oral doses of 2–16 mg/kg may be due to saturation of the low capacity enzyme and increased involvement of CYP3A12 at higher doses. Twenty-one metabolites have been identified with the major (pharmacologically active) metabolite being CJ-18,518, a product of hydroxylation. Plasma protein binding of maropitant is high (99.5%). Half-life is 8.84 hours (range: 6.07–17.7 hrs) for 1 mg/kg SC; 4.03 hours (range: 2.58–7.09 hrs) for 2 mg/kg. Maropitant is eliminated primarily by the liver. Urinary recovery of maropitant and its major metabolite is minimal (<1%). Large inter-patient pharmacokinetic variations have been observed.

In cats, bioavailability is about 50% (PO) and 100+% (SC). Terminal elimination half-life is approximately 15 hours (Hickman et al. 2008).

**Contraindications/Precautions/Warnings**

Use with caution in dogs with hepatic dysfunction as maropitant is hepatically metabolized.

Use with caution with other medications that are highly protein bound, although clinical significance has not been determined.

Use with caution in puppies less than 11 weeks old, a higher frequency and greater severity of histological evidence of bone marrow hypoplasia was seen in puppies treated with maropitant than in control puppies.

**Adverse Effects**

Maropitant is well tolerated in dogs. Pre-travel vomiting and hypersalivation are the two most common side effects seen after administration of the tablets at the higher dosage required for prevention of motion sickness. Swelling or pain at the injection site has been reported following SC administration of the drug. While the label states that the drug should be stored at room temperature, one study found that when the injection was stored in the refrigerator and immediately injected, dogs had less pain at the injection site (Narshetty et al. 2007). Diarrhea (4–8%) & anorexia (1.5–5.2%) were the most common side effects noted during U.S. field studies.

Very limited information is available for cats, but in a study in 30 cats at various dosages (0.5–5 mg/kg SC over 15 days) was well tolerated. Localized reactions at injection sites were noted in some cats (Hickman et al. 2008).
Reproductive/Nursing Safety
The safe use of maropitant has not been evaluated in dogs used for breeding, pregnant or lactating bitches. Maropitant should only be used in pregnant or lactating bitches following a benefit/risk assessment by the veterinarian.

Overdosage/Acute Toxicity
Single dose toxicity was studied in mice and rats after oral and intravenous administration. No adverse events were reported after oral administration of up to 30 mg/kg (mice) and 100 mg/kg (rats) and after IV administration of 6.5 mg/kg (mice) and 2.5 mg/kg (rats). The clinical signs of overdosage in mice and rats were similar and independent from the route of administration and included decreased activity, irregular or labored respiration, ataxia and tremors. Salivation, nasal discharge and “raspy” breathing were also noted in rats after oral dosing, while the excretion of reddish urine was observed in some mice and rats following intravenous administration.

In dogs, tolerance has been confirmed in doses of up to 3 times the recommended oral dose of 8 mg/kg, for 3 times longer than the proposed maximum duration of treatment. A GLP compliant study revealed no adverse events in dogs after repeated oral doses delivered by oral gavage (5 mg/kg PO q 24h x 93 days). In the same study at 20 mg/kg/day, effects included emesis in two females on day 1, body weights losses of 8–15% when compared to those at start of study, ECG changes (slight increases in P-R interval, P wave duration and QRS amplitude were noted over the course of treatment), slightly lower serum albumin and slightly higher adrenal weights (females) at 20 mg/kg/day in both sexes.

Oral toxicokinetic studies with the primary metabolite were conducted in mice, rats, rabbits and dogs, indicating that the metabolite was well tolerated.

Drug Interactions
During field safety and efficacy studies, a number of medications were used concomitantly with maropitant. Many dogs received multiple medications. The most common concomitant medication was metronidazole. Other commonly used concomitant medications included: dextrose/Ringers solution IV, sodium chloride IV, amoxicillin, ampicillin, cefazolin, cephalaxin, enrofloxacin, sulfamethoxazole/trimethoprim, famotidine, sucralfate, cimetidine, dexamethasone, ivermectin, ivermectin/pyrantel, pyrantel, lufenuron/milbemycin, milbemycin, moxidectin, vitamin B, and vaccines. There were no problems observed with any of these drugs in conjunction with maropitant.

Laboratory Considerations
- No specific concerns noted.

Doses
- **DOGS:**
  - Prevention of acute vomiting:
    - 1 mg/kg SC given at least one hour prior to anticipated emetogenic event and q24h thereafter for up to 5 consecutive days.
    - 2 mg/kg PO given at least two hours prior to anticipated emetogenic event and q24h thereafter for up to 5 consecutive days.
  - Treatment of acute vomiting:
    - 1 mg/kg SC q24h for up to 5 consecutive days.
  - **Note:** If a longer duration of therapy is needed, a 48 hour washout period is recommended due to accumulation of the drug.
  - Prevention of vomiting due to motion sickness:
    - 8 mg/kg (minimum dose) PO given at least two hours prior to travel and q24h for up to 2 consecutive days;
  - **Note:** If a longer duration of therapy is needed, a 72 hour washout period is recommended.
    - (Label Information; Cerenia®—Pfizer)

- **CATS:**
  - a) As an antiemetic: One pharmacokinetic study suggests a dose of 1 mg/kg SC or PO. (Richter 2009)
  - b) As an antiemetic: 0.5–1 mg/kg SC once daily for up to 5 days. (Marks 2008)

Monitoring
- Clinical efficacy measured by decreased episodes of vomiting
- Adverse effects

Client Information
- Tablets should not be tightly wrapped or embedded in food/snacks as this may delay dissolution of tablets
- Avoid prolonged fasting before administration of tablets
- Feeding a small meal or snack one hour before administration of tablets for motion sickness will minimize the occurrence of pre-trip vomiting following administration of tablets

Chemistry/Synonyms
- Classified as a substituted quinuclidine, maropitant’s molecular weight is 678.81. The chemical name is (2S,3S)-2-benzhydryl-N-(5-tert-butyl-2-methoxybenzyl)quinuclidin-3-amine citrate.
- Maropitant may also be known as CJ-11,972.

Storage/Stability
- Maropitant injectable solution contains a preservative and is designed for multi-dose use. The product label states that the vial should be stored at controlled room temperature 20–25°C (68–77°F) with excursions permitted between 15–30°C (59–86°F) and be used within 28 days of first vial puncture in accordance with FDA requirements. Although the product may be chemically stable beyond this time, multiple punctures may lead to contamination of the product; therefore, extended use beyond the labeled discard date is discouraged.
- Maropitant tablets are packaged in foil to protect them from moisture uptake, which was observed in less protective packaging. A European stability study indicated...
Mavacoxib is a very long acting oral NSAID that is licensed for use in dogs in the UK, Europe and elsewhere. In the UK it is labeled “for the treatment of pain and inflammation associated with degenerative joint disease in dogs aged 12 months or more in cases where continuous treatment exceeding one month is indicated.” At present, its place in the NSAID armamentarium for canine use is to be determined. It could be of benefit in those cases where owners have difficulty adhering to a daily oral dosing regimen, but adverse effects could persist for many weeks after the drug was last given.

In a study comparing the safety and efficacy of mavacoxib with carprofen in 124 dogs, efficacy comparing the two were statistically equivalent and each had a similar rate and profile of adverse effects (Johnson et al. 2009).

**Pharmacology/Actions**

In dogs, mavacoxib appears to be a relative selective inhibiting cyclooxygenase (COX)-1 versus COX-2. It is believed to predominantly inhibit cyclooxygenase-2 (COX-2) and spare COX-1 at therapeutic dosages. This, theoretically, would inhibit production of the prostaglandins that contribute to pain and inflammation (COX-2) and spare COX-1 at therapeutic dosages. This study was done in vitro and do not necessarily correlate perfectly with clinical effects seen in actual patients.

**Pharmacokinetics**

Pharmacokinetic values for mavacoxib in dogs are widely patient variable. Average bioavailability after oral dosing is about 46% when fasted, but nearly doubles (87%) when given with food. Peak levels occur in about 11 hours, but range widely. In most dogs, blood levels of those thought to be therapeutic occur in approximately one hour after dosing when given with food. Apparent volume of distribution (steady-state) averaged 1.6 L/kg and the drug is highly bound to canine plasma proteins (98%). Total body clearance was a very low 2.7 mL/hour/kg and it is primarily cleared by biliary excretion. The average terminal half-life was 16.6 days (range: 8-39 days) (Cox et al. 2010).

**Contraindications/Precautions/Warnings**

The UK labels lists the following contraindications: Dogs less than 12 months of age and/or less than 5 kg body weight; dogs with GI disorders including ulceration and bleeding, evidence of a hemorrhagic disorder, impaired renal or hepatic function, cardiac insufficiency, (history of) hypersensitivity to the active substance, sulfonamides or to any of the excipients. Do not use in pregnant, breeding or lactating animal or use concomitantly with glucocorticoids or other NSAIDs. Do not administer other NSAIDs within 1 month of the last administration of mavacoxib. It also states to avoid use in any dehydrated, hypovolemic or hypotensive animal, as there is a potential risk of increased renal toxicity. Concurrent administration of potentially nephrotoxic medicinal products should be avoided.

**Adverse Effects**

Limited clinical experience, but appears to be relatively safe and effective

**Adverse effect profile expected to be similar to other canine-approved NSAIDs**

**Primary benefit appears to be for patients whose owners have difficulty adhering to a daily oral dosing regimen; but adverse effects may persist as well**

**Uses/Indications**

Mavacoxib is a very long acting oral NSAID that is licensed for use in dogs in the UK, Europe and elsewhere. In the UK it is labeled “for the treatment of pain and inflammation associated with degenerative joint disease in dogs aged 12 months or more in cases where continuous treatment exceeding one month is indicated.” At present, its place in the NSAID armamentarium for canine use is to be determined. It could be of benefit in those cases where owners have difficulty adhering to a daily oral dosing regimen, but because of its long half-life and duration of action, adverse effects could persist for many weeks after the drug was last given.

In a study comparing the safety and efficacy of mavacoxib with carprofen in 124 dogs, efficacy comparing the two were statistically equivalent and each had a similar rate and profile of adverse effects (Johnson et al. 2009).
As mavacoxib is a new agent, its adverse effect profile has not been fully determined in dogs; field studies have indicated that it causes similar adverse effects seen with other NSAIDs, but it is not known if this drug will have fewer or greater incidences of adverse effects when compared with other FDA-approved NSAIDs. NSAID adverse effects in dogs can include: inappetence, diarrhea, vomiting, depression and renal toxicity.

Reproductive/Nursing Safety
The safety of mavacoxib has not been established during pregnancy and lactation. The UK label states: Do not use in pregnant, breeding or lactating animals. Studies in pregnant rabbits with another coxib-class NSAID (firocoxib) at dosages approximating those given to dogs, demonstrated maternotoxic and fetotoxic effects.

Overdosage/Acute Toxicity
In overdose safety studies performed in dogs, repeated doses (at labeled dosage frequency) of 5 and 10 mg/kg did not demonstrate adverse events, abnormal clinical chemistry or significant histological abnormalities. At 15 mg/kg, vomiting, and softened/mucoid feces and increases in clinical chemistry parameters reflecting decreased renal function were noted. Doses of 25 mg/kg cause GI ulceration. One study dog died from GI perforation and peritonitis at the 25 mg/kg dose (Krautmann et al. 2009).

Oral acute overdoses of mavacoxib, should be managed as with other NSAID toxicity, but because of the drug’s very long duration of effect, prolonged monitoring and treatment may be required; consulting a veterinary poison center or the drug sponsor’s hotline seems prudent until more experience has been gained with this agent.

As with any NSAID, overdosage can lead to gastrointestinal and renal effects. The ASPCA Animal Poison Control Center (APCC) has not yet set a dosage level of concern for renal damage for dogs or cats. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis is warranted.

Drug Interactions
At the time of writing, no drug interactions have been reported with mavacoxib, but the manufacturer warns that use in conjunction with other NSAIDs or corticosteroids be avoided. It is also possible mavacoxib could cause increased renal dysfunction if used with other drugs that can cause or contribute to renal dysfunction (e.g., diuretics, aminoglycosides), but the clinical significance of this potential interaction is unclear. The following drug interactions are either expected or are for dogs receiving mavacoxib and may be of clinical significance:

▲ ACE INHIBITORS (e.g., enalapril, benazepril): Some NSAIDs can reduce effects on blood pressure. Because ACE inhibitors potentially can reduce renal blood flow, use with NSAIDs could increase the risk for renal injury. However, one study in dogs receiving tepoxalin did not show any adverse effect. It is unknown what effects, if any, occur if other NSAIDs and ACE inhibitors are used together in dogs.
▲ ASPIRIN: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea). Washout periods several weeks long are probably warranted when switching from mavacoxib to aspirin therapy in dogs.
▲ CORTICOSTEROIDS (e.g., prednisone): May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
▲ DIGOXIN: NSAIDs may increase serum levels
▲ FLUCONAZOLE: Administration has increased plasma levels of celecoxib in humans and potentially could also affect mavacoxib levels in dogs
▲ FUROSEMIDE: NSAIDs may reduce saline and diuretic effects
▲ METHOTREXATE: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
▲ NEPHROTOXIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity development
▲ NSAIDS, OTHER: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

Laboratory Considerations
▲ None identified

Doses
▲ DOGS:
  a) For the treatment of pain and inflammation associated with degenerative joint disease in dogs aged 12 months or more in cases where continuous treatment exceeding one month is indicated: 2 mg/kg PO given immediately before or with the dog’s main meal. Care should be taken to ensure that the tablet is ingested. The treatment should be repeated 14 days later; thereafter the dosing interval is one month. A treatment cycle should not exceed 7 consecutive doses (6.5 months). THIS IS NOT A DAILY NSAID. (Label Information—Trocoxil®; Pfizer U.K.)

Monitoring
▲ Baseline and periodic CBC and serum chemistry (including BUN/serum creatinine, and liver function assessment)
▲ Baseline history and physical
▲ Efficacy of therapy
▲ Adverse effect monitoring via client

Client Information
▲ Give doses exactly as directed by veterinarian, do not give extra doses or increase the dose without veterinarian’s guidance
▲ Give the medication with the dog’s largest meal of the day. The drug is much better absorbed from the stomach if given with food.
▲ Contact the veterinarian if any of the following adverse effects persist or are severe: loss of appetite, vomiting, change in bowel movements (e.g., stool color), change in behavior, decrease in water consumption, or urination; these could potentially occur after many weeks after the last dose was given. Immediately report to the veterinarian if any of the following adverse effects occur: bloody stool/diarrhea, bloody vomiting, or allergic reaction (facial swelling face, hives, red, itchy skin)
▲ Since dogs may find the chewable tablets’ taste desirable, the drug should be stored out of reach of animals and children
Mavacoxib is structurally related to the human NSAID celecoxib and categorized as a diaryl substituted pyrazole. Its chemical name is 4-[5-(4-fluorophenyl)-1H-pyrazol-1-yl]-benzenesulfonamide. Mavacoxib’s solubility in water is relatively low (0.006 mg/mL).

Mavacoxib may also be known as mavacoxibum; PHA 739,521; or UNII-YFT7X7SR77. A common trade name is **Trocoxil®**.

**Storage/Stability**

Store in the original packaging at room temperature out of reach of pets and children.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None in USA at time of writing.

In the UK and elsewhere: Mavacoxib Oral Chewable Tablets: 6 mg, 20 mg, 30 mg, 75 mg, & 95 mg; **Trocoxil®** (Pfizer); (Rx)

**HUMAN-LABELED PRODUCTS:** None

**References**

---

**MECHLORETHAMINE HCL**

(me-klor-eth-a-meen) Mustargen®

**ANTINEOPLASTIC**

**Prescriber Highlights**

- **Antineoplastic for lymphoreticular neoplasms or pleural & peritoneal effusions (intracavitary)**
- **Contraindications (relative; risk vs. benefit):** Anemia, bone marrow depression, tumor cell infiltration into bone marrow, current infection, sensitivity to mechlorethamine, or patients who have received previous chemotherapy or radiotherapy
- **Adverse Effects:** Bone marrow depression, GI effects (vomiting, nausea), ototoxicity (high dosages or regional perfusions); Potentially: alopecia, hyperuricemia, hepatotoxicity, peripheral neuropathy, & GI ulcers
- **Teratogen**
- **Avoid extravasation**

**Uses/Indications**

In small animals, mechlorethamine may be useful for the adjunctive treatment of lymphoreticular neoplasms or, with intracavitary administration, for treating pleural and peritoneal effusions. A change in owners of the pharmaceutical product has reportedly resulted in very large price increases for this medication and some veterinary oncologists are substituting dactinomycin for the mechlorethamine in MOPP rescue protocols.

**Pharmacology/Actions**

Mechlorethamine is an alkylating agent, thereby interfering with DNA replication, RNA transcription, and protein synthesis. It is cell cycle-phase nonspecific.

- With intracavitary administration, mechlorethamine causes sclerosing and an inflammatory response on serous membranes, thereby causing adherence of serosal surfaces.

**Pharmacokinetics**

Because mechlorethamine is so irritating to tissues it must be given IV for systemic use. It is incompletely absorbed after intracavitary administration. After injection, mechlorethamine is rapidly (within minutes) inactivated.

**Contraindications/Precautions/Warnings**

Mechlorethamine is contraindicated in patients with a known infection or have had a prior anaphylactic reaction to the drug.

- Mechlorethamine should be used only when its potential benefits outweigh its risks with the following conditions: anemia, bone marrow depression, tumor cell infiltration into bone marrow, sensitivity to mechlorethamine, or patients who have received previous chemotherapy or radiotherapy.

**Adverse Effects**

Bone marrow depression (leukopenia, thrombocytopenia) and GI effects (vomiting, nausea) are quite common and can be serious enough to halt therapy. Ototoxicity may occur with either high dosages or regional perfusions. Other potential effects include alopecia, hyperuricemia, hepatotoxicity, peripheral neuropathy, and GI ulcers.

Because severe tissue sloughing may occur, avoid extravasation.

**Reproductive/Nursing Safety**

Mechlorethamine is a teratogen in lab animals. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Mechlorethamine can suppress gonadal function. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (**There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.**)

While it is not known whether mechlorethamine enters maternal milk, nursing puppies or kittens should receive milk replacer when the dam is receiving mechlorethamine.
mechlorethamine.

**Overdosage/Acute Toxicity**

Because of the toxic potential of this agent, overdoses must be avoided. Determine dosages carefully.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving mechlorethamine and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSANT DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection.

- **MYELOSUPPRESSIVE DRUGS** (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.

- **VACCINES, LIVE**: Live virus vaccines should be used with caution, if at all, during therapy.

**Laboratory Considerations**

- Mechlorethamine may raise serum uric acid levels. Drugs such as allopurinol may be required to control hyperuricemia.

**Doses**

**NOTE:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide and not as a dosage protocol. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS/CATS:**

Mechlorethamine is usually dosed as part of a lymphoma rescue protocol that includes vincristine (or vinblastine), procarbazine and prednisone (or prednisolone), the so-called MOPP protocol. Doses of mechlorethamine are usually 3 mg/m² IV given on days 0 and 7 of a 28 day protocol, but some are giving it on days 0 and 14 to better allow bone marrow to recover.

**Monitoring**

- CBC with platelets at least every 1–2 weeks until stable; then every 3 months
- Liver function tests; initially before starting treatment and then every 3–4 months
- Injection site for signs of extravasation

**Chemistry/Synonyms**

A bifunctional alkylating agent, mechlorethamine occurs as a hygroscopic, white, crystalline powder that is very soluble in water. After reconstitution with sterile water or sterile saline, the resultant solution is clear and has a pH of 3–5.

Mechlorethamine may also be known as: nitrogen mustard, mustine, HN2, chloromethine hydrochloride, chlorethazine hydrochloride, HN2 (mistine [chlormethine]), mechloretamine hydrochloride, mustine hydrochloride, nitrogen mustard (mustine [chlormethine]), NSC-762, WR-147650, Caryolysine®, Mustargen® and Oncocloramin®.

**Storage/Stability**

Store the powder for injection at room temperature. Mechlorethamine is highly unstable in neutral or alkaline aqueous solutions and rapidly degrades. While more stable in an acidic environment, the drug should be administered immediately after preparation.

**Compatibility/Compounding Considerations**

It is NOT recommended to mix mechlorethamine with any other medication or to dilute further beyond what is described in the package insert.

- Drugs that have been reported to be compatible with mechlorethamine when given via an IV Y-site include aztreonam, filgrastim, granisetron, melphalan, and ondansetron.

Unused portions of reconstituted drug can be neutralized by adding equal volumes of 5% sodium thiosulfate and 5% sodium bicarbonate. This solution is allowed to stand for 45 minutes and then can be discarded appropriately.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Mechlorethamine Powder for Injection: 10 mg; Mustargen® (Lundbeck); (Rx)

**References**

**MECLIZINE HCL**

(meck-li-zen) Antivert®
**Uses/Indications**

Meclizine is principally used in small animals as an antiemetic and for the treatment and prevention of motion sickness.

**Pharmacology/Actions**

Meclizine is a piperazine antihistamine and, beside its antihistamine activity, it also possesses antiemetic, CNS depressant, antispasmodic, and local anesthetic effects. The exact mechanisms of action for its antiemetic and anti-motion-sickness effects are not completely understood, but it is thought they are as a result of the drug’s central anticholinergic and CNS depressant activity. The antiemetic effect is probably mediated through the chemoreceptor trigger zone (CTZ).

**Pharmacokinetics**

Very little information is available. Meclizine is metabolized in the liver and has a serum half-life of about 6 hours.

**Contraindications/Precautions/Warnings**

Meclizine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyeloduodenal obstruction.

**Adverse Effects**

The usual adverse effect noted with meclizine is sedation; less frequently anticholinergic effects may be noted (dry mucous membranes, eyes, tachycardia, etc.). Contradictory CNS stimulation has also been reported. Cats may develop inappetence while receiving this medication.

**Reproductive/Nursing Safety**

Meclizine is considered teratogenic at high dosages in laboratory animals and cleft palates have been noted in rats at 25–50 times higher than labeled dosages. However, in humans, it has been suggested that meclizine possesses the lowest risk for teratogenicity for antiemetic drugs and that it is the drug of first choice to treat nausea/vomiting associated with pregnancy. In humans, the FDA categorizes this drug as category B for use during pregnancy *(Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)* It is unknown if meclizine enters milk; its anticholinergic activity may, potentially, inhibit lactation.

**Overdosage/Acute Toxicity**

Moderate overdosage may result in drowsiness alternating with hyperexcitability. Massive overdosages may result in profound CNS depression, hallucinations, seizures and other anticholinergic effects (tachycardia, urinary retention, etc.). Treatment is considered symptomatic and supportive. Consider gut emptying when patients present soon after ingestion. Avoid respiratory depressant medications.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving meclizine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS**: Use with other CNS depressants may cause additive sedation
- **ANTICHOLINERGIC DRUGS**: Other anticholinergic drugs may cause additive anticholinergic effects

**Laboratory Considerations**

- Because these drugs are antihistamines, they may affect the results of skin tests using allergen extracts. Do not use within 3–7 days before testing.

**Doses**

- **DOGS:**
  a) For supportive treatment of peripheral vestibular disease: 25 mg per dog PO once daily. Treatment is usually unnecessary after 72–96 hours. *(Hoskins 2005)*
  b) As a vestibular suppressant: 12.5–50 mg (total dose per dog) PO twice daily. *(Podell 2009)*
  c) As anti-emetic: 4 mg/kg PO once a day *(Dowling 2003)*
  d) For palliative treatment of vertigo: 25 mg per dog PO once daily. *(Schubert 2007)*

- **CATS:**
  a) 12.5 mg per cat PO once daily *(Pearce 2006)*
  b) 6.25 mg/5 kg of body weight PO *(Day 1993)*
  c) As anti-emetic: 4 mg/kg PO once a day *(Dowling 2003)*
  d) For palliative treatment of vertigo: 12.5 mg per cat PO once daily. *(Schubert 2007)*

- **RABBITS, RODENTS, SMALL MAMMALS:**
a) **Rabbits**: For Rolling, torticollis, motion sickness: 2–12 mg/kg PO once daily (Ivey & Morrisey 2000)

b) **Rabbits**: For adjunctive treatment of torticollis, head tilt (“wry neck”): 12.5 mg (total dose) PO q12–24h. (Johnson 2006)

### Monitoring
- **Efficacy**
- **Adverse effects**

### Client Information
- When using for motion sickness prevention, instruct client to give medication 30–60 minutes before travel.

### Chemistry/Synonyms
Meclizine HCl is a piperazine derivative antiemetic antihistamine.

Meclizine may also be known as: meclozine hydrochloride, meclizine hydrochloride; meclizinium chloride; meclozini hydrochloridum; parachloramine hydrochloride, Agyrax®, Ancolan®, Antivert®, Antrizine®, Bonamine®, Bonine®, Calmonal®, Chilcida®, D-Vert 300®, Dizmiss®, Dramamine II®, Dramine®, Duremesan®, Emetostop®, Marevot®, Meni-D®, Navicalm®, Neo-Istafene®, Nico-Vert®, Peremesin®, Peremesine®, Postadoxin N®, Postafene®, Postafen®, Postafene®, Ru-Vert-M®, Sea-Legs®, Suprimal®, Vergon®, and Vertin®.

### Storage/Stability
Meclizine products should be stored at room temperature in well-closed containers.

### Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
- Meclizine HCl Oral Tablets: 12.5 mg, 25 mg (plain and chewable) & 50 mg; Antivert® & Antivert/25® (Pfizer US); Antrizine® (Major); Dramamine® Less Drowsy Formula (Pharmacia & Upjohn); Bonine® (Pfizer); generic; (Rx and OTC).
- Meclizine Oral Capsules: 25 mg; Meni-D® (Seatrace); (Rx)

### References

---

**MEDETOMIDINE HCL**
(mee-de-toe-mi-deen) Domitor®

**ALPHA-2 ADRENERGIC AGONIST**

**Prescriber Highlights**

- Alpha2-adrenergic sedative analgesic used primarily in dogs & cats, but also may be useful in small mammals, exotics, etc.
- **Contraindications:** Cardiac disease, respiratory disorders, liver or kidney diseases, shock, severe debilitation, or animals stressed due to heat, cold or fatigue. Caution in very old or young animals
- **NOT recommended for use during pregnancy**
- **Adverse Effects:** Bradycardia, occasional AV blocks, decreased respiration, hypothermia, urination, vomiting, hyperglycemia, & pain on injection (IM). Rarely: prolonged sedation, paradoxical excitation, hypersensitivity, apnea & death from circulatory failure
- **Drug interactions**
- Do NOT confuse with detomidine or dexmedetomidine

**Uses/Indications**
Medetomidine is labeled for use as a sedative and analgesic in dogs over 12 weeks of age to facilitate clinical examinations and procedures, minor surgical procedures not requiring muscle relaxation, and minor dental procedures not requiring intubation. The manufacturer recommends the IV route of administration for dental procedures.

Medetomidine has also been used in cats, primarily in Europe. But there is apparently much less data available to evaluate its use; caution is advised.

**Pharmacology/Actions**
An alpha adrenergic receptor, medetomidine has an alpha2:alpha1 selectivity factor of 1620, and when compared to xylazine is reportedly 10X more specific for alpha2 receptors versus alpha1 receptors. The pharmacologic effects of medetomidine include: depression of CNS (sedation, anxiolysis), GI (decreased secretions, decreased motility, decreased peristalsis), respiratory depression (decreased respiration, decreased respiratory rate, increased laryngospasm), cardiovascular effects (decreased cardiac output, decreased systemic vascular resistance, decreased left ventricular contractility, decreased heart rate), and peripheral effects (decreased skin temperature, decreased pupil size).

**Mechanism of Action**
Medetomidine is a non-competitive antagonist of alpha2 adrenergic receptor in the CNS. It also has an alpha1 selectivity factor of 1620. Medetomidine has been used in dogs and cats and has been shown to produce analgesia and sedation with a long duration of action.

**Pharmacokinetics**
Medetomidine is rapidly absorbed after IV administration, with a mean time to peak of 0.5 hours. The elimination half-life is approximately 10 hours. Medetomidine is metabolized in the liver and excreted in the urine.

**Dosing**
The dosing of medetomidine varies depending on the animal and the desired effect. Generally, a dose of 0.01–0.025 mg/kg is used for sedation, and 0.05–0.1 mg/kg is used for surgical anesthesia. It is important to monitor the animal closely during administration and titrate the dose as needed.

**Precautions**
Medetomidine is contraindicated in animals with a history of cardiovascular disease, respiratory disorders, liver or kidney disease, or those stressed due to heat, cold, or fatigue. It is also contraindicated in animals with a history of hypersensitivity reactions. Medetomidine should be used with caution in pregnant animals.

**References**

---
alpha2 receptors versus alpha1 receptors. The pharmacologic effects of medetomidine include: depression of CNS (sedation, anxiolysis), GI (decreased secretions, varying affects on intestinal muscle tone) and endocrine functions, peripheral and cardiac vasoconstriction, bradycardia, respiratory depression, diuresis, hypethermia, analgesia (somatic and visceral), muscle relaxation (but not enough for intubation), and blanched or cyanotic mucous membranes. Effects on blood pressure are variable, but medetomidine can cause hypertension longer than does xylazine. Medetomidine also induces sedation for a longer period than does xylazine. Sedative effects persist longer than analgesic effects.

**Pharmacokinetics**

After IV or IM injection, onset of effect is rapid (5 min. for IV; 10–15 min. for IM). After SC injection, responses are unreliable and this method of administration cannot be recommended. The drug is absorbed via the oral mucosa when administered sublingually in dogs, but efficacy at a given dose may be less than IM dosing.

**Contraindications/Precautions/Warnings**

The label states that medetomidine is contraindicated in dogs having the following conditions: cardiac disease, respiratory disorders, liver or kidney diseases, shock, severe debilitation, or dogs stressed due to heat, cold, or fatigue.

Dogs that are extremely agitated or excited may have a decreased response to medetomidine; the manufacturer suggests allowing these dogs to rest quietly before administration of the drug. Dogs not responding to medetomidine should not be re-dosed. Use in very young or older dogs should be done with caution.

**Adverse Effects**

The adverse effects reported with medetomidine are essentially extensions of its pharmacologic effects including bradycardia, occasional AV blocks, decreased respiration, hypehermia, urination, vomiting, hyperglycemia, and pain on injection (IM). Rare effects have also been reported, including prolonged sedation, paradoxical excitation, hypersensitivity, apnea, and death from circulatory failure.

**Reproductive/Nursing Safety**

The drug is not recommended for use in pregnant dogs or those used for breeding purposes because safety data for use during pregnancy is insufficient; therefore, use only when the benefits clearly outweigh the drug’s risks.

**Overdosage/Acute Toxicity**

Single doses of up to 5X (IV) and 10X (IM) were tolerated in dogs, but adverse effects can occur (see above). Death has occurred rarely in dogs (1 in 40,000) receiving 2X doses.

Because of the potential of additional adverse effects occurring (heart block, PVC’s, or tachycardia), treatment of medetomidine-induced bradycardia with anticholinergic agents (atropine or glycopyrrolate) is usually not recommended. Atipamezole is probably a safer choice to treat any medetomidine-induced effect.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving medetomidine and may be of significance in veterinary patients:

- **ATROPINE, GLYCOPYRROLATE:** The use of atropine or glycopyrrolate to prevent or treat medetomidine-caused bradycardia is controversial as tachycardia and hypertension may result. This is more important when using higher doses of medetomidine (>20 micrograms/kg) and concomitant use is discouraged.
- **OPIATES:** Enhancement of sedation and analgesia may occur when medetomidine is used concurrently with fentanyl, butorphanol, or meperidine, but adverse effects may be pronounced as well. Reduced dosages and monitoring is advised if contemplating combination therapy.
- **PROPOFOL:** When propofol is used after medetomidine, hypoxemia may occur. Dosage adjustments may be required along with adequate monitoring.
- **YOHIMBINE:** May reverse the effects of medetomidine; but atipamezole is preferred for clinical use to reverse the drug’s effects

**Laboratory Considerations**

- Medetomidine can inhibit ADP-induced **platelet aggregation** in cats.

**Doses**

**DOGS:**

- For sedation/analgesia:
  a) 10–40 micrograms/kg IM; higher doses do not cause greater sedation, but increase the duration of effect (McGrath & Ko 1997)
  b) For use with an IM opioid: 5–10 micrograms/kg. (Hardie 2000)
  c) In the cardiovascular-stable patient, as a constant rate infusion for analgesia with an initial loading dose of 1 micro-gram/kg IV, then CRI of 1 to 3 micrograms/kg/hour. (Quandt 2009)

**CATS:**

- For sedation/analgesia:
  a) 40–80 micrograms/kg IM; higher doses do not cause greater sedation, but increase the duration of effect (McGrath & Ko 1997)
  b) For use with an IM opioid: 5–10 micrograms/kg (Hardie 2000)
  c) 0.001–0.01 mg/kg (1–10 micrograms/kg) IV, IM or SC (Carroll 1999)
  d) For large, exotic cat (tigers, etc.) immobilization: Midazolam (0.1 mg/kg) plus medetomidine (0.05–0.07 mg/kg) IM followed by ketamine (4–10 mg/kg) IM, if needed. May antagonize with atipamezole (0.25–0.35 mg/kg) IV, SC. (Curro 2002)

**SMALL MAMMALS/RODENTS:**

- For chemical restraint:
  a) Rats: 0.25–0.5 mg/kg IM;
  b) Guinea pig: 0.5 mg/kg IM;
Rabbits: 0.25–0.5 mg/kg IM (Burke 1999)

FEERTS:
As a sedative/analgesic:

- 15 minutes prior to medetomidine, give atropine (0.05 mg/kg) or glycopyrrolate (0.01 mg/kg) then give medetomidine at 60–80 micrograms/kg IM or SC. Sedation lasts for up to 3 hours. May be reversed with atipamezole (400 micro-gрамs/kg IM).
- For injectable anesthesia: Butorphanol 0.1 mg/kg, Ketamine 5 mg/kg, Medetomidine 80 micrograms/kg. Combine in one syringe and give IM. May need to supplement with isoflurane (0.5–1.5%) for abdominal surgery. (Finkler 1999)

BIRDS:
For sedation/analgesia:

- 0.1 mg/kg IM; limited data available on duration of effect, adverse effects, etc. (Clyde & Paul-Murphy 2000)

REPTILES:

- Medium to small land Tortoises: Medetomidine 100–150 micrograms/kg with ketamine 5–10 mg/kg IV or IM;
- Freshwater Turtles: Medetomidine 150–300 micrograms/kg with ketamine 10–20 mg/kg IV or IM;
- Giant Land Tortoises: 200 kg Aldabra tortoise: Medetomidine 40 micrograms/kg with ketamine 4 mg/kg IV or IM;
- Smaller Aldabra tortoises: Medetomidine 40–80 micrograms/kg with ketamine 4–8 mg/kg IV or IM. Wait 30–40 minutes for peak effect.
- Iguanas: Medetomidine 100–150 micrograms/kg with ketamine 5–10 mg/kg IV or IM; Reversal of all dosages with atipamezole is 4–5 times the medetomidine dose. (Heard 1999)

ZOOF, EXOTIC, WILDLIFE SPECIES:
For use of medetomidine in zoo, exotic and wildlife medicine refer to specific references, including:

- The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJSe

Monitoring
- Level of sedation and analgesia; heart rate; body temperature
- Heart rhythm, blood pressure, respiration rate, and pulse oximetry should be considered, particularly in higher risk patients if the drug is to be used

Client Information
- This drug should be administered and monitored by veterinary professionals only
- Clients should be made aware of the potential adverse effects associated with its use, particularly in dogs at risk (older, preexisting conditions)

Chemistry/Synonyms
An alpha2-adrenergic agonist, medetomidine occurs as a white or almost white crystalline substance. It is soluble in water. While the compound exists as two stereoisomers, only the D-isomer is active.

Medetomidine HCl may also be known as MPV-785 and Domitor®.

Storage/Stability
The commercially available injection should be stored at room temperature (15–30°C) and protected from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Medetomidine HCl for Injection: 1 mg/mL in 10 mL multidose vials; Domitor® (Pfizer); (Rx). FDA-approved for use in dogs over 12 weeks of age. Although still listed in the FDA’s Green Book, it may not be currently marketed in the USA.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

References

MEDIUM CHAIN TRIGLYCERIDES
(MCT OIL)
Prescriber Highlights

- Lipid sometimes used to provide calories & fatty acids to dogs with restricted fat intake due to chronic infiltrative disease of small intestine or fat malabsorption syndromes present.
- Most clinicians use dietary therapy instead of MCT oil today
- Cautions: Significant hepatic disease (e.g., portacaval shunts, cirrhosis, etc.)
- Adverse Effects: Unpalatability (dogs), bloating, flatulence, & diarrhea

Uses/Indications
MCT oil as a separate compound (not as an ingredient in commercial foods) is sometimes used to offset the caloric reduction when long-chain triglycerides found in dietary fat are restricted, usually in chronic infiltrative diseases of the small intestine or when there is fat malabsorption of any cause. Because of expense and unpalatability to dogs, many clinicians are bypassing MCT oil and having their clients prepare homemade, highly digestible, ultra-low fat diets (e.g., white turkey meat plus rice/potato) or using very low fat prescription diets.

MCT oil may be useful as a base-vehicle to administer drugs to cats. A study evaluating the acceptance of low-dose (0.1 mL/kg) MCT oil, gelatin capsules, or thin-film dissolving strips, found that owner-perceived acceptability by cats of MCT oil and thin-film strips cats was significantly higher than gelatin capsules (Traas et al. 2010).

Pharmacology/Actions
Medium chain triglycerides (MCT) are more readily hydrolyzed than conventional food fat. They also require less bile acids for digestion, are not dependent for chylomicron formation or lymphatic transport, and are transported by the portal vein. Medium chain triglycerides are not a source for essential fatty acids.

MCT oil supplementation (as coconut oil) to the diet of cats did not cause food aversion or significant effects on lipid metabolism (Trevizan et al. 2010).

Pharmacokinetics
No specific information located; see Pharmacology above.

Contraindications/Precautions/Warnings
MCT oil should be used with caution in patients with significant hepatic disease (e.g., portacaval shunts, cirrhosis, etc.). Medium chain triglycerides are rapidly absorbed via the portal vein and if their hepatic clearance is impaired, significantly high systemic blood and CSF levels of medium chain fatty acids can occur. This may precipitate or exacerbate hepatic coma.

Adverse Effects
Adverse effects seen with MCT oil in small animals include unpalatability, bloating, flatulence, and diarrhea. These may be transient and minimized by starting doses at the low end of the spectrum and then gradually increasing the dose. Fat-soluble vitamin supplementation (Vitamins A, D, E, and K) by using a commercial feline or canine vitamin-mineral supplement has been recommended.

Reproductive/Nursing Safety
Although, no reproductive safety data was located, MCT oil would likely not cause problems.

Overdosage/Acute Toxicity
Overdosage would likely exacerbate the GI adverse effects noted above. Treat severe diarrhea supportively if necessary.

Drug Interactions
- None listed, but MCT oil could, theoretically, affect absorption of drugs that are dependent on fat for oral absorption (e.g., griseofulvin, fat soluble vitamins, etc.).

Doses
- DOGS:
  - To offset the caloric reduction when long-chain triglycerides found in dietary fat are restricted:
    - a) Orally ½–4 teaspoons divided per day with food (Williams 2000)
    - b) 0.5–2 mL/kg per day added to food. (Simpson 2009)
    - c) 1–2 mL/kg per day (Steiner 2003)

Monitoring
- Adverse Effects
- Efficacy (weight, stool consistency)

Client Information
- Because of the unpalatability of the oil, it should be mixed with small quantities of food before offering to the patient.

Chemistry/Synonyms
MCT Oil is a lipid fraction of coconut oil consisting principally of the triglycerides C8 (approx. 67%) and C10 (approx. 23%) saturated fatty acids. Each 15 mL contains 115 kCal (7.67 kCal/mL).

Medium chain triglycerides may also be known as: triglycerida saturata media, Alembicol D®, Liprocil®, Liquigen®, MCT®, Mytic 810®, Structolipid®, and...
Medium chain triglycerides may also be known as: triglycerida satura media, Alembicol D®; Liprocil®, Liquigen®; MCT®, Mytic 810®, Structolipid®, and Tecceme®.

Storage/Stability
Unless otherwise noted by the manufacturer, store at room temperature in glass bottles.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Medium Chain Triglycerides Oil: in quart bottles; MCT® (Mead Johnson Nutritionals); (OTC)

MEDROXYPROGESTERONE ACETATE
(me-droks-e-pro-jes-te-ron) Provera®

PROGESTIN

Prescriber Highlights

- Synthetic progestin used primarily to treat sexually dimorphic behavior problems such as roaming, inter-male aggressive behaviors, spraying, mounting, etc.; sometimes used to treat feline psychogenic dermatitis & alopecia
- Because of its serious adverse effect profile, particularly in small animals, consider safer alternatives first
- Contraindications: Do not use in pre-pubescent cats or dogs, diabetics, pseudopregnant bitches, females in diestrus or with prolonged heat, uterine hemorrhage or discharge
- Adverse Effects: Increased thirst, appetite, weight gain, depression, lethargy, personality changes, adrenocortical depression, mammary changes (including enlargement, milk production, & neoplasms), diabetes mellitus, pyometra, & temporary inhibition of spermatogenesis
- SC injection may cause permanent local alopecia, atrophy & depigmentation may occur
- Drug-lab (including pathology) interactions

Uses/Indications

In cats, medroxyprogesterone acetate (MPA) has been used when either castration is ineffective or undesirable to treat sexually dimorphic behavior problems such as roaming, inter-male aggressive behaviors, spraying, mounting, etc. MPA has also been used as a tranquilizing agent to treat syndromes such as feline psychogenic dermatitis and alopecia, but treatment with “true” tranquilizing agents may be preferable.

In dogs, MPA may be useful for treating progestin-responsive dermatitis, aggressive behaviors, long-term reproductive control, treatment of young German shepherd dwarfs, short-term treatment of benign prostatic hypertrophy, and luteal insufficiency.

Progestrones have been used in horses for many purposes, including management of the spring transition period, prevention of estrus behavior, induction of estrous cycle synchrony, pregnancy maintenance, and modification of stallion behavior (Dascanio 2009). MPA does not appear to effectively suppress estrous behavior or follicular activity in normal cycling mares (Gee et al. 2008).

In humans, parenteral MPA has been used as a long-acting contraceptive in females, to decrease sexually deviant behavior in males, and as an antineoplastic agent for some carcinomas (see Pharmacology section above). Oral MPA is used in human females to treat secondary amenorrhea and to treat abnormal uterine bleeding secondary to hormone imbalances.

Pharmacology/Actions

Progestins are primarily produced endogenously by the corpus luteum. They transform proliferative endometrium to secretory endometrium, enhance myometrium hypertrophy and inhibit spontaneous uterine contraction. Progestins have a dose-dependent inhibitory effect on the secretion of pituitary gonadotropins and can have an anti-insulin effect. Medroxyprogesterone has exhibited a pronounced adrenocorticoid effect in animals (species not listed) and can suppress ACTH and cortisol release. MPA is anti-estrogenic and will also decrease plasma testosterone levels in male humans and dogs.

MPA has antineoplastic activity against endometrial carcinoma and renal carcinoma (efficacy in doubt) in human patients. The mechanism for this activity is not known.

Pharmacokinetics

No specific pharmacokinetic parameters in veterinary species were located for this drug. It has been reported (Beaver 1989) that injectable MPA has an approximate duration of action of 30 days when used to treat behavior disorders in cats. When administered IM to women, MPA has contraceptive activity for at least 3 months.

Contraindications/Precautions/Warnings

Progestagen therapy can cause serious adverse effects (see below). Safer alternative treatments should be considered when possible, otherwise, weigh the potential risks versus benefits before instituting therapy. Many clinicians believe that progestogens are grossly overused.

Do not use MPA prior to puberty in cats, as chronic, severe mammary hypertrophy may result. Use in doses before puberty may precipitate subclinical uterine or
**Laboratory Considerations**

In humans, progestins in combination with estrogens (e.g., oral contraceptives) have been demonstrated to increase thyroxine-binding globulin (TBG) with resultant increases in total circulating thyroid hormone. Decreased T3 resin uptake also occurs, but free T4 levels are unaltered. Liver function tests may also be altered.

The manufacturer recommends notifying the pathologist of patient medroxyprogesterone exposure when submitting relevant specimens.

**Doses**

**DOGS:**

a) For apparent luteal insufficiency in bitches: 0.1 mg/kg PO once daily. Treatment is discontinued several days prior to the expected due date to avoid prolonged gestation. In humans, progestins have caused congenital heart defects, limb-reduction deformities, hypospadias in male fetuses, and mild virilization of the external genitalia of female fetuses, especially when administered to women during the first 4 months of pregnancy. Facial deformities were reported in one of the four pups in a litter from a bitch treated with MPA for hypoluteoidism. In most instances, the potential benefits of progesterone treatment for hypoluteoidism during the second half of pregnancy outweigh the maternal and fetal risks. (Gorlinger et al. 2005), (Johnson 2008)

b) For long-term reproductive control: 2.5–3 mg/kg IM q5 months (Romagnoli 2002; Romagnoli 2006; Romagnoli 2009)

c) For adjunctive treatment of aggressive behaviors: 10 mg/kg IM or SC (see Adverse Effects above) as necessary; works best when combined with behavior modification. To treat inter-male aggression: as above, but do not exceed 3 treatments per year. (Voith & Marder 1988)

d) For treatment of young German shepherd dwarfs: medroxyprogesterone acetate at 2.5–5 mg/kg initially at 3 week intervals and subsequently at 6 week intervals has resulted in some increase in body size and development of an adult hair coat. (Kooistra 2006)

e) For treatment of benign prostatic hypertrophy; best used to maintain breeding potential for short time prior to castration; use with caution: MPA at 0.3 mg/kg SC once; effects last approximately 10 months. (Lane 2006)

f) For progestin-responsive dermatitis: 20 mg/kg IM; May repeat in 3–6 months if needed (Kunkle 1986)

**CATS:**

a) To treat behavioral disorders: To reduce marking in neutered male cats when all other drugs have been unsuccessful: Medroxyprogesterone acetate at 5–20 mg/kg SC or IM three to four times yearly. (Landsberg 2007)

b) For feline psychogenic alopecia and dermatitis: 75–150 mg IM or SC (see Adverse Effects above); repeat as necessary, but never more often than every 2–3 months (Walton 1986)

c) For progestagen-responsive dermatitis: 50–100 mg IM; may repeat in 3–6 months if needed (Kunkle 1986)

d) To treat recurrent abortion secondary to progesterone-deficiency: 1–2 mg/kg IM once weekly, stop treatment 7–10 days prior to parturition (Barton & Wolf 1988)

For long-term reproductive control:

a) 2.5–5 mg PO once weekly; 25 mg injected every 6 months to postpone estrus (Henik et al. 1985)
MEGESTROL ACETATE
(me-jers-trole) Ovaban®, Megace®

PROGESTIN

Prescriber Highlights

- Synthetic progesterin used in *dogs (female)*: for postponement of estrus & the alleviation of false pregnancy; *Dogs (male)*: benign prostatic hypertrophy. 
  
  *Caution:* Many dermatologic & behavior-related conditions

- Contraindications: Pregnant animals or with uterine disease, diabetes mellitus, or mammary neoplasias; should not be used treat bitches with pseudo-pregnancy; females should not be treated during diestrus, or with uterine hemorrhage

- Adverse Effects: 
  
  *Caution:* Thrombophlebitis

  *Adverse Effects:*

  - *Caution:* Thrombophlebitis

  - Contraindications: Pregnant animals or with uterine disease, diabetes mellitus, or mammary neoplasias; should not be used treat bitches with pseudo-pregnancy; females should not be treated during diestrus, or with uterine hemorrhage

  - Adverse Effects: 

**References**

Uses/Indications
Megestrol acetate (Ovaban®—Schering) is FDA-approved for use in dogs only for the postponement of estrus and the alleviation of false pregnancy. In male dogs, it has been used for benign prostatic hypertrophy. It is used clinically for many dermatologic and behavior-related conditions, primarily in the cat. See the Dosage section for specific indications and dosages for both dogs and cats.

Megestrol acetate is indicated in humans for the palliative treatment of advanced carcinoma of the breast or endometrium.

Pharmacology/Actions
Megestrol acetate possesses the pharmacologic actions expected of the other progestationals discussed (e.g., medroxyprogesterone acetate). It has significant anti-estrogen and glucocorticoid activity (with resultant adrenal suppression). It does not have anabolic or masculinizing effects on the developing fetus.

Pharmacokinetics
Megestrol acetate is well absorbed from the GI tract and appears to be metabolized completely in the liver to conjugates and free steroids.

The half-life of megestrol acetate is reported to be 8 days in the dog.

Contraindications/Precautions/Warnings
Megestrol acetate is contraindicated in pregnant animals or in animals with uterine disease, diabetes mellitus, or mammary neoplasias. It has been recommended that MA not be used in dogs prior to their first estrous cycle or for anestrus therapy in dogs with abnormal cycles. The manufacturer (Schering) recommends that mating be prevented should estrus occur within 30 days of cessation of MA therapy.

This agent should not be used during pregnancy or to treat bitches with pseudo-pregnancy. Females should not be treated during diestrus, or with uterine hemorrhage. Do not use in females with prolonged heat unless cystic ovarian disease is confirmed and surgery or GNRH or hCG are not viable options. Animals with diabetes should not receive megestrol.

Because this drug can suppress adrenal function, exogenous steroids may need to be administered if the patient is stressed (e.g., surgery, trauma).

For estrus control, the manufacturer recommends that drug must be given for the full treatment regimen to be effective. The package insert states that “Ovaban® should not be given for more than two consecutive treatments,” but the reasons for this are unclear; some theriogenologists question the need for this precaution.

When used for reproductive control, it has been recommended that patients: 1) undergo a thorough reproductive history to rule out occurrence of estrus within the last 1–2 months (female in diestrus); 2) complete physical exam; 3) palpation of mammary glands to rule out mammary nodules; 4) vaginal smear to rule out presence of estrus (Romagnoli 2002; Romagnoli 2009)

In humans, megestrol acetate is to be used with caution in patients with thrombophlebitis and is contraindicated as a test for pregnancy.

Adverse Effects
In cats, megestrol acetate can induce a profound adrenocortical suppression, adrenal atrophy, and an iatrogenic “Addison’s” syndrome can develop at “standard” dosages (2.5–5 mg every other day) within 1–2 weeks. Once the drug has been discontinued, serum cortisol levels (both resting and ACTH-stimulated) will return to normal levels within a few weeks. Clinical signs of adrenocortical insufficiency (e.g., vomiting, lethargy) are uncommon, but exogenous steroid support should be considered if the animal is stressed (surgery, trauma, etc.). Cats may develop a transient diabetes mellitus while receiving MA. Polydipsia/polyuria, personality changes, increased weight, endometritis, cystic endometrial hyperplasia, mammary hypertrophy and neoplasias may also occur. Increased appetite and weight gain is not consistently seen, but MA is occasionally used as an appetite stimulant. Rarely, megestrol acetate can cause hepatotoxicity (increased alkaline phosphatase) in cats.

Megestrol potentially can exacerbate latent viral infections (e.g., FHV-1).

Limited clinical studies have suggested that megestrol acetate may cause less cystic endometrial hyperplasia than other progestational agents, but cautious use and vigilant monitoring is still warranted.

In dogs, increased appetite and weight gain, lethargy, change in behavior or hair color, mucomeatra, endometritis, cystic endometrial hyperplasia, mammary enlargement and neoplasia, acromegaly, adrenocortical suppression or lactation (rare) may occur. One dog reportedly developed diabetes mellitus after use.

Reproductive/Nursing Safety
No effects were noted in either the bitch or litter when pregnant dogs received 0.25 mg/kg/day for 32 days during the first half of pregnancy; reduced litter sizes and puppy survival were detected when the dose was given during the last half of pregnancy. Fetal hypospadias are possible if progestational agents are administered during pregnancy.

During the first 4 months of pregnancy in humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

During the last 5 months of pregnancy in humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Detectable amounts of progestins enter the milk of mothers receiving these agents. Effects on nursing infants have not been established.

Overdosage/Acute Toxicity
No information was located regarding acute overdosage of megestrol acetate. In humans, dosages of up to 800 mg/day caused no observable adverse reactions.

Toxicity studies performed in dogs at dosages of 0.1–0.25 mg/kg/day PO for 36 months yielded no gross abnormalities in the study population. Histologically, cystic endometrial hyperplasia was noted at 36 months, but resolved when therapy was discontinued. At dosages of 0.5 mg/kg/day PO for 5 months, a reversible uterine hyperplasia was seen in treated dogs. Dosages of 2 mg/kg/day demonstrated early cystic endometritis in biopsies done on dogs at 64 days.

Drug Interactions
- CORTICOSTEROIDS: Megestrol used with corticosteroids (long-term) may exacerbate adrenocortical suppression and diabetes mellitus.
- RIFAMPIN: May decrease progestin activity if administered concomitantly. This is presumably due to microsomal enzyme induction with resultant increase in progestin metabolism. The clinical significance of this potential interaction is unknown.

Doses
- **DOGS:**
  - Estrus control:
For estrus control:

a) To halt cycle in proestrus: 2.2 mg/kg once daily for 8 days starting during the first 3 days of proestrus. While the timing of the next cycle is variable, it may be prolonged with 2.2 mg/kg/day for 4 days, then 0.55 mg/kg/day for 16–20 days.

b) For suppression during proestrus (first 3 days): 2.2 mg/kg once daily for 8 days (92% efficacy). Bitch must be controlled until behavioral signs of estrus disappear. If mating occurs during first 3 days of therapy, stop treatment and consider mismating therapy. There is an increased likelihood of pyometra developing if progestins are used concomitantly with estrogens. If mating occurs after 3 or more days of therapy continue at a dosage rate of 3–4 mg/kg PO.

c) 0.55 mg/kg PO for 32 days, beginning at least 7 days prior to proestrus (Burke 1985)

To postpone an anticipated cycle: 0.55 mg/kg/day for 16–20 days.

To delay an anticipated heat during anestrus: 0.55 mg/kg PO for 32 days initiated 7 days prior to proestrus. Recommend doing vaginal cytology prior to therapy. If no erythrocytes are seen, initiate therapy if cycle time frame is appropriate. If erythrocytes are seen, delay therapy until proestrus therapy can be instituted. Do not repeat therapy more often than once every 6 months. (Woody 1989)

c) 2 mg/kg (or less) administered for <2 weeks in proestrus, or <2 mg/kg administered for a longer duration in anestrus. A typical dose for estrus suppression is 2 mg/kg PO once daily for 8 consecutive days, while a typical dose for temporary postponement is 0.5 mg/kg PO once daily in late anestrus. (Romagnoli 2002; Romagnoli 2006; Romagnoli 2009)

For benign prostatic hypertrophy:

a) 0.5 mg/kg PO daily for 4–8 weeks (Root Kustritz & Klausner 2000)

b) 0.55 mg/kg PO daily (Purswell 1999)

c) 0.1–0.5 mg/kg per day for 3–8 weeks; best used to maintain breeding potential for short time prior to castration; use with caution. (Lane 2006)

For pseudocyesis (false pregnancy):

a) 0.5 mg/kg PO once daily for 8 days (Barton & Wolf 1988)

To prevent vaginal hyperplasia development:

a) 2.2 mg/kg PO for 7 days early in proestrus (Wykes 1986)

b) 0.55 mg/kg PO once daily for 7 days (Olson & Olson 1986)

For behavior disorders:

a) For adjunctive treatment of aggressive or unacceptable masculine behavior: 1.1–2.2 mg/kg PO once daily for 2 weeks, then 0.5–1.1 mg/kg once daily for 2 weeks. Should be used with behavior modification. (Voith & Marder 1988)

CATS:

For suppression of estrus:

a) In anestrus: 5 mg/cat PO every 2 weeks or 2.5 mg/cat per week (better if divided into 2 doses given every 3.5 days); In proestrus: 5 mg/cat per day for 4 days, then 5 mg PO every 3 week. (Romagnoli 2006; Romagnoli 2009)

b) If in behavioral estrus, signs may be inhibited by giving 5 mg/day PO until estrus stops (generally within 3–5 days), then 2.5–5 mg PO once weekly for 10 weeks

Postponement of estrus (if started during diestrus): 2.5 mg PO daily for 8 weeks

Postponement of estrus (if started during anestrus): 2.5 mg PO once weekly for up to 18 months. Recommend allowing cat to have a cycle (unmedicated) before beginning another treatment cycle. (Woody 1989)

c) If started in diestrus: 2.5 mg per day PO for up to 2 months

If started in anestrus: 2.5 mg per week for up to 18 months

For prevention of estrus: 5 mg daily PO for 3 days as soon as behavioral signs of estrus are seen; next estrus period will occur in approximately 4 weeks. (Romatowski 1989) (information from package insert; Ovarid®—Glaxovet)

For treatment of idiopathic feline miliary dermatitis:

a) 2.5–5 mg once every other day, followed by weekly maintenance dosages. May be necessary to treat for animal’s lifetime. Reserve use for severe cases; explain risks to owner and do not exceed 2.5 mg per week during maintenance phase. (Kwochka 1986)

As appetite stimulant:

a) 0.25–0.5 mg/kg q24h for 3–5 days, then q48–72h (Smith 2003)

As an alternative treatment for immune-mediated skin diseases:

a) 2.5–5 mg PO once daily for 10 days, then every other day (Giger & Werner 1989)

For adjunctive therapy of eosinophilic granulomas:

a) 0.5 mg/kg PO once daily for 2 weeks, then twice weekly as needed (Coppoc 1988)

For eosinophilic ulcers:

a) Alone or in combination with methylprednisolone acetate (Depo-Medrol®): 5–10 mg PO every other day for 10–14 doses, then every 2 weeks as needed (DeNovo et al. 1989)

As a “last ditch” alternative for treating feline atopy:

a) Remission of clinical signs can often be achieved with an oral dose of 2.5–5 mg per cat PO every 48 hours for 1-3 weeks. This dose is then used once weekly. (Rosychuk 2007)

For feline plasma cell gingivitis:

a) 2.5 mg PO once daily for 10 days, then once every other day for 5 treatments, then as needed (Morgan 1988)

As a secondary therapy (thyroid hormone replacement first choice) for treatment of feline endocrine alopecia (FEA):

a) 5 mg PO every second to third day initially, then 2.5 mg PO once to twice weekly (Thoday 1986)

For feline psychogenic alopecia and dermatitis:

a) 0.5 mg/kg PO every second to third day initially, then 2.5 mg PO once to twice weekly (Thoday 1986)
For feline psychogenic alopecia and dermatitis:

a) 2.5–5 mg every other day initially, then taper to the lowest maintenance dosage possible, given weekly as needed (Walton 1986)

For adjunctive therapy (with urine acidification, increased urine crystalloid solubility, and antispasmodics if required) for persistent hematuria and urethritis in a non-obstructed cat:

a) 2.5–5 mg PO once daily to every other day (with prednisone: 2.5–5 mg PO daily) (Lage et al. 1988)

For urine marking, intraspecies aggression, anxiety:

a) 2 mg/kg/day for 5 days, then 1 mg/kg/day for 5 days, then 0.5 mg/kg/day for 5 days (Romatowski 1989) (information from package inserts; Ovarid®—Glaxovet)

b) To reduce marking in neutered male cats when all other drugs have been unsuccessful: megestrol acetate at 2.5–10 mg (total dose) per cat PO once daily for one week, then reduce to once or twice weekly. (Landsberg 2007)

c) 5 mg per cat once daily for 2 weeks, then wean to lowest effective maintenance dose. Has poor efficacy in neutered males (50%) and spayed females (10%); many potential adverse effects. (Levine 2008)

**Monitoring**

- Weight
- Blood glucose (draw baseline before therapy)
- Mammary gland development and appearance
- Adrenocortical function
- Liver enzymes if long-term treatment
- Efficacy

**Client Information**

- The client should fully understand the potential risks of therapy (see Adverse Effects above) before starting therapy and should report changes in mammary glands or other signs associated with adverse reactions (e.g., PU/PD, extreme lethargy, behavior changes, etc.) to the veterinarian.

**Chemistry/Synonyms**

A synthetic progestin, megestrol acetate (MA) occurs as an essentially odorless, tasteless, white to creamy white, crystalline powder that is insoluble in water, sparingly soluble in alcohol, and slightly soluble in fixed oils. It has a melting range of 213°C–219°C over a 3° range and a specific rotation of +48° to +12°.

Megestrol acetate may also be known as: BDH-1298, compound 5071, megestrol acetate, NSC-71423, Acestrol®, Borea®, Endace®, Gynodal®, Maygace®, Megace®, Megastro®, Megefren®, Megestrin®, Megestrol®, Meltonar®, Meprogest®, Mestrel®, Nia®, Niagentin®, Ovabrin®, Prazoken®, and Varigestrol®.

**Storage/Stability**

Megestrol acetate tablets should be stored in well-closed containers at a temperature of less than 40°C. The tablets can be crushed and administered with food. The veterinary manufacturer recommends storing the tablets from 2°C–30°C (36°F–86°F).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Megestrol Acetate Oral Tablets: 5 mg, 20 mg; available in bottles of 250 and 500 tablets, and in 30 foil strips of 8 and packaged in cartons of 240 tablets; Ovaban® (Schering-Plough); (Rx). FDA-approved for use in dogs only.

**HUMAN-LABELLED PRODUCTS:**

Megestrol Acetate Tablets: 20 mg & 40 mg; Megace® (Bristol-Meyers Oncology); generic; (Rx)

Megestrol Acetate Suspension: 40 mg/mL in 240 mL & 125 mg/mL in 150 mL; Megace® (Bristol-Meyers Oncology); Megace ES® (Par Pharmaceutical Inc); (Rx)

**References**

**MEGLUMINE ANTIMONIATE**

(img-boo- meen an-thih-mohne-ee-ate)

Glucantime®, Gulcantim®
PENTAVALENT ANTIMONY ANTILEISHMANIAL

Prescriber Highlights

- Pentavalent antimony compound used for treating leishmaniasis (with or without allopurinol) in dogs
- Not available in USA
- Extreme caution (relatively contraindicated) in patients with cardiac, hepatic or renal insufficiency
- Primary adverse effects noted in dogs with meglumine antimoniate are injection site reactions, lethargy & gastrointestinal effects (inappetence, vomiting)
- Resistance to treatment has been reported
- Treatment is prolonged & cost may be substantial

Uses/Indications
Meglumine antimoniate is used alone or in combination with allopurinol to treat leishmaniasis in dogs. It is available commercially in some Mediterranean and South American countries but not in the USA.

Pharmacology/Actions
Pentavalent antimony compounds such as meglumine antimoniate and sodium stibogluconate selectively inhibit the leishmanial enzymes required for glycolytic and fatty acid oxidation. Pentavalent antimony compounds rarely are successful in eradicating *Leishmania* organisms completely in infected dogs. When used with allopurinol, synergy for treating leishmaniasis and reduced risk for antimonial drug-resistance development may occur.

Pharmacokinetics
After subcutaneous or intramuscular injections in dogs systemic bioavailability is about 92%; highest tissue concentrations are found in the liver, spleen, and skin. Within 9 hours of dosing, 80% of the antimony is excreted in the urine. Reduced renal function can cause increased antimoniate half-lives.

Contraindications/Precautions/Warnings
Patients with renal, hepatic or cardiac failure are more likely to develop serious adverse effects with this agent; weigh the potential risks versus benefits carefully before treating. Decreased renal function in particular, may lead to drug accumulation and an increased risk for toxicity. In dogs with severe renal failure (IRIS stages III-IV) the correction of fluid and acid-base imbalances prior to treatment with allopurinol alone has been recommended (Koutinas & Koutinas 2007).

Hypersensitivity reactions have been reported in people, and any patient with previous hypersensitivity to meglumine antimoniate should not receive the drug.

Adverse Effects
Primary adverse effects noted in dogs are injection site reactions (cutaneous abscesses/cellulitis), lethargy, and gastrointestinal effects (inappetence, vomiting). Transient increases in liver enzymes have been reported.

Potentially, the drug may be nephrotoxic in dogs, but this is difficult to evaluate in clinically-infected dogs as renal dysfunction is one of the likely consequences of the infection. A study done in healthy dogs showed diffuse proximal tubule cell vacuolization and multifocal areas with coagulative necrosis under light microscopy. Electron microscopy showed reduced organellar content, loss or attenuation of brush border, cellular detachment from the basement membrane, apical blebbing and individual cell necrosis. The authors concluded that meglumine antimoniate caused severe tubular damage (Brovida et al. 2009).

Drug resistance may occur. After several courses of treatment, decreased sensitivity of *L. infantum* to meglumine antimoniate or antimonials has been reported.

In humans, increased serum lipase, amylase, creatinine, urea nitrogen, and increased QT interval on ECG, have been reported. Occasionally, decreases in white blood cell counts and hemoglobin have been reported in humans.

Reproductive/Nursing Safety
There is limited information available. Pregnant rats given up to 300 mg/kg on days 6–15 caused increased fetal resorptions and increased rates of abnormalities of the atlas bone. Weigh the risks versus benefits when deciding to treat during pregnancy. It is unknown if the drug enters maternal milk.

Overdosage/Acute Toxicity
No specific overdose information was located. Depending on the dosage, a single overdose could potentially cause renal, hepatic, pancreatic, and hematologic effects, but gastrointestinal effects (vomiting) and lethargy would be the most likely outcomes. It is recommended to observe the patient and contact an animal poison control center for further guidance with an overdose situation.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving meglumine antimoniate and may be of significance in veterinary patients (dogs):

- **AGENTS THAT CAN PROLONG QT INTERVAL** (e.g., tricyclic antidepressants, disopyramide, quinidine, procainamide, etc.): meglumine antimoniate may prolong QT interval further with increased risk for arrhythmias

Laboratory Considerations
- No specific laboratory interactions or considerations noted

Doses

**DOGS:**

- As first line treatment: meglumine antimoniate at 75–100 mg/kg SC once daily for 4–8 weeks, with allopurinol (10 mg/kg PO twice daily for at least 6–12 weeks). Resistance to treatment has been reported.
a) As first line treatment: meglumine antimoniate at 75–100 mg/kg SC once daily for 4–8 weeks, with allopurinol (10 mg/kg PO twice daily for at least 6–12 months. (Solano-Gallego et al. 2009)

b) Meglumine antimoniate at a minimum dosage of 100 mg/kg SC daily for 3–4 weeks; better results are obtained with longer durations (4–6 weeks) of treatment. Protocol with allopurinol may reduce relapse rates: meglumine antimoniate as above with allopurinol at 20–40 mg/kg PO daily for a minimum of 3 weeks. Followed with long-term treatment with allopurinol (alone) at 20–40 mg/kg PO daily or intermittently (one week treatment per month). (Noli & Auxilia 2005)

c) Meglumine antimoniate (100 mg/kg/day SC) until resolution; with allopurinol at 20 mg/kg PO q12h for 9 months. (Brosey 2005)

Monitoring
- Efficacy (PCR preferred)
- CBC (baseline and periodic)
- Liver enzymes; renal function tests (serum creatinine, BUN); serum lipase and amylase (baseline and periodic)
- Urinalysis (baseline and periodic)

Client Information
- Clients should understand that treatment with this drug can be prolonged and expensive, and that a “cure” (complete eradication) is unlikely

Chemistry/Synonyms
Meglumine antimoniate is 1-Deoxy-1-methylamino-D-glucitol antimoniate. It has a molecular weight of 366. One gram contains approximately 272 mg of antimony.

Meglumine antimoniate may also be known as: meglumine antimonate, N-methylglucamine antimoniate, RP-2168, antimony meglumine, Protostib, 1-Deoxy-1-methylamino-D-glucitol antimoniate, Glucantime® and Glucantim®.

Storage/Stability
Unless otherwise specified by the manufacturer, commercially available ampules should be stored below 40°C, preferably between 15°–30°C; protect from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA.

May be available via the CDC, see: http://www.cdc.gov/ncidod/srp/drugs/drug-service.html

HUMAN-LABELED PRODUCTS: None in the USA

Meglumine antimoniate may be available in several countries, including Brazil, Venezuela, and in Europe; trade names include: Glucantime® and Glucantim®. Commercially it is available as a solution containing 1.5 grams of meglumine antimoniate (425 mg pentavalent antimony) per 5 mL.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the Instructions for Legally Importing Drugs for Compassionate Use in the USA found in the appendix.

References

MELARSONIME
(mee-ler-soe-meen) Immiticide®
ARSENCAL ANTIPARASITIC

Prescriber Highlights
- Organic arsenical for heartworm disease
- Contraindications: Class IV (very severe) heartworm disease; weigh risk vs. potential benefits in pregnant, lactating, or breeding dogs
- Reportedly very toxic to cats; not currently recommended
- Adverse Effects: Many possible, most common are: Injection site reactions coughing/gagging, depression/lethargy, anorexia/inappetence, excessive salivation, fever, lung congestion, vomiting, pulmonary thromboembolism
- Special IM injection technique; do not give IV or SC
- Avoid human exposure
- Calculate dosages very carefully
- Strict cage rest after treatment recommended

Uses/Indications
Melsarsonime is indicated for the treatment of stabilized class I, II, and III heartworm disease caused by immature (4 month old, stage L5) to mature adult infections of D. immitis in dogs. When compared with thiactarsamide, melsarsonime appears to be more efficacious, less irritating to tissues, and does not cause hepatic necrosis.
Doses noted.

prophylactic medications, and various other drugs commonly used to stabilize and support dogs with heartworm disease and that no adverse drug interactions were

The manufacturer reports that during clinical field trials, melarsomine was given to dogs receiving antiinflammatory agents, antibiotics, insecticides, heartworm

Drug Interactions

vomiting, and fever have been noted in infected dogs that have received inadvertent overdoses (2X).

Salivation, restlessness, panting, vomiting, edema, tremors, lethargy, ataxia, cyanosis, stupor, and death. Signs of diarrhea, excessive salivation, restlessness, panting,

There is low margin of safety with melarsomine dosages. A 3X dose (7.5 mg/kg) in healthy dogs have demonstrated respiratory inflammation and distress, excessive

Safety has not been established for use in pregnant, lactating, or breeding dogs. Risks versus potential benefits of therapy should be weighed before use.

Reproductive/Nursing Safety

Approximately ½ of dogs show signs of injection site reactions (pain, swelling, tenderness, reluctance to move) after receiving melarsomine. Most of these signs resolve within weeks, but, rarely, severe injection reactions can occur. Firm nodules at the injection site can persist indefinitely. SC or IV injections must be avoided.

Adverse Effects

Contraindications/Precautions/Warnings

Melarsomine is contraindicated in dogs with class IV (very severe) heartworm disease. Class IV is having caval syndrome (heartworms present in venae cavae and right atrium). Melarsomine is reportedly very toxic to cats and its use cannot be recommended for this species at this time.

Older dogs (>8 years) may be more susceptible to adverse effects than younger dogs.

Do NOT give IV or SC; significant toxicity or tissue damage may occur. Administer only deep IM as directed (lumbar epaxial muscles (L3-L5). Do not administer at any other site.

While all dogs with heartworm disease are at risk for post-treatment pulmonary thromboembolism, those with severe pulmonary artery disease are at increased risk for post treatment morbidity and mortality. Strict exercise restriction after administration can decrease the severity associated with thromboembolic events. Cage rest (2-4 weeks) in the veterinary clinic is recommended if feasible. If clinic cage rest and observation are not possible, owners should be advised that unless the patient’s exercise is restricted, thrombolic events are more likely and can be fatal. Wash hands after use or wear gloves. Avoid drug contact with animal’s eyes; if exposed wash with copious amounts of water. Avoid human exposure. If human exposure occurs, contact a physician.

Reproductive/Nursing Safety

Safest has not been established for use in pregnant, lactating, or breeding dogs. Risks versus potential benefits of therapy should be weighed before use.

Overdosage/Acute Toxicity

There is low margin of safety with melarsomine dosages. A 3X dose (7.5 mg/kg) in healthy dogs have demonstrated respiratory inflammation and distress, excessive salivation, restlessness, panting, vomiting, edema, tremors, lethargy, ataxia, cyanosis, stupor, and death. Signs of diarrhea, excessive salivation, restlessness, panting, vomiting, and fever have been noted in infected dogs that have received inadvertent overdoses (2X).

Treatment with dimercaprol (BAL in Oil) may be considered to treat melarsomine overdoses. Clinical efficacy of melarsomine may be reduced, however.

Drug Interactions

The manufacturer reports that during clinical field trials, melarsomine was given to dogs receiving antiinflammatory agents, antibiotics, insecticides, heartworm prophylactic medications, and various other drugs commonly used to stabilize and support dogs with heartworm disease and that no adverse drug interactions were noted.

ASPIRIN: Has been shown not to reduce adverse effects and may complicate therapy; use is not recommended

CNS DEPRESSANT DRUGS: Drugs that have similar adverse effects (e.g., depression caused by CNS depressants, etc.) may cause additive adverse effects or increase their incidence when used with melarsomine

Doses

CAUTION: Because of the low margin of safety; calculate dosages very carefully. Do not confuse mg/lb with mg/kg!

DOGS:

For treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information.

Immiticide® (Merial) product support phone number: 888-637-4251

For treatment of heartworm disease:

a) After diagnosis, determine the class (stage) of the disease. Note: The manufacturer provides worksheets that assist in the classification and treatment regime determination. It is highly recommended to use these treatment records to avoid confusion and document therapy.

Class I, & II: 2.5 mg/kg deep IM as directed (lumbar epaxial muscles (L3-L5) twice 24 hours apart and rest. Use alternating sides with each administration.
Class I, & II: 2.5 mg/kg deep IM as directed (lumbar epaxial muscles (L3-L5) twice 24 hours apart and rest. Use alternating sides with each administration.

In 4 months, the regimen may be repeated.

Class III: 2.5 mg/kg deep IM as directed (lumbar epaxial muscles (L3-L5). Strict rest and give all necessary systemic treatment. One month later, give 2.5 mg/kg deep IM as directed (lumbar epaxial muscles (L3-L5) twice 24 hours apart.

Note: Recommended needle size for dogs 10 kg or less = 23 gauge 1 inch; 10 kg or more body weight = 22 gauge 1.5 inch. (Package Insert; Immiticide®—Merial)

b) The three-injection alternative protocol 2.5 mg/kg deep IM as directed (lumbar epaxial muscles; L3-L5). Strict rest and give all necessary systemic treatment. One month later, give 2.5 mg/kg deep IM as directed (lumbar epaxial muscles; L3-L5) twice 24 hours apart is the treatment of choice of the American Heartworm Society and several university teaching hospitals, regardless of stage of disease, due to the increased safety and efficacy benefits and subsequently fewer dogs that require further treatment with melarsomine. (American Heartworm Society; www.heartwormsociety.org; accessed 2010)

Monitoring/Client Information

- Clinical efficacy
- Adverse effects; dogs should be observed for 24 hours after the last injection
- Strict exercise restriction after dosing is extremely important
- Because of the seriousness of the disease and the potential for morbidity and mortality associated with the treatment, clients should give informed consent before electing to treat.

Chemistry/Synonyms
An organic arsenical compound, melarsomine dihydrochloride has a molecular weight of 501 and is freely soluble in water.

Melarsomine may also be known as Immiticide®. Its CAS registry is 128470-15-5.

Storage/Stability/Preparation
The unreconstituted powder should be stored upright at room temperature. Once reconstituted, the solution should be kept in the original container and kept refrigerated for up to 24 hours. Do not freeze. Do not mix with any other drug.

Reconstitute with 2 mL of the diluent provided (sterile water for injection) with a resultant concentration of 25 mg/mL. Once reconstituted, the solution should be kept in the original container and kept refrigerated for up to 24 hours. Do not freeze.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS:
Melarsomine Dihydrochloride Powder for Injection: 50 mg/vial; Immiticide® (Merial); (Rx). FDA-approved for use in dogs.

HUMAN-LABELLED PRODUCTS: None

---

MELATONIN
(mel-a-tone-in) Regulin®
HORMONE

Prescriber Highlights

- Oral & implantable pineal gland hormone
- Potential uses include: As a reversible estrus suppression agent in cats, treatment of alopecia in dogs, sleep & behavior disorders in cats & dogs, adjust seasonally controlled fertility in sheep, goats, & horses, & adjunctive treatment for adrenal disease in ferrets
- Adverse effects appear to be minimal, but little experience
- Potential contraindications include: Pregnancy, sexually immature animals, & liver dysfunction

---

Uses/Indications
Melatonin may be useful to treat Alopecia-X in Nordic breeds, canine pattern baldness, or canine recurrent flank alopecia in dogs. It has been used anecdotally for the treatment of sleep cycle disorders in cats and geriatric dogs and to treat phobias and separation anxiety in dogs. Melatonin implants are used in the mink and fox pelt industries to promote the development of luxurious hair coats. Implants are also used to improve early breeding and ovulation rates in sheep and goats. Preliminary research is being done for this purpose in horses also. Preliminary evidence suggests that melatonin implants (18 mg) can provide short-term estrus control in cats. Melatonin may also have beneficial effects in treating hyperadrenocorticism, some types of hepatopathies, and colitis.

In pigs, one study (Bubenik, Ayles et al. 1998) demonstrated that 5 mg/kg in feed reduced the incidence of gastric ulcers in young pigs.

Pharmacology/Actions
Melatonin is involved with the neuroendocrine control of photoperiod dependent molting, hair growth and pelage color. Melatonin stimulates winter coat growth and spring shedding occurs when melatonin decreases. The mechanism of how melatonin induces these effects is not well understood. It may have direct effects on the hair follicle or alter the secretion of prolactin and/or melanocyte stimulating hormone.
Melatonin also increases serum prolactin levels, growth hormone, and increases response to growth hormone releasing hormone. Long-term use may decrease luteinizing hormone. Melatonin is also ostensibly a free radical scavenger.

**Pharmacokinetics**

No specific information was located.

**Contraindications/Precautions/Warnings**

Melatonin implants are considered contraindicated in pregnant or sexually immature animals. There are very specific times for administration depending on latitude, hemisphere, and breed. Animals that are nursing young may not benefit from implant therapy.

In humans, melatonin is considered contraindicated in patients with hepatic insufficiency as it is cleared hepatically. Use with caution in patients with renal impairment. Because of its CNS depressant qualities, melatonin is sometimes stated that it should be used with caution in patients with a history of cerebrovascular disease, depression or neurological disorders.

**Adverse Effects**

Melatonin appears to be quite safe in dogs. Side effects in dogs when given orally are rare but the hormone may cause sedation, and affect sex hormone secretion and fertility. Subcutaneous implants in dogs have been associated with sterile abscesses.

Adverse effects in ferrets have not been reported.

Adverse effects reported in humans include altered sleep patterns, hypothermia, sedation, tachycardia, confusion, headache, and pruritus.

**Reproductive/Nursing Safety**

No information was located; use with caution.

**Overdose/Acute Toxicity**

Little information is available; unlikely to cause significant morbidity after a single overdose.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving melatonin and may be of significance in veterinary patients:

- **BENZODIAZEPINES:** Melatonin may potentiate effects
- **SUCCINYLCHOLINE:** Melatonin may potentiate effects

**Laboratory Considerations**

- Melatonin can reduce cortisol and estradiol levels

**Doses**

**DOGS:**

For dermatologic conditions:

a) For experimental treatment of Alopecia-X in Nordic breeds, canine pattern baldness, or canine recurrent flank alopecia: Empirical dose of one to four 12 mg implants SC. Retreatment may be necessary once or twice a year. If implants are unavailable, oral melatonin at 3–6 mg every 8–12 hours may be tried. Although appears to be safe, recommend having owners sign a release form noting the “experimental” nature of treatment. (Paradis 2000)

b) For treatment of canine recurrent flank alopecia or seasonal flank alopecia: 2–3 mg per dog PO once daily for 3–5 days weekly or monthly or this as a daily dose. Doses of up to 10 mg per dog have used. Improvement is usually seen in one month with maximal improvement in 3 months. (Merchant 2000)

c) For treatment of Alopecia X: Neutering is recommended initially. If this fails to be of benefit (or the patient must be left intact), try melatonin for a 3-month period at 3–6 mg (total dose) PO 2-3 times a day. Treat until maximal response is noted and discontinue. Re-institute therapy if and when signs recur. Canine recurrent flank alopecia: 3–6 mg (total dose) PO 2-3 times a day for 2–3 months (until hair loss is not noted when expected as the season changes or until good hair regrowth is noted). Therapy is stopped once hair growth has been attained; re-institute for recurrences.

Color dilution alopecia: 1.5–6 mg PO 2–3 times a day, stop when good re-growth occurs and restart if needed. (Rosychuk 2008)

d) For treatment of Alopecia-X: Empirical dose is 3 mg–12 mg (depending on the dog’s size) PO 2 to 3 times a day. Perform a trial for at least 4 months before evaluating response; only reported side effect is drowsiness. (Torres 2007)

For sleep disorders (nocturnal activity):

a) 3–6 mg (total dose) PO q12–24h (Virga 2002)

b) 0.1 mg/kg PO q8h. May be useful as a sleep aid and for canine fears and phobias. (Landsberg 2008)

For idiopathic vacuolar hepatopathy:

a) Some have suggested administering melatonin 4–6 mg/day PO in dogs weighing 15 kg or less may improve liver enzymes and hepatic changes. More studies are required to confirm this finding. (Tweedt 2009)

For sleep disorders (nocturnal activity):

a) 3–12 mg (total dose) PO q12–24h (Virga 2002)

For suppression of estrus:

a) 18 mg implant SC suppressed estrus for 2-4 months. (Gimenez et al. 2009)

**CATS:**

For sleep disorders (nocturnal activity):

a) 3–12 mg (total dose) PO q12–24h (Virga 2002)

For suppression of estrus:

a) 18 mg implant SC suppressed estrus for 2-4 months. (Gimenez et al. 2009)

**FERRETS:**

For adjunctive treatment of adrenal disease:

a) 0.5–1 mg per ferret PO once daily 7–9 hours after sunrise has been anecdotally effective in alleviating alopecia, aggressive behavior, vulvar swelling and prostatomegaly. Improvement more likely in patients with adrenal hyperplasia or adenoma; less likely if adenocarcinoma. Has no effect on tumor growth or
metastasis. The implant form (5.4 mg) releases melatonin over a 3–4 month period. Response to melatonin, in general, is better in fall and winter. Can be used with other treatments (e.g., leuprolide, anastrozole, bicalutamide, finasteride). (Johnson 2006)

b) 1–2 mg per ferret PO once daily; or use 5.4 mg implant. May allow hair growth, refractory in a few months; implant may work better, does not control tumor growth. In ferret weighs under 600 grams may cause excessive drowsiness. (Johnson-Delaney 2009)

Monitoring

Clinical efficacy

Client Information

For use in small animals, must be administered as directed to be effective.

Relatively “experimental”; safety and efficacy are not clearly established.

Chemistry/Synonyms

A naturally occurring hormone produced in the pineal gland, melatonin occurs as a pale yellow, crystalline solid and has a molecular weight of 232. It can be derived from natural sources or by synthetic means.

Melatonin may also be known as: n-acetyl-5-methoxytryptamine, MEL, MLT, pineal hormone, Benedorm®, Buenas Noches®, Cronocaps®, Dermatonin®, Ferretonin®, HT90®, Melapure®, Melato®, Regulin®, Repentil®, Revenox®, and Transzone®.

Storage/Stability

Unless otherwise labeled, store at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Melatonin 5.4 mg implant product marketed for ferrets; Ferretonin® (Melatek); 1-877-635-2835; www.melatek.net; Approval status is not known

Melatonin 8 mg, 12 mg, 18 mg implant product marketed for dogs; Dermatonin® (Melatek); Approval status not known

An 18 mg implant for sustained subcutaneous release is available in a variety of countries. One trade name is Regulin®. It is labeled for use in sheep (UK and NZ) and goats (NZ) to improve early breeding and ovulation rates.

There reportedly are mink implants available in the United States from Neo-Dynamics (800-206-7227).

HUMAN-LABELED PRODUCTS:

Melatonin tablets are available in a variety of strengths from a variety of sources. Common strengths available range from 0.5 mg to 3 mg tablets. Sustained release capsules (3 mg) and oral liquid (500 micrograms/mL) may also be available. Because melatonin is considered a “nutrient” there is no official labeling or central quality control systems for it in the USA. Purchase from reputable sources.

References

MELOXICAM

(mel-ox-i-kam) Metacam®

NONSTEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- NSAID used in dogs & cats; COX-2 preferential
- May be useful as low-cost oral analgesic antiinflammatory for treating pain in calves after dehorning or castration
- Available as both an injectable & oral product
- GI adverse effects can occur

Uses/Indications

Meloxicam is principally used for the symptomatic treatment of osteoarthritis in dogs. Short-term (single dose injectable) use is also FDA-approved (in the USA) for cats for the control of postoperative pain and inflammation associated with orthopedic surgery, ovariohysterectomy and castration when administered prior to surgery. Recent work in calves suggests that oral meloxicam may be a cost-effective agent to treat painful procedures such as castration or dehorning (Coetzee et al. 2009).

Pharmacology/Actions

Meloxicam has antiinflammatory, analgesic, and antipyretic activity similar to other NSAIDs. Like other NSAIDs, meloxicam exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase, phospholipase A$_2$, and inhibition of prostaglandin synthesis. It is considered COX-2
In dogs, meloxicam is well absorbed after oral administration. Food does not alter absorption. Peak blood levels occur in about 7–8 hours after administration. The volume of distribution in dogs is 0.3 L/kg and about 97% is bound to plasma proteins. Meloxicam is extensively biotransformed to several different metabolites in the liver; none of these appear to have pharmacologic activity. The majority of these (and unchanged drug) are eliminated in the feces. A significant amount of enterohepatic recirculation occurs. Elimination half-life is species specific. The elimination half-life in dogs averages 24 hours (range: 12–36 hours); other species: pigs: 4 hours; horses: 3 hours; cattle: 13 hours.

In cats, subcutaneous injection is nearly completely absorbed. Peak levels occur about 1.5 hours after injection. Meloxicam is relatively highly bound to feline plasma proteins (97%) and volume of distribution is about 0.27 L/kg. After a single dose, total systemic clearance is approximately 130 mL/hr/kg and elimination half life is approximately 15 hours. Major pathway for biotransformation is oxidation and the major elimination route is fecal.

In ruminant calves (approx. 3 months old) oral meloxicam at 1 mg/kg was well absorbed and had an elimination half-life of about one day (Coetzee et al. 2009).

Contraindications/Precautions/Warnings
Meloxicam is contraindicated in dogs hypersensitive to it. Safe use has not been evaluated in dogs less than 6 months old. The European label states that safe use has not been evaluated in dogs less than 6 weeks old. Although not part of the label, it should probably not be used in dogs with active GI ulceration or bleeding. It should be used with caution in patients with impaired hepatic, cardiac or renal function and hemorrhagic disorders.

Due to its long half-life in dogs, a 5–7 day washout period after stopping meloxicam has been recommended before starting a new NSAID (KuKanich 2008). Meloxicam is contraindicated in cats with known hypersensitivity to meloxicam or other NSAIDs. The manufacturer warns that additional doses of meloxicam or other NSAIDs are contraindicated as no safe dosage for repeated NSAID administration has been established. Use in cats less than 4 months of age has not been established. Use preoperatively for cats undergoing major surgery where hypotensive episodes are possible; may be at higher risk for renal damage.

The human label states that no dosage adjustment is necessary in patients with mild to moderate hepatic or renal impairment. Use extreme caution in dehydrated, hypovolemic, or hypotensive animals as there is a potential increased risk of renal toxicity developing.

Adverse Effects
Experience in Europe and Canada has demonstrated a relatively safe adverse effect profile for meloxicam in dogs. GI distress is the most commonly reported adverse effect, and in US field trials vomiting, soft stools, diarrhea, and inappetence were the most common adverse effects reported. Renal toxicity appears to be quite low. Post-approval adverse effects reported have included GI effects (vomiting, anorexia, diarrhea, melena, ulceration), elevated liver enzymes, pruritus, azotemia, elevated creatinine, and renal failure.

In cats, single doses of meloxicam appear relatively safe. In field trials some cats developed elevated BUN, post-treatment anemia and, rarely, residual pain at the injection site. In other studies, meloxicam has caused GI effects (vomiting, diarrhea, inappetence), behavior changes, and lethargy. Repeated use of meloxicam in cats is controversial, as repeated doses have been associated with renal failure and death. Recently, the FDA has changed the label in the USA to warn against repeated doses in cats. However, low dose chronic use is licensed in some countries and the ISFM & AAFP guidelines for long-term NSAID use in cats suggests that benefits of treatment often outweigh the risks (Sparkes et al. 2010).

Reproductive/Nursing Safety
Safe use has not been established in dogs or cats used for breeding, or in pregnant or lactating animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Most NSAIDs are excreted in milk; use cautiously.

Overdosage/Acute Toxicity
The manufacturer warns to prevent accidental overdosing in small dogs, and to administer drops on food and not directly into the mouth. Treat symptomatically and supportively.

Drug Interactions
The following drug interaction has either been reported or are theoretical in humans or animals receiving meloxicam and may be of significance in veterinary patients:

- **ACE INHIBITORS (e.g., enalapril, benazepril):** Some NSAIDs can reduce effects on blood pressure
- **ANTICOAGULANTS (e.g., heparin, warfarin, etc.):** Increased chance for bleeding
- **ASPIRIN:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS (e.g., prednisone):** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **DIGOXIN:** NSAIDs may increase serum levels
- **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans and potentially could also affect meloxicam levels in dogs
- **FLUCOSAMIDE:** NSAIDs may reduce sulfuric and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.):** May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

Doses
When doses are listed in “drops” use with caution, as drug concentration per drop may be different in products marketed in various countries.

**DOGS:**

For FDA-approved indications (osteoarthritis, analgesia, inflammatory conditions):

- Initially 0.2 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg PO once daily in food or placed directly into mouth (not when feeding)

**NEW ZEALAND:**

- Initially 0.1 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg once daily in food or placed directly into mouth (not when feeding)

**EUROPE:**

- Initially 0.1 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg once daily in food or placed directly into mouth (not when feeding)

**UNITED STATES:**

- Initially 0.1 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg once daily in food or placed directly into mouth (not when feeding)

**CANADA:**

- Initially 0.1 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg once daily in food or placed directly into mouth (not when feeding)

**BENEFITS:**

- Pain relief
- Inflammation reduction
- Improved mobility

**RISKS:**

- GI distress (vomiting, diarrhea, inappetence)
- Renal failure
- Hypotension
- Hypovolemia
- Hypotensive episodes in cats undergoing major surgery

**SIDE EFFECTS:**

- Vomiting
- Diarrhea
- Soft stools
- Inappetence
- GI ulceration
- Gastrointestinal bleeding

**CAUTIONS:**

- Use with caution in patients with impaired hepatic, cardiac or renal function and hemorrhagic disorders.
- Use preoperatively for cats undergoing major surgery where hypotensive episodes are possible; may be at higher risk for renal damage.
- Use with caution in patients with impaired hepatic, cardiac or renal function and hemorrhagic disorders.
- Use extreme caution in dehydrated, hypovolemic, or hypotensive animals as there is a potential increased risk of renal toxicity developing.
CATS:

For pain:

a) For labeled indications: 0.3 mg/kg as a single one-time administration subcutaneous dose that should not be followed by additional doses of meloxicam or other NSAIDs. (Label information; Metacam® Injection for Cats—BIVI)

b) 0.2 mg/kg PO initially, followed by 0.1 mg/kg PO (in food) once daily for 2 days and then 0.025 mg/kg 2–3 times a week (McLaughlin 2000)

c) Chronic musculoskeletal disorders: Initial treatment is a single oral dose of 0.1 mg meloxicam/kg body weight on the first day. Treatment is to be continued once daily by oral administration (at 24-hour intervals) at a maintenance dose of 0.05 mg meloxicam/kg body weight. A clinical response is normally seen within 7 days. Treatment should be discontinued after 14 days at the latest if no clinical improvement is apparent. (Metacam® Oral Suspension for Cats—BIVI-U.K.)

d) For surgical pain: 0.2 mg/kg (or less) PO or SC once; 0.1 mg/kg (or less) SC, PO daily for 3–4 days

For chronic pain: 0.2 mg/kg (or less) PO, SC once; 0.1 mg/kg (or less) PO for 3–4 days; 0.025 mg/kg PO (0.1 mg maximum dose per cat) 2–3 times weekly (Matthews 2000)

HORSES:

For inflammation and pain associated with musculoskeletal disorders or colic pain (IV):

a) IV: Single intravenous injection at a dosage of 0.6/kg body weight (i.e. 3 mL/100kg body weight); may follow with oral dosing after 24 hours. Oral: Either mixed with food or directly into the mouth at a dosage of 0.6 mg/kg body weight, once daily, up to 14 days. Where the product is mixed with food, it should be added to a small quantity of food, prior to feeding. Withdrawal periods: Meat/Offal: 5 days (Label Directions; Metacam® Injection & Oral Suspension for Horses—BIVI-U.K.)

SWINE:

For use in acute respiratory infection with appropriate antibiotic therapy to reduce clinical signs in cattle. For use in diarrhea, in combination with oral rehydration therapy, to reduce clinical signs in calves of over one week of age and young non-lactating cattle. For adjunctive therapy in the treatment of acute mastitis, in combination with antibiotic therapy:

a) Single SC or IV injection at a dose rate of 0.5 mg/kg body weight (i.e 2.5 mL/100 kg body weight) in combination with antibiotic therapy or with oral rehydration therapy as appropriate. U.K. Withdrawal periods: Meat/Offal: 15 days; Milk: 120 hours. (Metacam® Injection—BIVI-UK)

FERRIES:

a) For post-surgical pain: 0.2 mg/kg PO or SC once. (Schoemaker 2008)

For musculoskeletal and mild visceral pain:

a) 0.2 mg/kg PO or SC once daily. Has a duration of action for 24–48 hours in most species; may be used for prolonged periods of time; also very effective when used in combination with opioids. (Mayer 2007)

b) 0.2–0.3 mg/kg PO once daily (q24h). Doses of 0.2 mg/kg once daily for 10 days was well tolerated by rabbits studied. (Carpenter et al. 2009)

BIRDS:

a) As an analgesic: 0.5 mg/kg IM is also commonly used in birds and may be the safest of the NSAID analgesics for avian species. As the side effects of all analgesics have not been studied in birds, these drugs should be used carefully in avian patients. (Echols 2008)

b) As adjunctive treatment for proventricular dilatation disease (PDD): 0.1–0.5 mg/kg PO q12h. (Oglesbee 2008)

ZOO, EXOTIC, WILDLIFE SPECIES:

For use of meloxicam in zoo, exotic and wildlife medicine refer to specific references, including:

b) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

Monitoring

■ Clinical efficacy
■ Adverse effects
■ Renal function and hepatic function if used chronically

Note: The following dosages are extra-label in the USA and in 2010 the drug sponsor (BIVI-USA) and the FDA issued the following: WARNING: Repeated use of meloxicam in cats has been associated with acute renal failure and death. Do not administer additional doses of injectable or oral meloxicam to cats. See Contraindications, Warnings and Precautions for detailed information.

However, in another document published in 2010, the ISFM and AAFP Consensus Guidelines: Long-Term Use of NSAIDs in Cats, in their summary points they state: “It is only recently that NSAIDs have become licensed for long-term use in cats in some countries. The panel believe that these drugs have a major role to play in the management of chronic pain in cats, but at present only limited feline-specific data are available. To date, published studies of the medium- to long-term use of the COX-1 sparing drug meloxicam in older cats and cats with chronic kidney disease provide encouraging data that these drugs can be used safely and should be used to relieve pain when needed. While further data are needed, and would undoubtedly lead to refinement of the guidelines presented here, the panel hope that these recommendations will encourage rational and safe long-term use of NSAIDs in cats, thereby improving patients’ quality of life in the face of painful disease conditions.” (Sparkes et al. 2010)
Shake oral liquid well before using. Carefully measure dose (oral liquid); do not confuse the markings on the syringe (provided by the manufacturer) with mL or kgs. If using drops to measure dose in small dogs, do not place drops directly into dog's mouth; mix with food. Otherwise, may place oral syringe into dogs mouth or mix with food. If animal develops adverse effects, contact the veterinarian.

If dispensed for outpatient use, obtain client information sheet for this medication.

Chemistry/Synonyms
A COX-2 receptor preferential NSAID, meloxicam occurs as a pale yellow powder. It is in the oxicam class, related to piroxicam. Meloxicam may also be known as: UH-AC-62, and UH-AC-62XX; many trade names are available.

Storage/Stability
Unless otherwise labeled, store the injection and oral liquid at room temperature.

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:**
Meloxicam Oral Suspension: 1.5 mg/mL (0.05 mg per drop in the USA product) in a honey-flavored base: 10 mL, 32 mL, 100 mL dropper bottles with measuring syringe (marked in 5 lb body weight increments); **Metacam® (BIVI); (Rx).** FDA-approved for use in dogs.

Meloxicam 5 mg/mL for Injection: 10 mL vial; **Metacam® Injection for Dogs (BIVI); (Rx).** FDA-approved for use in dogs.

Meloxicam 5 mg/mL for Injection: 10 mL vial; **Metacam® Injection for Cats (BIVI); (Rx).** FDA-approved for use in cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
Meloxicam Tablets: 7.5 mg & 15 mg; **Mobic® (Boehringer Ingelheim/Abbott); generic; (Rx)**

Meloxicam Oral Suspension: 7.5 mg/5 mL in 100 mL; **Mobic® (Boehringer Ingelheim/Abbott); Meloxicam (Roxane); (Rx)**

In Canada, **Mobicox® (Boehringer Ingelheim); (Rx)**

References

MELPHALAN
(mel-fa-lan) Alkeran®
ANTINEOPLASTIC
Prescriber Highlights
- Alkylation agent antineoplastic used for ovarian carcinoma, lymphoreticular neoplasms, osteosarcoma, mammary or pulmonary neoplasms, & multiple myeloma
- Contraindications (relative; risk vs. benefit): Anemia, bone marrow depression, current infection, impaired renal function, tumor cell infiltration of bone marrow, sensitivity to drug, or patients who have received previous chemotherapy or radiotherapy
- Adverse Effects: GI effects (anorexia, vomiting, diarrhea), pulmonary infiltrates or fibrosis, bone marrow depression (anemia, thrombocytopenia, leukopenia)
- Potential teratogen
- Determine dosages carefully

Uses/Indications
Melphalan may be useful in the treatment of a variety of neoplastic diseases, including ovarian carcinoma, lymphoreticular neoplasms, osteosarcoma, and mammary or pulmonary neoplasms. When combined with prednisone, it is considered the drug of choice for treating multiple myeloma. It has been used successfully in a rescue protocol combining dexamethasone, melphalan, dactinomycin and cytarabine to treat relapsed multicentric lymphoma in dogs.

Pharmacology/Actions
Melphalan is a bifunctional alkylating agent and interferes with RNA transcription and DNA replication, thereby disrupting nucleic acid function. Because it is bifunctional, it has affect on both dividing and resting cells. Melphalan does not require activation by the liver (unlike cyclophosphamide).
Pharmacokinetics
Melphalan absorption is variable and often incomplete. It is distributed throughout the body water, but it is unknown whether it crosses the placenta, blood brain barrier or enters maternal milk. Melphalan is eliminated principally by hydrolysis in plasma. In humans, terminal half-lives average about 90 minutes.

Contraindications/Precautions/Warnings
Melphalan should be used with the following conditions only when its potential benefits outweigh its risks: anemia, bone marrow depression, current infection, impaired renal function, tumor cell infiltration of bone marrow, sensitivity to melphalan or patients who have received previous chemotherapy or radiotherapy.

Adverse Effects
The most serious adverse effect likely with melphalan is bone marrow depression (anemia, thrombocytopenia, leukopenia). Potential adverse effects include GI effects (anorexia, vomiting, diarrhea), pulmonary infiltrates or fibrosis, or neurotoxic effects.

Reproductive/Nursing Safety
Safe use of melphalan during pregnancy has not been established; other alkylating agents are known teratogens. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Melphalan can suppress gonadal function.

While it is unknown whether melphalan enters maternal milk, nursing puppies or kittens should receive milk replacer when the bitch or queen is receiving melphalan.

Overdosage/Acute Toxicity
Because of the toxic potential of this agent, overdoses must be avoided. Determine dosages carefully.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving melphalan and may be of significance in veterinary patients:

CYCLOSPORINE: There are anecdotal reports of melphalan causing increased nephrotoxicity associated with systemic cyclosporine use in humans.

IMMUNOSUPPRESSANT DRUGS (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection.

MYELOSUPPRESSIVE DRUGS (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.

VACCINES, LIVE: Live virus vaccines should be used with caution, if at all, during therapy.

Laboratory Considerations
■ Melphalan may raise serum uric acid levels. Drugs such as allopurinol may be required to control hyperuricemia.

Doses
Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

a) For multiple myeloma: Several dosing schedules have been developed to treat canine multiple myeloma with melphalan. One recommended dosing regimen is 0.1 mg/kg PO q24h for 10 days, followed by 0.05 mg/kg PO q48h thereafter. Another source recommends 0.25 mg/kg/day PO for 4 days and 2 to 4 mg/day PO maintenance. Pulse therapy is another reported option (7 mg/m2 PO q24h for 5 days every 21 days). The recommended intravenous dose is 16 mg/m2 every 2 weeks for 4 doses and then every 4 weeks. A 50% dose reduction is recommended for animals with preexisting renal insufficiency. Clinical response can be assessed by improved clinical signs and reduced serum immunoglobulin. Melphalan should be administered indefinitely until clinical relapse, which may involve worsened bone pain, recurrence of bleeding diathesis, funduscopic changes, or elevated serum immunoglobulins. (Kitchell & Wiedemann 2004)
b) As part of a rescue protocol (DMAC) to treat relapsed multicentric lymphoma: Dactinomycin (0.75 mg/m2 IV), Cytarabine (300 mg/m2 IV over 4 hours or SC) and dexamethasone (1 mg/kg PO) on day 0 and melphalan (20 mg/m2 PO) and dexamethasone (1 mg/kg PO) on day 7. The cycle is repeated continuously every 2 weeks as long as a complete or partial remission is achieved. After four cycles, chlorambucil was substituted for melphalan at the same dose. If complete remission achieved, protocol was discontinued after 5–8 cycles and maintenance therapy with the LMP (chlorambucil, methotrexate, prednisone) or lomustine/prednisone protocols were instituted. If dogs developed grades 3 or 4 toxicosis, DMAC was discontinued and maintenance protocol was started. (Alvarez et al. 2006; Rassnick 2006)

CATS:
For chronic lymphocytic leukemia:

a) 2 mg/m2 PO every other day with or without prednisone at 20 mg/m2 PO every other day (Peterson and Couto 1994)

Monitoring
■ CBC with platelets at least every week for 2 weeks and then monthly thereafter. Significant myelosuppression requires an alteration in dose or frequency of administration.

Client Information
■ Clients must understand the importance of both administering melphalan as directed and immediately reporting any signs associated with toxicity (e.g., abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.).

Chemistry/Synonyms
Meperidine is a primary pharmacologic agonist. It is approximately ⅓ –⅛ as potent as morphine, but produces equivalent respiratory depression at equi-analgesic doses as morphi ne. Meperidine is primarily a Mu agonist. It is approximately ½–⅓th as potent as morphine, but produces equivalent respiratory depression at equi-analgesic doses as morphine. Like morphine, it can cause histamine release. It does not have antitussive activity at doses lower than those causing analgesia. Meperidine is the only used opioid that has vagolytic and negative inotropic properties at clinically used doses. One study in ponies demonstrated changes in jejunal activity after meperidine administration, but no effects on transit time or colonic electrical activity were noted.

**Pharmacology/Actions**

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Meperidine is primarily a Mu agonist. It is approximately ⅓–⅛th as potent as morphine, but produces equivalent respiratory depression at equi-analgesic doses as morphine. Like morphine, it can cause histamine release. It does not have antitussive activity at doses lower than those causing analgesia. Meperidine is the only used opioid that has vagolytic and negative inotropic properties at clinically used doses. One study in ponies demonstrated changes in jejunal activity after meperidine administration, but no effects on transit time or colonic electrical activity were noted.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Melphalan Oral Tablets: 2 mg, Alkeran® (GlaxoSmithKline); (Rx)
Melphalan Powder for Injection (lyophilized): 50 mg in single use vials with 10 mL of sterile diluent; Alkeran® (GlaxoSmithKline); (Rx)

**Uses/Indications**

Although no product is licensed in the United States for veterinary use, this agent has been used as an analgesic in several different species. It has been used as sedative/analgesic in small animals for both post-operative pain and for medical conditions such as acute pancreatitis and thermal burns, but usually other opiates are preferred as the drug has a short analgesic duration of activity and can cause significant histamine release. It is occasionally used in equine medicine in the treatment of colic and in other large animal species for pain control.

**Pharmacology/Actions**

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Meperidine is primarily a Mu agonist. It is approximately ½–⅓th as potent as morphine, but produces equivalent respiratory depression at equi-analgesic doses as morphine. Like morphine, it can cause histamine release. It does not have antitussive activity at doses lower than those causing analgesia. Meperidine is the only used opioid that has vagolytic and negative inotropic properties at clinically used doses. One study in ponies demonstrated changes in jejunal activity after meperidine administration, but no effects on transit time or colonic electrical activity were noted.

**Storage/Stability**

Store melphalan tablets in well-closed, light-resistant, glass containers in the refrigerator (2–8°C). It is recommended to dispense the tablets in glass containers.

Once reconstituted, the injectable product should not be reconstituted or a precipitate may form. It is stable at room temperature for 90 minutes after reconstitution. For administration, the reconstituted solution should be further diluted with sterile 0.9% sodium chloride to a concentration of not more than 0.45 mg/mL. This diluted solution is stable for 60 minutes at room temperature.

**References**

Pharmacokinetics
Although generally well absorbed orally, a marked first-pass effect limits the oral effectiveness of meperidine. After injection by IM or subcutaneous routes the peak analgesic effects occur between 30–60 minutes, with the IM route having a slightly faster onset. Duration of action is variable with effects generally lasting from 1–6 hours in most species. In dogs and cats, analgesic duration of only <2 hours and often less than 1 hour at clinically used doses. The drug is metabolized primarily in the liver (mostly hydrolysis with some conjugation) and approximately 5% is excreted unchanged in the urine.

Contraindications/Precautions/Warnings
Meperidine is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, or in patients receiving monamine oxidase inhibitors (MAOIs). It is also contraindicated in patients with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s disease), and in geriatric or severely debilitated patients.

Many clinicians state that meperidine should not be administered intravenously. If given IV, it must be given very slowly or severe hypotension can result. Meperidine should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Opiate analgesics are also contraindicated in patients who have been stung by the scorpion species Centruroides sculpturatus Ewing and C. gertschi Stahnke as they may potentiate these venoms. Meperidine should not be used for pain secondary to envenomations from Gila monsters or Mexican beaded lizards (Hackett 2007).

Adverse Effects
Meperidine may be irritating when administered subcutaneously and must be given very slowly IV or it may cause severe hypotension. It can cause pronounced histamine release, particularly with IV administration. At usual doses, the primary concern is the effect the opioids have on respiratory function. Decreased tidal volume, depressed cough reflex, and the drying of respiratory secretions may all have a detrimental effect on a susceptible patient. Bronchoconstriction following IV doses has been noted in dogs. Gastrointestinal effects may include: nausea, vomiting, and decreased intestinal peristalsis. In dogs, meperidine causes mydriasis (unlike morphine). If given orally, the drug may be irritating to the buccal mucosa and cause salivation; this is of particular concern in cats. Chronic administration can lead to physical dependence.

In horses undergoing general anesthesia, meperidine has been associated with a reaction that manifests as tachycardia with PVC’s, profuse sweating, and hyperpnea.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Most opiates are excreted into milk. Meperidine enters human breast milk at concentrations slightly higher than those found in serum, but effects on nursing offspring may not be significant.

Overdosage/Acute Toxicity
In most species, overdosage may produce profound respiratory and/or CNS depression. Other effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Some species (especially cats) may demonstrate CNS excitability (hyperreflexia, tremors) and seizures at doses greater than 20 mg/kg. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as they may potentiate these venoms. Meperidine should not be used for pain secondary to envenomations from Gila monsters or Mexican beaded lizards (Hackett 2007).

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving meperidine and may be of significance in veterinary patients:

- CNS DEPRESSANTS, OTHER (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.): May cause increased CNS or respiratory depression when used with meperidine
- DIURETICS: Opiates may decrease efficacy in CHF patients
- ISONIAZID: Meperidine may enhance INH adverse effects
- MONAMINE OXIDASE (MAO) INHIBITORS (e.g., amitraz, possibly selegiline): Meperidine is contraindicated in patients receiving monamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors in humans. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.
- MUSCLE RELAXANTS, SKELETAL: Meperidine may enhance neuromuscular blockade
- TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Meperidine may exacerbate the effects of tricyclic antidepressants
- WARFARIN: Opiates may potentiate anticoagulant activity

Laboratory Considerations
- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses
- DOGS:
  Analgesic duration in dogs usually lasts 45 minutes to 1 hour.
a) 5–10 mg/kg IM, SC. Duration of effect is short (30–60 minutes) (Mama 2002)
b) For perioperative pain: 3–5 mg/kg IM or SC. Duration of action 1–2 hours (Pascoe 2000)
c) In healthy dogs: 3–4 mg/kg IM as a pre-med; 1–2 mg/kg IM post-op. (Trim 2008)

**CATS:**

For perioperative pain:
a) 3–5 mg/kg IM or SC. Duration of action 1–2 hours (Pascoe 2000)
b) 2–5 mg/kg IM, SC. Duration of effect is short (30 minutes to an hour) (Mama 2002)
c) In healthy cats: 3–4 mg/kg IM as a pre-med; 1–2 mg/kg IM post-op. (Trim 2008)

Not recommended for cats. (Scherk 2003)

**FERRETS:**
a) 5–10 mg/kg SC or IM every 2–3 hours (Williams 2000)

**RABBITS, RODENTS, SMALL MAMMALS:**

a) Rabbits: For moderate pain: 5–10 mg/kg SC, IM q2–3h. Using Banana flavored oral syrup: 0.2 mg/mL in drinking water (Ivey & Morrisey 2000)
b) Analgesic (patient administered moderate pain relief): 0.2 mg/mL in drinking water (Huerkamp 1995)

**CATTLE:**

As an analgesic:
a) 3.3–4.4 mg/kg SC or IM (Jenkins 1987)
b) 500 mg IM (Booth 1988)
c) 150–200 mg/100 lbs IM or SC (or slow IV) (McConnell & Hughey 1987)

**HORSES:**

**Note:** Narcotics (meperidine included) may cause CNS excitement in the horse. Some recommend pretreatment with acepromazine (0.02–0.04 mg/kg IV), or xylazine (0.3–0.5 mg/kg IV) to reduce the behavioral changes caused by these drugs. **Warning:** Narcotic analgesics can mask the behavioral and cardiovascular signs associated with mild colic.

As an analgesic:
a) 2–4 mg/kg IM or IV (may cause excitement and hypotension with IV use) (Jenkins 1987)
b) 500 mg (total dose) IV (slowly, CNS excitement may occur) or 1000 mg (total dose) IM (Booth 1988)

**SWINE:**

As a restraining agent:
a) Given alone the drug does not give much restraint in large animals. Has been used in combination with promazine (2 mg/kg IM) and atropine (0.07–0.09 mg/kg IM) at a dose of 1–2 mg/kg IM as a preanesthetic 45–60 minutes before barbiturate/inhalant anesthesia. All the above should be given in separate sites (Booth 1988)

As an analgesic:
a) 2 mg/kg IM q4h IM as needed (Jenkins 1987)

**SHEEP & GOATS:**

As an analgesic:
a) Up to 200 mg total dose IM (Jenkins 1987)

**Monitoring**

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity

**Client Information**

- Oral dosage forms may cause mouth irritation.
- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

**Chemistry/Synonyms**

A synthetic opiate analgesic, meperidine HCl is a fine, white, crystalline, odorless powder that is very soluble in water, sparingly soluble in ether and soluble in alcohol. It has a pKa of 7.7–8.15 and a melting range of 186–189°C. The pH of the commercially available injectable preparation is between 3.5 and 6.

Meperidine HCl may also be known as: pethidine HCl, isonipecaine, meperidine hydrochloride, pethidini hydrochloridum; Alodan®, Centralgine®, Demerol®, Dolantin®, Dolantina®, Dolantine®, Dolestine®, or Dolosal®.

**Storage/Stability**

Meperidine is stable at room temperature. Avoid freezing the injectable solution and protect from light during storage. Meperidine has not exhibited significant adsorption to PVC IV bags or tubing in studies to date.

**Compatibility/Compounding Considerations**

Meperidine is reported to be physically compatible with the following fluids and drugs: sodium chloride 0.45 and 0.9%, Ringer’s injection, lactated Ringer’s injection,
Mercaptopurine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or a history of urate urinary stones.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

Meperidine HCl Injection: 25 mg/mL in 1 mL vials, amps & 1 mL Carpuject syringes; 50 mg/mL in 1 mL vials, 0.5 mL, 1 mL, 1.5 mL and 2 mL amps, 30 mL multidose vials and 1 mL Carpuject syringes; 75 mg/mL in 1 mL vials, amps & 1 mL Carpuject syringes; 100 mg/mL in 1 mL vials & amps, 20 mL multidose vials and 1 mL Carpuject syringes; Demerol® (Abbott); generic, (Rx, C-II)

Meperidine HCl Tablets: 50 mg & 100 mg; Demerol® (Sanofi-Synthelabo); generic; (Rx, C-II)

Meperidine HCl Syrup/Oral Solution: 50 mg/5 mL in 473 mL & 500 mL, Demerol® (Sanofi-Synthelabo); generic (Roxane); (Rx, C-II)

**Note:** Meperidine is listed as a Class-II controlled substance and all products require a prescription. Very accurate record keeping is required as to use and disposition of stock.

**Uses/Indications**

Rarely used in veterinary medicine. Veterinary uses of mercaptopurine have included adjunctive therapy of lymphosarcoma, acute leukemias, & severe rheumatoid arthritis or other autoimmune conditions (e.g., unresponsive ulcerative colitis)

**Pharmacology/Actions**

Intracellularly, mercaptopurine is converted into a ribonucleotide that acts as a purine antagonist, thereby inhibiting RNA and DNA synthesis. Mercaptopurine acts as an immunosuppressant, primarily inhibiting humoral immunity.

**Pharmacokinetics**

Absorption after oral dosing is variable and incomplete. Absorbed drug and its metabolites are distributed throughout the total body water. The drug crosses the blood-brain barrier, but not in levels significant enough to treat CNS neoplasms. It is unknown whether mercaptopurine enters milk.

Via the enzyme, xanthine oxidase, mercaptopurine is rapidly metabolized in the liver to 6-thiouric acid, which along with the parent compound and other metabolites are principally excreted in the urine.

**Contraindications/Precautions/Warnings**

Mercaptopurine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or a history of urate urinary stones.
Adverse Effects
At usual doses, GI effects (nausea, anorexia, vomiting, diarrhea) are most likely seen in small animals. However, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, and dermatologic reactions are, potentially, possible.

Reproductive/Nursing Safety
Mercaptopurine is mutagenic and teratogenic and is not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category D for use during pregnancy. (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) It is not known whether mercaptopurine is excreted in milk, but use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity
Toxicity may present acutely (GI effects) or be delayed (bone marrow depression, hepatotoxicity, gastroenteritis). It is suggested to use standard protocols to empty the GI tract if ingestion was recent and to treat supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving mercaptopurine and may be of significance in veterinary patients:

- **ALLOPURINOL:** The hepatic metabolism of mercaptopurine may be decreased by concomitant administration of allopurinol. In humans, it is recommended to reduce the mercaptopurine dose to ¼–⅓ usual if both drugs are to be used together.
- **AMINOSALICYLATES (mesalamine, sulfasalazine):** May increase risk for mercaptopurine toxicity
- **HEPATOTOXIC DRUGS (e.g., halothane, ketoconazole, valproic acid, phenobarbital, primidone, etc.):** Mercaptopurine should be used cautiously with other drugs that can cause hepatotoxicity. In humans, one study demonstrated increased hepatotoxicity when mercaptopurine was used in conjunction with doxorubicin.
- **IMMUNOSUPPRESSIVE DRUGS (e.g., azathioprine, cyclophosphamide, corticosteroids):** Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS (e.g., antineoplastics, chloramphenicol, flucytosine, amphotericin B, colchicine, etc.):** Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive. In humans, enhanced bone marrow depression has occurred when used concomitantly with trimethoprim/sulfa.
- **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all, during therapy
- **WARFARIN:** Mercaptopurine may reduce anticoagulant effect

Laboratory Considerations
- Mercaptopurine may give falsely elevated *serum glucose* and *uric acid* values when using a SMA (sequential multiple analyzer) 12/60.

Doses
**DOGS:**
- a) As an immunosuppressant in combination with corticosteroids for treating bullous pemphigoid: 2.2 mg/kg once daily (q24h), then q48h. (Swartout 2004)
- b) For erosive, immune-mediated polyarthritis in combination with corticosteroids: 2 mg/kg PO once daily (q24h) for 14–21 days, then q48h (every other day). (Beale & Worley 2004)
- c) For treatment of immune-mediated diseases or acute lymphocytic and granulocytic leukemias: 50 mg/m2 PO once daily (q24h) to effect, then every other day (q48h) or as needed. (Jacobs *et al.* 1992)

Monitoring
- Hemograms (including platelets) should be monitored closely; initially every 1–2 weeks and every 1–2 months once on maintenance therapy. It is recommended by some clinicians that if the WBC count drops to between 5,000–7,000 cells/mm$^3$ the dose be reduced by 25%. If WBC count drops below 5,000 cells/mm$^3$ treatment should be discontinued until leukopenia resolves.
- Liver function tests; serum amylase, if indicated
- Efficacy

Client Information
- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality.
- Clients should contact veterinarian should the animal exhibit signs of abnormal bleeding, bruising, anorexia, vomiting, or infection.
- Although, no special precautions are necessary with handling intact tablets, it is recommended to wash hands after administering the drug.

Chemistry/Synonyms
A purine analog, mercaptopurine occurs as a slightly yellow, crystalline powder. It is insoluble in water and has a pKa of 7.6.

Mercaptopurine may also be known as: 6-mercaptopurine, 6-MP, 6MP, mercaptopurinum, NSC-755, purinethiol, WR-2785, Flocofil®, Ismipur®, Mercap®, Mercaptina®, Puri-Nethol®, Purinethol®, and Varimer®.

Storage/Stability
Mercaptopurine tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS: None**
MEROPENEM
(mare-oh-pen-ehm) Merrem I.V.®
CARBAPENEM ANTIBIOTIC

Prescriber Highlights

- Carbapenem antibiotic similar to imipenem, but does not cause seizures & may be more effective against some resistant gram-negative infections
- Can be administered more rapidly and with less volume than imipenem
- Use should be reserved for documented resistant infections &/or when aminoglycosides not indicated (renal dysfunction, CNS infections)
- Seems well-tolerated in animal patients
- Must be given IV or SC
- Price is decreasing as now available as a generic

Uses/Indications
Meropenem may be useful in treating resistant gram-negative bacterial infections, particularly when aminoglycoside use would be risky (i.e., renal failure) or not effective (i.e., resistance or CNS infections).

Pharmacology/Actions
Meropenem has a broad antibacterial spectrum similar to that of imipenem, but meropenem is more active against Enterobacteriaceae and less so against gram-positive bacteria. Oxacillin-resistant Staphylococcus are usually resistant to meropenem. Because meropenem is more stable to renal dehydropeptidase-I than is imipenem, it does not require the addition of cilastatin to inhibit that enzyme. Meropenem may also have less potential to induce seizures than imipenem or ertapenem.

Pharmacokinetics
Meropenem must be administered via parenteral means. After SC injection in dogs, bioavailability is 84%. After IV injection in dogs, meropenem’s volume of distribution is approximately 0.37 L/kg and protein binding about 12%; half-life ≈ 40 minutes, and clearance ≈ 6.5 mL/min/kg. Concentrations of unbound drug in tissue fluid and plasma are similar.

In ewes, after IM injection meropenem was rapidly absorbed and had a bioavailability equal to that of intravenous dosing. Volume of distribution at steady state was 0.06 L/kg and protein binding about 43%; elimination half-life was about 43 minutes. 91% of the drug was recovered in the urine over 24 hours after IM injection.

Pharmacokinetic data for humans include: wide distribution in body tissues and fluids, including into the CSF and bile; very low protein binding ≈ 2%; in patients with normal renal function, elimination half-life is about an hour. One inactive metabolite has been identified, but the majority of the drug is eliminated via renal mechanisms (tubular secretions and glomerular filtration) and 70% of a dose is recovered unchanged in the urine over 12 hours.

Contraindications/Precautions/Warnings
Meropenem is contraindicated in patients hypersensitive to it or other carbapenems, and those that have developed anaphylaxis after receiving any beta-lactam antibiotic.

Adverse Effects
Meropenem is usually very well tolerated. Animals given the drug SC may show slight hair loss over injection sites. In human patients receiving meropenem, only GI effects (nausea, vomiting, diarrhea) have been reported to occur in greater than 1% of patients treated.

Reproductive/Nursing Safety
In humans, meropenem is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Meropenem is likely safe to use during lactation.

Overdosage/Acute Toxicity
Overdoses of meropenem are unlikely to occur in patients with normal renal function. In human trials, doses of 2 grams every 8 hours failed to demonstrate any significant adversity. Should an overdose occur, the drug can be discontinued if necessary or the next dose could be delayed by a few hours. Meropenem can be removed via hemodialysis when necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving meropenem and may be of significance in veterinary patients:
AMINOGLYCOSIDES: In vitro evidence of synergy against Pseudomonas aeruginosa

PROBENECID: May increase serum concentrations and elimination half-life of meropenem

Laboratory Considerations
- No specific laboratory interactions were noted for meropenem.

Doses

**DOGS/CATS:**

For treatment of susceptible infections:

- For bacteremia/sepsis: 24 mg/kg IV q24h (once daily) or 12 mg/kg SC q8h; For UTI: 12 mg/kg SC q12h;
- For CNS infections: 40 mg/kg IV or SC q8h. This dose is extrapolated from children and maximum dose per administration is 2 grams. To help prevent development of resistant strains that might infect humans, use should be limited or avoided unless ultimately necessary. (Greene et al. 2006)
- b) For systemic infections: 12 mg/kg q8h SC or 24 mg/kg IV q24h (once daily); for urinary tract infections 12 mg/kg q12h SC (Papich 2002)
- c) 125 mg (total dose) for small dogs and cats q8h IV or SC; 250 mg q8h IV or SC for medium dogs; 500 mg q8h IV or SC for large (>100 lbs.) dogs. **Note:** If serum creatinine greater than 4, may be given q12h. (Aucoin 2002)
- d) Cats: 8 mg/kg IV or SC q8h. (Hawkins 2009)

Monitoring
- There are no specific monitoring requirements for meropenem except to monitor for clinical efficacy.

Client Information
- This drug is generally used on an inpatient basis usually because of the seriousness of the infections treated, but clients could give SC injections at home, particularly when treating urinary tract infections.

Chemistry/Synonyms
- A synthetic carbapenem antibiotic, meropenem occurs as a clear to white to pale yellow powder or crystals. It is very slightly soluble in water or hydrated alcohol and practically insoluble in acetone or ether. When the commercially available injection is reconstituted the resulting pH is between 7.3 and 8.3.
- Meropenem may also be known as: ICI-194660, SM-7338, Meronem®, Meropen®, Merrem®, Optinem®, or Zeropenem®.

Storage/Stability
- The powder for injection should be stored at controlled room temperature (20–25°C; 69–77°F). When the commercially available powder for injection is reconstituted with sterile water for injection (up to a concentration of 50 mg/mL), it is stable (per the manufacturer) for up to 2 hours at room temperature; up to 12 hours when refrigerated. The package insert lists several options for dilution with several different solutions in plastic IV bags, syringes, minibags, etc. The longest time the drug the manufacturer states the drug is stable, is 48 hours when diluted in normal saline or sterile water for injection at concentrations from 1–20 mg/mL in plastic syringes and kept refrigerated.
- The manufacturer recommends that solutions of meropenem not be frozen, but meropenem concentrations of 1 and 22 mg/mL in dextrose 5% and sodium chloride 0.9% have been stored frozen at -20°C for up to 14 days with a calculated loss of potency of 10%.
- For subcutaneous administration in veterinary patients, meropenem has been diluted to a concentration of 20 mg/mL in sterile sodium chloride 0.9%. The solution should be protected from light and is reportedly stable if kept refrigerated for up to 96 hours. Once the refrigerated solution is brought back to room temperature it should be used within 6 hours. (Jordan 2004)

Compatibility/Compounding Considerations
- Meropenem has been reported compatible with vancomycin, ranitidine, morphine sulfate, metoclopramide, heparin, gentamicin, furosemide, dopamine, dobutamine, dexamethasone sodium phosphate, atropine, and aminophylline. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Meropenem Powder for solution for Injection: 500 mg & 1 gram in 20 mL, & 30 mL vials; Merrem® I.V.; (AstraZeneca); generic (Rx)

References

**METERGOLINE**
- (meh-tir-go-lin) Contralac®, Liserdol®
- SEROTONIN ANTAGONIST; PROLACTIN INHIBITOR

Prescriber Highlights
Serotonin antagonist prolactin inhibitor used primarily for pseudopregnancy in dogs
Not available commercially in USA
Primary adverse effects are GI (esp. vomiting) and behavior-related

Uses/Indications
Metergoline is an ergot-derivative drug that is used for pseudopregnancy in dogs. It is available as a veterinary product in several European and South American countries. It has been investigated as an abortifacient in dogs at high doses (0.4–0.6 mg/kg), similar to other ergot prolactin inhibitors it can only used reliably for this effect during the last 3 weeks of gestation (Nothling et al. 2003).

In humans, metergoline has been used for hyperprolactemia, prolactinomas, and for the prophylactic treatment of migraine headaches.

Pharmacology/Actions
Metergoline reduces prolactin primarily via its serotonin antagonism effects. It differs from cabergoline and bromocriptine in that it has both strong central and peripheral anti-serotonin effects, and only weak direct dopamine-2 agonist effects. Like those drugs, it also is an antagonist at dopamine-1 receptors. Potentially, metergoline could be used to induce estrus or treat pyometra in bitches.

Pharmacokinetics
Little information was located for dogs. Metergoline half-life is reportedly quite short (approx. 4 hours) and twice daily dosing is required.

In humans, metergoline oral bioavailability is about 25% and volume of distribution is 0.8 L/kg. It is metabolized in the liver to at least one active metabolite (1-desmethylmetergoline) which attains plasma levels higher than that of the parent drug. Elimination half-life of the parent drug is about 50 minutes; 1-desmethylmetergoline, 80-100 minutes.

Contraindications/Precautions/Warnings
Metergoline is contraindicated in dogs and cats that are pregnant unless abortion is desired (see indications). It should not be used in patients who are hypersensitive to ergot derivatives. Patients that do not tolerate cabergoline or bromocriptine may or may not tolerate metergoline. Patients with significantly impaired liver function should receive the drug with caution and, if required, possibly at a lower dosage.

Adverse Effects
Reported adverse effects for metergoline in dogs include behavior-related effects (anxiety, aggressiveness, depression, hyperexcitation, whining and escaping) and GI effects (anorexia, vomiting, nausea).

Reproductive/Nursing Safety
Metergoline is contraindicated in dogs and cats that are pregnant unless abortion is desired (see indications). Because it suppresses prolactin, it should not be used in nursing mothers.

Overdosage/Acute Toxicity
Little information is available. Vomiting is the most likely effect that would be seen in overdose situations.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving metergoline and may be of significance in veterinary patients:

» BROMOCRIPTINE, CABERGOLINE: May cause additive effects if used with metergoline

» CYPROHEPTADINE: May cause additive effects if used with metergoline

» METOCLOPRAMIDE: Use with metergoline may reduce the efficacy of both drugs and should be avoided

» SSRIS (e.g., fluoxetine, paroxetine, sertraline, etc.): Potentially could reduce the efficacy of each drug

Laboratory Considerations
No particular laboratory interactions or considerations were located for this drug.

Doses

» DOGS:

For treatment of pseudopregnancy:

a) 0.5 mg/kg (500 micrograms/kg) PO twice a day. Administration for 4-5 days is effective in treating pseudopregnancy signs and reducing milk production in most bitches. Occasional failures can be dealt with by repeating the treatment protocol and extending it to 8 to 10 days, or by using joint protocols of cabergoline plus metergoline or cabergoline plus bromocriptine. (Romagnoli 2009)

b) The recommended dose is 0.1 mg/kg, PO twice a day for 8 to 10 days. (Gobello et al. 2001)

c) In the study, dogs were given 0.1 mg/kg q12h PO with food for 10 days. At day 14 in the treatment group, 10 of 14 dogs had a full remission, and 3 of 14 dogs had partial (intermediate) remission of signs. In the treatment group, side effects were limited to hyperexcitation and nausea, did not lead to termination of therapy, and gradually dissipated during the second week of the protocol. (Castex et al. 2002)

To induce estrus:

a) Cabergoline and bromocriptine have consistently given positive results, while metergoline’s results have been more variable depending on dosage. Using low dose (0.1 mg/kg PO twice a day) the commercial oral preparation of metergoline administered from 100 days after ovulation until the following proestrus, the
interoestrous interval can be significantly shortened (Romagnoli 2006).

CATS:
For treatment of pseudopregnancy or to halt post-partum lactation:
   a) 0.125 mg/kg PO twice a day for 4–8 days. (Label Information—Contralac®; Virbac-Switzerland)

Monitoring
■ Efficacy and adverse effects
■ If used long term, liver function tests

Client Information
■ Give this medication with food; contact veterinarian if vomiting persists
■ Keep this an all medications away from pets and animals

Chemistry/Synonyms
Metergoline is an ergot derivative and has the chemical name: Benzyl (8S,10S)-(1,6-dimethylergolin-8-ylmethyl)carbamate.
   Metergoline may also be known as: FI-6337, MCE, Metergolini, Metergolin, Metergolina, Métergoline,Metergolinum, or Methergoline. A common trade name is Contralac® (veterinary) and Liserdol® (human).

Storage/Stability
Metergoline tablets should be stored at room temperature; protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
None in the USA, in several countries in Europe and South America: Metergoline 0.5 mg & 2 mg oral tablets are available; Contralac® (Virbac)

HUMAN-LABELED PRODUCTS:
None in USA. In some countries: Metergoline 4 mg tablets are available.

References

METFORMIN HCL
(met-fore-min) Glucophage®
ANTHYPERGLYCEMIC

Prescriber Highlights
■ Oral anti-hyperglycemic agent that potentially could be useful in the adjunctive treatment of non-insulin dependent diabetes mellitus (NIDDM) in cats; use is controversial and unlikely to be of benefit
■ Potentially useful for treating insulin resistance in horses, but has a negative pharmacokinetic profile (low PO bioavailability; fast half-life)
■ Contraindicated in patients hypersensitive to it; with renal dysfunction, metabolic acidosis, or temporarily when iodinated contrast agents are to be used (see Drug Interactions)
■ Adverse effects may include lethargy, inappetence, vomiting, & weight loss
■ Potentially significant drug interactions
■ Human dosage forms may be difficult to accurately dose in cats

Uses/Indications
Metformin may be useful in the adjunctive treatment of non-insulin dependent diabetes mellitus in cats. Only limited trials of the drug have been performed in cats, with only very limited success when the drug is used alone. Studies comparing its safety and efficacy with other oral antihyperglycemics (e.g., glipizide or insulin) were not located.
   There has been some research evaluating metformin for treating insulin resistance in horses.

Pharmacology/Actions
Metformin’s actions are multifaceted. At usual dosages, it increases insulin’s ability to transport glucose across cell membranes in skeletal muscle without increasing lactate production and inhibits formation of advanced glycosylation end-products. Metformin decreases hepatic glucose production, and may decrease intestinal absorption of glucose. It does not stimulate insulin production or release from the pancreas and, therefore, does not cause hypoglycemia.
Pharmacokinetics
A pharmacokinetic study done in cats (Chastain et al. 1999) showed that metformin is variably absorbed after oral administration 35–67%. In cats, steady-state volume of distribution was 0.55 L/kg; elimination half-life about 12 hours and total clearance was 0.15 L/hr/kg. Metformin is primarily eliminated via the kidneys. The authors concluded that the drug’s pharmacokinetics are similar to that seen in humans, and that a dosage of 2 mg/kg twice daily would give plasma concentrations known to be effective in humans.

In a small (4 subjects) pharmacokinetic study in horses, metformin demonstrated very low oral bioavailability (4% fed, 7% fasted). Maximum blood levels were around 0.4 micrograms/mL. Elimination half-life after IV dosing was about 25 minutes. (Hustace et al. 2009)

Contraindications/Precautions/Warnings
In humans (and presumably cats), metformin is contraindicated in patients hypersensitive to it, with renal dysfunction or metabolic acidosis. It is also temporarily contraindicated when iodinated contrast agents are to be used (see Drug Interactions).

Adverse Effects
In cats, metformin may cause lethargy, inappetence, vomiting, and weight loss. In a study evaluating metformin in diabetic cats (Nelson et al. 2004), 1 of 5 diabetic cats studied died 11 days after receiving metformin. As the cause of death was undetermined, metformin could not be ruled out as a causative factor. Hypoglycemia would not be an expected adverse effect when metformin is used as a single agent.

Reproductive/Nursing Safety
In pregnant humans, metformin is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Metformin is excreted in maternal milk in levels equivalent to those found in plasma. While adverse effects in nursing kittens would be unlikely, use with caution in lactating queens.

Overdosage/Acute Toxicity
Massive overdoses in humans (100 grams) caused hypoglycemia only 10% of the time, but lactic acidosis occurred. Lactic acidosis has been seen in human overdoses of 7 and 20 grams (total dose). It is unknown at what dose acidosis may occur in domestic animals. Ingestion of up to 1700 mg by children is not usually associated with significant toxicity.

There were 243 exposures to metformin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 231 were dogs with 27 showing clinical signs and the remaining 12 cases were cats with 2 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting and diarrhea.

In small animals hypoglycemia is not commonly seen in overdoses of metformin alone. It has a narrow margin of safety regarding GI upset. GI upset commonly occurs with ingestions of metformin in small animals.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving metformin and may be of significance in veterinary patients:

ACE INHIBITORS: May increase risk for hypoglycemia
CIMETIDINE: In humans, cimetidine can cause a 60% increase in peak metformin plasma levels and a 40% increase in AUC
CORTICOSTEROIDS: May reduce efficacy
DIURETICS, THIAZIDE: May reduce hypoglycemic efficacy
FUROSEMIDE: Can increase the AUC and plasma levels of metformin by 22% in humans; metformin can decrease the peak plasma concentrations and AUC of furosemide
IODINATED CONTRAST AGENTS, PARENTERAL: May cause acute renal failure and lactic acidosis if used within 48 hours of a metformin dose
ISONIAZID: May reduce hypoglycemic efficacy
SYMPATHOMIMETIC AGENTS: May reduce hypoglycemic efficacy

Laboratory Considerations
No specific laboratory interactions or considerations noted.

Doses
CATS:
a) The author states that “metformin has been shown toxic to cats and should not be used. It is also ineffective.” (Greco 2007)
b) For cats with non-insulin dependent diabetes mellitus (patients with detectable concentrations of insulin): 50 mg (total dose) per cat PO twice daily; may be efficacious only in cats with detectable concentrations of insulin at time of treatment (Nelson et al. 2004)
c) For early NIDDM: 2 mg/kg PO q12h (Melendez & Lorenz 2002)

BIRDS:
a) Recommended dosages include 100–500 mg/L of drinking water. (Lightfoot 2008)

Monitoring
Efficacy: Standard methods of monitoring efficacy for diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution, and perhaps serum fructosamine and/or glycosylated hemoglobin levels)
Renal function (baseline and annually)
Adverse effects
Adverse effects

Clients should understand the relative “investigational” nature of using this compound in cats and report any untoward effects to the veterinarian.

Chemistry/Synonyms

A biguanide oral anti-hyperglycemic agent, metformin HCl occurs as white to off-white crystals that are slightly soluble in alcohol and freely soluble in water. It is a weak base; a 1% aqueous solution of metformin HCl has a pKa of 6.68 and metformin base has a pKa of 12.4. Metformin HCl may also be known as dimethylbiguanide HCl or metformin hydrochloridium. There are many proprietary names outside of the USA for this drug.

Storage/Stability

Metformin HCl oral products (oral tablets, sustained-release tablets, and fixed dose combination products with glipizide or rosiglitazone) should be stored protected from light at a controlled room temperature of 20–25°C (68–77°F), excursions permitted to 15–30°C (59–86°F). The combination product containing metformin HCl and glyburide should be stored at temperatures up to 25°C (77°F) and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Metformin HCl Oral Tablets: 500 mg, 850 mg & 1000 mg; Glucophage® (Bristol-Myers Squibb); generic; (Rx)

Metformin HCl Extended-Release Oral Tablets: 500 mg, 750 mg & 1000 mg; Glucophage XR® (Bristol-Myers Squibb); Glumetza® (Depomed); Fortamet® (First Horizon); generic; (Rx)

Metformin HCl Oral Solution: 500 mg/5 mL in 118 mL & 473 mL; Riomet® (Ranbaxy); (Rx)

The are also fixed-dose oral tablet combination products available containing metformin and glyburide or glipizide.

References

METHADONE HCL

(meth-a-done) Dolophine®

OPIATE AGONIST

Prescriber Highlights

- Narcotic agonist that may be used as an alternative to morphine in dogs, cats
- Causes less histamine-release (with IV), sedation & vomiting than morphine
- Depending on country, may be significantly more expensive than morphine
- C-II controlled substance in USA

Uses/Indications

Methadone may be used as an alternative opioid preanesthetic or analgesic in dogs or cats. It is also being investigated for epidural use for horses. Poor oral bioavailability precludes oral dosing in dogs.

Pharmacology/Actions

In small animals methadone acts similarly to morphine with regard to its degree of analgesia and duration of action. Methadone is a mu-receptor agonist that also is a non-competitive inhibitor of NMDA (n-methyl-d-aspartate) receptors. Methadone can also reduce re-uptake of norepinephrine and serotonin which may contribute to its analgesic effects. Due to these other actions, methadone potentially may be more efficacious than other mu agonists (e.g., morphine) particularly for neuropathic or chronic pain. Methadone is more lipid-soluble than is morphine and approximately 1–1.5 times as potent. It does not cause significant histamine release when administered intravenously.

Refer to the monograph: Narcotic (opiate) Analgesic Agonists, Pharmacology of, for more information.

Pharmacokinetics

Limited information is available on the pharmacokinetics of methadone in domestic animals. In dogs, methadone has poor oral bioavailability and ketoconazole or omeprazole do not significantly affect oral bioavailability. Unlike in humans, CYP3A does not appear to be a major metabolic pathway for methadone biotransformation in dogs (KuKanich et al. 2005). Subcutaneous administration has a bioavailability of about 80% and peak levels occur around an hour after dosing. Terminal elimination half-life after intravenous dosing is about 1.75–4 hours in dogs; clearance is about 25-30 mL/kg/min. After SC administration, half-life is closer to 11 hours, but there was wide inter-patient variation. (Ingvast-Larsson et al. 2010).

In horses, orally administered methadone appears to be well absorbed, but is rapidly eliminated (half-life around 1 hour) (Linardi et al. 2008).

In humans, methadone is well absorbed from the GI tract (PO), and after subcutaneous or intramuscular injection. It is widely distributed and extensively bound to
Laboratory Considerations

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with heart failure, hypertension, head injuries, elevated CSF pressures, and in geriatric or severely debilitated patients.

Contraindications

Adverse Effects

Adverse effects from methadone can include panting, whining, sedation, defecation, constipation, bradycardia, and respiratory depression. Methadone tends to cause less sedation or vomiting than morphine.

Methadone in cats appears to cause less excitation or vomiting than some other μ-opioid agonists. In horses, methadone at IV doses of 0.1 mg/kg or greater has caused pronounced CNS excitement.

Reproductive/Nursing Safety

Methadone is relatively safe to use at low dosages for short periods during the first two trimesters of pregnancy, but it should be avoided late in term as significant respiratory depression and increased rates of stillbirths have been noted in humans. Infants of women who have been taking methadone for opiate addiction, have shown high rates of moderate to severe opiate withdrawal signs during the neonatal period, and long-term developmental problems.

Although methadone enters maternal milk, the American Academy of Pediatrics considers methadone compatible with breast-feeding in women.

Overdosage/Acute Toxicity

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Other toxic effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated. Animals should be closely observed since naloxone’s effects might diminish before sub-toxic levels of methadone are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression. Dialysis, charcoal hemoperfusion, or forced diuresis do not appear to be beneficial in treating methadone overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methadone and may be of significance in veterinary patients:

- **ANTIARRHYTHMICS, CLASS I & III** (e.g., lidocaine, procainamide, quinidine, amiodarone): Use with methadone may increase risks for arrhythmias
- **ALPHA2-AGONISTS** (e.g., medetomidine, xylazine): In a small study done in dogs, methadone potentiated the sedative and analgesic effects of medetomidine in dogs, but severe hypoxemia was seen in dogs breathing room air (Raekallio et al. 2009). Results from another study combining xylazine and methadone, suggested that methadone is a good alternative for sedation in dogs when combined with acepromazine or xylazine. A satisfactory degree of sedation was achieved with both combinations. The combination of methadone and xylazine appeared to result in better analgesia compared to xylazine alone (Monteiro et al. 2008).
- **AZOLE ANTIFUNGALS** (fluconazole, itraconazole, ketoconazole): May increase methadone levels (Does not appear to be true for dogs)
- **CALCIUM CHANNEL BLOCKERS**: Use with methadone may increase risks for arrhythmias
- **CNS DEPRESSANTS, OTHER** (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.): May cause increased CNS or respiratory depression when used with methadone
- **CORTICOSTEROIDS** (MINERALOCORTICOIDs): Use with methadone may increase potential for electrolyte abnormalities
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May inhibit metabolism of methadone and increase levels (Does not appear to be true for dogs)
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly selegiline): Meperidine with MAOIs in humans has caused severe CNS/behavior reactions and potentially could do the same with methadone; avoid concomitant use
- **MUSCLE RELAXANTS, SKELETAL**: Methadone may enhance neuromuscular blockade
- **PHENOBarBITAL, PHENyTOIN**: May decrease methadone levels (Probably does not affect dogs)
- **RIFAMPIN**: May decrease methadone levels (Probably does not affect dogs)
- **SSRI ANTIDEPRESSANTS** (fluoxetine, sertraline, etc.): May increase methadone levels
- **ST JOHN'S WORT**: May decrease methadone levels ( Probably does not affect dogs)
- **TRICYCLIC ANTIDEPRESSANTS** (clomipramine, amitriptyline, etc.): Methadone may exacerbate the effects of tricyclic antidepressants
- **WARFARIN**: Opiates may potentiate anticoagulant activity
- **ZIDOVUDINE**: Methadone may increase zidovudine levels

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma **amylase** and **lipase** values up to 24 hours following their administration.

Doses

- **DOGS:**
  a) As a pre-anesthetic: 0.2–0.5 mg/kg SC, IM; or a combination of methadone 0.1–0.3 mg/kg with acepromazine 0.02–0.05 mg/kg SC, IM (Cornell 2004)
  b) For pain: 0.1–0.25 mg/kg IM, SC, IV. Duration of effect 4–6 hours. (Otero 2006)
  c) For perioperative pain control: 0.1–0.5 mg/kg IM or SQ; duration of effect is 2–4 hours. (Pascoe 2006)
  d) For analgesia: 0.5 mg/kg IV q6h or 0.5–1 mg/kg q6-8h IV, IM or SC. (Posner & Papich 2009)
- **CATS:**
a) For perioperative pain control: 0.05–0.5 mg/kg IV, IM or SC q4–6h (Tranquilli 2003)
a) For an analgesic: 0.1–0.2 mg/kg PO. Anecdotal; author has not prescribed this drug. (Sellon 2007)

Monitoring
- Analgesic or preanesthetic efficacy
- At higher dosages, monitor for respiratory depression

Client Information
- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.
- If being used orally for pain control, be sure to keep out of reach of children and pets.

Chemistry/Synonyms
A synthetic diphenylheptane-derivative narcotic agonist, methadone HCl occurs as an odorless, colorless or white crystalline powder. It is freely soluble in water, chloroform, or alcohol and practically insoluble in ether or glycerol. The pH of a 1% solution in water is between 4.5 and 6.5. The commercially available injection has a pH from 3–6.5. The dispersible tablet formulation (Diskets®) contains insoluble ingredients that deter their use for injection.

Methadone may also be known as: Amidine HCl, amidone HCl, methadoni hydrochloridum, Phenadone, Adolam®, Biodone®, Cloro Nona®, Dolmed®, Eptadone®, Gobbidona®, Heptadon®, Ketadine®, Metadol®, Metasatin®, Methadil®, Methadose®, Methadubs®, Methex®, Pallidone®, Phyme®, Phystepon®, Pindadone®, Sedo®, Symoron®, or Synastone®.

Storage/Stability
Unless otherwise labeled, methadone products should be stored at room temperature and protected from light.

Compatibility/Compounding Considerations
Methadone injection is reportedly stable when mixed in a syringe with acepromazine. The injection is reportedly not compatible with pentobarbital, phenobarbital, amobarbital, or thiopental.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
- Methadone HCl Injection: 10 mg/mL in 20 mL multidose vials; generic; (Rx, C-II)
- Methadone HCl Oral Tablets: 5 mg & 10 mg; Dispersible Tablets 40 mg; Dolophine® Hydrochloride (Roxane); Methadose® (Mallinckrodt); generic; (Rx, C-II)
- Methadone HCl Oral Solution/Liquid Concentrate: 1 mg/mL, 2 mg/mL & 10 mg/mL in 30 mL (w/calibrated dropper), 500 mL, 946 mL, 1 L & 15 L; generic; Methadose® (Mallinckrodt); (Rx, C-II)

All methadone-containing products are C-II controlled substances in the USA. When used as an analgesic, methadone may be dispensed by any pharmacy or practitioner registered with the DEA for Class-II narcotics. When methadone is used to treat narcotic addiction, specialized approval must be obtained from the FDA and, usually, state regulators.

References

**METHAZOLAMIDE**
(meth-a-zol-a-mide) Neptazane®
CARBONIC ANHYDRASE INHIBITOR

Prescriber Highlights
- Oral carbonic anhydrase inhibitor used primarily for open angle glaucoma
- Contraindicated in patients with significant hepatic, renal, pulmonary or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis or electrolyte imbalance
Laboratory Considerations

- Primary adverse effects are GI-related, hypokalemia, metabolic acidosis
- Give oral doses with food if GI upset occurs
- Monitor with tonometry for glaucoma; check electrolytes

Uses/Indications
Orally administered methazolamide is used for the medical treatment of glaucoma. Topical carbonic anhydrase inhibitors (e.g., dorzolamide) are more commonly used today as they can lower IOP as well as systemic drugs and have fewer adverse effects.

Pharmacology/Actions
The carbonic anhydrase inhibitors act by a noncompetitive, reversible inhibition of the enzyme carbonic anhydrase. This reduces the formation of hydrogen and bicarbonate ions from carbon dioxide and reduces the availability of these ions for active transport into body secretions.

Pharmacologic effects of the carbonic anhydrase inhibitors include decreased formation of aqueous humor, thereby reducing intraocular pressure; increased renal tubular secretion of sodium and potassium and, to a greater extent, bicarbonate, leading to increased urine alkalinity and volume; anticonvulsant activity, which is independent of its diuretic effects (mechanism not fully understood, but may be due to carbonic anhydrase or a metabolic acidosis effect).

Pharmacokinetics
Little information is available. Methazolamide is absorbed from the GI tract albeit more slowly than acetazolamide. It is distributed throughout the body, including the CSF and aqueous humor. Methazolamide is at least partially metabolized in the liver.

Contraindications/Precautions/Warnings
Carbonic anhydrase inhibitors are contraindicated in patients with significant hepatic disease (may precipitate hepatic coma), renal or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis or electrolyte imbalance. They should not be used in patients with severe pulmonary obstruction unable to increase alveolar ventilation or those who are hypersensitive to them. Long-term use of carbonic anhydrase inhibitors is contraindicated in patients with chronic, noncongestive, angle-closure glaucoma as angle closure may occur and the drug may mask the condition by lowering intra-ocular pressures.

Adverse Effects
Potential adverse effects that may be encountered include GI disturbances (vomiting, diarrhea, inappetence), metabolic acidosis (with heavy panting), CNS effects (sedation, depression, disorientation, excitement, etc.), hematologic effects (bone marrow depression, thrombocytopenia), renal effects (crystalluria, dysuria, renal colic, polyuria, polydipsia), hypokalemia, hyperglycemia, hyponatremia, hyperuricemia, hepatic insufficiency, dermatologic effects (rash, etc.), and hypersensitivity reactions. Electrolyte imbalances may manifest as weakness or cardiac arrhythmias.

Combining methazolamide (oral dosing) with topical (ophthalmic) dorzolamide does not apparently yield additive reductions in intraocular pressure and may cause increased adverse effects.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Safety for use during nursing has not been established. But a related compound, acetazolamide, is excreted in the milk in concentrations unlikely to have pharmacologic effect.

Overdosage/Acute Toxicity
Information regarding overdosage of this drug is not readily available. It is suggested to monitor serum electrolytes, blood gases, volume status, and CNS status during an acute overdose. Treat symptomatically and supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methazolamide and may be of significance in veterinary patients:

- **ANTIDEPRESSANTS, TRICYCLIC**: Alkaline urine caused by methazolamide may decrease excretion
- **ASPIRIN (or other salicylates)**: Increased risk of methazolamide accumulation and toxicity; increased risk for metabolic acidosis; methazolamide increases salicylate excretion
- **DIGOXIN**: As methazolamide may cause hypokalemia, increased risk for toxicity
- **INSULIN**: Rarely, carbonic anhydrase inhibitors interfere with the hypoglycemic effects of insulin
- **METHENAMINE COMPOUNDS**: Methazolamide may negate effects in the urine
- **POTASSIUM, DRUGS AFFECTING (corticosteroids, amphotericin B, corticotropin, or other diuretics)**: Concomitant use may exacerbate potassium depletion
- **PHENOBARBITAL**: Increased urinary excretion, may reduce phenobarbital levels
- **PRIMIDONE**: Decreased primidone concentrations
- **QUINIDINE**: Alkaline urine caused by methazolamide may decrease excretion

Laboratory Considerations
- By alkalinizing the urine, carbonic anhydrase inhibitors may cause false positive results in determining **urine protein** using bromphenol blue reagent (Albustix®, Albutest®, Labstix®), sulfosalicylic acid (Bumistest®, Exton's® Test Reagent), nitric acid ring test, or heat and acetic acid test methods.
- Carbonic anhydrase inhibitors may **decrease iodine uptake** by the thyroid gland in hyperthyroid or euthyroid patients.
Carbonic anhydrase inhibitors may decrease iodine uptake by the thyroid gland in hyperthyroid or euthyroid patients.

**Doses**

**DOGS:**
- For medical treatment of glaucoma:
  a) 2.5–5 mg/kg PO q8–12h (Reinstein et al. 2009)
  b) 2–4 mg/kg PO two to three times a day (Diehl 2007)
  c) 3–5 mg/kg divided q12h PO (Millichamp 2006)
  d) 2–5 mg/kg PO two to three times a day (Collins 2006; Wilkie 2007)
  e) 2.2–4.4 mg/kg PO two to three times a day. (Pickett 2009)
  f) 2–10 mg/kg PO two to three times a day. (Giuliano 2009)

**CATS:**
- For medical treatment of glaucoma:
  a) 3–4 mg/kg PO twice a day. Cats may not tolerate oral carbonic anhydrase inhibitors (CAIs) as well as dogs. Reported side effects include lethargy, inappetence, vomiting. Topical CAIs may be better tolerated. (Powell 2003)
  b) 1–2 mg/kg PO q8-12h (Miller 2009)

**Monitoring**
- Intraocular pressure/tonometry
- Serum electrolytes, pH
- Baseline CBC with differential and periodic retests if using chronically
- Other adverse effects

**Client Information**
- If GI upset occurs, give with food.
- Notify veterinarian if abnormal bleeding or bruising occurs or if animal develops tremors or a rash.

**Chemistry/Synonyms**
A carbonic anhydrase inhibitor similar to dichlorphenamide, methazolamide occurs as a white to slightly yellow crystalline powder. It is very slightly soluble in water. Methazolamide may also be known as: GlauTabs®, Glaumetax®, MZM®, and Neptazane®.

**Storage/Stability**
Methazolamide tablets should be stored at room temperature in well-closed containers. Methazolamide tablets have an expiration date of 5 years after manufacture.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
- Methazolamide Tablets: 25 mg & 50 mg; generic; (Rx)

**References**

---

**METHENAMINE HIPPURATE**

*meth-en-a-meen* Hiprex®, Urex®

**URINARY ANTISEPTIC**

**Prescriber Highlights**
- Theoretically, converted into an urinary antiseptic; efficacy somewhat questionable in small animals
- Contraindications: Metabolic acidosis, hypersensitivity to it, renal insufficiency, severe hepatic impairment (due to ammonia production), or severe dehydration
- Adverse Effects: GI irritation; dysuria possible if used long-term
- Urine pH must be below 6.5 and ideally less than 6, to be effective
Uses/Indications
Methenamine is used as an antimicrobial agent for prophylaxis of recurrent urinary tract infection. It is not commonly used in veterinary medicine and little good evidence is available to confirm its efficacy in dogs or cats.

Pharmacology/Actions
In an acidic urinary environment (pH <6.5), methenamine is converted to formaldehyde. Formaldehyde is a non-specific antibacterial agent that exerts a bactericidal effect. It has activity on a variety of bacteria, including both gram-positive (Staphylococcus aureus, S. epidermidis, Enterococcus) and gram-negative organisms (E. Coli, Enterobacter, Klebsiella, Proteus, and Pseudomonas aeruginosa). Reported, methenamine has activity against fungal urinary tract infections.

Hippuric acid is added primarily to help acidify the urine, but it also has some non-specific antibacterial activity. Bacterial resistance to formaldehyde or hippuric acid does not usually occur.

Pharmacokinetics
Human data: While methenamine and its salts are well absorbed from the GI tract, up to 30% of a dose may be hydrolyzed by gastric acid to ammonia and formaldehyde. With enteric-coated tablets, the amount hydrolyzed in the gut is reduced. While absorbed, plasma concentrations of both formaldehyde and methenamine are very low and have negligible systemic antibacterial activity. Methenamine does cross the placenta and is distributed into milk.

Within 24 hours, 70–90% of a dose is excreted unchanged into the urine. In acidic urine, conversion to ammonia and formaldehyde takes place, maximal hydrolysis occurs at urine pH’s of 5.5 or less, but at pH’s below 6.5 some conversion occurs. Peak formaldehyde concentrations occur in the urine at about 2 hours post-dose (3–8 hours with enteric-coated tablets).

Contraindications/Precautions/Warnings
Methenamine and its salts are contraindicated in patients known to be hypersensitive to it, with renal insufficiency, metabolic acidosis, severe hepatic impairment (due to ammonia production), or severe dehydration.

Adverse Effects
The most likely adverse effect noted is gastrointestinal upset, with nausea, vomiting, and anorexia predominant. Some patients may develop dysuria, probably secondary to irritation due to high formaldehyde concentrations. Cats reportedly do not tolerate methenamine as well as dogs. Lipoid pneumonitis has been reported in some humans receiving prolonged therapy with the suspension. Potentially, systemic acidosis could occur.

Because methenamine requires acid urine to be beneficial, urine pH should ideally be kept at or below 5.5. Some urea-splitting bacteria (e.g., Proteus and some strains of staphylococci, Enterobacter and Pseudomonas) may increase urine pH. Addition of a urinary acidification program may be required using dietary modification and acidifying drugs (e.g., ascorbic acid, methionine, sodium biphosphate, ammonium chloride).

Reproductive/Nursing Safety
While methenamine crosses the placenta and lab animal studies have not demonstrated any teratogenic effects, it should be used with caution during pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Methenamine enters milk but no adverse effects have not been reported in nursing children of mothers taking methenamine.

Overdosage/Acute Toxicity
Dogs have received single IV dosages of up to 600 mg/kg of methenamine hippurate without overt toxic effects. Large oral overdoses should be handled using established gut emptying protocols, maintaining hydration status and supporting as required.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methenamine and may be of significance in veterinary patients:

- **SULFAMETHIAZOLE**: Use of methenamine with sulfamethiazole is not recommended. An insoluble precipitate may form.
- **URINE ALKALINIZING DRUGS (e.g., calcium or magnesium containing antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate, thiazide diuretics)**: Use of urinary alkalinizing drugs may reduce the efficacy of the methenamine

Laboratory Considerations
- Urinary values of the following compounds may be falsely elevated: catecholamines, vanillylmandelic acid (VMA), 17-hydrocorticosteroid
- Falsely decreased urinary values of estriol or 5-HIAA may occur
- Methenamine may cause may cause false-positive urine glucose determinations when using cupric sulfate solution (Benedict’s Solution, Clinistix®) and false-negative tests utilizing the glucose oxidase (Tes-Tape®, Clinistix®) method

Doses
**DOGS:**

Note: Methenamine mandelate has been discontinued in the USA, there does not appear to be a compelling reason that methenamine hippurate could not be substituted.

a) Methenamine mandelate: 10 mg/kg PO q6h; use with ammonium chloride to acidify urine and increase effectiveness (Grauer 2003)

b) Methenamine mandelate: 10 mg/kg PO q6h (Bartges 2007)

c) Methenamine mandelate: The dose is not well established but recommended doses are 10–20 mg/kg PO q 8-12h. If necessary, urine pH may need to be lowered by use of an acidifying diet and/or urinary acidifiers. (Adams 2009)

**CATS:**

a) Methenamine hippurate: 250 mg PO q12h (Panich 1982/ Bartges 2007)
a) Methenamine hippurate: 250 mg PO q12h (Papich 1992)(Bartges 2007)

### Monitoring
- Urine pH
- Efficacy

### Client Information
- Give after meals if GI distress occurs
- Encourage compliance

### Chemistry/Synonyms
Methenamine is chemically unrelated to other anti-infective agents. It is commercially available as methenamine hippurate. Methenamine hippurate occurs as a white, crystalline powder with a sour taste and contains approximately 44% methenamine and 56% hippuric acid. It is freely soluble in water.

Methenamine may also be known as: hexamine amygdalate, hexamine mandelate, mandelato de metenamina, Aci-steril®, Hiprex®, Reflux®, Urocedulamin®, and Urex®.

### Storage/Stability
Commercially available methenamine products should be stored at room temperature. Because acids hydrolyze methenamine to formaldehyde and ammonia, do not mix with acidic vehicles before administering.

### Compatibility/Compounding Considerations
Methenamine is physically **incompatible** when mixed with most alkaloids and metallic salts (e.g., ferric, mercuric or silver salts). Ammonium salts or alkalis will darken methenamine.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Methenamine Hipurate Oral Tablets: 1 gram; Hiprex® (Hoechst Marion Roussel); Urex® (3M Pharm); (Rx)

Note: For many years methenamine mandelate dosage forms were available commercially in the USA, but these products have reportedly been discontinued.

### References

---

**METHIMAZOLE**
(meth-im-a-zole) Tapazole®

### Prescriber Highlights
- Used for medical treatment of feline hyperthyroidism
- Potentially, transdermal gels with methimazole may have efficacy in cats (or owners) that cannot tolerate oral dosing
- **Contraindications:** Hypersensitivity to it
- **Caution:** History of or concurrent hematologic abnormalities, liver disease, or autoimmune disease
- **Adverse Effects:** Most occur within first 3 mos. of treatment: vomiting, anorexia, & depression most frequent. Eosinophilia, leukopenia, & lymphocytosis are usually transient. Rare, but serious: self-induced excoriations, bleeding, hepatopathy, thrombocytopenia, agranulocytosis, positive direct antiglobulin test, & acquired myasthenia gravis
- Place kittens on milk replacer if mother receiving drug
- Very bitter taste

### Uses/Indications
Methimazole is considered by most clinicians in North America the agent of choice when using drugs to treat feline hyperthyroidism. Sustained-release carbimazole is not presently available commercially and propylthiouracil has significantly higher incidences of adverse reactions when compared to methimazole and is rarely used today. Transdermal methimazole (in PLO gel; 2.5 mg twice daily) has been used with some therapeutic success in cats that do not tolerate oral dosing. Efficacy may require four or more weeks to detect. Studies are ongoing.

Methimazole appears to be useful for the prophylactic prevention of cisplatin-induced nephrotoxicity in dogs.

### Pharmacology/Actions
Methimazole interferes with iodine incorporation into tyrosyl residues of thyroglobulin, thereby inhibiting the synthesis of thyroid hormones. It also inhibits iodinated tyrosyl residues from coupling to form iodothyronine. Methimazole has no effect on the release or activity of thyroid hormones already formed or in the general
The following drug interactions have either been reported or are theoretical in humans or animals receiving methimazole and may be of significance in veterinary medicine:

**Warfarin: methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.**

**Anticoagulants:** methimazole may potentiate by methimazole. Recommendation: If methimazole and warfarin are used together, increased monitoring anticoagulant effect is warranted.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles: 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.**

**Phenobarbital: Concurrent use of phenobarbital may reduce the clinical effectiveness.**

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Digoxin:** Methimazole may decrease digoxin efficacy, but the veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Alpha blockers:** Veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Beta blockers:** Veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Phenobarbital:** Veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzimidazoles:** Methimazole may reduce hepatic oxidation of benzimidazoles and increase blood levels.

**Phenobarbital:** Methimazole may reduce hepatic oxidation of benzimidazoles and increase blood levels.

**Theophylline:** Veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.

**Benzodiazepines:** Methimazole can reduce hepatic oxidation of benzodiazepines and increase blood levels.

**Benzimidazoles:** 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy for transdermal administration.

**Phenobarbital:** Concurrent use of phenobarbital may reduce the clinical effectiveness.

**Theophylline:** A reduction in dose may be needed when the patient becomes euthyroid.

**Warfarin:** Methimazole may decrease clotting factor metabolism and reduce the effects of warfarin. However, patients euthyroid on methimazole and receiving warfarin may develop hypoprothrombinemia if methimazole is stopped and they become thyrotoxic again. The veterinary label states: A reduction in dose may be needed when the patient becomes euthyroid.
are within normal limits, and serum T4 concentration is greater than 26 nmol/L after 2 weeks of therapy, the dose is increased to 2.5 mg PO twice daily and the same parameters are checked in another 2 weeks. The dosage should then be increased every 2 weeks by 2.5 mg per day until serum T4 is between 13 and 26 nmol/L or adverse effects develop. Serum T4 concentrations decline into the reference range within 1–2 weeks, once the cat is receiving an effective dose. (Nelson 2003)

d) If no signs of renal insufficiency/failure, begin at 5 mg (total dose) PO twice daily in cases with severely increased T4 levels. If renal insufficiency present (or not sure), start at 2.5 mg twice daily. If azotemia and overt renal failure, start at 1.25 mg twice a day. Monitor in 1–2 weeks (T4, CBC with platelet count, renal blood parameters, urinalysis). Monitor for other signs of adverse effects. Based on clinical signs and bloodwork, dose can be increased slowly. Monitor every 2–3 weeks for the first 3 months, then every 3–6 months thereafter. (Ward 2003)

**Monitoring**

During first 3 months of therapy (baseline values and every 2–3 weeks):

- CBC, platelet count
- Serum T4
- If indicated by symptomatology: liver function tests, ANA
- After stabilized (at least 3 months of therapy):
  - T4 at 3–6 month intervals
  - Other diagnostic tests as dictated by adverse effects
- The label for the feline-approved product states: Hematology, biochemistry, and TT4 should be evaluated prior to initiating treatment and monitored after 3 weeks and 6 weeks of treatment. Thereafter, bloodwork should be monitored every 3 months and the dose adjusted as necessary. Cats receiving doses greater than 10 mg per day should be monitored more frequently.

**Client Information**

- It must be stressed to owners that this drug will decrease excessive thyroid hormones, but does not cure the condition and that compliance with the treatment regimen is necessary for success.
- The manufacturer warns that: Pregnant women or women who may become pregnant, and nursing mothers should wear gloves when handling tablets, litter or bodily fluids of treated cats.

**Chemistry/Synonyms**

A thioimidazole-derivative antithyroid drug, methimazole occurs as a white to pale buff crystalline powder, having a faint characteristic odor and a melting point of 144–147°C. It is freely soluble (1 gram in 5 mL) in water or alcohol.

Methimazole may also be known as: thiamazole, mercazolylum, methylmercaptopimidazole, thiamazolum; tiamazol, Antitiroide®, Danantizol®, Favistan®, Felimazole®, Mercaptizol®, Metibasol®, Strumazol®, Tapazol®, Thiacapzol®, Thyrozo®; Thirodril®; and Unimazole®.

**Storage/Stability**

Methimazole tablets should be stored in well-closed, light-resistant containers at room temperature; protect from moisture.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

- Methimazole Tablets (sugar-coated): 2.5, & 5 mg; Felimazole® (Dechra); (Rx). FDA-approved (USA) for use in cats.

**HUMAN-LABELLED PRODUCTS:**

- Methimazole Tablets (plain & scored): 5 mg, 10 mg, 15 mg & 20 mg; Tapazole® (Monarch); Northyx® (Centrix); generic; (Rx)

**References**

Uses/Indications
In small animals, methionine has been used primarily for its urine acidification effects in the treatment and prevention of certain types (e.g., struvite) of stone formation and to reduce ammoniacal urine odor. Use is generally not recommended unless urine pH is >6.5. In food animals, it has been used as a nutritional supplement in swine and poultry feed and in the treatment of ketosis in cattle. It has been touted as a treatment for laminitis in horses and cattle (purportedly provides a disulfide bond substrate to maintain the hoof-pedal bone bond), but definitive studies demonstrating its effectiveness for this indication are lacking.

The drug is used in humans to reduce urine ammonia (pH) and odor.

Pharmacology/Actions
Methionine has several pharmacologic effects. It is an essential amino acid (L-form) and nutrient, a lipotrope (prevents or corrects fatty liver in choline deficiency), and a urine acidifier. Two molecules of methionine can be converted to 1 molecule of cysteine. Methionine supplies both sulphydryl and methyl groups to the liver for metabolic processes. Choline is formed when methionine supplies a methyl group to ethanolamine. After methionine is metabolized, sulfate is excreted in the urine as sulfuric acid, thereby acidifying it.

Pharmacokinetics
No information is available on the pharmacokinetics of this agent in veterinary species or humans.

Contraindications/Precautions/Warnings
Methionine (in therapeutic doses) is contraindicated in patients with renal failure or pancreatic disease. If used in patients with frank hepatic insufficiency, methionine can cause increased production of mercaptan-like compounds and intensify the signs of hepatic dementia or coma. Methionine should not be given to animals with preexisting acidosis, oxalate or urate calculi. It is not recommended for use in kittens.

Adverse Effects
At usual doses, gastrointestinal distress can occur; give with food to alleviate this effect and to enhance efficacy. Methionine may cause Heinz-body hemolytic anemia in cats. See Overdosage (below) for other potential adverse effects.

Unmonitored use with an acidifying diet (e.g., s/d, c/d), may lead to signs associated with overdose.

Reproductive/Nursing Safety
No specific information was located; methionine could, potentially, cause fetal acidosis.

Overdosage/Acute Toxicity
Methionine may be toxic to kittens who consume other cats’ food in which methionine has been added. When methionine was administered at a dose of 2 grams orally per day to mature cats, anorexia, methemoglobinemia, Heinz body formation (with resultant hemolytic anemia), ataxia and cyanosis were noted. Metabolic acidosis, particularly in combination with an acidifying diet may occur with overdoses in any species. No specific information was located on the treatment of methionine overdosage.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methionine and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc): The aminoglycosides are more effective in an alkaline medium; urine acidification may diminish these drugs effectiveness in treating bacterial urinary tract infections
- **ERYTHROMYCIN**: Is more effective in an alkaline medium; urine acidification may diminish erythromycin effectiveness in treating bacterial urinary tract infections
- **QUINIDINE**: Urine acidification may increase the renal excretion of quinidine

**Doses**

**DOGS:**
For urine acidification:

a) At approximately 100 mg/kg PO q12h methionine is safe and effective in dissolving presumed infection-induced struvite uroliths in dogs in combination with an appropriate anti-microbial agent without using a struvite dissolution diet. Successful dissolution occurs when uroliths decrease in size by at least 50% at the 1 month re-evaluation. If uroliths do not decrease in size by at least 50% at the 1 month re-evaluation, then consideration should be given to (1) lack of compliance, (2) inappropriate dosage, (3) difficulty in controlling the bacterial urinary tract infection, or (4) uroliths being composed of other minerals, most likely calcium oxalate, in addition to or instead of struvite. (Bartges & Moyers 2010)

b) In struvite dissolution therapy if diet and antimicrobials do not result in acid urine: 0.2–1 gram PO q8h (Kirk 1986; Lage et al. 1988)

**CATS:**
For urine acidification:

a) 1000–1500 mg per day given in the food once daily (if diet and antimicrobials do not reduce pH) (Lewis et al. 1987)

b) 0.2–1 gram PO once daily (Lage et al. 1988)

**CATTLE:**

a) 20–30 grams PO (Jenkins 1988)

**HORSES:**

a) 22 mg/kg PO once daily for one week; then 11 mg/kg PO once daily for 1 week; then 5.5 mg/kg PO once daily for one week (Robinson 1987)

b) 12.5 grams IV in one liter saline/dextrose solution (may be effective in Senecio-induced liver damage (Rossoff 1974)

Monitoring
Monitoring

- Urine pH (Urine pH’s of ≤6.5 have been recommended as goal of therapy)
- Blood pH if signs of toxicity are present
- CBC in cats exhibiting signs of toxicity

Client Information

- Give with meals or mixed in food, unless otherwise instructed by veterinarian.

Chemistry/Synonyms

A sulfur-containing amino acid, methionine occurs as a white, crystalline powder with a characteristic odor. One gram is soluble in about 30 mL of water and it is very slightly soluble in alcohol. 74.6 mg is equivalent to 1 mEq of methionine.

Methionine may also be known as: dl-methionine, racemethionine, M, s-methionine, l-methionine, methioninum, Acimethin®, Acimol®, Ammonil®, DL-Methionine Tablets®, M-Caps®, Methigel®, Methio-Form®, Methiotrans®, Methnine®, Neutrodor®, Pedameth®, Uromethin®.

Storage/Stability

Methionine should be stored at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Methionine is labeled for use in dogs, cats, and horses in pharmaceutical dosage forms, but at the time of review 02/11, there were no methionine products listed in the FDA’s “Green Book” of approved products. Products labeled as nutritional may be approved for use in other species. Depending on the product, methionine may be available without prescription. Methionine is an ingredient in many other nutritional products.

Methionine Tablets: 200 mg and 500 mg; Ammonil® Tablets (Virbac), DL-Methionine Tablets® (V.E.T.); (Rx). Labeled for use in cats and dogs.

Methionine Tablets Chewable: 500 mg; Methio-Form® (Vet-A-Mix); (Rx). Labeled for use in cats and dogs.

Methionine Powder (concentration varies with product); Trade Names/Products include: d-l-methionine Powder (Butler, First Priority). Labeled for use in dogs and cats.

Methionine Gel: 400 mg (8%) in 120.5 gram tubes. Methigel® (Vetoquinol); (OTC). Labeled for use in cats and dogs.

HUMAN-LABELED PRODUCTS:

Methionine Capsules: 500 mg; generic; (Rx)

Topical Ointments, cream, lotion, pads and powder available.

References

METHOCARBAMOL

(meth-ok-car-ba-mol) Robaxin®

MUSCLE RELAXANT

Prescriber Highlights

- Oral & injectable centrally acting muscle relaxant; appears useful in treating muscle tremors associated with toxic agents
- Contraindications: Food animals, renal disease (injectable only), hypersensitivity to it
- Adverse Effects: Sedation, salivation, emesis, lethargy, weakness, & ataxia
- Give IV slowly (don’t exceed 2 mL/min); avoid extravasation; do not give SC

Uses/Indications

In dogs and cats, methocarbamol is indicated (FDA approved) “as adjunctive therapy of acute inflammatory and traumatic conditions of the skeletal muscle and to reduce muscular spasms.” In horses, intravenous use is indicated (FDA approved) “as adjunctive therapy of acute inflammatory and traumatic conditions of the skeletal muscle to reduce muscular spasms, and effect striated muscle relaxation.” (Package insert; Robaxin®V—Robins). Intravenous methocarbamol has been found useful in treating tremors associated with various toxicities in dogs and cats.

Pharmacology/Actions

Methocarbamol’s exact mechanism of causing skeletal muscle relaxation is unknown. It is thought to work centrally, perhaps by general depressant effects. It has no direct relaxant effects on striated muscle, nerve fibers, or the motor endplate. It will not directly relax contracted skeletal muscles. The drug has a secondary sedative effect.
**Pharmacokinetics**

Limited pharmacokinetic data is available in veterinary species. In humans, methocarbamol has an onset of action of about 30 minutes after oral administration. Peak levels occur approximately 2 hours after dosing. Serum half-life is about 1–2 hours. The drug is metabolized and the inactive metabolites are excreted into the urine and the feces (small amounts).

In horses, plasma clearances appear to be dose dependent after IV administration (Muir, Sams, and Ashcraft 1984), lower clearances were measured after higher doses were given. The serum half-life of methocarbamol in the horse is approximately 60–70 minutes. Guaiifenesin is a minor metabolite of methocarbamol, but because of very low concentrations, it probably has no clinical effect in the horse.

**Contraindications/Precautions/Warnings**

Because the injectable product contains polyethylene glycol 300, the manufacturer lists known or suspected renal pathology as a contraindication to injectable methocarbamol therapy. Polyethylene glycol 300 has been noted to increase preexisting acidosis and urea retention in humans with renal impairment.

Methocarbamol should not be used in patients hypersensitive to it or in animals to be used for food purpose. Do not administer subcutaneously and avoid extravasation. Do not exceed 2 mL per minute when injecting IV in dogs and cats.

**Adverse Effects**

Side effects can include sedation, salivation, emesis, lethargy, weakness, and ataxia in dogs and cats. Sedation and ataxia are possible in horses. Because of its CNS depressant effects, methocarbamol may impair the abilities of working animals.

**Reproductive/Nursing Safety**

Methocarbamol should be used with caution during pregnancy as studies demonstrating its safety during pregnancy are lacking. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

It is not known whether methocarbamol is excreted in milk. Exercise caution, but the American Academy of Pediatrics classifies methocarbamol as compatible with women breastfeeding.

**Overdosage/Acute Toxicity**

Overdosage is generally characterized by CNS depressant effects (loss of righting reflex, prostration). Excessive doses in dogs and cats may be represented by emesis, salivation, weakness, and ataxia. If the overdose is after oral administration, emptying the gut may be indicated if the overdose was recent. Do not induce emesis if the patient’s continued consciousness is not assured. Other clinical signs should be treated if severe and in a supportive manner.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving methocarbamol and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER**: Additive depression may occur when given with other CNS depressant agents
- **PYRIDOSTIGMINE**: One human patient, with myasthenia gravis and taking pyridostigmine, developed severe weakness after receiving methocarbamol

**Laboratory Considerations**

- Urinary values of the following compounds may be falsely elevated: vanillylmandelic acid (VMA), or 5-HIAA

**Doses**

**DOGS:**

a) Injectable: For relief of moderate conditions: 44 mg/kg IV; For controlling severe effects of strychnine and tetanus: 55–220 mg/kg IV, do not exceed 330 mg/kg/day. Administer half the estimated dose rapidly, then wait until animal starts to relax and continue administration to effect.

   Tables: Initially, 132 mg/kg/day PO divided q8h–q12h, then 61–132 mg/kg divided q8–12h. If no response in 5 days, discontinue. (Package insert; Robaxin®–V—Fort Dodge)

b) For muscle relaxation for intervertebral disk disease: 15–20 mg/kg PO three times daily.

   For muscle relaxation for certain toxicosis (e.g., strychnine, metaldehyde, tetanus): 150 mg/kg IV (Morgan 1988)

c) To help control severe tremors associated with tremorgenic Mycotoxin intoxication: 55–220 mg/kg IV to effect at a rate no more than 2 mL/minute (Schell 2000)

d) To help control tremors associated with Guarna (Paillinia spp.; caffeine) toxicity: 50–220 mg/kg IV, administered slowly and to effect; do not exceed 330 mg/kg/day. (Atkins 2006)

**CATS:**

a) Injectable: For relief of moderate conditions: 44 mg/kg IV; For controlling severe effects of strychnine and tetanus: 55–220 mg/kg IV, do not exceed 330 mg/kg/day. Administer half the estimated dose rapidly, then wait until animal starts to relax and continue administration to effect.

   Tablets: Initially, 132 mg/kg/day PO divided q8h–q12h, then 61–132 mg/kg divided q8–12h. If no response in 5 days, discontinue. (Package insert, Robaxin®–V–Fort Dodge)

b) For adjunctive treatment (control of seizures/muscle tremors) of permethrin toxicity: initially administered at 50–150 mg/kg IV. First half is given IV slowly over approximately 5-10 minutes and the second half of the dose being given as needed to effect. The dose can be repeated up to a maximum of 330 mg/kg/day; in severely affected cases, the total daily dose can be calculated and given over 24 hours as a constant rate infusion. (Boag 2009)

**CATTLE:**

a) For treatment of CNS hyperactivity: 110 mg/kg IV (Bailey 1986)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)
**HORSES:**

(a) For moderate conditions: 4.4–22 mg/kg IV to effect; for severe conditions: 22–55 mg/kg IV (Package insert, Robaxin®-V—Fort Dodge)

(b) 15–25 mg/kg IV by slow infusion (Robinson 1987)

c) To give orally: Use 2–3 times the recommended IV dose (Cunningham et al. 1992)

d) For acute rhabdomyolysis: 15–25 mg/kg slow IV infusion. May repeat up to four times daily if needed to decrease muscle cramping. (Hanson 1999)

**Monitoring**

- Level of muscle relaxation/sedation

**Client Information**

- Animal’s urine color may darken, but need not be a concern.

**Chemistry/Synonyms**

A centrally acting muscle relaxant related structurally to guaifenesin, methocarbamol occurs as a fine, white powder with a characteristic odor. In water, it has a solubility of 25 mg/mL. The pH of commercial injection is approximately 4–5.

Methocarbamol may also be known as: guaiphenesin carbamate, Labycarbol®, Laxan®, Lumirelax®, Miowas®, Musxan®, Myocin®, Myomethol®, Ortoton®, Remisol®, Rexin®, Robinax®, and Traumacur®.

**Storage/Stability**

Methocarbamol tablets should be stored at room temperature in tight containers; the injection should be stored at room temperature and not frozen. Solutions prepared for IV infusion should not be refrigerated as a precipitate may form. Because a haze or precipitate may form, all diluted intravenous solutions should be physically inspected before administration.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

**Note:** As of autumn 2010, the two veterinary products below are still listed in the FDA’s Green Book, but their marketing status is uncertain. The injectable is listed in the “Fort Dodge to Pfizer” acquired product listing, but is not listed on the Pfizer Animal Health website.

Methocarbamol Tablets: 500 mg; Robaxin®-V (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Methocarbamol Injection: 100 mg/mL in vials of 20 mL and 100 mL; Robaxin®-V (Pfizer); (Rx). FDA-approved for use in dogs, cats, and horses not intended for food.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Methocarbamol Tablets: 500 mg & 750 mg; Robaxin® Robaxin-750® (Schwarz Pharma); generic; (Rx)

Methocarbamol Injection: 100 mg/mL in 10 mL vials; Robaxin® (Baxter); (Rx)

**METHOHEXITAL SODIUM**

(meth-o-hek-si-tal) Brevital®

ULTRA-SHORT ACTING BARBITURATE

**Prescriber Highlights**

- Infrequently used ultra-short acting barbiturate for anesthesia induction, or for anesthesia for very short procedures, especially in sight hounds.

- Can cause very rough recoveries in dogs if used alone; premed or continuation of gas anesthesia during methohexital recovery may help reduce/prevent rough recoveries.

- Contraindications: Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, & conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.)

- **NOT** recommended for use in cattle

- Avoid extravasation

- No analgesic or muscle relaxant properties

- Adverse Effects: Apnea, hypotension, tremors, or seizures during recovery
Uses/Indications
Methohexital is sometimes used in small animals as an ultrashort acting anesthetic agent, but, propofol has largely supplanted methohexital’s use in small animals. However, because it is not dependent on redistribution to fat to reverse its effect, it may be useful in canine sight hound breeds. Because methohexital can induce anesthesia very rapidly, it may also be useful when general anesthesia must be administered to a patient with a full stomach, as an ET tube may be placed rapidly before aspiration of vomitus can occur.

Pharmacology/Actions
Methohexital is an ultra-short acting methylated oxybarbiturate anesthetic agent. It is about twice as potent as thiopental and has a duration of action about ½ as long. Like all the barbiturates, methohexital acts by depressing the reticular activating center of the brain.

Pharmacokinetics
After IV injection, methohexital rapidly causes anesthesia (15–60 seconds). Its distribution half-life is 5–6 minutes. When used alone, a single dose will cause surgical anesthesia for 5–15 minutes. Unlike the thiobarbiturates, methohexital is rapidly metabolized by the liver and is not dependent on redistribution to fat to reverse its effects. No drug is detectable in the body 24 hours after administration. Its elimination half-life is reported to be 3–5 hours. Recovery times in small animals average 30 minutes.

Contraindications/Precautions/Warnings
Contraindicated in patients hypersensitive to barbiturates or who do not have adequate veins for safe IV administration. Relative contraindications include: seizure-prone animals, severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypotonic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). These relative contraindications do not preclude the use of methohexital, but dosage adjustments must be considered and the drug must be given slowly and cautiously.

Repeated dosing or using an IV infusion are not recommended as recovery times can be significantly prolonged and increase the risk for complications.

Because of its unpredictability in cattle, it is not recommended for use in this species.

Adverse Effects
Methohexital can cause profound respiratory depression. The lethal dose may only be 2–3 times that of the anesthetic dose. Because excitement (including muscle tremors and seizures) can occur upon recovery, methohexital is generally recommended for use with a premed. Postoperative seizures have been reported and can be treated with IV diazepam.

In small animals (especially dogs), methohexital may induce rougher recoveries when compared to thiopental or other anesthetics. Premedication or using gas anesthetics during methohexital recovery phase may be helpful to reduce or prevent this occurrence.

Because of its rapid elimination and very short action, there is a possibility that methohexital’s effects may diminish before inhalant anesthesia takes full effect.

Too rapid an injection may lead to apnea and hypotension. Barbiturates do not provide analgesia or any muscle relaxation.

Because it can be very irritating to tissues and localized necrosis can occur in soft tissue, methohexital solutions must be only given IV, and perivascular injection must be avoided. Extravasation injuries can be treated with multiple infiltrates of sterile normal saline. Lidocaine can be injected to reduce pain.

Reproductive/Nursing Safety
While safety of methohexital has not been established in pregnancy, doses of up to 7 times those of humans given to pregnant rabbits and rats resulted in no overt teratogenicity or fetal harm. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Small amounts of thiopental have been detected in milk following administration of large doses to humans. It is unlikely that methohexital poses much risk to nursing offspring.

Overdosage/Acute Toxicity
See Adverse Effects above; figure dosages carefully.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methohexital and may be of significance in veterinary patients:

CNS DEPRESSANT DRUGS (e.g., ALPHA2-AGONISTS, opioids, etc): When used with other CNS depressant drugs, methohexital may have additive effects. Use with a pre-med is usually preferred to reduce methohexital dosage required for inductions and to decrease rough recoveries.

Doses

**DOGS:**

a) For induction with premedication: 5 mg/kg; give ½ to ¼ of dose over 10 seconds. In 30 seconds if adequate plane is not reached to allow intubation, give additional drug. Delay will result in poor induction due to rapid redistribution. (McKelvey & Hollingshead 2000)

b) For induction or sole anesthetic in non-premedicated dogs or cats: 11 mg/kg IV, give approximately ½ the dose rapidly and then titrate to effect. If premedicated, give 5.5–6.6 mg/kg IV, 10–30% is given rapidly IV and then the remainder titrated to effect. (Paddleford 1999)

**CATS:**

a) For induction or sole anesthetic in non-premedicated dogs or cats: 11 mg/kg IV, give approximately ½ the dose rapidly and then titrate to effect. If premedicated, give 5.5–6.6 mg/kg IV, 10–30% is given rapidly IV and then the remainder titrated to effect. (Paddleford 1999)

Monitoring

**C-IV Controlled Substance; relatively expensive**
Monitoring

- Plane of anesthesia
- Respiratory rate/depth
- Cardiac rate, rhythm and blood pressure
- Upon recovery, monitor for CNS stimulation (seizures)

Client Information

- Methohexital should be used in a setting only where adequate monitoring and support are available.

Chemistry/Synonyms

An ultra-short acting barbiturate agent, methohexital occurs as a white, crystalline powder. It is freely soluble in water.

Methohexital sodium may also be known as: compound 25398, enallynymalnatrium, methohexitone sodium, Brevimytal®, Brevital®, and Brietal®.

Storage/Stability

Methohexital sodium powder for injection should be stored at room temperature (less than 25°C). Preferably, reconstitute the powder for injection with sterile water for injection. D5W or 0.9% sodium chloride may also be used, particularly when making concentrations of 0.2% (to avoid extreme hypotonicity). While the manufacturer states that not to make concentrations greater than 1%, some veterinary anesthesiologists will make concentrations of up 6% (especially when using in large animals). Do not use solutions with bacteriostatic agents to prepare the solution.

The labeling for this product was changed to reduce the permitted time after reconstitution to 24 hours primarily since the product did not contain preservatives. Formerly, the labeling stated that after reconstituting with sterile water for injection, solutions are stable for at least 6 weeks at room temperature and as long as the solution remains clear and colorless, it is permissible to use. Solutions of D5W or normal saline are not stable for much more than 24 hours after reconstituting. A study demonstrated that solutions reconstituted with sterile water to a concentration of 10 mg/mL were stable up to 6 weeks when refrigerated and did not show any antimicrobial growth (Beeman et al. 1994).

Compatibility/Compounding Considerations

Methohexital solutions are alkaline. Do NOT mix with acidic drugs (e.g., atropine or succinylcholine). Refer to specialized references before attempting to mix methohexital with another drug. Methohexital is incompatible with silicone. Do not allow contact with silicone-treated rubber stoppers or silicone treated parts of disposable syringes.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Methohexital Sodium Powder for Injection: 500 mg & 2.5 grams in 50 mL multiple dose vials; Brevital® Sodium (JHP Pharm); (Rx, C-IV)

References

METHOTREXATE

METHOTREXATE SODIUM
(meth-oh-trez-ate) MTX, Amethopterin
ANTINEOPLASTIC, IMMUNOSUPPRESSIVE

Prescriber Highlights

- Antineoplastic/Immunosuppressant used primarily for lymphomas & some solid tumors in dogs & cats
- Contraindications: Preexisting bone marrow depression, severe hepatic or renal insufficiency, or hypersensitivity to the drug
- Caution: If patient susceptible or has preexisting clinical signs associated with the adverse reactions associated with this drug (see below)
- Adverse Effects: GI (diarrhea, nausea, & vomiting); Higher dosage: listlessness, GI toxicity (ulcers, mucosal sloughing, stomatitis), hematopoietic toxicity (nadir at 4–6 days), hepatoopathy, renal tubular necrosis, alopecia, depigmentation, pulmonary infiltrates & fibrosis; anaphylaxis (rare)
- Avoid human exposure
- Teratogenic; may affect spermatogenesis
- Determine dosages accurately
- Drug interactions

Uses/Indications

Indicated for lymphomas and some solid tumors in dogs and cats.
Low-dose methotrexate has been used in some cats with lymphatic cholangitis that have not responded to prednisolone or chlorambucil. In human medicine, methotrexate is also being used to treat refractory rheumatoid arthritis and severe psoriasis.

**Pharmacology/Actions**

An S-phase specific antimetabolite antineoplastic agent, methotrexate competitively inhibits folic acid reductase, preventing the reduction of dihydrofolate to tetrahydrofolate and affecting production of purines and pyrimidines. Rapidly proliferating cells (e.g., neoplasms, bone marrow, GI tract epithelium, fetal cells, etc.) are most sensitive to the drug’s effects.

Dihydrofolate reductase has a much greater affinity for methotrexate than either folic acid or dihydrofolic acid and coadministration of folic acid will not reduce methotrexate’s effects. Leucovorin calcium, a derivative of tetrahydrofolic acid, can block the effects of methotrexate.

Methotrexate also has immunosuppressive activity, possibly due to its effects on lymphocyte replication. Tumor cells have been noted to develop resistance to methotrexate that may be due to decreased cellular uptake of the drug.

**Pharmacokinetics**

Methotrexate is well absorbed from the GI tract after oral administration of dosages <30 mg/m2 with a bioavailability of about 60%. In humans, peak levels occur within 4 hours after oral dosing, and between 30 minutes and 2 hours after IM injection.

Methotrexate is widely distributed in the body and is actively transported across cell membranes. Highest concentrations are found in the kidneys, spleen, gallbladder, liver, and skin. When given orally or parenterally, methotrexate does not reach therapeutic levels in the CSF. When given intrathecally, methotrexate attains therapeutic levels in the CSF and also passes into the systemic circulation. Methotrexate is about 50% bound to plasma proteins and crosses the placenta.

Methotrexate is excreted almost entirely by the kidneys via both glomerular filtration and active transport. Serum half-life is less than 10 hours and generally between 2–4 hours.

**Contraindications/Precautions/Warnings**

Methotrexate is contraindicated in patients with preexisting bone marrow depression, severe hepatic or renal insufficiency, or hypersensitivity to the drug. It should be used with caution in patients who are susceptible to, or have preexisting clinical signs associated with, the adverse reactions associated with this drug.

When administering MTX, either wear gloves or immediately wash hands after handling. Gloves are particularly important if handling split, broken, or crushed tablets. Preparation of intravenous solutions should ideally be performed in a vertical laminar flow hood.

**Adverse Effects**

In dogs and cats, gastrointestinal side effects are most prevalent with diarrhea, nausea, inappetence (especially cats) and vomiting (especially dogs) seen. Higher dosages may lead to listlessness, GI toxicity (ulcers, mucosal sloughing, stomatitis), hematopoietic toxicity (nadir at 4–6 days), hepatopathy, renal tubular necrosis, alopecia, depigmentation, pulmonary infiltrates, and fibrosis. CNS toxicity (encephalopathy) may be noted if methotrexate is given intrathecally. Rarely, anaphylaxis may be seen.

**Reproductive/Nursing Safety**

Methotrexate is teratogenic, embryotoxic, and may affect spermatogenesis in male animals. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Methotrexate is contraindicated in nursing mothers. It is excreted in breast milk in low concentrations with a milk:plasma ratio of 0.08:1. Nursing offspring should be switched to milk replacer if the dam requires methotrexate.

**Overdosage/Acute Toxicity**

Acute overdosage in dogs is associated with exacerbations of the adverse effects outlined above, particularly myelosuppression and acute renal failure. Acute tubular necrosis is secondary to drug precipitation in the tubules. In dogs, the maximally tolerated dose is reported to be 0.12 mg/kg q24h for 5 days. 10 mg/kg is considered a lethal dose if leucovorin rescue is not performed.

Treatment of acute oral overdoses include emptying the gut and preventing absorption using standard protocols if the ingestion is recent. Additionally, oral neomycin has been suggested to help prevent absorption of MTX from the intestine. In order to minimize renal damage, forced alkaline diuresis should be considered. Urine pH should be maintained between 7.5–8 by the addition of 0.5–1 mEq/kg of sodium bicarbonate per 500 mL of IV fluid.

Leucovorin calcium is specific therapy for methotrexate overdoses. It should be given as soon as possible, preferably within the first hour and, definitely, within 48 hours. Doses of leucovorin required are dependent on the MTX serum concentration. Humans having serum concentrations greater than 5 x 10^{-7} M at 48 hours are likely to develop severe toxicity. Leucovorin in doses ranging from 25–200 mg/m2 every 6 hours doses is given until serum levels fall below 1 x 10^{-8} M. Dogs treated with leucovorin at 15 mg/m2 every 3 hours IV for 8 doses, then IM q6h for 8 doses were able to tolerate very high MTX doses.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving methotrexate (MTX) and may be of significance in veterinary patients:

- **AMIODARONE**: Prolonged PO administration of amiodarone (>2 weeks) may inhibit MTX metabolism
- **ASPARAGINASE**: Asparaginase given concomitantly with MTX may decrease MTX efficacy
- **AZATHIOPRINE**: Potential for increased risk for hepatic toxicity
- **CHLORAMPHENICOL**: May displace MTX from plasma proteins increasing risk for toxicity, but also may reduce MTX absorption and enterohepatic recirculation
- **CISPLATIN**: May have synergistic action with MTX, but alter the renal elimination of MTX
- **CYCLOSPORINE**: May increase MTX levels
- **FOLIC ACID**: May reduce MTX efficacy, but folate deficiency increases MTX toxicity
- **NEOMYCIN (oral)**: Oral neomycin may decrease the absorption of oral methotrexate if given concomitantly
**NSAIDS, SALICYLATES**: In humans, severe hematologic and GI toxicity has resulted in patients receiving both MTX and non-steroidal antiinflammatory agents; use caution in dogs also on MTX

**PENICILLINS**: May decrease MTX renal elimination

**PROBENECID**: May inhibit the tubular secretion of MTX and increase its half-life

**PYRIMETHAMINE**: Pyrimethamine, a similar folic acid antagonist, may increase MTX toxicity and should not be given to patients receiving MTX

**RETINOIDS**: Potential for increased risk for hepatic toxicity

**SULFASALAZINE**: Potential for increased risk for hepatic toxicity

**SULFONAMIDES**: May displace MTX from plasma proteins increasing risk for toxicity

**TETRACYCLINES**: May displace MTX from plasma proteins increasing risk for toxicity, but also may reduce MTX absorption and enterohepatic recirculation

**THEOPHYLLINES**: MTX may reduce theophylline elimination

**TRIMETHOPRIM/SULFA**: Rarely, may increase myelosuppression of MTX

**VACCINES, LIVE**: Live virus vaccines should be used with caution, if at all during therapy

**Laboratory Considerations**

Methotrexate may interfere with the microbiologic assay for folic acid.

**Doses**

Dosages of methotrexate sodium are expressed in terms of methotrexate as are the dosage forms. **Note**: Because of the potential toxicity of this drug to patients, and potentially, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide and not as a dosage protocol. When using MTX as part of chemotherapy protocols, consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS:**

For susceptible neoplastic diseases (usually as part of a multi-drug protocol):

a) As part of the LMP protocol for maintenance of canine lymphoma: Chlorambucil 20 mg/m2 PO every 15 days; Methotrexate 2.5–5 mg/m2 PO twice a week; Prednison 20 mg/m2 PO every other day. When Vincristine is added it is at a dose of 0.5–0.7 mg/m2 and is given every 15 days alternating weeks with the chlorambucil. (Berger 2005)

b) In combination with other antineoplastics (per protocol) 5 mg/m2 PO twice weekly or 0.8 mg/kg IV every 21 days; alternatively 2.5 mg/m2 PO daily (USPC 1990)

**CATS:**

a) For susceptible neoplastic diseases (usually as part of a multi-drug protocol): 2.5 mg/m2 PO 2–3 times weekly; 0.3–0.8 mg/m2 IV every 7 days (O’Keefe & Harris 1990)

b) For non-suppurative cholangitis/cholangiohepatitis (CCHC) syndrome with fibrosis: A total dose of 0.4 mg per cat total dose given on one day in three divided doses: 0.26 mg at hour zero, 0.13 mg at the 12 and 24 hour dosing. Repeat every 7-10 days. Use in conjunction with ursodeoxycholic acid (15 mg/kg PO q24h) and folate (0.25 mg/kg PO q24h). (Scherk 2007)

**Monitoring**

- **Efficacy**
- **Toxicity:**
  a) Monitor for clinical signs of GI irritation and ulceration
  b) Complete blood counts (with platelets) should be performed weekly early in therapy and eventually every 4–6 weeks when stabilized. If WBC is <4000/mm³ or platelet count is <100,000/mm³ therapy should be discontinued
  c) Baseline renal function tests. Continue to monitor if abnormal
  d) Baseline hepatic function tests. Monitor liver enzymes on a regular basis during therapy.

**Client Information**

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality.
- Clients should contact the veterinarian if the patient exhibits clinical signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising.
- Wear gloves when administering tablets (particularly if crushed or split); if gloves are not used, wash hands thoroughly after handling tablets.

**Chemistry/Synonyms**

A folic acid antagonist, methotrexate is available commercially as the sodium salt. It occurs as a yellow powder that is soluble in water. Methotrexate sodium injection has a pH of 7.5–9.

Methotrexate and methotrexate sodium may also be known as: MTX, amethopterin, 4-Amino-4-deoxy-10-methylpteroyl-L-glutamic acid, 4-Amino-10-methylfolic acid, CL-14377, alpha-methopterin, methotrexatum, metotrexato, NSC-740, WR-19039; there are many trade names available.

**Storage/Stability**

Methotrexate sodium tablets should be stored at room temperature (15–30°C) in well-closed containers and protected from light. The injection and powder for injection should be stored at room temperature (15–30°C) and protected from light.

**Compatibility/Compounding Considerations**
**Contraindications/Precautions/Warnings**

Methotrexate sodium is reportedly physically **compatible** with the following intravenous solutions and drugs: Amino acids 4.25%/dextrose 25%, D5W, sodium bicarbonate 0.05 M, cephalothin sodium, cytarabine, 6-mercaptopurine sodium, sodium bicarbonate, and vincristine sulfate. In syringes, methotrexate is physically **compatible** with: bleomycin sulfate, cyclophosphamide, doxorubicin HCl, fluorouracil, furosemide, leucovorin calcium, mitomycin, vinblastine sulfate, and vincristine sulfate.

Methotrexate sodium **compatibility information conflicts** is or is dependent on diluent or concentration factors with the following drugs or solutions: heparin sodium and metoclopramide HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Methotrexate sodium is reportedly physically **incompatible** when mixed with the following solutions or drugs: bleomycin sulfate (as an IV additive only; compatible in syringes and Y-lines), fluorouracil (as an IV additive only; compatible in syringes and Y-lines), prednisolone sodium phosphate, droperidol, and ranitidine HCl.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Methotrexate Sodium Tablets (plain & scored): 2.5 mg, 5 mg, 7.5 mg, 10 mg & 15 mg; *Rheumatrex® Dose Pack* (STADA); *Trexal®* (Barr); generic; (Rx)

Methotrexate Sodium Injection: 25 mg/mL (as base) in 2 mL & 10 mL vials; preservative-free in 2 mL, 4 mL, 8 mL, 10 mL, 20 mL, & 40 mL single-use vials; *Methotrexate LPF® Sodium* (Xanodyne); generic; (Rx)

Methotrexate Powder for Injection, lyophilized: 1 gram preservative free in single-use vials; generic; (Rx)

**References**

**METHYLENE BLUE (meth-i-leen)**

**ANTIDOTE**

**Prescriber Highlights**

- Thiazine dye used to primarily treat methemoglobinemia in ruminants
- Contraindications: Cats (most agree), lactating dairy animals, renal insufficiency; hypersensitive to methylene blue; or given as an intraspinal (intrathecal) injection
- Not very effective in horses
- Adverse Effects: Heinz body anemia or other red cell morphological changes, methemoglobinemia, & decreased red cell life spans. Cats most sensitive, but to a lesser degree, dogs & horses also.
- A 180-day slaughter withdrawal time has been suggested, but 14 days may be sufficient (see doses)

**Uses/Indications**

Methylene blue is used primarily for treating methemoglobinemia secondary to oxidative agents (nitrates, chlorates) in ruminants. It is also employed occasionally as adjunctive or alternative therapy for cyanide toxicity.

Intra-operative methylene blue is also being used to preferentially stain islet-cell tumors of the pancreas in dogs in order to aid in their surgical removal or in determining the animal’s prognosis.

**Pharmacology/Actions**

Methylene blue is rapidly converted to leucomethylene blue in tissues. This compound serves as a reducing agent that helps to convert methemoglobin (Fe+++ to hemoglobin (Fe++). Methylene blue is an oxidating agent, and, if high doses (species dependent) are administered, may actually cause methemoglobinemia.

**Pharmacokinetics**

Methylene blue is absorbed from the GI tract, but is usually administered parenterally in veterinary medicine. It is excreted in the urine and bile, primarily in the colorless form, but some unchanged drug may be also excreted.

**Contraindications/Precautions/Warnings**

Methylene blue is contraindicated in patients with renal insufficiency, or are hypersensitive to methylene blue. It cannot be given as an intraspinal (intrathecal) injection. Because cats may develop Heinz body anemia and methemoglobinemia secondary to methylene blue, it is considered contraindicated in this species by most...
Because cats may develop Heinz body anemia and methemoglobinemia secondary to methylene blue, it is considered contraindicated in this species by most clinicians. Methylene blue is considered relatively ineffective in reducing methemoglobin in horses.

**Adverse Effects**

The greatest concern with methylene blue therapy is the development of Heinz body anemia or other red cell morphological changes, methemoglobinemia, and decreased red cell life spans. Cats tend to be very sensitive to these effects; the drug is usually considered contraindicated in them, but dogs and horses can also develop these effects at relatively low dosages.

When injected SC or if extravasation occurs during IV administration, necrotic abscesses may develop.

**Reproductive/Nursing Safety**

Safe use of this agent during pregnancy has not been demonstrated. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

No information on lactation safety was found.

**Overdosage/Acute Toxicity**

The LD50 for IV administered 3% methylene blue is approximately 43 mg/kg in sheep.

**Drug Interactions**

None reported

**Laboratory Considerations**

Methylene blue can cause a green-blue color in urine and may affect the accuracy of urinalysis.

**Doses**

**DOGS:**

To preferentially stain islet-cell tumors of the pancreas:

a) 3 mg/kg in 250 mL sterile normal saline and administered IV over 30–40 minutes intraoperatively. Initial tumor staining requires approximately 20 minutes after infusion has begun and is maximal at about 25–35 minutes after infusion is started. Tumors generally appear to be a reddish-violet in color versus a dusky blue (background staining). (Fingeroth & Smeak 1988)

To treat methemoglobinemia:

a) Secondary to phenol exposure: A single, slow IV infusion of 4 mg/kg of methylene blue; may use with 20 mg/kg ascorbic acid PO (Dorman & Clark 2000)

b) For severe methemoglobinemia: 1 mg/kg as a 1% solution given slowly IV over several minutes. A dramatic response should occur during the first 30 minutes after treatment. It may be repeated if necessary, but it should be used cautiously as can cause Heinz body anemia. Measure hematocrit for 3 days after treatment. (Harvey 2006)

**CATS:**

To treat methemoglobinemia:

a) Secondary to phenol exposure: A single, slow IV infusion of 1.5 mg/kg of methylene blue, may use with 20 mg/kg ascorbic acid PO (Dorman & Clark 2000)

b) 1–1.5 mg/kg IV one time only (Christopher 2000)

c) For severe methemoglobinemia: 1 mg/kg as a 1% solution given slowly IV over several minutes. A dramatic response should occur during the first 30 minutes after treatment. It may be repeated if necessary, but it should be used cautiously as can cause Heinz body anemia. Measure hematocrit for 3 days after treatment. (Harvey 2006)

**RUMINANTS:**

Note: When used in food animals, FARAD recommends a minimum milk withdrawal time of 4 days after the last treatment. Because of concerns of carcinogenicity, an extremely conservative withdrawal time for meat of 180 days has been recommended; however, available data suggest that a much shorter withdrawal time of 14 days would be sufficient. (Haskell et al. 2005)

For methemoglobin-producing toxins (nitrites, nitrates, chlorates):

a) Using a 1% solution, methylene blue is given at 4–15 mg/kg IV q6h. (Osweiler 2007)

b) For nitrate poisoning in cattle: 5–15 mg/kg as a 1% solution in physiologic saline. With severe cases, repeat treatment at a lower dose may be required. In animals that do not succumb, recovery occurs by 24 hours. (Hall 2006)

For cyanide toxicity:

a) 4–6 grams IV per 454 kg (1000 lb.) of body weight (Oehme 1986)

**HORSES:**

For methemoglobinemia secondary to chlorate toxicity:

a) 4.4 mg/kg as 1% solution by intravenous drip; may repeat in 15–30 minutes if clinical response is not obtained. (Schmitz 2004)

**Monitoring**

- Methemoglobinemia
- Red cell morphology, red cell indices, hematocrit, hemoglobin

**Client Information**

Because of the potential toxicity of this agent and the seriousness of methemoglobin-related intoxications, this drug should be used with close professional supervision only.
Methylene blue may be very staining to clothing or skin. Removal may be accomplished using hypochlorite solutions (bleach).

**Chemistry/Synonyms**

A thiazine dye, methylene blue occurs as dark green crystals or crystalline powder that has a bronze-like luster. It may have a slight odor and is soluble in water and sparingly soluble in alcohol. When dissolved, a dark blue solution results. Commercially available methylene blue injection (human-labeled) has a pH from 3–4.5.

Methylene blue may also be known as: methylthioninium chloride, azul de metileno, blu di metilene, CI basic blue 9, colour index no. 52015, methylene blue, methylenii caeruleum, methylthioninii chloridum, schultz no. 1038, tetramethylthionine chloride trihydrate, Azul Metile®, Collubleu®, Desmoidpillen®, Vitableu®, Urole Blue® and Zumetil®.

**Storage/Stability**

Unless otherwise instructed by the manufacturer, store methylene blue at room temperature.

**Compatibility/Compounding Considerations**

Methylene blue is reportedly physically **incompatible** when mixed with caustic alkalies, dichromates, iodides, and oxidizing or reducing agents.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

None FDA-approved as pharmaceuticals for internal use. A 1% (10 mg/mL) methylene blue solution (Centaur) is labeled for animal use as a dye, laboratory indicator and reagent. It is available in pint and gallon bottles. Methylene Blue, USP powder may be available from chemical supply houses.

**HUMAN-LABELLED PRODUCTS:**

Methylene Blue Injection: 10 mg/mL in 1 mL & 10 mL amps; generic; (Rx)

**References**

---

**METHYLPHENIDATE**

(meth-ill-fen-i-date) Ritalin®

**CNS STIMULANT**

**Prescriber Highlights**

- Amphetamine-like drug that may be useful for treating cataplexy/narcolepsy or hyperkinesis/hyperactivity in dogs
- Use with caution in dogs with seizure disorders, cardiac disease/hypertension, or in aggressive animals
- Adverse effects are primarily CNS stimulation-related
- Class-II controlled drug in USA

**Uses/Indications**

Methylphenidate may be useful for diagnosing and treating cataplexy/narcolepsy or hyperactivity in dogs.

**Pharmacology/Actions**

Methylphenidate has stimulating effects on the central nervous and respiratory systems similar to that of amphetamines. It also has weak sympathomimetic activity, and at normal dosages has little effect on peripheral circulation.

**Pharmacokinetics**

In dogs, there is limited information available. Single PO doses of immediate-release 20 mg tablets to 7–19 kg beagles gave peak levels of about 60 micrograms/mL in about 15 minutes after dosing. Clearance was about 0.27 L/hr and elimination half-life around an hour. With 20 mg sustained-release tablets there was much more inter-patient variation, serum concentrations peaked around 30 minutes after dosing, peak levels of 19 micrograms/mL were much lower then the immediate-release tablets. Clearance was about 0.97 L/hr and elimination half-life was approximately 40 minutes. For reference, the therapeutic plasma concentration of methylphenidate is thought to be between 1–10 micrograms/mL. (Giorgi et al. 2010)

In humans, methylphenidate (regular tablets) is rapidly and well absorbed from the GI tract. Food in the GI tract may increase the rate, but not the extent, of drug absorbed. Peak levels occur about 2 hours post-dose. The drug is extensively metabolized during the first-pass; protein binding is low. Terminal elimination half-life is approximately 3 hours; less than 1% is excreted unchanged in the urine.

**Contraindications/Precautions/Warnings**

The risks associated with methylphenidate should be carefully considered before using this drug in dogs with seizure disorders, cardiac disease/hypertension, or in aggressive animals.
Adverse Effects
Most likely adverse effects to be encountered include increased heart and respiratory rates, anorexia, tremors and hyperthermia (particularly exercise-induced).

Reproductive/Nursing Safety
In humans, the FDA categorizes methylphenidate as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). Methylphenidate was associated with teratogenic effects in rabbits, but at massive dosages (200 mg/kg/day).

It is unknown if methylphenidate enters maternal milk.

Overdosage/Acute Toxicity
In dogs, dosages of 1 mg/kg (or below) can cause toxic reactions; there is one report of a fatality after a dog ingested 3.1 mg/kg, but research dogs have survived doses of 20 mg/kg/day for 90 days. A cat given a 5 mg tablet of methylphenidate showed signs of tremors, agitation, mydriasis, tachycardia, tachypnea and hypertension; signs resolved 25 hours post-ingestion with supportive care (dark cage, diazepam, fluids).

Expected signs associated with an overdose in dogs are generally CNS over-stimulation and excessive sympathomimetic effects and can include: hyperactivity, salivation, diarrhea, head bobbing, agitation, tachycardia, hypertension, tremors, seizures, and hyperthermia. Consider the dosage form (extended-release vs. regular tablets) when considering treatment options and expected onset and duration of effects. Employ treatment using standard gut detoxification techniques (emetic, activated charcoal, cathartic, etc.); however, emesis should be avoided in animals displaying signs associated with toxicity or that are otherwise at risk for emesis-related adverse effects. Treatment is basically supportive by controlling signs associated with toxicity. Phenothiazines (e.g., acepromazine, chlorpromazine) may be useful in controlling agitation; beta-blockers can help control tachycardia; external cooling may be used for hyperthermia; and cyproheptadine may help prevent serotonin syndrome.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methylphenidate and may be of significance in veterinary patients:

- **ANTICONVULSANTS (phenobarbital, primidone, phenytoin):** Methylphenidate may increase serum levels
- **CLONIDINE:** Rare cases (in humans) of cardiovascular effects (including death); mechanism not understood and causality not established
- **HYPOTENSIVE DRUGS:** Methylphenidate may reduce effects
- **MAO INHIBITORS (including amitraz and potentially, selegiline):** Could lead to hypertensive crisis
- **SSRI ANTIDEPRESSANTS (e.g., fluoxetine, sertraline, etc.):** Methylphenidate may inhibit metabolism and increase levels
- **TRICYCLIC ANTIDEPRESSANTS (e.g., amitriptyline, clomipramine, etc.):** Methylphenidate may inhibit metabolism and increase levels
- **WARFARIN:** Methylphenidate may inhibit warfarin metabolism and increase INR

Laboratory Considerations
- No specific laboratory interactions were noted for this drug.

Doses
- **DOGS:**
  a) For treatment of narcolepsy/cataplexy: 5–10 mg (total dose) PO once daily. (Joseph 2000)
  b) For treatment of narcolepsy/cataplexy (to supplement imipramine at 0.5–1 mg/kg PO q8–12h): Methylphenidate: 0.25–0.5 mg/kg PO or 5–10 mg (total dose) PO q12–24h (Shell 2003)
  c) For diagnosis and treatment of hyperkinesis: 5–20 mg (total dose) q8–12h; give for 3 days and assess for improvement of target behaviors (anxiety, overactivity, learning ability) (Siebert 2003)
  d) For hyperkinesis-hyperactivity: Small dogs: 5+ mg total dose PO q12h; Large Dogs: 20–40 mg total dose PO q12h (Virga 2002)

Monitoring
- Clinical efficacy
- Occasional physical exam to monitor vital signs, body weight
- In humans, it is recommended to do periodic CBC with differential and platelet counts during prolonged therapy.

Client Information
- Clients should understand that this drug has significant potential for abuse by humans and to keep it safely secure.
- Clients should report untoward stimulatory effects to the veterinarian.
- If using an extended-release product, do not crush tablet or capsule.

Chemistry/Synonyms
A CNS stimulant related to amphetamines, methylphenidate HCl occurs as fine, white odorless, crystalline powder. It is freely soluble in water and soluble in alcohol.

Methylphenidate may also be known as: **Attenta®, Daytrana®, Equasym®, Focalin®, Metadate ER®, Methylin®, Ritaline®, Ritalin®, Ritalin®, Ritaphen®, Rubifen®, or Tranquilyn®.**

Storage/Stability
Unless otherwise noted on the label, methylphenidate tablets and extended-release tablets and capsules should be stored in tight, light-resistant containers at room temperature.
Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methylphenidate Oral Tablets: 5 mg, 10 mg & 20 mg; Chewable Tablets: 2.5 mg, 5 mg & 10 mg; Extended-Release Tablets: 10 mg, 18 mg, 20 mg, 27 mg, 36 mg & 54 mg; Extended-Release Capsules: 20 mg, 30 mg, 40 mg, 50 mg & 60 mg; Methylin® (Mallinckrodt); Ritalin®, Ritalin® LA, & Ritalin-SR® (Novartis); Metadate ER® & Metadate CD® (UCB); Concerta® (Janssen); (Rx; C-II)

Methylphenidate Oral Solution: 5 mg/5 mL & 10 mg/5 mL in 500 mL; Methyltin® (Sciele); (Rx; C-II)

Methylphenidate Transdermal Patch: 10 mg/9 h (1.1 mg/h; 27.5 mg total), 15 mg/9 h (1.6 mg/h; 41.3 mg total), 20 mg/9 h (2.2 mg/h; 55 mg total) & 30 mg/9 h (3.3 mg/h; 82.5 mg total); Daytrana® (Shire); (Rx; C-II)

METHYPREDNISOLONE ACETATE

METHYPREDNISOLONE SODIUM SUCCINATE

(meth-ill-pred-niss-oh-lone) Medrol®, Depo-Medrol®

GLUCOCORTICOID

Prescriber Highlights

• Oral & parenteral glucocorticoid that is 4–5X more potent than hydrocortisone; no appreciable mineralocorticoid activity

• Contraindicated (relatively): Systemic fungal infections, manufacturer lists: “in viral infections … animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, & Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, & active tuberculosis necessitates carefully controlled use.”

• Acetate can cause significant HPA axis suppression. In cats, extracellular hyperglycemia can cause volume expansion and may predispose cats to congestive heart failure. IM administration generally reserved when owners cannot adhere to oral treatment regimens

• Usual therapy goal is to use as much as is required & as little as possible for as short an amount of time as possible

• Primary adverse effects are “Cushingoid” in nature with sustained use

• Many potential drug & lab interactions

Uses/Indications

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopathies, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally.

High dose fast-acting corticosteroid use for shock or CNS trauma is controversial; recent studies have not demonstrated significant clinical benefit and it actually may cause increased deleterious effects.

Pharmacology/Actions

Methylprednisolone may be administered either orally or parenterally. Its relative antiinflammatory potency is approximately 5 times that of cortisol. It has negligible to very slight mineralocorticoid activity. Once in the systemic circulation it has an approximate duration of activity of 12–36 hours. Duration of activity is not dependent on elimination half-life.

Glucocorticoids have effects on virtually every cell type and system in mammals. For more information, refer to the Glucocorticoid Agents, General Information monograph.

Pharmacokinetics

Methylprednisolone administered orally is relatively well absorbed and extensively distributed. The liver is the primary site for metabolism (oxidation); most of the drug is excreted renally as metabolites. Elimination half-life is multiphasic and does not appreciably effect duration of action.

The sodium succinate IV injection is water soluble and considered very fast acting.

The acetate IM injection is slowly absorbed and can have a duration of effect of weeks to months.

**Contraindications/Precautions/Warnings**

The original manufacturer (Upjohn Veterinary) states that the drug (tablets) should not be used in dogs or cats “in viral infections, ... animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, and Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, and active tuberculosis necessitates carefully controlled use.”

The injectable acetate product is contraindicated as outlined above when used systemically. When injected intrasynovially, intratendinously, or by other local means, it is contraindicated in the “presence of acute local infections.”

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

**Adverse Effects**

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen, but high-dose short-term adverse effects can occur. With long-term use adverse effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. In dogs, high-dose methylprednisolone sodium succinate has been associated with diarrhea, blood in stools (melaena, hematochezia) vomiting, GI bleeding, and anorexia. Many other potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when administering the drug. Adverse effects in dogs can include dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipemias, activation or worsening of diabetes mellitus, muscle wasting, and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PP/PU, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and, potentially, more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term high dose therapy can lead to “Cushingoid” effects, however. In cats, the long-acting acetate salt has been implicated in causing extracellular hyperglycemia leading to volume expansion and may predispose patients to congestive heart failure; however, current evidence for this effect is not strong.

Corticosteroid-related diabetes mellitus may be related to increased urinary excretion of chromium and potentially could respond to chromium supplementation.

**Reproductive/Nursing Safety**

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Use with caution in nursing dams. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may, potentially, inhibit growth, interfere with endogenous corticosteroid production or cause other unwanted effects in nursing offspring. However, in humans, several studies suggest that amounts excreted in breast milk are negligible when methylprednisolone doses are less than or equal to 8 mg/day. Larger doses for short periods may not harm the infant.

**Overdose/Acute Toxicity**

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving methylprednisolone and may be of significance in veterinary patients:

- **AMPHOTERICIN B**: Administered concomitantly with glucocorticoids may cause hypokalemia; in humans, there have been cases of CHF and cardiac enlargement reported after using methylprednisolone to treat Amphotericin B adverse effects
- **ANALGESICS, OPIATE and/or ANESTHETICS, LOCAL (epidural injections)**: Combination with glucocorticoids in epidurals has caused serious CNS injuries and death; do not use more volumes than very small intrathecal test doses of these agents with glucocorticoids
- **ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN**: Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES**: May increase the metabolism of glucocorticoids and decrease blood levels
- **CYCLOPHOSPHAMIDE**: Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE**: Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIURETICS, POTASSIUM-DEPLETING (e.g., spironolactone, triamterene)**: Administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE**: May reduce methylprednisolone blood levels
- **ESTROGENS**: The effects of methylprednisolone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN**: Insulin requirements may increase in patients receiving glucocorticoids
Monitoring

There are a plethora of doses and protocols associated with many specific indications for systemic administration of glucocorticoids, but there are four primary uses:

**Doses**

- **Laboratory Considerations**
  - Methylprednisolone acetate may reduce post-ACTH cortisol concentrations by 20–50%.
  - Glucocorticoids may increase serum cholesterol.
  - Glucocorticoids may increase serum and urine glucose levels.
  - Glucocorticoids may decrease serum potassium.
  - Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce T3 & T4 values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I131 by the thyroid may be decreased by glucocorticoids.
  - Reactions to skin tests may be suppressed by glucocorticoids.
  - False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.
  - Glucocorticoids may cause neutrophilia within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation.
  - Glucocorticoids can cause lymphopenia which can persist for weeks after drug discontinuation in dogs.

**Doses**

There are a plethora of doses and protocols associated with many specific indications for systemic administration of glucocorticoids, but there are four primary uses and dose ranges: 1) replacement or supplementation (e.g., relative adrenal insufficiency associated with septic shock) of glucocorticoid effects secondary to hypoadrenocorticism, 2) as an antiinflammatory, 3) as an immunosuppressive, and 4) as an antineoplastic agent. Current evidence does not support high dose use for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma, or sepsis.

**DOGS:**

_Note: If using methylprednisolone tablets or methylprednisolone sodium succinate for IV injection, refer to the prednisolone dose section to determine an appropriate dose for the condition treated using prednisone or prednisolone. That dose can be converted to a near equivalent dose for methylprednisolone by dividing it by 1.25 (e.g., if the dose is 5 mg of prednisone or prednisolone, the methylprednisolone dose would be 4 mg)._  

For labeled uses:

- **Oral:** Dogs weighing 5–15 lbs: 2 mg; Dogs weighing 15–40 lbs: 2–4 mg; Dogs weighing 40–80 lbs: 4–8 mg; these total daily doses should be divided and given 6–10 hours apart. (Label information; Medrol®—Pfizer)
  - Intramuscularly: 2–120 mg IM (average 20 mg); depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; Depo-Medrol®—Upjohn) The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.
  - For intralesional (sub-lesional) use:
    - A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

**CATS:**

_Note: If using methylprednisolone tablets or methylprednisolone sodium succinate for IV injection, refer to the prednisolone dose section to determine an appropriate dose for the condition treated using prednisone or prednisolone. That dose can be converted to a near equivalent dose for methylprednisolone by dividing it by 1.25 (e.g., if the dose is 5 mg of prednisone or prednisolone, the methylprednisolone dose would be 4 mg)._  

For labeled uses:

- **Oral:** Cats weighing 5–15 lbs: 2 mg; Cats weighing >15 lbs: 2–4 mg. These total daily doses should be divided and given 6–10 hours apart. (Label information; Medrol®—Pfizer)
  - Intramuscularly using methylprednisolone acetate (Depo-Medrol®): up to 20 mg (average 10 mg) IM; depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; Depo-Medrol®—Upjohn)
  - For intralesional (sub-lesional) use:
    - A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

**HORSES:**

As an antiinflammatory (glucocorticoid effects):

- For labeled uses: Methylprednisolone acetate 200 mg IM repeated as necessary (Package insert; Depo-Medrol®—Upjohn). The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.
  - For intra-articular use: Methylprednisolone acetate 100 mg IA (McClure 2002)

KETOCONAZOLE and other AZOLE ANTIMYCOTICS: May decrease the metabolism of glucocorticoids and increase methylprednisolone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis.

MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin): May decrease the metabolism of glucocorticoids and increase methylprednisolone blood levels.

MITOTANE: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency.

NSAIDS: Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration.

PHENOBARBITAL: May increase the metabolism of glucocorticoids and decrease methylprednisolone blood levels.

RIFAMPIN: May increase the metabolism of glucocorticoids and decrease methylprednisolone blood levels.

VACCINES: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoid.

WARFARIN: Methylprednisolone may affect INR’s; monitor.

**Monitoring**

1) **Pituitary Testing:**
   - **Rapid post-ACTH rise test:** Prednisolone acetate may be given IV at 2 mg/kg in 3 divided doses to test for hypercortisolemia. (Label information; Depo-Medrol®—Upjohn)
   - **I131 uptake:** Thyroid gland atrophy may be decreased by glucocorticoids.

2) **Other Testing:**
   - **False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.
   - **Glucocorticoids may cause neutrophilia within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation.
   - **Glucocorticoids can cause lymphopenia which can persist for weeks after drug discontinuation in dogs.

3) **Vaccines:**
   - Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoid.

4) **Other Testing:**
   - **False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.
   - **Glucocorticoids may cause neutrophilia within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation.
   - **Glucocorticoids can cause lymphopenia which can persist for weeks after drug discontinuation in dogs.

**Doses**

There are a plethora of doses and protocols associated with many specific indications for systemic administration of glucocorticoids, but there are four primary uses and dose ranges: 1) replacement or supplementation (e.g., relative adrenal insufficiency associated with septic shock) of glucocorticoid effects secondary to hypoadrenocorticism, 2) as an antiinflammatory, 3) as an immunosuppressive, and 4) as an antineoplastic agent. Current evidence does not support high dose use for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma, or sepsis.

**DOGS:**

_Note: If using methylprednisolone tablets or methylprednisolone sodium succinate for IV injection, refer to the prednisolone dose section to determine an appropriate dose for the condition treated using prednisone or prednisolone. That dose can be converted to a near equivalent dose for methylprednisolone by dividing it by 1.25 (e.g., if the dose is 5 mg of prednisone or prednisolone, the methylprednisolone dose would be 4 mg)._  

For labeled uses:

- **Oral:** Dogs weighing 5–15 lbs: 2 mg; Dogs weighing 15–40 lbs: 2–4 mg; Dogs weighing 40–80 lbs: 4–8 mg; these total daily doses should be divided and given 6–10 hours apart. (Label information; Medrol®—Pfizer)
  - Intramuscularly: 2–120 mg IM (average 20 mg); depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; Depo-Medrol®—Upjohn) The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.
  - For intralesional (sub-lesional) use:
    - A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

**CATS:**

_Note: If using methylprednisolone tablets or methylprednisolone sodium succinate for IV injection, refer to the prednisolone dose section to determine an appropriate dose for the condition treated using prednisone or prednisolone. That dose can be converted to a near equivalent dose for methylprednisolone by dividing it by 1.25 (e.g., if the dose is 5 mg of prednisone or prednisolone, the methylprednisolone dose would be 4 mg)._

  - Intramuscularly using methylprednisolone acetate (Depo-Medrol®): up to 20 mg (average 10 mg) IM; depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; Depo-Medrol®—Upjohn)
  - For intralesional (sub-lesional) use:
    - A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

**HORSES:**

As an antiinflammatory (glucocorticoid effects):

- For labeled uses: Methylprednisolone acetate 200 mg IM repeated as necessary (Package insert; Depo-Medrol®—Upjohn). The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.
  - For intra-articular use: Methylprednisolone acetate 100 mg IA (McClure 2002)

Monitoring
Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

Chemistry/Synonyms

Methylprednisolone is a synthetically produced glucocorticoid. Both the free alcohol and the acetate ester occur as odorless, white or practically white, crystalline powder. They are practically insoluble in water and sparingly soluble in alcohol.

Methylprednisolone sodium succinate occurs as an odorless, white or nearly white, hygroscopic, amorphous solid. It is very soluble in both water and alcohol.

Methylprednisolone may also be known as: 6alpha-methylprednisolone, methylprednisolonom, NSC-19987, A-Methapred®, Alergol® 
Caberdelta MO®, Citipranol®, Cortisone®, Depo-Medrol®, Exemestone®, Firmacort®, Medrate®, Medrol®, Medtrone®, Mega-Star®, Metilpre®
Metisona®, Methapred®, Metypred®, Metysolon®, Predni M®, Prednilen®, Reactenol®, Sieropresol®, Solomet®, Solu-Medrol®, Summicort® and Urbason®

Storage/Stability

Commercially available products of methylprednisolone should be stored at room temperature (15–30°C); avoid freezing the acetate injection. After reconstituting the sodium succinate injection, store at room temperature and use within 48 hours; only use solutions that are clear.

Compatibility/Compounding Considerations

Methylprednisolone sodium succinate injection is reportedly physically compatible with the following fluids and drugs: amino acids 4.25%/dextrose 25%, amphotericin B (limited amounts), chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dopamine HCl, heparin sodium, metoclopramide, metoprolol succinate, metoprolol tartrate, nafcillin sodium, penicillin G sodium, metoclopramide, amphotericin B (limited amounts), chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dopamine HCl, heparin sodium, metoclopramide, metoprolol succinate, metoprolol tartrate, nafcillin sodium, penicillin G sodium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Methylprednisolone Tablets: 4 mg tablets, Medrol®; (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Methylprednisolone Acetate Injection: 20 mg/mL in 10 mL and 20 mL vials, and 40 mg/mL in 5 mL vials; Depo-Medrol® (Pfizer); generic; (Rx). FDA-approved for IM and intrasynovial injection in dogs and horses; for IM injection in cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

A 10 ppb tolerance has been established for methylprednisolone in milk.

**HUMAN-LABELED PRODUCTS:**

Methylprednisolone Oral Tablets: 2 mg, 4 mg, 8 mg, 16 mg, 24 mg & 32 mg; Medrol® (Upjohn); generic; (Rx)

Methylprednisolone Acetate Injection: 20 mg/mL, 40 mg/mL, 80 mg/mL suspension in 1 mL (40 & 80 mg only), 5 mL & 10 mL vials; Depo-Medrol® (Pfizer); generic; (Rx)

Methylprednisolone Sodium Succinate Powder for Injection: 40 mg/vial in 1 mL & 3 mL vials and 1 mL Univials and Act-O-Vials; 125 mg/vial in 2 mL & 5 mL vials and 2 mL Univials and Act-O-Vials; 500 mg/vial in 1 mL, 4 mL, 8mL (with or without diluent) and 20 mL vials; 1 gram/vial in 1 mL, 8 mL, 50 mL, & 1 gram vials (with or without diluent), 8 mL Act-O-Vials; 2 grams/vial in 2 grams vials with diluent; Solu-Medrol® (Pfizer); A-Methapred® (Hospira); generic; (Rx)

Prescriber Highlights

- Androgenic & anabolic agent that may be useful to suppress estrus, treat testosterone-responsive alopecia, & pseudopregnancy in dogs
- Use in cats is controversial as hepatotoxicity may be more prevalent
- Contraindicated in pregnancy or hepatic dysfunction
- Most serious adverse effect is hepatotoxicity

Uses/Indications
In female dogs, methyltestosterone may be useful for suppression of estrus, treating estrogen-dependent mammary tumors, pseudopregnancy, or certain hormonal-dependent alopecias. In male dogs, it may be useful for treating deficient libido and certain hormonal alopecias. In cats, methyltestosterone may be useful for certain hormonal-dependent alopecias and to increase libido in toms. Because of the potential for abuse by humans, and potential toxicity (especially hepatotoxicity) in animals, use of methyltestosterone is somewhat controversial in veterinary medicine, particularly in racing Greyhounds and cats.

Pharmacology/Actions
Methyltestosterone is an androgen with anabolic effects. It has a methyl-group at the 17 position of the steroid nucleus of testosterone, resulting in better oral absorption and slower hepatic metabolism than testosterone. Androgens are required for both the development and maintenance of male sexual characteristics and function. The anabolic effects of methyltestosterone include stimulating erythropoiesis, enhancing nitrogen balance and protein anabolism (in the presence of sufficient protein and calories) and retention of potassium, sodium, and phosphorus.

Pharmacokinetics
Methyltestosterone is absorbed from the GI tract and oral mucosa. It undergoes less first pass metabolism than orally administered testosterone. In dogs, methyltestosterone is metabolized in the liver. Principle metabolites found in urine are glucuronidated forms (both conjugated and free) of methyltestosterone. Unlike in humans, sulfated forms are not a major metabolic component.

In humans, peak levels occur about 2 hours after oral dosing; elimination half-life is approximately 3 hours.

Contraindications/Precautions/Warnings
Methyltestosterone is contraindicated in patients with hepatic dysfunction and during pregnancy (see Reproductive Safety). It should be used with extreme caution in animals with heart failure. Prolonged use in young animals can cause premature epiphyseal closure.

Adverse Effects
Adverse effects in animals include: hepatotoxicity, virilization of females (clitoral hypertrophy), vaginal discharge, prostatic hyperplasia and increased aggression in males. Chronic dosing in dogs of 2–6 mg/kg/day for 27 weeks caused hepatotoxicity characterized by enlarged periportal hepatocytes, and hemosiderin in macrophages. Cats may be more susceptible to hepatic injury than are dogs.

Reproductive/Nursing Safety
Spermatogenesis suppression in males may occur with high dosage methyltestosterone secondary to a negative feedback mechanism. Methyltestosterone may suppress estrus in females (see Uses). After the drug is discontinued, normal reproductive function usually returns in both males and females.

Methyltestosterone is contraindicated during pregnancy. Dose-related genital masculinization of female fetuses is well described. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

Overdosage/Acute Toxicity
Information on the acute toxicity of methyltestosterone is limited. Nausea and edema are the most likely effects of a single overdose. Consider liver function monitoring with large overdoses.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving methyltestosterone and may be of significance in veterinary patients:

- CYCLOSPORINE: Methyltestosterone may increase serum cyclosporine levels
- INSULIN; ORAL ANTIDIABETIC AGENTS: Methyltestosterone may decrease serum glucose levels
- WARFARIN: Methyltestosterone may increase anticoagulant effects

Laboratory Considerations
Methyltestosterone or other androgens can decrease thyroxine-binding globulin concentrations. This can cause decreased serum levels of total T4 and increased resin uptake of T4 and T3. Clinically, this is unimportant, as free thyroid hormone concentrations are not affected.

Doses

**DOGS/CATS:**

- Dogs: For Alopecia X when melatonin fails: 1 mg/kg to a maximum dose of 30 mg (total dose) PO once daily. Generally tolerated well, but can cause hepatotoxicity, aggressive behavior and/or seborrhea. Get baseline liver profile and then again one and two months after starting treatment. Stop after maximal hair re-growth is noted. (Rosychuk 2008)
b) Dogs: For treatment of testosterone-responsive dermatosis: 1 mg/kg PO every other day, to a maximum dose of 30 mg. Once dog responds, then every 4–7 days. (Nelson & Elliott 2003)

c) Dogs: To suppress estrus in Greyhounds: 5 mg (total dose) once weekly or divided, two times a week. (Eilts 2005)

d) Dogs: For estrus suppression: 25–50 mg (total dose) twice weekly PO. (Romagnoli 2003)

e) Dogs/Cats: For anti-estrogenic activity, development of male sexual characteristics (anatomical and behavioral), negative feedback on gonadotropin release from pituitary, and anabolic effects: 0.5 mg/kg PO once daily; dose may need to be adjusted, but should not exceed 1 mg/kg. (Label information; Orandrone®—Intervet UK. Note: This product has reportedly been withdrawn from the U.K. market.)

Monitoring
- Hepatic function (liver enzymes, icterus, anorexia/weight loss/vomiting)

Client Information
- Potential adverse effects include: liver toxicity, masculinization or vaginal discharge in females, prostate problems and aggression in males
- Contact veterinarian if any of the following occur: changes in behavior, anorexia/weight loss/vomiting, or signs of icterus

Chemistry/Synonyms
Methyltestosterone occurs as white or creamy-white, odorless, crystals or crystalline powder. It is slightly hygroscopic, practically insoluble in water, freely soluble in alcohol, and sparingly soluble in vegetable oils.

Methyltestosterone may also be known as NSC-9701 or by its chemical name, 17beta-Hydroxy-17alpha-methyladrost-4-ene-3-one, Android®, Methitest®, Testred® and Virilon®. A tradename for a veterinary product formerly available in the U.K. is Orandrone® (Intervet).

Storage/Stability
Unless otherwise specified by the manufacturer, methyltestosterone tablets or capsules should be stored below 40°C, preferably between 15°–30°C in well-closed containers.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See appendix for more information.

HUMAN-LABELED PRODUCTS:
Methyltestosterone Tablets: 10 mg & 25 mg; Methitest® (Global), generic; (Rx, C-III)
Methyltestosterone Buccal Tablets: 10 mg; generic; (Rx, C-III)
Methyltestosterone Capsules: 10 mg; Testred® & Android® (Valeant), Virilon® (Star); (Rx, C-III)

References

**METOCLOPRAMIDE HCL**
(met-oh-kloe-pra-mide) Reglan®
GI PROKINETIC AGENT

Prescriber Highlights
- Stimulates upper GI motility & has antiemetic properties; more potent as an antiemetic (in dogs) than a prokinetic agent. May be a poor antiemetic in cats.
- Contraindications: GI hemorrhage, obstruction or perforation, hypersensitivity
- Relatively contraindicated: Seizure disorders, pheochromocytoma
- Adverse Effects: Dogs: Changes in mentation & behavior, constipation; Cats: Signs of frenzied behavior or disorientation, constipation; Horses: IV use, severe CNS effects, behavioral changes & abdominal pain; Foals: Adverse effects less common

Uses/Indications
Metoclopramide has been used in veterinary species for both its GI stimulatory and antiemetic properties. It has been used clinically for gastric stasis disorders, gastroesophageal reflux, to allow intubation of the small intestine, as a general antiemetic (for parvovirus, uremic gastritis, etc.), and an antiemetic to prevent or treat chemotherapy-induced vomiting.

Pharmacology/Actions
The primary pharmacologic effects of metoclopramide are associated with the GI tract and the CNS. In the GI tract, metoclopramide stimulates motility of the upper GI without stimulating gastric, pancreatic or biliary secretions. While the exact mechanisms for these actions are unknown, it appears that metoclopramide sensitizes upper GI motility and may also stimulate the release of a GI-specific prokinetic neurotransmitter from the brain to the GI tract. The exact mechanism for the antiemetic effect is unknown, but it may be related to its dopamine type 2 receptor blocking properties in the brain.
The following drug interactions have either been reported or are theoretical in humans or animals receiving oral metoclopramide and may be of significance in:

**Drug Interactions**

- CNS DEPRESSANTS
  - e.g., barbiturates, benzodiazepines
  - May enhance anticholinergic effects of metoclopramide
  - May antagonize GI motility effects of metoclopramide

- CHOLINERGIC DRUGS
  - e.g., bethanechol
  - May enhance metoclopramide’s GI effects
  - Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.

- CYCLOSPORINE
  - May enhance sedative effects

In overdose situations in humans, metoclopramide has enhanced absorption of these agents

**Pharmacokinetics**

Metoclopramide is absorbed well after oral administration, but a significant first-pass effect in some human patients may reduce systemic bioavailability to 30%. There appears to be a great deal of interpatient variation with this effect. Bioavailability after intramuscular administration has been measured to be 74–96%. After oral dosing, peak plasma levels generally occur within 2 hours.

The drug is well distributed in the body and enters the CNS. Metoclopramide is only weakly bound to 13–22% of plasma proteins. The drug also crosses the placenta and enters the milk in concentrations approximately twice those of plasma.

Metoclopramide is primarily excreted in the urine in humans. Approximately 20–25% of the drug is excreted unchanged in the urine. The majority of the rest of the drug is metabolized to glucuronidated or sulfated conjugate forms and then excreted in the urine. Approximately 5% is excreted in the feces. The half-life of metoclopramide in the dog has been reported to be approximately 90 minutes.

**Overdosage/Acute Toxicity**

The oral LD50 doses of metoclopramide in mice, rats, and rabbits are 465 mg/kg, 760 mg/kg and 870 mg/kg, respectively. Because of the high dosages required for lethality, it is unlikely an oral overdose will cause death in a veterinary patient. Likely clinical signs of overdosage include sedation, ataxia, agitation, extrapyramidal signs, and prolactin secretion stimulation effects.

**Contraindications/Precautions/Warnings**

Metoclopramide is contraindicated in patients with GI hemorrhage, obstruction or perforation, and in those hypersensitive to it. It is relatively (some say absolutely) contraindicated in patients with seizure disorders or head trauma. In patients with pheochromocytoma, metoclopramide may induce a hypertensive crisis. Several veterinary references state that metoclopramide is contraindicated with concurrent phenothiazine therapy (see Drug Interactions).

Metoclopramide should be avoided in dogs with pseudopregnancy as it can cause prolactin release (Romagnoli 2009).

Dosage adjustment may be required when used as a CRI in patients with renal failure. One reference suggests based upon anecdotal experience, reducing the CRI 25-50% of standard dosage (Trepanier, L. 2008).

**Adverse Effects**

In dogs, the most common (although infrequent) adverse reactions seen are changes in mentation and behavior (motor restlessness, involuntary spasms, aggression, and hyperactivity to drowsiness/depression). Cats may exhibit signs of frenzied behavior or disorientation. Both species can develop constipation while receiving this medication.

In adult horses, IV metoclopramide administration has been associated with the development of severe CNS effects. Alternating periods of sedation and excitement, behavioral changes and abdominal pain have been noted. These effects appear to be less common in foals.

Other adverse effects that have been reported in humans and are potentially plausible in animals include extrapyramidal effects, nausea, diarrhea, transient hypertension, and elevated prolactin levels.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy(Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Metoclopramide is excreted into milk and may concentrate at about twice the plasma level, but there does not appear to be significant risk to nursing offspring.

**Overdosage/Acute Toxicity**

The oral LD50 doses of metoclopramide in mice, rats, and rabbits are 465 mg/kg, 760 mg/kg and 870 mg/kg, respectively. Because of the high dosages required for lethality, it is unlikely an oral overdose will cause death in a veterinary patient. Likely clinical signs of overdosage include sedation, ataxia, agitation, extrapyramidal effects, nausea, vomiting, and constipation.

There is no specific antidotal therapy for metoclopramide intoxication. If an oral ingestion was recent, the stomach should be emptied using standard protocols. Anticholinergic agents (diphenhydramine 2.2 mg/kg IV, benztropine, etc.) that enter the CNS may be helpful in controlling extrapyramidal effects. Peritoneal dialysis or hemodialysis is not thought to be effective in enhancing the removal of the drug.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral metoclopramide and may be of significance in veterinary patients:

- **ASPIRIN, ACETAMINOPHEN, ALCOHOL:** In overdose situations in humans, metoclopramide has enhanced absorption of these agents

- **ANESTHETICS:** If metoclopramide is used concurrently IV, acute hypotension has been reported

- **ATROPINE (and related anticholinergic compounds):** May antagonize the GI motility effects of metoclopramide

- **CEPHALEXIN:** In dogs, oral metoclopramide was shown to increase cephalexin peak plasma concentrations and area under the curve. No dosage adjustments are required. (Prados et al. 2007)

- **CHOLINERGIC DRUGS (e.g., bethanechol):** May enhance metoclopramide’s GI effects

- **CNS DEPRESSANTS (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.):** Metoclopramide may enhance CNS depressant effects

- **CYCLOSPORINE:** Metoclopramide increase the rate and extent of GI absorption
**OPIATE ANALGESICS:** May antagonize the GI motility effects of metoclopramide and enhance metoclopramide’s CNS effects.

**MAO INHIBITORS** (including amitraz and potentially, selegiline): Could cause hypertension

**PHENOTHIAZINES** (e.g., acepromazine, chlorpromazine, etc.) and **BUTYROPHENONES** (e.g., droperidol, azaperone): May potentiate the extrapyramidal effects of metoclopramide.

**PROPOFOL:** In humans, metoclopramide reduces induction requirements of propofol by 20-25%.

**SSRI ANTIDEPRESSANTS** (e.g., fluoxetine, sertraline, paroxetine): Potential for enhanced extrapyramidal effects

**TETRACYCLINES:** Metoclopramide increases the rate and extent of GI absorption

**Doses**

**DOGS:**
- a) As an antiemetic: 0.1–0.4 mg/kg q6h PO, SC or IM; or 1–2 mg/kg/day as a continuous IV infusion (Washabau & Elie 1995)
- b) As an antiemetic: Best results are observed when given as a CRI at 0.01–0.02 mg/kg every hour or 1 to 2 mg/kg every 24 hours. (Twedt 2008)
- c) To treat vomiting associated with pancreatitis: 0.01–0.02 mg/kg/hr IV as a CRI or 0.1–0.5 mg/kg IM q8h (Waddell 2007)
- d) For vomiting disorders, gastroesophageal reflux, delayed gastric emptying, ileus, intestinal pseudo-obstruction: 0.2–0.5 mg/kg PO q8h PO or parenterally (may be given as a constant rate IV infusion at 0.01–0.02 mg/kg/hr) (Hall 2008)
- e) For adjunctive treatment of esophagitis: 0.2–0.4 mg/kg PO q8h. Metoclopramide has a limited effect on esophageal motility. (Glazer & Walters 2008)
- f) For post-operative ileus: 0.2–0.5 mg/kg PO or SC at least 30 minutes prior to a meal and at bedtime, or as an IV CRI of 0.01–0.02 mg/kg/hour. (Dowling 2007)
- g) As an antiemetic/prokinetic: 0.2–1 mg/kg PO, SC, IM 4 times a day, or as a CRI at 0.08–0.16 mg/kg/hour (2–4 mg/kg/day). For chemotherapy-induced vomiting, maropitant or drugs like ondansetron are more effective, but metoclopramide is much less expensive. If using metoclopramide, use high dosages (1mg/kg). (Richer 2009)
- h) To induce milk let-down for secondary agalactia: oxytocin 0.25–1 Unit (total dose) SC q2h. Neonates are removed for 30 minutes post-injection, and then encouraged to suckle, or gentle stripping of the glands performed. Metoclopramide at 0.1–0.2 mg/kg SC q12h (dopamine antagonist) can be used to promote milk production. Therapy is usually rewarding within 24 hours. (Davidson 2009)
- i) To increase bladder contractility:
  - a) 0.2–0.5 mg/kg PO q8h (Lane 2000)

**CATS:**
- a) As a prokinetic for adjunctive treatment of esophagitis: 0.2–0.4 mg/kg PO q8h. Cisapride considered superior. (Glazer & Walters 2008)
- b) 0.2–0.4 mg/kg PO, SC 3–4 times daily; or as a continuous IV infusion (1–2 mg/kg per day) (Trepanier, LA 1999)
- c) 0.2–0.5 mg/kg q8h PO or parenterally (may be given as a constant rate IV infusion at 0.01–0.02 mg/kg/hr) (Hall & Washabau 2000)
- d) To increase bladder contractility: 0.2–0.5 mg/kg PO q8h (Lane 2000)
- e) To induce milk let-down for secondary agalactia: oxytocin 0.25–1 Unit (total dose) SC q2h. Neonates are removed for 30 minutes post-injection, and then encouraged to suckle, or gentle stripping of the glands performed. Metoclopramide at 0.1–0.2 mg/kg SC q12h (dopamine antagonist) can be used to promote milk production. Therapy is usually rewarding within 24 hours. (Davidson 2009)

**RABBITS, RODENTS, SMALL MAMMALS:**
- a) Rabbits: 0.2–1 mg/kg PO or SC q6–8h (Ivey & Morrisey 2000)
- b) Rabbits: To assist in removing gastric hairballs: 0.5 mg/kg PO once a day (up to three times a day) (Burke 1999)
- c) Rabbits: 0.5 mg/kg SC or PO q8-24h. Useful pro-motile drug in rabbits with ileus. Do not administer in the presence of an obstruction. (Bryan 2009)
- d) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.2–1 mg/kg PO, SC, IM q12h (Adamcak & Otten 2000)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)
- To stimulate the gastrointestinal tract:
  - a) 0.04 mg/kg/hr as a CRI (Lester 2004)
  - b) For reflux esophagitis: 0.02–0.1 mg/kg SC q4–12 hours; horses may be prone to the extrapyramidal neurologic side effects of metoclopramide. (Jones & Blikslager 2004)

**Monitoring**
- Clinical efficacy
- Adverse effects

**Client Information**
- Contact veterinarian if animal develops clinical signs of involuntary movement of eyes, face, or limbs; or develops a rigid posture.

**Chemistry/Synonyms**
A derivative of para-aminobenzoic acid, metoclopramide HCl occurs as an odorless, white, crystalline powder with PKas of 0.6 and 9.3. One gram is approximately soluble in 0.7 mL of water or 3 mL of alcohol. The injectable product has a pH of 3–6.5.

Metoclopramide HCl may also be known as: AHR-3070-C, DEL-1267, metoclopramidi hydrochloridum, and MK-745; many trade names are available.

**Storage/Stability**
Metoclopramide is photosensitive and must be stored in light resistant containers. All metoclopramide products should be stored at room temperature. Metoclopramide
tachyarrhythmias, premature ventricular contractions (PVC's, VPC's), systemic hypertension, and treating cats with hypertrophic cardiomyopathy. There is increasing evidence that metoprolol is relatively safe to use in animals with bronchospastic disease, it is often chosen over propranolol. It may be effective in supraventricular tachycardia.

**Dosage Forms/Regulatory Status**

**VETERINARY-LAbeLED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LAbeLED PRODUCTS:**

All doses expressed in terms of metoclopramide monohydrate.

Metoclopramide HCl Oral Tablets: 5 mg & 10 mg; Disintegrating Tablets: 5 mg & 10 mg; Reglan® (Alaven); Metozolv® (Salyx); generic; (Rx)

Metoclopramide HCl Oral Syrup: 1 mg/mL in 480 mL & 10 mL vials; and 2 mL amps; reglan® (Alaven); Metozolv® (Salyx); generic; (Rx)

Metoclopramide HCl Injection Solution: 5 mg/mL in 2 mL, 10 mL, & 30 mL vials; and 2 mL ampules; preservative free in 2 mL, 10 mL & 30 mL vials; and 2 mL & 10 mL ampuls; Reglan® (Wyeth-Ayerst); generic; (Rx)

**References**

**METOPROLOL TARTRATE**

**METOPROLOL SUCCINATE**

(me-toe-pro-lole) Lopressor®, Toprol XL®

**BETA-ADRENERGIC BLOCKER**

**Prescriber Highlights**

- Beta-blocker used for supraventricular tachyarrhythmias, premature ventricular contractions (PVC's, VPC's), systemic hypertension, & treatment in cats with hypertrophic cardiomyopathy
- Probably safer to use than propranolol in animals with bronchoconstrictive disease
- Contraindications: Overt or unstable heart failure, hypersensitivity beta-blockers, greater than first-degree heart block, or sinus bradycardia
- Caution: Significant hepatic insufficiency, bronchospastic lung disease, CHF, hyperthyroidism (masks clinical signs, but may be useful for treatment), labile diabetics, & sinus node dysfunction
- Adverse Effects: Most common in geriatric animals or those that have acute decompensating heart disease, include: bradycardia, lethargy & depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, bronchoconstriction, syncope, & diarrrhea
- Try to wean off drug gradually

**Uses/Indications**

Because metoprolol is relatively safe to use in animals with bronchospastic disease, it is often chosen over propranolol. It may be effective in supraventricular
patients. The following drug interactions have either been reported or are theoretical in humans or animals receiving metoprolol and may be of significance in veterinary medicine.

**Pharmacology/Actions**

Metoprolol is a relatively specific beta1-blocker and is sometimes characterized as a second generation beta blocker. At higher dosages, this specificity may be lost and beta2 blockade can occur. Metoprolol does not possess any intrinsic sympathomimetic activity like pindolol nor does it possess membrane-stabilizing activity like pindolol or propranolol. Cardiovascular effects secondary to metoprolol’s negative inotropic and chronotropic actions include: decreased sinus heart rate, slowed AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia.

**Pharmacokinetics**

Metoprolol tartrate is rapidly and nearly completely absorbed from the GI tract, but it has a relatively high first pass effect (50%) so systemic bioavailability is reduced. The drug has very low protein binding characteristics (5–15%) and is distributed well into most tissues. Metoprolol crosses the blood-brain barrier and CSF levels are about 78% of those found in the serum. It crosses the placenta and levels in milk are higher (3-4X) than those found in plasma. Metoprolol is primarily biotransformed in the liver; unchanged drug and metabolites are then principally excreted in the urine. Reported half-lives in various species: Dogs: 1.6 hours; Cats: 1.3 hours; Humans 3–4 hours.

**Contraindications/Precautions/Warnings**

Metoprolol is contraindicated in patients with overt or unstable heart failure, hypersensitivity to this class of agents, greater than first-degree heart block, or sinus bradycardia. Non-specific beta-blockers are generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blocker therapy. They are also relatively contraindicated in patients with bronchospastic lung disease.

Metoprolol should be used cautiously in patients with significant hepatic insufficiency or sinus node dysfunction.

Metoprolol (at high dosages) can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients.

Metoprolol can mask the clinical signs associated with thyrotoxicosis, but it may be used clinically to treat the clinical signs associated with this condition.

**Adverse Effects**

It is reported that adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Adverse effects considered clinically relevant include: bradycardia, lethargy, weakness and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction (less so with beta1 specific drugs like metoprolol). Syncope and diarrhea have also been reported in canine patients with beta-blockers.

Exacerbation of clinical signs has been reported following abrupt cessation of beta-blockers in humans. It is recommended to withdraw therapy gradually in patients who have been receiving the drug chronically.

**Reproductive/Nursing Safety**

Safe use during pregnancy has not been established, but adverse effects to fetuses have apparently not been documented. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.).

Metoprolol is excreted in milk in very small quantities and is unlikely to pose significant risk to nursing offspring.

**Overdosage/Acute Toxicity**

There is limited information available on metoprolol overdose. Humans have apparently survived dosages of up to 5 grams. The most predominant clinical signs expected would be extensions of the drug’s pharmacologic effects: hypotension, bradycardia, bronchospasm, cardiac failure, and, potentially, hypoglycemia.

There were 8 exposures to metoprolol reported to the ASPCA Animal Poison Control Center (APCC) during 2005–2006. In these cases 7 were dogs with 1 showing clinical signs and the remaining case was a cat that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy and tachycardia. If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered. Use caution inducing emesis as coma and seizures may develop rapidly. Monitor: ECG, blood glucose, potassium, and, blood pressure. Treatment of the cardiovascular effects is symptomatic. Use fluids and pressor agents to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol, given cautiously, has been recommended. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with a digitalis glycosides, diuretics, and oxygen. Glucagon (5–10 mg IV—Human dose) may increase heart rate and blood pressure and reduce the cardiodepressant effects of metoprolol.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving metoprolol and may be of significance in veterinary patients:

- **ANESTHETICS, GENERAL (with myocardial depressant effects):** Increased risk for heart failure and hypotension
- **CALCIUM-CHANNEL BLOCKERS (e.g., diltiazem, verapamil, amiodipine):** Concurrent use of beta-blockers with calcium channel blockers (or other negative inotropics) should be done with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **DIGOXIN:** Use with metoprolol may increase negative effects on SA or AV node conduction
- **DIURETICS (thiazides, furosemide):** May increase hypotensive effect of metoprolol
- **HYDRALAZINE:** May increase the risks for pulmonary hypertension in uremic patients
- **QUINIDINE:** May increase metoprolol plasma concentrations
- **RESERPINE:** Potential for additive effects (hypotension, bradycardia)
- **SSRI ANTIDEPRESSANTS (e.g., fluoxetine, sertraline, paroxetine):** May increase metoprolol plasma concentrations
- **SYMPATHOMIMETICS (metaproterenol, terbutaline, beta-effects of epinephrine, phenylpropanolamine, etc.):** May have their actions blocked by metoprolol and they may, in turn, reduce the efficacy of atenolol
DOGS:

As an oral beta blocker:

a) For rate control in chronic atrial fibrillation: 0.25–1 mg/kg PO q12-24h. (Saunders et al. 2009)

b) For CHF: The role of beta-blocker therapy in dogs with congestive heart failure is unclear. Beta-blockers are best employed in animals that are minimally symptomatic with early/mild heart failure, or in animals in later stages of CHF that are already well controlled on a stable cardiac drug regimen. Metoprolol has been used at 0.2 mg/kg PO twice daily, with slow titration upwards every 2–3 weeks up to 0.4–6.6 mg/kg PO three times a day. Many dogs will not tolerate this upward titration. (Rush 2008)

c) To decrease the incidence atrial fibrillation and flutter in dogs undergoing valve surgery: Using sustained release metoprolol (Toprol-XR®) at 0.4–1 mg/kg PO q24h administered before and as soon as feasible after surgery. (Orton 2006)

CATS:

As an oral beta blocker:

a) 2–15 mg (total dose) PO q8h (Brovida 2002)

Monitoring

Cardiac function, pulse rate, ECG if necessary, BP if indicated

Toxicity (see Adverse Effects/Overdosage)

Client Information

To be effective, the animal must receive all doses as prescribed

Notify veterinarian if animal becomes lethargic or exercise intolerant, has shortness of breath or cough, or develops a change in behavior or attitude

Chemistry/Synonyms

A beta1 specific adrenergic blocker, metoprolol tartrate occurs as a white, crystalline powder having a bitter taste. It is very soluble in water. Metoprolol succinate occurs as a white, crystalline powder and is freely soluble in water.

Metoprolol may also be known as: CGP-2175E; H-93/26, and metoprolol; many trade names are available.

Storage/Stability

Store all products protected from light. Store tablets in tight, light-resistant containers at room temperature. Avoid freezing the injection.

Compatibility/Compounding Considerations

The injection is compatible with D5W and normal saline, and at Y-sites with morphine sulfate.

Compounded preparation stability: Metoprolol oral suspension compounded from the commercially available tablets has been published (Allen & Erickson 1996). Triturating twelve (12) metoprolol tartrate 100 mg tablets with 60 mL of Ora-Plus® and qs ad to 120 mL with Ora-Sweet® or Ora-Sweet SF® yields a 10 mg/mL metoprolol tartrate oral suspension that retains >95% potency for 60 days when stored at both 4°C and 25°C and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Metoprolol Tartrate Oral Tablets: 25 mg, 50 mg & 100 mg; Lopressor® (Novartis); generic; (Rx)

Metoprolol Succinate Extended-Release Tablets: 25 mg, 50 mg, 100 mg & 200 mg; Toprol XL® (AstraZeneca); generic; (Rx)

Metoprolol Tartrate Injection: 1 mg/mL in 5 mL amps and Carpuject sterile cartridge units; Lopressor® (Novartis); generic; (Rx)

References

METRONIDAZOLE

METRONIDAZOLE BENZOATE

(me-troe-ni-daz-ole) Flagyl®

ANTIBIOTIC, ANTIPARASITIC

Prescriber Highlights

- Injectable & oral antibacterial (anaerobes) & antiprotozoal agent
- Prohibited by the FDA for use in food animals
- Contraindications: Hypersensitivity to it or nitroimidazole derivatives. Extreme caution: in severely debilitated, pregnant or nursing animals; hepatic
Uses/Indications
Although there are no veterinary-approved metronidazole products, the drug has been used extensively in the treatment of Giardia in both dogs and cats. It is also used clinically in small animals for the treatment of other parasites (Trichomonas and Balantidium coli) as well as treating both enteric and systemic anaerobic infections.

In horses, metronidazole has been used clinically for the treatment of anaerobic infections.

Pharmacology/Actions
Metronidazole is a concentration-dependent bactericidal agent against susceptible bacteria. Its exact mechanism of action is not completely understood, but it is taken-up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible for the drug's antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria.

Metronidazole has activity against most obligate anaerobes including Bacteroides spp. (including B. fragilis), Fusobacterium, Veillonella, Clostridium spp., Peptococcus, and Peptostreptococcus. Actinomyces is frequently resistant to metronidazole.

Metronidazole is also trichomonacidal and amebicidal in action and acts as a direct amebicide. Its mechanism of action for its antiprotozoal activity is not understood. It has therapeutic activity against Entamoeba histolytica, Trichomonas, Giardia, and Balantidium coli. It acts primarily against the trophozoite forms of Entamoeba rather than encysted forms.

Finally, metronidazole has some inhibitive actions on cell-mediated immunity.

Pharmacokinetics
Metronidazole is relatively well absorbed after oral administration. Metronidazole is rather lipophilic and is rapidly and widely distributed after absorption. It is distributed to most body tissues and fluids, including bone, abscesses, the CNS, and seminal fluid. It is less than 20% bound to plasma proteins in humans. Metronidazole is primarily metabolized in the liver via several pathways. Both the metabolites and unchanged drug are eliminated in the urine and feces.

The oral bioavailability in dogs is high, but interpatient variable, with ranges from 50–100% reported. If given with food, absorption is enhanced in dogs, but delayed in humans. Peak levels occur about one hour after oral dosing.

In a single-dose study in cats (Sekis et al. 2009), the oral bioavailability of metronidazole benzoate is variable, but averages around 65%. Peak levels after oral dosing appear to be highly variable in cats (ranging from 1–8 hours) and peak serum concentrations are somewhat lower in cats than in dogs or humans. Mean systemic clearance is slower in cats than dogs (2.49 mL/kg/min vs. 1.53 mL/kg/min). Despite the concern that glucuronidation is a metabolic pathway for metronidazole, terminal elimination half-life is only slightly (not significantly) longer (5-6 hours) in cats.

The oral bioavailability of the drug in horses averages about 80% (range 57–100%). If administered rectally to horses, bioavailability is decreased by about 50%. Elimination half-life in the horse is about 2.9-4.3 hours.

Contraindications/Precautions/Warnings
Metronidazole is contraindicated in animals hypersensitive to the drug or nitroimidazole derivatives. It has been recommended not to use the drug in severely debilitated, pregnant or nursing animals. Metronidazole should be used with caution in animals with hepatic dysfunction. If the drug must be used in animals with significant liver impairment, consider using only 25–50% of the usual dose.

Because of the risk for neurotoxicity in dogs, total daily doses of metronidazole should not exceed 65 mg/kg per day (Tams 2007).

Adverse Effects
Adverse effects reported in dogs include neurologic disorders, lethargy, weakness, neutropenias, hepatotoxicity, hematuria, anorexia, nausea, vomiting, and diarrhea. Neurologic toxicity in dogs may be manifested after acute high dosages or, more likely, with chronic moderate to high-dose therapy. Clinical signs reported are described below in the Overdosage section.

In cats, vomiting, inappetence, hepatotoxicity and rarely, central nervous toxicity can occur with metronidazole therapy (Scorza & Lappin 2004). Genotoxicity was detected in peripheral blood mononuclear cells collected from cats after 7 days of oral metronidazole, but resolved within 6 days of discontinuing the drug. Clinical significance, particularly with chronic therapy, is yet to be determined. (Sekis et al. 2009)

In horses, metronidazole may occasionally cause anorexia, ataxia and depression, particularly when used at higher dosages. There have been reported cases of Clostridium difficile and C. perfringens diarrhea and death after use of metronidazole.

Metronidazole tablets have a sharp, metallic taste that animals find unpleasant. Placing in capsules or using compounded oral suspensions may alleviate the problem of dosing avoidance.

Reproductive/Nursing Safety
Metronidazole’s potential for teratogenicity is somewhat controversial; some references state that it has been teratogenic in some laboratory animal studies, but others state that it has not. However, unless the benefits to the mother outweigh the risks to the fetus(es), it should not be used during pregnancy, particularly during the first 3 weeks of gestation. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Because of the potential for tumorigenicity, consider using alternative therapy or switching to milk replacer for nursing patients.

Overdosage/Acute Toxicity
Signs of intoxication associated with metronidazole in dogs and cats, include anorexia and/or vomiting, depression, mydriasis, nystagmus, ataxia, head-tilt, deficits of proprioception, joint snapping, disorientation, tremors, seizures, bradycardia, rigidity and stiffness. These effects may be seen with acute overdoses, doses in dogs above 60 mg/kg per day, or in some animals on chronic therapy when using "recommended" doses (e.g., 30 mg/kg/day).

Metronidazole is prohibited for use in food animals by the FDA.
In dogs, common signs of metronidazole toxicity include generalized ataxia with a very rapid positional nystagmus. Most often, dogs have neurological deficits localized to the central vestibular system and/or cerebellum. Dogs with mild to moderate clinical signs usually improve rapidly within 1-2 days, once metronidazole has been discontinued. (Vernau 2009).

Diazepam has been used successfully to decrease the CNS effects associated with metronidazole toxicity, but has not been evaluated in a controlled manner. See the Diazepam monograph or the reference by Evans, Levesque, et al for more information (Evans et al. 2002).

Acute overdoses should be handled by attempting to limit the absorption of the drug using standard protocols. Extreme caution should be used before attempting to induce vomiting in patients demonstrating CNS effects or aspiration may result. If acute toxicity is seen after chronic therapy, the drug should be discontinued and the patient treated supportively and symptomatically. Neurologic clinical signs may require several days before showing signs of resolving.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving metronidazole and may be of significance in veterinary patients:

- **ALCOHOL**: May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction when given with metronidazole.
- **CIMETIDINE**: May decrease the metabolism of metronidazole and increase the likelihood of dose-related side effects.
- **PHENOBARBITAL or PHENYTOIN**: May increase the metabolism of metronidazole, thereby decreasing blood levels.
- **WARFARIN**: Metronidazole may prolong the PT in patients receiving warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

**Laboratory Considerations**

- Metronidazole can cause falsely decreased readings of **AST (SGOT)** and **ALT (SGPT)** when determined using methods measuring decreases in ultraviolet absorbance when NADH is reduced to NAD.

**Doses**

- **DOGS:**
  
  **Note**: Doses are for metronidazole base unless otherwise noted. If using metronidazole benzoate adjust dosages unless provided by pharmacy as “mg/mL of the base”. 1 mg of metronidazole base = 1.6 mg of metronidazole benzoate.

  For treatment of Giardia:
  a) 15–25 mg/kg PO q12–24h daily for 5–7 days (Lappin 2006)
  b) 22 mg/kg PO twice daily for 5 days. May be combined with fenbendazole (50 mg/kg PO once daily for 3 or 5 days) to relieve clinical signs and eliminate parasites. (Payne & Artzer 2009)

  For other protozoal infections:
  a) *Entamoeba histolytica* or *Pentatrichomas hominis*: 25 mg/kg PO q12h for 8 days (Lappin 2000)
  
  For anaerobic infections:
  a) For sepsis: 15 mg/kg IV q12h (Hardie 2000)
  
  For eliminating Helicobacter gastritis infections:
  a) Using triple therapy: Metronidazole 15.4 mg/kg q8h, amoxicillin 11 mg/kg q8h and bismuth subsalicylate (original *Pepto-Bismol®*) 0.22 mL/kg PO q4–6h. Give each for 3 weeks. (Hall 2000)

  For adjunctive therapy of plasmacytic/lymphocytic enteritis:
  a) 10–30 mg/kg PO q8–24h for 2–4 weeks in refractory cases (Leib, M.S. et al. 1989)
  
  For *Clostridium perfringens* enterotoxosis:
  a) 10–20 mg/kg PO twice daily for 7–28 days. (Tams 2007)

  For inflammatory bowel disease:
  a) 10–20 mg/kg PO two to three times a day has been used in the treatment of mild to moderate cases of large bowel IBD. (Washabau 2009)
  b) For ulcerative colitis in dogs refractory to other therapies (e.g., sulfasalazine, immunosuppressants, diet, etc.): 10–20 mg/kg PO twice daily–three times a day; may be beneficial in treating for 2–4 weeks those dogs with chronic colitis having unexplained diarrhea (Leib, M. 2000).
  c) 10–15 mg/kg PO q8–12h; combine with prednisone to manage moderate to severe cases. (Marks 2007)
  d) In cases of predominantly large bowel diarrhea (colitis with typical clinical presentation) if parasiticide treatment and elimination diet fail, a therapeutic trial can be made: metronidazole 20–25 mg/kg PO twice daily for 5-10 days with the addition of fiber to the diet (e.g., psyllium at 0.5 tablespoon for toy breeds, 1 tablespoon for small dogs, 2 tablespoons for medium dogs, and 3 tablespoons for large dogs. However, sampling of mucosal biopsies prior to further treatment may be the best course of action. (Gaschen 2008)

  For treatment of medial canthus syndrome (tear staining):
  a) 100–200 mg (total dose) PO once per day for 10 days each month. (Krohne 2008)

- **CATS:**
  
  **Note**: Doses are for metronidazole base unless otherwise noted. If using metronidazole benzoate adjust dosages unless provided by pharmacy as “mg/mL of the base”. 1 mg of metronidazole base = 1.6 mg of metronidazole benzoate.

  For treatment of Giardia:
  a) 15–25 mg/kg PO q12–24h daily for 5–7 days (Lappin 2006)
  b) 25 mg/kg PO q12h for 7 days (Zoran 2007)
  c) 22 mg/kg PO twice daily for 5 days. May be combined with fenbendazole (50 mg/kg PO once daily for 3 or 5 days) to relieve clinical signs and eliminate parasitic infection. (Payne, 2009)
parasites. (Payne, 2009)

For other protozoal infections:

a) *Entamoeba histolytica* or *Pentatrichomas hominis*: 25 mg/kg PO q12h for 8 days (Lappin, 2000)

For treating *H. pylori*:

a) Metronidazole 10–15 mg/kg PO two times a day; clarithromycin 7.5 mg/kg PO two times a day; amoxicillin 20 mg/kg PO twice daily for 14 days (Simpson 2003)

For anaerobic infections:

a) For sepsis: 15 mg/kg IV q12h (Hall 2000)

For adjunctive therapy of GI conditions:

a) 10–20 mg/kg PO once to twice daily. Very bitter; mask flavor. (Williams 2000)

b) For inflammatory bowel disease: 50 mg/kg PO once daily. (Johnson-Delaney 2008)

c) For hepatic encephalopathy: 7.5 mg/kg PO q8–12h (Cornelius *et al.* 2000)

**FERRETS:**

Note: Doses are for metronidazole base unless otherwise noted. If using metronidazole benzoate adjust dosages unless provided by pharmacy as “mg/mL of the base”. 1 mg of metronidazole base = 1.6 mg of metronidazole benzoate.

For eliminating *Helicobacter mustelae* gastritis infections:

a) Using triple therapy: Metronidazole 22 mg/kg, amoxicillin 22 mg/kg and bismuth subsalicylate (original Pepto-Bismol®) 17.6 mg/kg PO. Give each 3 times daily for 3–4 weeks. (Hall 2000)

b) Amoxicillin 30 mg/kg PO q8h, metronidazole 20 mg/kg PO q8h, & bismuth subsalicylate 7.5 mg/kg PO q8h. All are given for 21-28 days. (Johnson-Delaney 2008)

c) For anaerobic infections: 20 mg/kg PO q12h for 3–5 days or 40 mg/kg PO once daily; 5 mg/kg slow IV q12h. (Ivey & Morrisey 2000)

**RABBITS, RODENTS, SMALL MAMMALS:**

Note: Doses are for metronidazole base unless otherwise noted. If using metronidazole benzoate adjust dosages unless provided by pharmacy as “mg/mL of the base”. 1 mg of metronidazole base = 1.6 mg of metronidazole benzoate.

a) Rabbits: For anaerobic infections: 20 mg/kg PO q12h for 3–5 days or 40 mg/kg PO once daily; 5 mg/kg slow IV q12h. (Ivey & Morrisey 2000)

b) Chinchillas: 10–40 mg/kg PO once daily as an antimicrobial; 50–60 mg/kg PO twice daily for 5 days as an antiparasiticide (Giardia) (Hayes 2000)

c) Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 20–60 mg/kg PO q8–12h. Mice: 3.5 mg/mL in water for 5 days. Rats: 10–40 mg per rat PO once daily. Chinchillas, Guinea pigs: 10–40 mg/kg PO once daily. Gerbils, Hamsters: 7.5 mg/70–90 grams of body weight PO q8h. Add sucrose to improve palatability. (Adamcak & Otten 2000)

d) For susceptible infections: 10–30 mg/kg PO once to twice daily. Very bitter; mask flavor. (Williams 2000)

**HORSES:**

For susceptible anaerobic infections:

a) 20–25 mg/kg PO q8–12h; for treatment of colitis due to *Clostridium* spp., may dose at 15 mg/kg PO q8h. Can also dose at same dosages rectally if unable to dose PO. Metronidazole is uncommonly associated with diarrhea and neurologic side effects. (Bentz 2007)

b) For metritis secondary to *B. fragilis*: 15–25 mg/kg PO q12h. (LeBlanc 2009)

c) Foals: Oral metronidazole therapy should be strongly considered for all foals with severe diarrhea as about 35% of foals tested are positive for toxins associated with clostridia. Oral metronidazole is typically administered at 15–25 mg/kg PO q8h, but doses of 25 mg/kg q12h have recently also been recommended. May also give IV; authors use a loading dose of 15 mg/kg, and then give 7.5 mg/kg q6h based on the human dose recommendation. (Corley & Hollis 2009)

d) Foals with *C. perfringens*: 10–15 mg/kg PO 3–4 times a day (dose depends on severity); if animal has an ileus and is intolerant of oral feeding give IV at 10 mg/kg IV 4 times a day (Slovis 2003)

e) For *L. intracellularis* infections: metronidazole 10–15 mg/kg PO q8–12h with either oxytetracycline (10–18 mg/kg via slow IV q24h) or chloramphenicol (44 mg/kg PO q6–8h). (Frazer 2007)

**BIRDS:**

For susceptible infections (anaerobes; giardia):

a) 10–50 mg/kg PO q12h. (Oglesbee 2009)

b) Ratites (not to be used for food): 20–25 mg/kg PO twice daily (Jenson 1998)

**REPTILES/AMPHIBIANS:**

a) For anaerobic infections in most reptile species: 150 mg/kg PO once; repeat in one week.

For amoebae and flagellates in most species: 100–275 mg/kg PO once; repeat in 1–2 weeks.

In *Drymarchon* spp., *Lampropeltis pyromelana*, and *L. zonata*: 40 mg/kg PO once; repeat in 2 weeks (Gauvin 1993)

b) In reptiles and amphibians treatment for amoebae, flagellates and ciliates is typically with metronidazole 100 mg/kg PO repeated in 2 weeks; or 50 mg/kg PO once daily for 3-5 days; repeat pm. As is the case with all medications used in reptiles and amphibians, each animal has to be treated on a case-by-case basis for all medications; in the literature there are several different doses as well as treatment schedules listed. (de la Navarre 2003)
A synthetic, nitroimidazole antibacterial and antiprotozoal agent, metronidazole occurs as white to pale yellow crystalline powder or crystals with a pKa of 2.6. It is sparingly soluble in water or alcohol. Metronidazole base is commercially available as tablets or solution for IV injection and metronidazole HCl is available as injectable powder for reconstitution. The hydrochloride is very soluble in water.

Metronidazole benzoate is the benzoic ester of metronidazole. It occurs as a white to slightly yellow, crystalline powder that is practically insoluble in water, slightly soluble in alcohol, and soluble in acetone. As it is less soluble in aqueous solutions than is the base, it does not taste as bad.

Metronidazole may also be known as: Bayer-5360, metronidazolum, SC-32642, NSC-50364, RP-8823, and SC-10295; many trade names are available.

**Storage/Stability**

Metronidazole tablets and HCl powder for injection should be stored at temperatures less than 30°C and protected from light. The injection should be protected from light and freezing and stored at room temperature.

Specific recommendations on the reconstitution, dilution, and neutralization of metronidazole HCl for injection are detailed in the package insert of the drug and should be referred to if this product is used. Do not use aluminum hub needles to reconstitute or transfer this drug as a reddish-brown discoloration may result in the solution.

**Compatibility/Compounding Considerations**

The following drugs and solutions are reportedly physically **compatible** with metronidazole ready-to-use solutions for injection: amikacin sulfate, aminophylline, carbenicillin disodium, cefazolin sodium, cefotaxime sodium, cefoxitin sodium, cefuroxime sodium, cephalothin sodium, chloramphenicol sodium succinate, clindamycin phosphate, disopyramide phosphate, gentamicin sulfate, heparin sodium, hydrocortisone sodium succinate, hydromorphone HCl, magnesium sulfate, meperidine HCl, morphine sulfate, moxalactam disodium, multielectrolyte concentrate, multivitamins, netilmicin sulfate, penicillin G sodium, and tobramycin sulfate.

**Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.**

The following drugs and solutions are reportedly physically **incompatible** (or compatibility data conflicts) with metronidazole ready-to-use solutions for injection: aztreonam, cefamandole naftate, and dopamine HCl.

Metronidazole hydrochloride is very bitter tasting and even with taste masking or flavoring agents is universally unpalatable to veterinary patients. Although not commercially available in the United States, the metronidazone ester of benzoic acid, metronidazole benzoate, is relatively palatable to animal patients and is often used in extemporaneously compounded suspensions, particularly for cats to reduce the drug’s bitterness. If using metronidazole benzoate adjust dosages from those for the base unless provided by pharmacy as “mg/mL of the base”. 1 mg of metronidazole base in extemporaneously compounded suspensions, particularly for cats to reduce the drug’s bitterness. If using metronidazole benzoate adjust dosages from those for the base unless provided by pharmacy as “mg/mL of the base”.

Metronidazole may also be known as: Bayer-5360, metronidazolum, SC-32642, NSC-50364, RP-8823, and SC-10295; many trade names are available.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

Metronidazole is prohibited for use in food animals by the FDA.

**HUMAN-LABELLED PRODUCTS:**

- **Metronidazole Oral Tablets:** 250 mg & 500 mg; Flagyl® (Pfizer); generic; (Rx)
- **Metronidazole Oral Capsules:** 375 mg; Flagyl 375® (Pfizer); generic; (Rx)
- **Metronidazole Extended-Release Oral Tablets:** 750 mg; Flagyl ER® (Pfizer); (Rx)
- **Metronidazole Injection:** 5 mg/mL in 100 mL vials and single-dose containers; generic; (B. Braun); Metronidazole in Sodium Chloride (Claris Lifesciences); (Rx)
- **Bismuth Subsalicylate, Metronidazole & Tetracycline HCl Combination Tablets & Capsules:** 262.4 mg bismuth subsalicylate, 250 mg metronidazole; 500 mg tetracycline; Helidac® (Procter & Gamble); (Rx)
- **Lotions, gels, vaginal products and creams also available.**

**References**

Metyrapone
(me-er-ah-pone) Metopirone®

ADRENAL STEROID INHIBITOR

Prescriber Highlights

- Adrenal steroid synthesis inhibitor primarily used in cats with hyperadrenocorticism; may be most useful for short-term treatment to stabilize patient before adrenalectomy
- Seems well tolerated in cats at recommended doses
- May alter insulin requirements; monitor blood glucose closely
- Has had availability issues

Uses/Indications

Metyrapone may be useful to treat cats with hyperadrenocorticism, especially short-term in an attempt to stabilize the patient prior to adrenalectomy. Clinical experience is quite limited, but it appears to give consistent results and not be overly toxic to cats. Resolving hypercortisolism should reduce insulin antagonism and reduce or eliminate the need for exogenous insulin in some cats (Feldman 2009). Metyrapone may potentially be useful in treating hyperadrenocorticism in ferrets and small mammals (e.g., hamsters), but there is little, if any, information available on its use in these species.

Metyrapone is used with other biochemical and laboratory evaluations in the diagnostic evaluation of hypothalamic-pituitary adrenal corticotropin hormone-function. It is also used for treatment of Cushing’s Syndrome (not an FDA-approved indication).

Pharmacology/Actions

Metyrapone reduces cortisol and corticosterone production by inhibiting hydroxylation of 11-deoxycortisol to cortisol in the adrenal cortex. ACTH production can increase as the negative feedback mechanism is inhibited. With time, this may override the effects of metyrapone on the adrenal gland. Metyrapone can also suppress synthesis of aldosterone, and cause a mild natriuresis. Continued inhibition stimulates increased ACTH production that can ultimately override the inhibitory effects. Mineralocorticoid deficiency does not usually occur with long-term metyrapone therapy because inhibition of the 11-beta-hydroxylation reaction increases production of 11-desoxycorticosterone, a mineralocorticoid that can cause hypertension in patients receiving long-term metyrapone therapy.

Pharmacokinetics

No information on the pharmacokinetics of metyrapone was located for cats. In humans, metyrapone is well absorbed after oral administration. Peak levels occur in around 2 hours. Metyrapone’s major metabolite, metyrapol, is active and formed via reduction; it has a half-life about twice as long as metyrapone. Both metyrapone and metyrapol are conjugated with glucuronide in humans. As cats are unable to effectively glucuronidate, it is unclear what metabolic path(s) metyrapone takes in this species.

No information on the pharmacokinetics of metyrapone was located for cats. In humans, metyrapone is used with other biochemical and laboratory evaluations in the diagnostic evaluation of hypothalamic-pituitary adrenal corticotropin hormone-function. It is also used for treatment of Cushing’s Syndrome (not an FDA-approved indication).

Contraindications/Precautions/Warnings

Metyrapone may not be used in animals that are hypersensitive to it or have adrenal cortical insufficiency.

Use cautiously (enhanced monitoring) in cats with concurrent diabetes; monitor blood glucose closely as hypoglycemia can develop rapidly.

Adverse Effects

Metyrapone appears to be relatively well tolerated in cats. Dosages ranging from 195–250 mg/cat/day (divided) have been used in cats with hyperadrenocorticism without observed toxicity (Bruyette 2010). The following adverse effects have been reported in human patients taking metyrapone: headache, dizziness, sedation, allergic rash, nausea, vomiting, and abdominal pain. Rarely, metyrapone can cause bone marrow depression.

Reproductive/Nursing Safety

Metyrapone should be given to pregnant queens only if clearly needed. Animal reproduction studies have not been conducted with metyrapone. In women given the drug in the 2nd and 3rd trimester, evidence of fetal pituitary response to the enzymatic block was detected. The FDA has assigned metyrapone to category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans).

Metyrapone’s safety in lactating animals and their offspring is not known.
Metyrapone’s safety in lactating animals and their offspring is not known.

Overdosage/Acute Toxicity
The oral LD50 in rats (mg/kg) was 521 mg/kg. Metyrapone overdoses likely would cause GI effects and, possibly, acute adrenocortical insufficiency. Other effects that may be seen include: hypoglycemia, hyponatremia, hypochloremia, hyperkalemia, cardiac arrhythmias, hypotension, dehydration, and impairment of consciousness. There is no specific antidote. Standard decontamination protocols should be considered with intravenous hydrocortisone, saline and glucose. Monitoring and support for several days may be required. Contact an animal poison control center for more information and guidance.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving metyrapone and may be of significance in veterinary patients:

- **ACETAMINOPHEN (Do NOT use in cats):** In humans, there is an increased risk for acetaminophen toxicity
- **CORTICOSTEROIDS:** Decreases the efficacy of metyrapone.

Laboratory Considerations
- In humans, the following drugs have been reported to interfere with the results of the metyrapone test: antidepressants such as amitriptyline, antithyroid drugs, phenothiazines, barbiturates, corticosteroids, cyproheptadine, and hormones such as estrogens and progesterone.
- The metyrapone test may not be reliable in humans with hyper- or hypothyroidism.

Doses
- **CATS:**
  
  For treatment of hyperadrenocorticism:
  
  a) Metyrapone has been used to successfully treat hyperadrenocorticism in the cat; recommended dose is 65 mg/kg PO every 8 to 12 hours. (Scott-Moncrieff 2010)

Monitoring
- Blood glucose should be closely monitored in cats, particularly those that are diabetic
- Clinical signs associated with hyperadrenocorticism or hypoadrenocorticism

Client Information
- Metyrapone will likely need to compounded from the commercially available capsule, follow specific storage requirements.
- To reduce the chances for vomiting, give this medication with food.
- Contact veterinarian immediately if cat develops any of the following signs: will not eat, weakness or lack of normal energy, vomiting, excessive drinking or urinating, or diarrhea.

Chemistry/Synonyms
- Metyrapone occurs as a white to light amber, fine, crystalline powder, with a characteristic odor. It is sparingly soluble in water; soluble in chloroform and methyl alcohol.
- Metyrapone may also be known as SU-4885, metirapon, metirapona, or metyraponum. A common trade name is Metopirone®.

Storage/Stability
- Store metyrapone at room temperature in a well-closed, light-resistant container.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Metyrapone Oral Capsules: 250 mg; Metopirone® (Ciba-Geigy); (Rx)

References

**MEXILETINE HCL**

(mex-i-let-teen) Mexitil®

ORAL ANTIARRHYTHMIC

Prescriber Highlights
- Oral antiarrhythmic with similar effects as lidocaine; used for V tach, PVC’s; often used with atenolol
- Extreme caution: Pre-existing 2nd or 3rd degree AV block (without pacemaker), or in patients with cardiogenic shock
- Caution: Severe congestive heart failure or acute myocardial infarction, hepatic function impairment, hypotension, intraventricular conduction abnormalities, sinus node function impairment, seizure disorder, or sensitivity to the drug
- Adverse Effects: GI distress, including vomiting (give with meals to alleviate); Potentially: CNS effects (trembling, unsteadiness, dizziness, depression), shortness of breath, PVC’s & chest pain could occur; rarely (reported in humans): seizures, agranulocytosis, & thrombocytopenia

- Relatively expensive (compared to quinidine)

- Drug-drug; drug-lab interactions

---

Uses/Indications
Mexiletine may be useful to treat some ventricular arrhythmias, including PVC’s and ventricular tachycardia in small animals. Ventricular tachycardias that have responded to lidocaine usually (but not always) respond to mexiletine as well. Mexiletine may have less cardiodepressant effects and appears to have fewer adverse effects than either procainamide or quinidine, but it is much more costly.

Mexiletine may be useful treating certain myopathies in dogs such as myotonia congenita (most studied in miniature schnauzers and Chow Chows) and myokymia in Jack Russell Terriers.

Pharmacology/Actions
Mexiletine is considered a class IB antiarrhythmic agent and is similar to lidocaine in its mechanism of antiarrhythmic activity. It inhibits the inward sodium current (fast sodium channel), thereby reducing the rate of rise of the action potential, Phase O. In the Purkinje fibers, automaticity is decreased, action potential is shortened and, to a lesser extent, effective refractory period is decreased. Usually conduction is unaffected, but may be slowed in patients with preexisting conduction abnormalities.

Pharmacokinetics
Mexiletine is relatively well absorbed from the gut and has a low first-pass effect. In humans, it is moderately bound to plasma proteins (60–75%), and is metabolized in the liver to inactive metabolites with an elimination half-life of about 10–12 hours. Half-lives may be significantly increased in patients with moderate to severe hepatic disease, or in those having severely reduced cardiac outputs. Half-lives may be slightly prolonged in patients with severe renal disease or after acute myocardial infarction.

Contraindications/Precautions/Warnings
Mexiletine should be used with extreme caution, if at all, in patients with pre-existing 2nd or 3rd degree AV block (without pacemaker), or with cardiogenic shock. It should be used only when the benefits of therapy outweigh the risks when the following medical conditions exist: severe congestive heart failure or acute myocardial infarction, hepatic function impairment, hypotension, intraventricular conduction abnormalities, sinus node function impairment, seizure disorder, or sensitivity to the drug.

Adverse Effects
The most likely adverse effect noted in animals is GI distress, including vomiting. Giving with meals may alleviate this. Potentially (reported in humans): CNS effects (trembling, unsteadiness, dizziness, depression), shortness of breath, PVC’s and chest pain could occur. Rarely, seizures, agranulocytosis, and thrombocytopenia have been reported in humans.

Reproductive/Nursing Safety
Lab animal studies have not demonstrated teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Because mexiletine is secreted into maternal milk, it has been recommended to use milk replacer if the mother is receiving the drug.

Overdosage/Acute Toxicity
Toxicity associated with overdosage may be significant. Case reports in humans have noted that CNS signs always preceded cardiovascular signs. Treatment should consist of GI tract emptying protocols when indicated, acidification of the urine to enhance urinary excretion, and supportive therapy. Atropine may be useful if hypotension or bradycardia occur.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving mexiletine and may be of significance in veterinary patients:

- **ANTACIDS, ALUMINUM-MAGNESIUM:** May slow the absorption of mexiletine
- **ATROPINE:** May reduce the rate of oral absorption
- **CIMETIDINE:** May increase or decrease mexiletine blood levels
- **GRIZEOFULVIN:** May accelerate the metabolism of mexiletine
- **LIDOCAINE:** May cause additive adverse effects
- **METOCLOPRAMIDE:** May accelerate the absorption of mexiletine.
- **OPIATES:** May slow the absorption of mexiletine.
- **PHENOBARBITAL, PRIMIDONE, PHENYTOIN:** May accelerate the metabolism of mexiletine
- **RIFAMPIN:** May accelerate the metabolism of mexiletine
- **THEOPHYLLINE (aminophylline):** Metabolism may be reduced by mexiletine, thereby leading to theophylline toxicity
- **URINARY ACIDIFYING DRUGS (e.g., methionine, ammonium chloride, potassium phosphate, sodium phosphate):** May accelerate the renal excretion of mexiletine
- **URINARY ALKALINIZING DRUGS (e.g., citrates, bicarb, carbonic anhydrase inhibitors):** May reduce the urinary excretion of mexiletine
Laboratory Considerations

- Some human patients (1–3%) have had AST values increase by as much as three times or more above the upper limit of normal. This is reportedly a transient effect and asymptomatic.

Doses

**DOGS:**

For treating or assisting in treatment of ventricular arrhythmias:

a) 5–8 mg/kg PO q8h (Fox 2003)

b) 4–10 mg/kg PO q8h (Hogan 2004)

c) For Boxers with ventricular arrhythmias: mexiletine at 5–7.5 mg/kg three times daily with sotalol at 1.5–3 mg/kg twice daily; was successful in 7/8 dogs treated in study, warrants further investigation. (Prosek et al. 2006)

d) 4–8 mg/kg PO q8h, combined with atenolol (0.5 mg/kg PO q12–24h) (Moise 2000)

e) For familial arrhythmic cardiomyopathy of Boxers: 5–8 mg/kg PO q8h with atenolol at 12.5 mg (total dose) q12h (Meurs 2003)

f) 5–6 mg/kg PO q8h; always give with food to avoid nausea. (Meurs 2006)

For treating myotonia congenital (most studied in Chow Chows and miniature schnauzers) or myokymia in Jack Russell terriers:

a) 8.3 mg/kg PO q8h (Lorenz 2007)

Monitoring

- In humans, therapeutic plasma concentrations are: 0.5–2 micrograms/mL; toxicity may be noted at therapeutic levels
- ECG
- Adverse effects

Client Information

- Give with food to reduce risk for vomiting or nausea
- Reinforce adherence to prescribed therapy.

Chemistry/Synonyms

A class IB antiarrhythmic, mexiletine HCl occurs as a white or almost white, odorless, crystalline powder. It is freely soluble in water.

Mexitil®

Mexiletine may also be known as: Ko-1173, mexiletini hydrochloridum, Mexifen®, Mexitin®, Mexitil®, Myovek® and Ritalmex®.

Storage/Stability

Mexitilene capsules should be stored in tight containers at room temperature.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Mexitilene Oral Capsules: 150 mg, 200 mg & 250 mg; generic; (Rx)

References

MIBOLERONE

(mye-boe-le-rone) Cheque® Drops

ANDROGEN; ANABOLIC

Prescriber Highlights

- Availability an issue; now a controlled substance in the USA
- Androgenic, anabolic, antigonadotropic used to suppress estrus, treat pseudocyesis (false pregnancy) or severe galactorrhea in dogs
- Contraindications: Perianal adenoma, perianal adenocarcinoma or other androgen-dependent neoplasias, pregnant or lactating bitches, ongoing or history of liver or kidney disease. The manufacturer also recommends not using the drug in Bedlington terriers.
- NOT for use in cats
- Adverse Effects: Prepuberal females: premature epiphyseal closure, clitoral enlargement, & vaginitis. Adult bitch: mild clitoral hypertrophy, vulvovaginitis, increased body odor, abnormal behavior, urinary incontinence, voice deepening, riding behavior, enhanced clinical signs of seborrhea
vulvovaginitis, increased body odor, abnormal behavior, urinary incontinence, voice deepening, riding behavior, enhanced clinical signs of seborrhea oleosa, epiphora (tearing), hepatic changes (intranuclear hyaline bodies), & increased kidney weight (without pathology), hepatic dysfunction (rare)

Uses/Indications
*Cheque® Drops* was labeled as indicated “for estrous (heat) prevention in adult female dogs not intended primarily for breeding purposes.” In clinical trials it was 90% effective in suppressing estrus.

Although not approved, mibolerone at dosages of 50 micrograms per day will prevent estrus in the cat, but its use is generally not recommended because of the very narrow therapeutic index of the drug in this species (see the Adverse Effects and Overdosage sections for more information).

Pharmacology/Actions
Mibolerone acts by blocking the release of luteinizing hormone (LH) from the anterior pituitary via a negative feedback mechanism. Because of the lack of LH, follicles will develop to a certain point, but will not mature and hence no ovulation or corpus luteum development occurs. The net result is a suppression of the estrous cycle if the drug is given prior to (as much as 30 days) the onset of proestrus. After discontinuation of the drug, the next estrus may occur within 7-200 days (avg. 70 days).

Pharmacokinetics
Mibolerone is reported to be well absorbed from the intestine after oral administration and is rapidly metabolized in the liver to over 10 separate metabolites. Excretion is apparently equally divided between the urine and feces.

Contraindications/Precautions/Warnings
Mibolerone is contraindicated in female dogs with perianal adenoma, perianal adenocarcinoma or other androgen-dependent neoplasias. It is also contraindicated in patients with ongoing, or a history of, liver or kidney disease. The manufacturer recommends not using the drug in Bedlington Terriers.

Adverse Effects
Immature females (dogs) may be more prone to develop adverse reactions than more mature females. In prepuberal females, mibolerone can induce premature epiphyseal closure, clitoral enlargement, and vaginitis. Adverse effects that may be seen in the adult bitch include mild clitoral hypertrophy (may be partially reversible), vulvovaginitis, increased body odor, abnormal behavior, urinary incontinence, voice deepening, riding behavior, enhanced clinical signs of seborrhea oleosa, epiphora (tearing), hepatic changes (intranuclear hyaline bodies), and increased kidney weight (without pathology). Although reported, overt hepatic dysfunction would be considered to occur rarely in dogs. With the exception of residual mild clitoral hypertrophy, adverse effects will generally resolve after discontinuation of therapy.

In the cat, dosages of 60 micrograms/day have caused hepatic dysfunction and 120 micrograms/day have caused death. Other adverse effects that have been noted in cats include clitoral hypertrophy, thyroid dysfunction, os clitorides formation, cervical dermis thickening, and pancreatic dysfunction.

Reproductive/Nursing Safety
Mibolerone should not be used in pregnant bitches; masculinization of the female fetuses will occur. Alterations seen may include: changes in vagina patency, multiple urethral openings in the vagina, a phallus-like structure instead of a clitoris, formation of testes-like structures, and fluid accumulation in the vagina and uterus. Because it may inhibit lactation, it should not be used in nursing bitches.

The manufacturer recommends discontinuing the product after 24 months of use. It should not be used to try to attempt to abbreviate an estrous period or in bitches prior to their first estrous period.

Overdosage/Acute Toxicity
Many toxicology studies have been performed in dogs. The drug did not cause death in doses up to 30,000 micrograms/kg/day when administered to beagles for 28 days. For a more detailed discussion of the toxicology of the drug, the reader is referred to the package insert for *Cheque® Drops*.

In the cat, dosages as low as 120 micro-grams/day have resulted in fatalities.

Drug Interactions
Increased seizure activity has been reported in a dog after receiving mibolerone who was previously controlled on *phenytoin*. Mibolerone should generally not be used concurrently with *progestins* or *estrogens*.

Laboratory Considerations
Mibolerone has been reported to cause thyroid dysfunction in cats.

Doses
**DOGS:**
For suppression of estrus (treatment must begin at least 30 days prior to proestrus):

- **a)** Bitches weighing:
  - 0.5–11 kg: 30 micrograms (0.3 mL) PO per day
  - 12–22 kg: 60 micrograms (0.6 mL) PO per day
  - 23–45 kg: 120 micrograms (1.2 mL) PO per day
  - >45 kg: 180 micrograms (1.8 mL) PO per day

  German shepherds or German shepherd crosses: 180 micrograms (1.8 mL) PO per day; regardless of weight (Package Insert; *Cheque® Drops*—Upjohn)

- **b)** As above, but should dog come into estrus after receiving the drug for 30 or more days, stop drug and determine that the dog is not pregnant before resuming therapy. If owner compliance has been determined, increase dosage by 20–50%. (Burke 1985; Woody 1989)

For pseudocyesis (false pregnancy):
a) Use 10 times the dosage listed above for suppression of estrus PO once daily for 5 days (Barton & Wolf 1988)
b) 16 micrograms/kg PO once daily for 5 days (Concannon 1986)

For cystic endometrial hyperplasia (CEH):
a) 30 micrograms/25lb. body weight PO daily during 6 months. (Fontbonne 2006)

For treatment of severe galactorrhea:
a) 8–18 micrograms/kg PO once a day for 5 days. Once discontinued, prolactin may surge and galactorrhea resume. (Olson et al. 1986)

**CATS:**

**WARNING:** Because of the very low margin of safety with this drug in cats, it cannot be recommended for use in this species.

**Monitoring**

- Clinical signs of estrus
- Liver function tests (baseline, annual, or as needed)
- Physical examination of genitalia

**Client Information**

- It must be stressed to owners that compliance with dosage and administration direction is crucial for this agent to be effective.

**Chemistry/Synonyms**

A non-progestational, androgenic, anabolic, antigonadotropic, 19-nor-steroid, mibolerone occurs as a white, crystalline solid.

Mibolerone may also be known as: dimethyl-nortestosterone, NSC-72260, and U-10997.

**Storage/Stability**

The original manufacturer (Upjohn) states that the compound in Cheque® Drops is stable under ordinary conditions and temperatures. If using a compounded preparation, follow specific instructions from the pharmacy.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Commercially prepared mibolerone preparations are apparently no longer being marketed. Mibolerone may be available from compounding pharmacies. Mibolerone is now categorized as a Class-III controlled substance in the USA.

**HUMAN-LABELED PRODUCTS:** None

**References**

---

**MIDAZOLAM HCL**

(mid-ay-zoe-lam) Versed®

**PARENTERAL BENZODIAZEPINE**

**Prescriber Highlights**

- Injectable benzodiazepine used primarily as a pre-op med; unlike diazepam may be given IM
- Contraindications: Hypersensitivity to benzodiazepines; acute narrow-angle glaucoma. Caution: Hepatic or renal disease, debilitated or geriatric patients, & those in coma, shock, or with significant respiratory depression.
- Adverse Effects: Potential for respiratory depression is of most concern
- Avoid intra-carotid injection
- Drug interactions

**Uses/Indications**

In veterinary patients, midazolam is used principally as a premedicant for general anesthesia. Alone, it does not appear to provide predictable sedation in animals. Animals may become sedated or dysphoric and excited. Cats may be more prone to develop the “excited” effect more than dogs. When used in combination with other drugs (i.e., opioids or ketamine), midazolam does provide more predictable sedation.

Midazolam may also be of benefit to treat status epilepticus when given either IV or IM (not rectally).

In humans, midazolam has been suggested for use as a premedicant before surgery, and as a conscious sedative when combined with potent analgesic/anesthetic drugs (e.g., ketamine or fentanyl). In humans, midazolam reduces the incidences of “dreamlike” emergence reactions and increases in blood pressure and cardiac rate caused by ketamine.

When combined with the thiobarbiturate induction agents (e.g., thiopental, thiamylal), midazolam has less cardiopulmonary depressant effects, is water-soluble, can be

---
interactions have either been reported or are theoretical in humans or animals receiving midazolam and may be of significance in veterinary patients: See the precautions noted above (Contraindications/Precautions) when using midazolam with other agents for preoperative use in small animals. The following drug

**Drug Interactions**

Flumazenil's high cost, supportive therapy may be more suitable in all but the largest overdoses.

Very limited information is currently available. The IV LD50 in mice has been reported to be 86 mg/kg. It is suggested that accidental overdoses be managed in a

**Overdosage/Acute Toxicity**

If isoflurane will be used as the general anesthetic, use ketamine/midazolam with caution as bradycardia, hypotension and reduced cardiac output are possible. Midazolam/opioid combinations can cause less cardiovascular depression, but greater respiratory depression, than acepromazine/opioid.

Midazolam and butorphanol used during isoflurane anesthesia can cause decreased blood pressure, heart rate and enhanced respiratory depression.

**Adverse Effects**

The primary concern using midazolam in veterinary patients is the possibility of respiratory depression. In dogs, after morphine/acepromazine pre-op, midazolam given at 0.2 mg/kg IV prior to propofol anesthesia caused excitement in some patients (Covey-Crump & Murison 2008).

Few adverse effects have been reported in human patients receiving midazolam. Most frequently, effects on respiratory rate, cardiac rate and blood pressure have been reported. Respiratory depression has been reported in patients who have received narcotics or have COPD. The following adverse effects have been reported in more than 1%, but less than 5% of patients receiving midazolam: pain on injection, local irritation, headache, nausea, vomiting, and hiccups.

**Reproductive/Nursing Safety**

Although midazolam has not been demonstrated to cause fetal abnormalities, in humans, other benzodiazepines have been implicated in causing congenital abnormalities if administered during the first trimester of pregnancy. Infants born of mothers receiving large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, hypotonia, etc. Withdrawal symptoms have occurred in infants whose mothers chronically took benzodiazepines during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Midazolam is excreted in milk and may cause CNS effects in nursing neonates. Exercise caution when administering to a nursing mother.

**Overdosage/Acute Toxicity**

Very limited information is currently available. The IV LD50 in mice has been reported to be 86 mg/kg. It is suggested that accidental overdoses be managed in a supportive manner, similar to diazepam. Flumazenil could be used to antagonize midazolam effects, but because of midazolam's short duration of effect and flumazenil's high cost, supportive therapy may be more suitable in all but the largest overdoses.

**Drug Interactions**

See the precautions noted above (Contraindications/Precautions) when using midazolam with other agents for preoperative use in small animals. The following drug interactions have either been reported or are theoretical in humans or animals receiving midazolam and may be of significance in veterinary patients:

- **AZOLE ANTIFUNGALS (ketoconazole, itraconazole, fluconazole):** May increase midazolam levels
- **CALCIUM CHANNEL BLOCKERS (diltiazem, verapamil):** May increase midazolam levels
- **CIMETIDINE:** May increase midazolam levels

Midazolam is metabolized in the liver, principally by microsomal oxidation. An active metabolite (alpha-hydroxymidazolam) is formed, but because of its very short half-life and lower pharmacologic activity, it probably has negligible clinical effects. The serum half-life and duration of activity of midazolam in humans is considerably shorter than that of diazepam. Elimination half-lives in dogs average 77 minutes; in humans, approximately 2 hours (vs. approx. 30 hrs for diazepam).

In dogs, rectal bioavailability of midazolam is very low and this route is not useful clinically.

**Administrative/Precautions/Warnings**

The manufacturer lists the following contraindications for use in humans: hypersensitivity to benzodiazepines, or acute narrow-angle glaucoma. Additionally, intra-carotid artery injections must be avoided.

Use cautiously in patients with hepatic or renal disease, and in debilitated or geriatric patients. Patients with congestive heart failure may eliminate the drug more slowly. The drug should be administered to patients in coma, shock, or with significant respiratory depression very cautiously.

When used alone, midazolam does not possess significant effects on cardiorespiratory function, but in combination with other agents, cardiorespiratory effects may be noted. Increased heart rate and blood pressure may be noted when used with ketamine. If this combination is used after an opioid has been administered, these effects may be diminished. If isoflurane will be used as the general anesthetic, use ketamine/midazolam with caution as bradycardia, hypotension and reduced cardiac output are possible.

Midazolam/opioid combinations can cause less cardiovascular depression, but greater respiratory depression, than acepromazine/opioid.

Midazolam and butorphanol used during isoflurane anesthesia can cause decreased blood pressure, heart rate and enhanced respiratory depression.

**Adverse Effects**

The primary concern using midazolam in veterinary patients is the possibility of respiratory depression.

**Contraindications/Precautions/Warnings**

The manufacturer lists the following contraindications for use in humans: hypersensitivity to benzodiazepines, or acute narrow-angle glaucoma. Additionally, intra-carotid artery injections must be avoided.

Use cautiously in patients with hepatic or renal disease, and in debilitated or geriatric patients. Patients with congestive heart failure may eliminate the drug more slowly. The drug should be administered to patients in coma, shock, or with significant respiratory depression very cautiously.

When used alone, midazolam does not possess significant effects on cardiorespiratory function, but in combination with other agents, cardiorespiratory effects may be noted. Increased heart rate and blood pressure may be noted when used with ketamine. If this combination is used after an opioid has been administered, these effects may be diminished. If isoflurane will be used as the general anesthetic, use ketamine/midazolam with caution as bradycardia, hypotension and reduced cardiac output are possible.

Midazolam/opioid combinations can cause less cardiovascular depression, but greater respiratory depression, than acepromazine/opioid.

Midazolam and butorphanol used during isoflurane anesthesia can cause decreased blood pressure, heart rate and enhanced respiratory depression.
CIMETIDINE: May increase midazolam levels

CNS DEPRESSANTS, OTHER: May increase the risk of respiratory depression

MACROLIDES (erythromycin, clarithromycin): May increase midazolam levels

OPIATES: May increase the hypnotic effects of midazolam and hypotension has been reported when used with meperidine

PHENOBARBITAL: May decrease peak levels and AUC of midazolam

rifampin: May decrease peak levels and AUC of midazolam

THIOPENTAL: Midazolam may decrease the dosages required

Doses

DOGS:

As a preoperative agent:

a) 0.2–0.4 mg/kg IV or IM with an opioid such as hydromorphone (0.1 mg/kg IV or 0.2 mg/kg IM) (Day 2002)
b) 0.1–0.3 mg/kg; may be used in combination with ketamine in a 50:50 mixture (volume/volume) at a dose of 1 mL/9.1 kg (1 mL/20 lb), this equates to a dose of 0.28 mg/kg of midazolam and 5.5 mg/kg of ketamine (Reed 2002)
c) 0.1–0.5 mg/kg IV (Hellyer 2005)

For status epilepticus:

a) 0.25 mg/kg IV (Kniipe 2006)
b) 0.2–0.4 mg/kg IV or IM (not per rectum); may repeat once. (Hopper 2006)
c) 0.07–0.2 mg/kg IV or IM; effects are short-lived, so if seizures recur a CRI can be helpful given at 0.05–0.5 mg/kg/hour. (Thomas 2010)

CATS:

As a preoperative agent:

a) 0.2–0.4 mg/kg IV or IM with an opioid such as hydromorphone (0.1 mg/kg IV or 0.2 mg/kg IM) (Day 2002)
b) 0.05–0.5 mg/kg; a dose of 0.3 mg/kg being the most effective when mixed with ketamine to allow for intubation. May be used in combination with ketamine in a 50:50 mixture (volume/volume) at a dose of 1 mL/9.1 kg (1 mL/20 lb), this equates to a dose of 0.28 mg/kg of midazolam and 5.5 mg/kg of ketamine. (Reed 2002)
c) 0.1–0.5 mg/kg IV (Hellyer 2005)

For status epilepticus:

a) 0.07–0.2 mg/kg IV or IM; effects are short-lived, so if seizures recur a CRI can be helpful given at 0.05–0.5 mg/kg/hour. (Thomas 2010)

RABBITS, RODENTS, SMALL MAMMALS:

a) Rabbits: As a tranquilizer (to increase relaxation of lightly anesthetized animals and permit ET intubation): 1 mg/kg IV as needed (Huerkamp 1995)
b) Rabbits: 1–2 mg/kg IM, IV. (Ivey & Morrisey 2000)
c) Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: 1–2 mg/kg IM (Adamcak & Otten 2000)
d) As a preanesthetic: Rabbits: 0.5–5 mg/kg IM or IV; Rodents: 3–5 mg/kg IM or IV; often beneficial to minimize stress, anxiety and patient struggling. May be reversed with flumazenil if necessary (0.1 mg/kg IV, but may precipitate seizures)

Injectable anesthesia: Rodents: midazolam (5 mg/kg) + ketamine (100 mg/kg) + buprenorphine (0.05 mg/kg) IP.

Rabbits: Midazolam (0.05 mg/kg) + buprenorphine (0.03 mg/kg) + ketamine (10 mg/kg) IM (Bennett 2009)

e) As an induction agent in rabbits: 0.05–0.5 mg/kg IV (typically via a marginal ear vein). The low end of the dosage range is usually given and topped up as necessary. In non-sedated animals, prior preparation of the area with topical local anesthetics may be useful. Intravenous midazolam leads to further sedation of the patient, sufficient to allow intubation, but may also induce apneic side effects. This, together with fentanyl’s respiratory depression, can potentially compound the possibility of hypoxia. It is important therefore, that midazolam is given to effect and that pre-oxygenation is performed. Intubation is considered essential when using this protocol. Note: Not all patients require midazolam induction for purposes of intubation. An assessment of the patient can be made in the first 10 minutes post premedicant delivery. Some rabbits may be sufficiently sedated to allow intubation at this point. (Vella 2009)

HORSES:

As a preoperative agent:

a) 0.011–0.0.44 mg/kg IV (Mandsager 1988)

For seizure control in foals:

a) 2–5 mg (total dose) for a 50 kg foal given IV; rapid IV administration may result in apnea and hypotension. A CRI may be used at a dose of 1–3 mg/hour for a 50 kg foal. (Bentz 2006)
b) 2–5 mg (total dose) for a 50 kg foal given IV or IM; may be repeated to effect. (Toppin 2007)

BIRDS:

a) For adjunctive use (with an analgesic) for pain control: 1–2 mg/kg IM or IV (Clyde & Paul-Murphy 2000)
b) As a pre-med for anxious or easily stressed birds (e.g., macaws, African greys, raptors and many wild birds) midazolam at 1 mg/kg IM is used. This will cause mild sedation and relaxation. Doses as high as 6 mg/kg have been reported resulting in considerable sedation.

As part of an injectable anesthetic regimen: Injectable anesthetics are only occasionally used in birds for short procedures or in situations where inhalant anesthetics are not available. Ketamine at 10–30 mg/kg and midazolam at 2–6 mg/kg can be used. The midazolam can be reversed with flumazenil (0.1 mg/kg) if necessary. Butorphanol can be added for analgesia at a dose of 1–2 mg/kg. (Morrisey 2010)

ZOO, EXOTIC, WILDLIFE SPECIES:
For use of midazolam in zoo, exotic and wildlife medicine refer to specific references, including:

- **Handbook of Veterinary Chemical Immobilization, 3rd Ed.** Kreeger, T.J. and J.M. Armeno. 2007.
- **Exotic Animal Formulary, 3rd Ed.** Carpenter, J.W., Saunders. 2005
- **The 2009 American Association of Zoo Veterinarians Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at:** http://goo.gl/BHRih or http://goo.gl/9UJse

### Monitoring

- Level of sedation
- Respiratory and cardiac signs

### Client Information

- This agent should be used in an inpatient setting only or with direct professional supervision where cardiorespiratory support services are available.

### Chemistry/Synonyms

Midazolam HCl is a benzodiazepine that occurs as a white or yellowish crystalline powder. Solubility in water is dependent upon pH. At a pH of 3.4 (approximately the pH of commercial injection), 10.3 mg are soluble in one mL of water.

Midazolam HCl may also be known as Ro-21-3981/003, Versed®, Dormicum®, Dormonid®, Fulsed®, Hypnovel®, Midaselect®, and Zolamid®.

### Storage/Stability

It is recommended to store midazolam injection at room temperature (15°C–30°C) and protected from light. After being frozen for 3 days and allowed to thaw at room temperature, the injectable product was physically stable. Midazolam is stable at a pH from 3–3.6.

### Compatibility/Compounding Considerations

Midazolam is reportedly physically compatible when mixed with the following products: DSW, normal saline, lactated Ringer’s, atropine sulfate, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, ketamine HCl, meperidine HCl, morphine sulfate, nalbuphine HCl, promethazine HCl, sufentanil citrate, and scopolamine HBr.

**Compounded preparation stability:** Midazolam hydrochloride oral suspension compounded from the commercially available injectable solution has been published (Steedman et al. 1992). Diluting midazolam 5 mg/mL injection in a 1:1 ratio with Syrupal® yields a 2.5 mg/mL midazolam hydrochloride oral solution that retains >90% potency for 56 days when stored at both 7°C, 20°C, and 40°C and protected from light.

### Formulations

**HUMAN-LABELED PRODUCTS:**

- **Intravenous:** 1 mg/mL vials
- **Intramuscular:** 1 mL, 2 mL, 5 mL vials
- **Syrup:** 2 mg/mL in 118 mL, generic (Roxane); (Rx, C-IV)
- **Syrup:** 2 mg/mL in 118 mL, generic (Roxane); (Rx, C-IV)
- **Injection:** 2 mL syringes; generic; (Rx, C-IV)

**VETERINARY-LABELED PRODUCTS:**

- **Oral Suspension:** 2 mg/mL in 118 mL; 10 mL vials, & 2 mL syringes; generic; (Rx, C-IV)
- **Injection:** 1 mg (as HCl)/mL in 2 mL, 5 mL vials

**Respiratory and cardiac signs**

- **Level of sedation**

**MACROLIDE ANTIPARASITIC**

For information on the combination product with lufenuron (Sentinel®), see the lufenuron monograph

**Prescriber Highlights**

- GABA inhibitor in invertebrates used for heartworm prophylaxis, microfilaricide, & treat demodicosis, etc.
- **Contraindications:** No absolute contraindications
Uses/Indications
Milbemycin tablets are labeled as a once-a-month heartworm preventative (Dirofilaria immitis) and for hookworm control (Ancylostoma caninum). It has activity against a variety of other parasites, including adult hookworms (A. caninum), adult roundworms (T. canis, T. leonina) and whipworms (Trichuris vulpis). Monthly administered milbemycin does not appear to be as effective as ivermectin as an adulticide, especially against older heartworms. In cats, milbemycin has been used successfully to prevent larval infection of Dirofilaria immitis.

Milbemycin, like ivermectin can be used for treatment of generalized demodicosis in dogs, but treatment can be significantly more expensive. It is likely safer to use in breeds susceptible to ABCB1-1 (formerly MDR1-allele) genetic mutation (Collies, Shelties, Australian shepherds, etc.) at the doses used for this indication, but neuro toxicity is possible. Older dogs, those that have had a long duration of disease prior to treatment, and dogs with pododemodicosis appear have a lower success rate with milbemycin treatment.

Pharmacology/Actions
Milbemycin is thought to act by disrupting the transmission of the neurotransmitter gamma amino butyric acid (GABA) in invertebrates.

Pharmacokinetics
No specific information was located. At labeled doses, milbemycin is considered effective for at least 45 days after infection by D. immitis larva.

Contraindications/Precautions/Warnings
Because some dogs with a high number of circulating microfilaria will develop a transient, shock-like syndrome after receiving milbemycin, the manufacturer recommends testing for preexisting heartworm infections.

If using milbemycin at doses greater than labeled in breeds susceptible to the ABCB1 genetic mutation, genetic testing is recommended before initiating therapy.

The manufacturer states to not use the product (Interceptor®) in puppies less than 4 weeks of age or less than 2 lbs. of body weight or in kittens less than 6 weeks of age or less than 1.5 lbs. of body weight.

Adverse Effects
At labeled doses, adverse effects appear to be infrequent in microfilaria-free dogs, including breeds susceptible to neurologic toxicity (see Overdosage below). In a recent study where dogs of breeds susceptible to the ABCB1 mutation were given milbemycin at doses from 1–2.2 mg/kg PO daily, all ABCB1 mutant/mutant dogs experienced CNS toxicity, while no ABCB1 wild-type/wild-type or ABCB1 mutant/wild-type dogs experienced toxicity (Barbet et al. 2009).

Eight week old puppies receiving 2.5 mg/kg (5X label) for 3 consecutive days showed no clinical signs after the first day, but after the second or third consecutive dose, showed some ataxia and trembling.

Reproductive/Nursing Safety
The manufacturer states that safety in breeding, pregnant, and lactating queens and breeding toms has not been established.

Studies in pregnant dogs at daily doses 3X those labeled showed no adverse effects to offspring or bitch.

Milbemycin does enter maternal milk; at standard doses, no adverse effects have been noted in nursing puppies.

Overdosage/Acute Toxicity
Beagles have tolerated a single oral dose of 200 mg/kg (200 times monthly rate). Rough-coated collies have tolerated doses of 10 mg/kg (20 times labeled) without adversity. Toxic doses can cause mydriasis, hypersalivation, lethargy, ataxia, pyrexia, seizures, coma and death. There is no specific antidotal treatment and supportive therapy is recommended.

Drug Interactions
The manufacturer states that the drug was used safely during testing in dogs receiving other frequently used veterinary products, including vaccines, anthelmintics, antibiotics, steroids, flea collars, shampoos and dips.

The following drug interactions have either been reported or are theoretical in humans or animals receiving GABA agonists and may be of significance in veterinary patients:

BENZODIAZEPINES: Effects may be potentiated by milbemycin; use together not advised in humans

Caution is advised if using other drugs that can inhibit p-glycoprotein particularly in those dogs at risk for ABCB1-1 (formerly MDR1-allele) mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”), unless tested “normal”: Drugs and drug classes involved include:

AMIODARONE
AZOLE ANTIFUNGALS (e.g., ketoconazole)
CARVEDILOL
CYCLOSPORINE
DILTIAZEM
ERYTHROMYCIN; CLARITHROMYCIN
QUINIDINE
SPIRONOLACTONE
TAMOXIFEN
VERAPAMIL
Doses

**DOGS:**

For prophylaxis and treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information

As a parasiticide:

a) For heartworm prophylaxis, control of adult hookworms (A. caninum), adult roundworms (T. canis, T. leonina) and whipworms (Trichuris vulpis) in dogs 4 weeks of age or older and at least 2 lbs. body weight: Minimum dosage is 0.5 mg/kg PO once a month. (Label information; Interceptor®—Novartis)

b) 0.5–0.99 mg/kg PO once monthly (also controls hookworm, roundworm and whipworm infestations) (Calvert 1994)

c) For control of fleas (prevents egg development), heartworm prophylaxis, control of adult hookworms (A. caninum), adult roundworms (T. canis, T. leonina) and whipworms (Trichuris vulpis) in dogs 4 weeks of age or older and at least 2 lbs. body weight: Minimum dosage is 0.5 mg/kg PO once a month. (Label directions; Sentinel®—Novartis) [Note: when used with nitenpyram (Capstar®) adult fleas are controlled as well]

For microfilaricide chemotherapy:

a) In adulticide-pretreated dogs: Use preventative/prophylaxis dosage; repeat in 2 weeks if necessary. If heartworm transmission season has started, continue monthly prophylaxis. (Knight 1995)

b) In adulticide-pretreated dogs: Approximately one month after melarsomine give milbemycin at 0.5 mg/kg PO. (Legendre & Toal 2000)

For treatment of generalized demodicosis:

a) Recommend a microfilaria check prior to therapy. Begin at a dose of 1 mg/kg/day PO with a skin scraping after 30 days. If minimal improvement is seen, the dosage should be increased to 2 mg/kg. If no improvement is seen after a second thirty days, either an increase to 3 mg/kg/day of milbemycin can be tried or an alternative therapy should be used. Most clients will not be able to afford this drug if it is priced at the monthly heartworm preventative price. Ivermectin sensitive breeds may be able to tolerate this therapy better than ivermectin, but side effects still can be seen that include ataxia, tremors and stupor. Dogs homozygous for the MDR1-1 delta gene mutation can show neurologic side effects at doses between 1 and 2.2 mg/kg/day. (Merchant 2009)

For treatment of cheyletiellosis:

a) 2 mg/kg PO every 7 days for 3 doses (White 2000)

For treatment of scabies:

a) 2 mg/kg PO every 7 days for 3 doses or 0.75 mg/kg once daily for 30 days (White 2000)

For chronic rhinitis caused by (Pneumonyssus caninum):

a) 1 mg/kg PO once every 10 days for 3 treatments. (Kuehn 2010)

**CATS:**

For prevention of heartworm; treat adult hookworm and adult roundworms:

a) 2 mg/kg PO once monthly (Label directions; Interceptor® Flavor Tabs for Cats—Novartis)

**REPTILES:**

For nematodes:

a) 0.5–1 mg/kg PO; repeat in 2 weeks. If 14 days after second dose, fecal is positive a third dose is given and the cycle continued until parasites are cleared. Milbemycin appears to be safe in chelonians (unlike ivermectin). (de la Navarre 2003)

Client Information

Review importance of compliance with therapy and to be certain that the dose was consumed.

Chemistry/Synonyms

Milbemycin oxide consists of approximately 80% of the A₄ derivatives and 20% of the A₃ derivatives of 5-didehydromilbemycin. Milbemycin is considered to be a macrolide antibiotic structurally.

Milbemycin may also be known as CGA-179246, Interceptor® and Sentinel®.

Storage/Stability

Store milbemycin oxide tablets at room temperature.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Milbemycin Oxime Oral Tablets: 2.3 mg (brown, 2–10 lbs), 5.75 mg (green, 11–25 lbs), 11.5 mg (yellow, 26–50 lbs), 23 mg (white, 51–100 lbs), dogs >100 lbs are provided the appropriate combination of tablets; Interceptor® Flavor Tabs; (Novartis); (Rx). FDA-approved for use in dogs and puppies >4 weeks of age and 2 lbs or greater.

Milbemycin Oxime Oral Tablets: 5.75 mg (1.5–6 lbs), 11.5 mg (6.1–12 lbs), 23 mg (white, 12.1–25 lbs); Interceptor® Flavor Tabs; (Novartis); (Rx). FDA-approved for cats and kittens >6 wks old and >1.5 lbs.

Milbemycin/Lufenuron Oral Tablets (with Nitenpyram Oral Tablets in the combination flea management system) for Dogs:

For dogs 2–10 lb: 46 mg milbemycin/lufenuron, (11.4 mg nitenpyram)

For dogs 11–25 lb: 115 mg milbemycin/lufenuron, (11.4 mg nitenpyram)

For dogs 26–50 lb: 230 mg milbemycin/lufenuron, (57 mg nitenpyram)

For dogs 51–100 lb: 460 mg milbemycin/lufenuron, (57 mg nitenpyram)
Overdoses likely would cause GI signs (vomiting, etc.). Potentially, hepatic, renal, and retinal toxicity are possible in large overdoses. A specific antidote for

**Overdosage/Acute Toxicity**

Miltefosine is labeled as contraindicated in pregnant, lactating and breeding animals and during pregnancy and breastfeeding in humans. When pregnant rats were dosed at 1.2 mg/kg/day and higher during the early embryonic development (up to day 7 of pregnancy), an increased risk for embryotoxic, fetotoxic and teratogenic effects was determined. In pregnant rabbits given 2.4 mg/kg/day and higher during the organogenesis phase, embryotoxic and fetotoxic effects were also seen.

Male rats given miltefosine daily at 8.25 mg/kg showed testicular atrophy and impaired fertility; this was reversible within 10 weeks.

It is not known if miltefosine is excreted into milk. The canine and human labels state that it should not be used in nursing mothers.

**Overdosage/Acute Toxicity**

Overdoses likely would cause GI signs (vomiting, etc.). Potentially, hepatic, renal, and retinal toxicity are possible in large overdoses. A specific antidote for
Drug Interactions
No drug interactions have been reported for miltefosine at present.

Laboratory Considerations
- No specific concerns noted.

Doses

**DOGS:**

For canine leishmaniasis:

a) The product should be administered at 2 mg/kg PO, poured onto food, with a full or partial meal once a day for 28 days. (From the translated label Information — Milteforan®, Virbac-France)

b) As an alternative treatment to meglumine antimoniate and allopurinol: Miltefosine 2 mg/kg PO once daily for 28 days with allopurinol (10 mg/kg PO q12h, orally for at least 6 months). (Zini 2010)

Monitoring
- Baseline and periodic renal function and hepatic enzymes
- Adverse effects (especially vomiting); patient weight

Client Information
- Give with food, to help reduce the chance for vomiting
- If vomiting or severe diarrhea occur, contact veterinarian
- Wear disposable gloves when administering this product as it has caused skin reactions
- Because this drug has caused birth defects, it should not be handled by pregnant women
- Do not allow treated dogs to lick persons immediately after intake of the medication
- To avoid foaming, do not shake the vial

Chemistry/Synonyms
Miltefosine is a phospholipid derivative (alkylphosphocholine) that is structurally related to the phospholipid components of cell membranes. The commercially available canine product (Milteforan®) is a clear, colorless, viscous solution containing 20 mg/mL of miltefosine. Excipients in the solution include hydroxypropylcellulose, propylene glycol, and water.

Miltefosine may also be known as D-18506, HDPC, hexadecylphosphocolina, hexadecylphosphocholine, miltefosiini, miltefosina, miltéfosine, or miltefosinum. Trade names include: Milteforan®, Miltex® and Impavido®.

Storage/Stability
This veterinary medicinal product does not require any special storage conditions. Avoid freezing the solution.

Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:**
None in the USA. Elsewhere, a canine licensed product may be available. Miltefosine Oral Solution: 20 mg/mL in 30 mL, 50 mL & 90 mL vials; Milteforan® (Virbac); (Rx)

**HUMAN-LABELLED PRODUCTS:**
Impavido® is approved as an orphan drug by FDA. In countries where leishmaniasis in humans is endemic, 10 mg and 50 mg capsules (Impavido®) may be marketed.

**MINERAL OIL**

White Petrolatum

**LUBRICANT LAXATIVE**

**Prescriber Highlights**

- Lubricant laxative
- Cautions: Debilitated or pregnant patients, & patients with hiatal hernia, dysphagia, esophageal or gastric retention
- Use caution when administering by tube to avoid aspiration
- Adverse Effects: Lipid pneumonitis if aspirated; granulomatous reactions in liver etc. if significant amounts are absorbed from gut; oil leakage from the anus; long-term use may lead to decreased absorption of fat-soluble vitamins (A, D, E, & K)
the anus; long-term use may lead to decreased absorption of fat-soluble vitamins (A, D, E, & K).

- **Drug interactions**

**Uses/Indications**

Mineral oil is commonly used in horses to treat constipation and fecal impactions. It is also employed as a laxative in other species as well, but used less frequently. Mineral oil has been administered after ingesting lipid-soluble toxins (e.g., kerosene, metaldehyde) to retard the absorption of these toxins through its laxative and solubility properties.

Petrolatum containing products (e.g., Felaxin®, Laxatone®, Kat-A-Lax®, etc.) may be used in dogs and cats as a laxative or to prevent/reduce “hair-balls” in cats.

**Pharmacology/Actions**

Mineral oil and petrolatum act as laxatives by lubricating fecal material and the intestinal mucosa. They also reduce reabsorption of water from the GI tract, thereby increasing fecal bulk and decreasing intestinal transit time.

**Pharmacokinetics**

It has been reported that after oral administration, emulsions of mineral oil may be up to 60% absorbed, but most reports state that mineral oil preparations are only minimally absorbed from the gut.

**Contraindications/Precautions/Warnings**

No specific contraindications were noted with regard to veterinary patients. In humans, mineral oil (orally administered) is considered contraindicated in patients less than 6 yrs. old, debilitated or pregnant patients, and patients with hiatal hernia, dysphagia, esophageal or gastric retention. Use caution when administering by tube to avoid aspiration, especially in debilitated or recalcitrant animals. To avoid aspiration in small animals, orally administered mineral oil should not be attempted when there is an increased risk of vomiting, regurgitation, or other preexisting swallowing difficulty. Many clinicians believe that mineral oil should not be administered orally to small animals due to the risk for aspiration and, if used as a laxative, should be administered rectally.

**Adverse Effects**

When used on a short-term basis and at recommended doses, mineral oil or petrolatum should cause minimal adverse effects. The most serious effect that could be encountered is aspiration of the oil with resultant lipid pneumonitis; prevent this by using the drug only in appropriate cases, when “tubing”, ascertain that the tube is in the stomach, and administer the oil at a reasonable rate.

Granulomatous reactions have occurred in the liver, spleen and mesenteric lymph nodes when significant quantities of mineral oil are absorbed from the gut. Oil leakage from the anus may occur and be of concern in animals with rectal lesions or in house pets. Long-term administration of mineral oil/petrolatum may lead to decreased absorption of fat-soluble vitamins (A, D, E, and K). No reports were found documenting clinically significant hypovitaminosis in cats receiving long-term petrolatum therapy, however.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Oral mineral oil should be safe to use during nursing.

**Overdosage/Acute Toxicity**

No specific information was located regarding overdoses of mineral oil; but it would be expected that with the exception of aspiration, the effects would be self-limiting. See adverse effects section for more information.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving mineral oil and may be of significance in veterinary patients:

- **DOCUSATE:** Theoretically, mineral oil should not be given with docusate (DSS) as enhanced absorption of the mineral oil could occur. However, this does not appear to be of significant clinical concern with large animals.

- **VITAMINS A, D, E, K:** Chronic administration of mineral oil may affect Vitamin K and other fat-soluble vitamin absorption. It has been recommended to administer mineral oil products between meals to minimize this problem.

**Doses**

- **DOGS:**

  **Note:** Because of the risk for aspiration, liquid mineral oil is rarely recommended for PO administration today.

  As a laxative:
  a) 2–60 mL PO (Jenkins 1988; Kirk 1989)
  b) 5–30 mL PO (Davis 1985)
  c) 5–25 mL PO (Burrows 1986)

- **CATS:**

  **Note:** Because of the risk for aspiration, liquid mineral oil is rarely recommended for PO administration today.

  As a laxative (See specific label directions for “Cat Laxative” Products):
  a) 2–10 mL PO (Jenkins 1988), (Kirk 1989)
  b) 2–6 mL PO (Davis 1985)
  c) 5 mL per day with food (Sherding 1989)
**RABBITS, RODENTS, SMALL MAMMALS:**

a) **Rabbits:** As a laxative/remove hairballs: Using feline laxative product: 1–2 mL/day for 3–5 days (Ivey & Morrisey 2000)

**CATTLE:**

- **Note:** Administer via stomach tube.

  As a laxative:
  - a) 1–4 liters (Howard 1986)
  - b) Adults: 0.5–2 liters; Calves: 60–120 mL (Jenkins 1988)

  For adjunctive treatment of metaldehyde poisoning:
  - a) 8 mL/kg; may be used with a saline cathartic (Smith 1986)
  - For adjunctive treatment of nitrate poisoning:
  - a) 1 liter per 400 kg body weight (Osweiler & Ruhr 1986)

**HORSES:**

  As a laxative (Administer via stomach tube):
  - a) For large colon impactions: 2–4 quarts q12–24 hours, may take up to 5 gallons. Mix 1–2 quarts of warm water with the oil to ease administration and give more fluid to the horse. Pumping in at a moderate speed is desirable over gravity flow. (Sellers & Lowe 1987)
  - b) For sand colic: In this experimental study, 0.5 kg psyllium was mixed with 1 liter of mash and given twice daily and 2 liters of mineral oil via NG tube were administered once daily. This combination was more effective (measured ash content of feces) than giving mineral oil alone. (Hotwagner, 2008)
  - c) Adults: 2–4 liters, may be repeated daily; Foals: 240 mL (Clark, 1987)
  - d) Adults: 0.5–2 liters; Foals: 60–120 mL (Jenkins 1988)

**SWINE:**

  a) As a laxative: 50–100 mL; administer via stomach tube (Howard 1986)

**SHEEP & GOATS:**

  a) As a laxative: 100–500 mL; administer via stomach tube (Howard 1986)

**BIRDS:**

  Use as a laxative and to aid in the removal of lead from the gizzard:
  - a) 1–3 drops per 30 grams of body weight or 5 mL/kg PO once. Repeat as necessary. Give via tube or slowly to avoid aspiration. (Clubb 1986)

**Monitoring**

- Clinical efficacy
- If possibility of aspiration: auscultate, radiograph if necessary

**Client Information**

- Follow veterinarian’s instructions or label directions for “cat laxative” products.
- Do not increase dosage or prolong treatment beyond veterinarian’s recommendations.

**Chemistry/Synonyms**

Mineral oil, also known as liquid petrolatum, liquid paraffin or white mineral oil occurs as a tasteless, odorless (when cold), transparent, colorless, oily liquid that is insoluble in both water and alcohol. It is a mixture of complex hydrocarbons and is derived from crude petroleum. For pharmaceutical purposes, heavy mineral oil is recommended over light mineral oil, as it is believed to have a lesser tendency to be absorbed in the gut or aspirated after oral administration.

White petrolatum, also known as white petroleum jelly or white soft paraffin, occurs as a white or faintly yellow unctuous mass. It is insoluble in water and almost insoluble in alcohol. White petrolatum differs from petrolatum only in that it is further refined to remove more of the yellow color.

Mineral Oil may also be known as: liquid paraffin, 905 (mineral hydrocarbons), dickflussiges paraffin, heavy liquid petrolatum, huile de vaseline epaisse, liquid petrolatum, oleum petrolei, oleum vaselini, paraffinum liquidum, paraffinum subliquidum, vaselinol, vaselinum liquidum, and white mineral oil; many trade names are available.

**Storage/Stability**

Petrolatum products should be stored at temperatures less than 30°C.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Mineral oil products have not been formally FDA-approved for use in food animals. These products and preparations are available without a prescription (OTC).

**Petrolatum Oral Preparations**

- Liquid Mineral Oil: available in gallons or 55 gallon drums.

- Cat “Laxative” Products: Products may vary in actual composition; some contain liquid petrolatum in place of white petrolatum and may have various flavors (tuna, caviar, malt, etc.). Trade names include (not necessarily complete): Laxatone®, Laxa-Stat® (Evsco and Tomlyn Health); Vedalax® (Vedco); Cat Lax® (Pharmaderm); Vetscription® Hairball Remedy (Sergeant’s); Hairball Preparation® (Vet Solutions); Hartz® Health Measures Hairball Remedy (Hartz Mountain); Petromalt® (Virbac); Petrotone® (Butler); Felilax® (Vetus)

**HUMAN-LABELED PRODUCTS:**

Mineral Oil Liquid: in 180 mL and 473 mL; generic; (OTC)
Minocycline is well absorbed after oral absorption regardless of the presence of food. Minocycline is highly lipid soluble and is distributed widely throughout the body. Therapeutic levels can be found in the CSF (whether meninges are inflamed or not), prostate, saliva, and eye. Minocycline is extensively metabolized in the liver and primarily excreted as inactive metabolites in the feces and urine. Less than 20% is excreted unchanged in the urine. The half-life in dogs is about 7 hours.

Contraindications/Precautions/Warnings
Minocycline should be considered contraindicated in patients hypersensitive to tetracyclines, those that are pregnant or nursing, or in animals less than 6 months old. Minocycline is considered to be less likely to cause these abnormalities than other more water-soluble tetracyclines (e.g., tetracycline, oxytetracycline). Unlike either oxytetracycline or tetracycline, minocycline can be used in patients with moderate renal insufficiency without dosage adjustment. Oliguric renal failure may require dosage adjustment.

Adverse Effects
The most commonly reported side effects of oral minocycline therapy in dogs and cats are nausea and vomiting. To alleviate these effects, the drug could be given with food without clinically significant reductions in drug absorption. Dental or bone staining can occur when minocycline exposure occurs in utero or in early life. More rarely, increases in hepatic enzymes and ototoxicity are possible.

IV injections of minocycline in dogs have caused urticaria, shivering, hypotension, dyspnea, cardiac arrhythmias, and shock when given rapidly. Give IV slowly.

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi. Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

Minocycline is considered to be less likely to cause these abnormalities than other more water-soluble tetracyclines (e.g., tetracycline, oxytetracycline). Unlike either oxytetracycline or tetracycline, minocycline can be used in patients with moderate renal insufficiency without dosage adjustment. Oliguric renal failure may require dosage adjustment.

Adverse Effects
The most commonly reported side effects of oral minocycline therapy in dogs and cats are nausea and vomiting. To alleviate these effects, the drug could be given with food without clinically significant reductions in drug absorption. Dental or bone staining can occur when minocycline exposure occurs in utero or in early life. More rarely, increases in hepatic enzymes and ototoxicity are possible.

IV injections of minocycline in dogs have caused urticaria, shivering, hypotension, dyspnea, cardiac arrhythmias, and shock when given rapidly. Give IV slowly.

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

In humans, minocycline (or other tetracyclines) has also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias. CNS effects (dizziness, lightheadedness) have been reported in people taking minocycline. A blue-gray pigmentation of skin and mucous membranes may occur.

Reproductive/Nursing Safety
There are several products available that are emulsions of mineral oil and may be more palatable for oral administration. Because of expense and with no increase in efficacy, they are used only in small animals. They may be dosed as described above, factoring in the actual percentage of mineral oil in the preparation used. Trade names include: Kondremul® Plain (Heritage Consumer Prod); (OTC) Various generic products are available.

Mineral Oil Emulsions:

Mineral Oil Liquid:
in 180 mL and 473 mL; generic; (OTC)

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

References
A semisynthetic tetracycline, minocycline HCl occurs as a yellow, crystalline powder. It is soluble in water and slightly soluble in alcohol.

Minocycline may also be known as: minocyclini hydrochloridum, Asolmicina®. Cyclimycin®, Cyclomin®, Dermirex®, Meibi®, Minogal®, and Minox®; many other trade names are available.

Reproductive/Nursing Safety

Because tetracyclines can retard fetal skeletal development and discolour deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Minocycline has been shown to impair fertility in male rats. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Tetracyclines are excreted in milk. Milk:plasma ratios vary between 0.25 and 1.5. While minocycline probably has less effect on teeth and bones than other tetracyclines, its use should be avoided during nursing.

Overdosage/Acute Toxicity

Minocycline oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Although it is less vulnerable to chelation with cations than other tetracyclines, oral administration of divalent or trivalent cation antacids may bind some of the drug and reduce GI distress. Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving minocycline and may be of significance in veterinary patients:

**ANTACIDS, ORAL:** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations. Oral antacids, saline cathartics, or other GI products containing aluminum, calcium, magnesium, zinc, or bismuth cations are most commonly associated with this interaction. Minocycline has a relatively low affinity for divalent or trivalent cations, but it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing product.

**BISMUTH SUBSALICYLATE, KAOLIN, PECTIN:** May reduce absorption

**IRON, ORAL:** Oral iron products are associated with decreased tetracycline absorption, and administration of iron salts should preferably be given 3 hours before or 2 hours after the tetracycline dose.

**ISOTRETINOIN:** When used with minocycline may increase the risk for nervous system effects

**PENICILLINS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides. There is a fair amount of controversy regarding the actual clinical significance of this interaction, however.

**WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment.

Laboratory Considerations

Tetracyclines reportedly can cause false-positive urine glucose results if using the cupric sulfate method of determination (Benedict’s reagent, Clinitest®), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines.

Tetracyclines reportedly have caused false-negative results in determining urine glucose when using the glucose oxidase method (Clinistix®, Tes-Tape®).

Doses

**DOGS:**

a) For susceptible soft tissue and urinary tract infections: 5–12 mg/kg PO or IV q12h for 7–14 days. (Greene et al. 2006)

b) For Brucellosis: Gentamicin 5 mg/kg SC once daily (q24h) for 7 days; 2-courses of treatment, treating on weeks one and four; plus Minocycline at 25 mg/kg PO once daily (q24h) for 4 weeks. Eventually, doxycycline can be substituted for minocycline at the same dosage to lower cost. Infected animals may need to be treated for two or more 4-week courses. Sequential antibody tests at 3 to 6 monthly intervals are recommended to monitor treatment. Monitor renal function secondary to gentamicin therapy. (Hartmann & Greene 2005)

c) For adjunctive treatment of Nocardiosis, Actinomycosis: 5–25 mg/kg PO, IV q12h (Lemarie 2003)

d) For Brucillosis in animals that are housed singly and neutered: Minocycline at 25 mg/kg PO once daily for 14 days with dihydrostreptomycin (Note: not currently available in the USA) at 5 mg/kg IM twice daily for 7 days. (Root Kustritz 2007)

e) For Ehrlichiosis (E. canis) in dogs with a positive test result and clinical signs consistent with the infection: 10 mg/kg PO (rarely IV) q12h for 28 days. (Ford 2009)

**CATS:**

a) For hemotropic mycoplasmosis: 6–11 mg/kg PO q12h for 21 days. (Greene et al. 2006)

b) For adjunctive treatment atypical mycobacterial dermal infections: 5–12.5 mg/kg PO, IV q12h (Hnilica 2003)

c) For adjunctive treatment of Nocardiosis, Actinomycosis: 5–25 mg/kg PO, IV q12h (Lemarie 2003)

d) For susceptible mycobacterial, L-Forms, or mycoplasma infections: 5–12.5 mg/kg PO q12h. (Bonenberger 2009)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Oral minocycline products may be administered without regard to feeding. Milk or other dairy products do not significantly alter the amount of minocycline absorbed.

- Give as prescribed for as long as veterinarian recommends even if animal appears well.

Chemistry/Synonyms

A semisynthetic tetracycline, minocycline HCl occurs as a yellow, crystalline powder. It is soluble in water and slightly soluble in alcohol.

Minocycline may also be known as: minocyclini hydrochloridum, Asolmicina®, Cyclimycin®, Cyclomin®, Dermirex®, Meibi®, Minogal®, and Minox®; many other trade names are available.
Storage/Stability
Store the oral preparations at room temperature in tight containers. Do not freeze the oral suspension. The injectable should be stored at room temperature and protected from light. After reconstituting with sterile water for injection, solutions with a concentration of 20 mg/mL are stable for 24 hours at room temperature.

Compatibility/Compounding Considerations
While minocycline is compatible with the usual intravenous fluids (including Ringer’s and lactated Ringer’s) do not add any other calcium containing fluid as precipitation could result.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Minocycline HCl Oral Tablets: 50 mg, 75 mg & 100 mg; Extended-Release: 45 mg, 65 mg, 90 mg, 115 mg & 135 mg; Dynacin® (Medicis); Myrac® (Glades); Solodyn® (Medicis); generic; (Rx)
Minocycline HCl Oral Capsules: 50 mg, 75 mg & 100 mg; Dynacin® (Medicis); generic; (Rx)
Minocycline HCl Pellet-filled Oral Capsules: 50 mg & 100 mg; Minocin® (Lederle); (Rx)
Minocycline HCl Oral Suspension: 50 mg/5 mL in 60 mL; Minocin® (Lederle); (Rx)
Minocycline HCl Powder for Injection lyophilized for solution: 100 mg in vials; Minocin® (Triax); (Rx)
Minocycline HCl Powdered Microspheres, Extended-Release, dental: 1 mg; Arestin® (Cord Logistics); (Rx)

References

MIRTAZAPINE
(mir-taz-ah-pen) Remeron®
TETRACYCLIC ANTIDEPRESSANT; 5-HT3 ANTAGONIST

Prescriber Highlights

- Used in veterinary medicine primarily as an appetite stimulant & antiemetic in dogs & cats
- Can be used in conjunction with other antiemetics
- Primary side effect is sedation. In cats vocalization and increased affection can be noted.
- Use lowest effective dose to reduce sedative properties
- Do not exceed 30 mg per day when used for appetite stimulation

Uses/Indications
Veterinary uses of mirtazapine include treatment of chemotherapy-induced nausea and vomiting (CINV); anorexia associated with renal failure (azotemia), congestive heart failure, gastro-intestinal disorders, liver disease, or neoplasia. Other suggested uses include stress induced diseases; insomnia; post-pyometra symptoms; and post-operative inappetence.

Pharmacology/Actions
The antidepressant activity of mirtazapine appears to be mediated by antagonism at central pre-synaptic alpha2–receptors, which normally acts as a negative feedback mechanism that inhibits further norepinephrine (NE) release. By blocking these receptors, mirtazapine overcomes the negative feedback loop and results in a net increase in NE. This mechanism may also contribute to the appetite stimulating effects of the medication since NE acts at other a-receptors to increase appetite. Additionally, mirtazapine antagonizes several serotonin (5HT) receptor subtypes. The drug is a potent inhibitor of the 5HT2 and 5HT3 receptors and of histamine (H1) receptors. Antagonism at the 5HT3 receptors accounts for the anti-nausea and antiemetic effects of the drug, and its action at H1-receptors produces prominent sedative effects. It is a moderate peripheral alpha1 adrenergic antagonist, a property that may explain the occasional orthostatic hypotension associated with its use; it is a moderate antagonist of muscarinic receptors, which may explain the relatively low incidence of anticholinergic effects.

Pharmacokinetics
In cats after oral dosing of either 1.88 mg (low dose; LD) or 3.75 mg (high dose, HD), mean elimination half-lives were between 10.2–15.4 hours. Mean clearance was 10.5 mL/kg/min (LD) and 18 mL/kg/min (HD). A single low dose of mirtazapine was well tolerated and resulted in a half-life that is compatible with 24 hour dosing intervals in healthy cats (Quimby et al. 2009).

Following oral administration in humans, mirtazapine is rapidly and completely absorbed. Studies in rats showed a linear relationship between the effects of mirtazapine and measured plasma and brain concentrations. Peak plasma concentrations are reached within about 2 hours after an oral dose in humans. Food has minimal effects on both the rate and extent of absorption and does not require adjustments in the dose. Oral bioavailability of mirtazapine is about 20% for rats and
Laboratory Considerations

Drug Interactions

Activated charcoal be administered in addition to other standard monitoring activities in an overdose situation. Mirtazapine ingestion of upwards of 10-fold therapeutic dose in humans exhibits minimal toxicity requiring no acute intervention and only 6 hours of observation.

Overdosage/Acute Toxicity

In nursing mothers. Mirtazapine is distributed into human breast milk and safe use in humans during nursing cannot be assured. In one case report mirtazapine increases in post-implantation losses and pup deaths, as well as decreased pup birth weight. No fetal harm was reported in any of several case reports of mirtazapine there are no animal reproduction studies and no adequate studies in humans.

Adverse Effects

Mirtazapine appears to be well tolerated in both dogs and cats, but use has been limited and controlled trials are lacking. Besides the desirable side effect of appetite stimulation, other currently reported side effects in animals include drowsiness/sedation, vocalization, increased affection in cats, hypotension, and tachycardia (all dose-dependent).

Reproductive/Nursing Safety

In humans, mirtazapine is FDA pregnancy category C (animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans). However, reproductive studies in rats, rabbits, and dogs have shown no evidence of teratogenicity. Additional studies in hamsters, rabbits, and rats showed no evidence of fetal genetic mutation or reduction in parental fertility, although there were increases in post-implantation losses and pup deaths, as well as decreased pup birth weight. No fetal harm was reported in any of several case reports of mirtazapine use during pregnancy nor in animal studies.

In animals, mirtazapine is excreted in very small amounts in milk, the implications of which are currently unknown; consequently, it may be prudent to use caution in nursing mothers. Mirtazapine is distributed into human breast milk and safe use in humans during nursing cannot be assured. In one case report mirtazapine concentrations were detected in breast milk, but the examining neuropediatrician detected no adverse effects (including weight gain or sedation) in the infant.

Overdosage/Acute Toxicity

Mirtazapine ingestion of upwards of 10-fold therapeutic dose in humans exhibits minimal toxicity requiring no acute intervention and only 6 hours of observation. Similar effects were seen in patients receiving up to 30 times the recommended dose. Despite these reports, the package insert for mirtazapine recommends that activated charcoal be administered in addition to other standard monitoring activities in an overdose situation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mirtazapine and may be of significance in veterinary patients:

- **CLONIDINE**: Mirtazapine may cause increases in blood pressure
- **DIAZEPAM (and other benzodiazepines)**: Minimal effects on mirtazapine blood levels, but may cause additive impairment of motor skills
- **FLUOXAMINE**: May cause increased serum concentrations of mirtazapine
- **LINEZOLID**: Increased risk for serotonin syndrome
- **SELEGILINE, AMITRAZ**: Increased risk for serotonin syndrome; MAO inhibitors considered contraindicated with mirtazapine
- **TRAMADOL**: Increased risk for serotonin syndrome

*In vitro* studies identify mirtazapine as a substrate for several hepatic cytochrome CYP450 isoenzymes including 2D6, 1A2, and 3A4. Mirtazapine is not a potent inhibitor of any of these enzymes; clinically significant pharmacokinetic interactions are not likely with drugs metabolized by CYP enzymes.

Laboratory Considerations

No specific concerns noted.
**Doses**

Since no safety or efficacy trials have been performed in animals to date, currently recommended doses are based on extrapolations from human medicine and clinical experience in veterinary practice. According to the product package insert and several anecdotal reports, no adjustment is needed in liver disease or kidney dysfunction, although starting at the lower end of the dosage range and titrating up if needed is recommended in such situations.

**Note:** At doses exceeding 30 mg per day, mirtazapine loses its appetite stimulating properties in humans. Since the ceiling dose for cats and dogs is not currently known, total daily doses ≤30 mg are recommended for appetite stimulation depending upon the weight of the pet.

**DOGS:**

As an appetite stimulant and/or antiemetic:

a) 0.6 mg/kg PO q 24 h not to exceed 30 mg per day for appetite stimulation (Jordan 2007)

Dogs <20 lb. = 3.75 mg PO q24h;

21–50 lb. = 7.5 mg PO q 24h;

50–75 lb. = 15 mg PO q24h;

>75 lb. = 15 mg PO q12h or 30 mg PO q24h (once daily) (Jordan 2007)

**CATS:**

As an appetite stimulant and/or antiemetic:

a) 3.75 mg (¼ of a 15 mg tablet) PO q72h (every 3 days) (Jordan 2007)

b) 3 mg per cat PO q72h (every 3 days) (Churchill 2006)

c) 3–4 mg per cat PO q72h (every 3 days) (Scherk 2006)

**Monitoring**

- Clinical efficacy measured by the following parameters: increased appetite, decreased episodes of vomiting, and weight gain

**Adverse Effects**

**Client Information**

- Give only the prescribed dose.
- Report excessive drowsiness or vocalization to your veterinarian.
- If your animal is receiving the orally disintegrating tablets, make sure hands are dry before handling the tablet. Place the tablet under the animal’s tongue and hold mouth closed for several seconds to allow it to dissolve (should occur quickly). After the tablet has melted, offer the patient water.
- May be given without regard to food.

**Chemistry/Synonyms**

A member of the piperazino-azepine group of compounds, mirtazapine is classified as an atypical tetracyclic antidepressant and is not chemically related to other antidepressants. Mirtazapine, with a molecular weight of 265.36, occurs as a white to creamy white crystalline powder that is slightly soluble in water.

Mirtazapine may also be known as 6-azamianserin, Org-3770, mepirzapine and Remeron®; many trade names for international products are available.

**Storage/Stability**

The coated tablets and the orally disintegrating tablets should be stored at 25°C (77°F) with excursions permitted to 15–30°C (59–86°F). Protect from light and moisture. The stability of the orally disintegrating tablets once removed from the tablet blister is unknown and immediate use is recommended.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

Mirtazapine Oral Tablets: 7.5 mg, 15 mg, 30 mg & 45 mg; Remeron® (Organon), generic; (Rx)

Mirtazapine Orally Disintegrating Tablets: 15 mg, 30 mg & 45 mg; Remeron SolTab® (Organon), generic; (Rx)

**References**

**MISOPROSTOL**

(mye-so-prost-ole) Cytotec®

**PROSTAGLANDIN E1 ANALOG**

**Prescriber Highlights**

- Prostaglandin E1 analog for treating or preventing gastric ulcers, especially associated with NSAIDs; may also be useful as an abortifacient, & to treat atopy or cyclosporine-induced nephrotoxicity

- Contraindications: Pregnancy, nursing mothers (diarrhea in the nursing offspring)
Caution: Sensitivity to prostaglandins or prostaglandin analogs; patients with cerebral or coronary vascular disease

Adverse Effects: GI distress (diarrhea, abdominal pain, vomiting, & flatulence); Potentially, uterine contractions & vaginal bleeding in female dogs

Pregnant women should handle with caution

Uses/Indications
Misoprostol may be useful as primary or adjunctive therapy in treating or preventing gastric ulceration, especially when caused or aggravated by non-steroidal antiinflammatory drugs (NSAIDs). Misoprostol is most useful to prevent GI ulceration or GI adverse effects (anorexia, vomiting) associated with NSAID therapy. While it can be used for treating gastric ulcers, other drugs are probably just as effective and less expensive. It does not appear to be very effective in reducing gastric ulceration secondary to high dose corticosteroid therapy.

Misoprostol may be efficacious in reducing or reversing cyclosporine-induced nephrotoxicity. More data is needed to confirm this effect. There is some evidence for efficacy for pentoxyfylline and misoprostol as anti-inflammatory medications in dogs, but due to the modest benefits, relatively high costs and adverse effects associated with these medications, they probably should not be used as first line medications to treat dogs with atopic dermatitis (Olivry, T. et al. 2010).

Misoprostol’s effects on uterine contractility and cervical softening/opening make it effective as an adjunctive treatment in pregnancy termination.

Pharmacology/Actions
Misoprostol has two main pharmacologic effects that make it a potentially useful agent. By a direct action on parietal cells, it inhibits basal and nocturnal gastric acid secretion as well as gastric acid secretions that are stimulated by food, pentagastrin or histamine. Pepsin secretion is decreased under basal conditions, but not when stimulated by histamine.

Misoprostol also has a cytoprotective effect on gastric mucosa. Probably by increasing production of gastric mucosa and bicarbonate, increasing turnover and blood supply of gastric mucosal cells, misoprostol enhances mucosal defense mechanisms and healing in response to acid-related injuries.

Other pharmacologic effects of misoprostol include increased amplitude and frequency of uterine contractions, stimulating uterine bleeding, and causing total or partial expulsion of uterine contents in pregnant animals.

Pharmacokinetics
Approximately 88% of an oral dose of misoprostol is rapidly absorbed from the GI tract, but a significant amount is metabolized via the first-pass effect. The presence of food and antacids will delay the absorption of the drug. Misoprostol is rapidly de-esterified to misoprostol acid which is the primary active metabolite. Misoprostol and misoprostol acid are thought equal in their effects on gastric mucosa. Both misoprostol and the acid metabolite are fairly well bound to plasma proteins (approximately 90% bound). It is not believed that misoprostol enters maternal milk, but it is unknown whether the acid enters milk.

Misoprostol acid is further biotransformed via oxidative mechanisms to pharmacologically inactive metabolites. These metabolites, the free acid and small amounts of unchanged drug are principally excreted into the urine. In humans, the serum half-life of misoprostol is about 30 minutes and its duration of pharmacological effect is about 3–6 hours.

Contraindications/Precautions/Warnings
It should be used in patients with the following conditions only when its potential benefits outweigh the risks: Sensitivity to prostaglandins or prostaglandin analogs; patients with cerebral or coronary vascular disease (although not reported with misoprostol, some prostaglandins and prostaglandin analogs have precipitated seizures in epileptic human patients, and have caused hypotension which may adversely affect these patients).

Adverse Effects
The most prevalent adverse effect seen with misoprostol is GI distress, usually manifested by diarrhea, abdominal pain, vomiting, and flatulence. Adverse effects are often transient and resolve over several days or may be minimized by dosage adjustment or giving doses with food. Potentially, uterine contractions and vaginal bleeding could occur in female dogs.

Reproductive/Nursing Safety
Misoprostol is contraindicated during pregnancy due to its abortifacient activity. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

It is unlikely that misoprostol is excreted in milk because it is rapidly metabolized, however, it is not known if the active metabolite (misoprostol acid) is excreted in milk. Misoprostol is not recommended for nursing mothers as it potentially could cause significant diarrhea in the nursing offspring.

Overdosage/Acute Toxicity
There is limited information available. Overdoses in laboratory animals have produced diarrhea, GI lesions, emesis, tremors, focal cardiac, hepatic or renal tubular necrosis, seizures, and hypotension.

There were 11 exposures to misoprostol reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, all 11 were dogs with 4 showing clinical signs.

Overdoses should be treated seriously and standard gut emptying techniques employed when applicable. Resultant toxicity should be treated symptomatically and supportive.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving misoprostol and may be of significance in veterinary patients:

**ANTACIDS, MAGNESIUM-CONTAINING:** Magnesium-containing antacids may aggravate misoprostol-induced diarrhea. If an antacid is required, an aluminum-only antacid may be a better choice. Antacids and food do reduce the rate of misoprostol absorption and may reduce the systemic availability, but probably do not affect therapeutic efficacy.
For the prevention and treatment of GI ulcers:
a) For prevention of aspirin-induced gastric injury: Study suggests that misoprostol 3 micrograms/kg PO q12h is as effective as misoprostol 3 micrograms/kg PO q8h. (Ward et al. 2003)
b) 2–5 micrograms/kg PO four times daily. The main indication for misoprostol use is the prevention or treatment of gastric ulceration from NSAIDs. It is uncertain if misoprostol will improve healing of established gastric ulcers and apparently does not have distinct advantages over other antacids in treating ulcers not associated with NSAIDs. (Twedt 2008)
c) 2–5 micrograms/kg PO q8–12h (Dowling 2003; Marks 2008; Valdes 2009)
d) Major indication is preventing GI mucosal injury in dogs with arthritis that require long-term NSAID therapy; can also be used to treat cases of gastroduodenal ulcer disease caused by NSAIDs: 3 micrograms/kg PO three times a day. (Leib 2008)

For reproductive system indications:
a) As an adjunctive therapy for the termination of mid-term pregnancy in the bitch: Pregnancy is confirmed with ultrasound and begun no sooner than 30 days after breeding. 1–3 micrograms/kg misoprostol given intravaginally once daily concurrently with prostaglandin F2alpha (Lutalyse®) at 0.1 mg/kg SC three times daily for 3 days and then 0.2 mg/kg SC three times daily to effect. Monitor efficacy with ultrasound. (Cain 1999)
b) For treating pyometra/metritis: Give aplepristone 10 mg/kg SC on days 1, 2, 8, 15, 29. Give misoprostol 10 micrograms/kg PO twice daily on days 3 through 12. Approximately 75% of cases show significant clinical improvement without developing the adverse effects associated with the prostaglandins (PGF2alpha, cloprostenol). (Fontbonne 2007)
c) As part of an abortifacient protocol after mismating: Misoprostol 1–3 micrograms/kg once daily administered as a vaginal suppository to promote cervical dilation. This allows for a reduced dinoprost (PGF2 alpha) dose (0.1 mg/kg SC q8h for 2 days, then 0.2 mg/kg q8h SC to effect). Abortion usually occurs after 5 days. (Shaw 2007)

As an adjunctive therapy for atopic dermatitis:
a) Target dosage of 5 micrograms/kg PO three times daily. Modest improvement in clinical signs. (Olivry, T et al. 2003)
b) 6 micrograms/kg q8h PO for 30 days (Campbell 1999)

HORSES:
a) For adjunctive treatment of acute colitis: 5 micrograms/kg q8h (route not listed; assume PO—Plumb). (Adherton et al. 2009)
b) For equine gastric ulcer syndrome: 5 micrograms/kg PO q8h. (Buchanan & Andrews 2003)
c) To induce cervical relaxation: From a case report of post-breeding endometritis in a maiden mare in which the cervix remained closed during estrus and acted as a barrier to uterine clearance: After uterus was lavaged and catheter removed, 1000 micrograms (total dose) of misoprostol as a compounded cream was applied to the caudal os and lumen of the cervix. Oxytocin (20 Unis IM) was administered immediately following lavage and again every 6 hours until the following morning. (Nie & Barnes 2003)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Pregnant women should handle the drug with caution.
- If diarrhea or other GI adverse effects become severe or persist, reduce dose or give with food or aluminum antacids to alleviate. Severe diarrheas may require supportive therapy.

Chemistry/Synonyms

A synthetic prostaglandin E1 analog, misoprostol occurs as a yellow, viscous liquid having a musty odor.

Misoprostol may also be known as: SC-29333, Arhotoct®, Arthrotec®, Artotec®, Artrenac Pro®, Artrocte®, Condrocte®, Corrigast®, Cyprostol®, Cytotec®, Cytolog®, Diclecta®, Glexos®, Menpros®, Misodex®, Misofenac®, Naprotec®, Normulen®, Oxpapros®, and Symbol®.

Storage/Stability

Misoprostol tablets should be stored in well-closed containers at room temperature. After manufacture, misoprostol has an expiration date of 18 months.

Dose Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELLED PRODUCTS:

Misoprostol Tablets: 100 micrograms & 200 micrograms; Cytotec® (Pfizer); generic; (Rx)

References

Associated with clinical symptomatology, these effects may be more pronounced with long-term therapy or in dogs with preexisting liver disease. If adverse effects are noted, it is recommended to temporarily halt mitotane therapy and supplement with glucocorticoids. Owners should be provided with a small supply of prednisolone tablets to initiate treatment. Should the clinical signs persist 3 hours after steroids are supplemented, consider other medical problems.

Most common adverse effects seen with initial therapy in dogs include lethargy, ataxia, weakness, anorexia, vomiting, and/or diarrhea; liver changes possible. Neurologic signs can be seen, but are not common. Adverse effects are commonly associated with plasma cortisol levels of less than 1 microgram/dL or a too rapid decrease of plasma cortisol levels into the normal range. Adverse effects may also be more commonly seen in dogs weighing less than 5 kg, which may be due to the inability to accurately dose. The incidence of one or more of these effects is approximately 25% and they are usually mild. If adverse effects are noted, it is recommended to temporarily halt mitotane therapy and supplement with glucocorticoids. Owners should be provided with a small supply of prednisolone tablets to initiate treatment. Should the clinical signs persist 3 hours after steroids are supplemented, consider other medical problems.

Liver changes (congestion, centrolobular atrophy, and moderate to severe fatty degeneration) have been noted in dogs given mitotane. Although not commonly associated with clinical symptomatology, these effects may be more pronounced with long-term therapy or in dogs with preexisting liver disease.
The following drug interactions have either been reported or are theoretical in humans or animals receiving mitotane and may be of significance in veterinary patients:

administering charcoal and a cathartic should be considered after a recent ingestion. It is recommended that the patient be closely monitored and given glucocorticoids

Overdosage/Acute Toxicity

No specific recommendations were located regarding overdoses of this medication. Because of the drug’s toxicity and long half-life, emptying the stomach and administering charcoal and a cathartic should be considered after a recent ingestion. It is recommended that the patient be closely monitored and given glucocorticoids if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mitotane and may be of significance in veterinary patients:

CNS DEPRESSANT DRUGS: If mitotane is used concomitantly with drugs that cause CNS depression, additive depressant effects may be seen

INSULIN: Diabetic dogs receiving insulin may have their insulin requirements decreased when mitotane therapy is instituted

PHENOBARBITAL: Can induce enzymes and reduce the efficacy of mitotane, conversely mitotane can induce hepatic microsomal enzymes and increase the metabolism of phenobarbital

SPIRONOLACTONE: In dogs, spironolactone has been demonstrated to block the action of mitotane; it is recommended to use an alternate diuretic if possible

Laboratory Considerations

Mitotane will bind competitively to thyroxine-binding globulin and decreases the amount of serum protein-bound iodine. Serum thyroxine concentrations may be unchanged or slightly decreased, but free thyroxine values remain in the normal range. Mitotane does not affect the results of the resin triiodothyronine uptake test.

Mitotane can reduce the amounts measurable 17-OHCS in the urine, which may or may not reflect a decrease in serum cortisol levels or adrenal secretion.

Doses

For medical treatment of pituitary-dependent hyperadrenocorticism (bilateral adrenal hyperplasia): Note: The information provided below (in “a and b”) is a synopsis of the referenced authors' treatment protocols. It is strongly recommended to refer to the original references or other detailed discussions on the treatment of hyperadrenocorticism before instituting therapy for the first time.

a) Beginning by reducing dog’s food allotment by one-third the day before (Saturday) therapy. Owners should give ⅓ the daily allotment that morning and ⅓ the daily allotment that evening. This should make the dog quite hungry. No dog with a poor appetite should ever be treated medically for pituitary-dependent hyperadrenocorticism (PDH). Initiate therapy at home (on Sunday): 25 mg/kg twice a day, PO with food. Glucocorticoids are not routinely administered nor dispensed. Give until one of the following occurs: Polydipsic dogs’ water consumption approaches 60 mL/kg/day of water, dog takes longer to consume a meal or it develops partial or complete anorexia, dog vomits, is unusually listless, or has diarrhea. Any of these observations demand the owner stop therapy and have the dog examined by a veterinarian. Any reduction in appetite indicates that the induction phase of therapy is completed. Water intake is a less-consistent parameter in determining therapeutic end-point. Beginning on 2nd day of therapy, contact owner daily during the induction phase to monitor the situation and encourage.

When dog’s appetite is reduced or 8 days of induction therapy have occurred (whichever comes first), history and physical repeated, ACTH response test, BUN, serum sodium, and potassium redone. If the dog has responded clinically, stop mitotane until ACTH response test can be evaluated. Successful therapy is indicated by pre- and post-ACTH serum cortisol concentrations >1.5 mcg/dL and <5 micrograms/dL. Goals of therapy are to achieve resolution of clinical signs. Most dogs respond between 4 and 9 days of therapy.

Maintenance therapy: Is begun once dog seems much improved or normal to owner or if post-ACTH serum cortisol is <5 micrograms/dL (Note: reference states 54g/dL, but this is an obvious “typo”). Each dog must be treated individually. Dogs generally receive 25–50 mg/kg per week. If <1 microgram/dL, withhold medication for 2 weeks and restart at 25 micrograms/kg/week. Whenever possible, the weekly dose of medication should be divided in as many doses as possible (e.g., if dog receiving 500 mg/week; divide tablet into quarters and give 4 times a week). Four weeks after therapy started, ACTH stimulation test rechecked. If post-ACTH results are 1–3.5 micrograms/dL, dog receives 25 mg/kg/week and recheck in 4 weeks. If 3.5–7.5 micrograms/dL, dog receives 50 mg/kg/week and recheck in 4 weeks. If >7.5 micrograms/dL, be sure the drug is being administered properly. If given properly, may mix with corn oil and mixed with food. These animals should also be evaluated for other conditions (e.g., renal disease, diabetes mellitus). ACTH stimulation results should be used as a guide for dosage adjustment, but owner opinion is the most important factor. (Feldman, B.F. 1989; Feldman, E. 2000)(Feldman, E. 2007)

b) Induction phase 30–50 mg/kg/day PO with a meal once daily or divided q12h for 7–10 days. If adverse effects (lethargy, vomiting, weakness, diarrhea) occur, discontinue mitotane and give glucocorticoids (prednisolone) at 0.15–0.25 mg/kg/day) until dog can be evaluated. If decreased appetite occurs discontinue mitotane and evaluate with an ACTH stimulation test. Perform ACTH stimulation test at end of 10 day period or sooner if adverse effects occur. Goal is to have basal and post-ACTH cortisol between 1-5 micrograms/dL (normal for most labs). If basal and post ACTH cortisol falls below 1 microgram/dL, temporarily suspend mitotane and supplement with glucocorticoids until circulating cortisol normalizes (usually 2–4 weeks, but may take several weeks to months). If basal or post ACTH cortisol is above normal, continue daily mitotane and recheck ACTH stimulation tests at 5–10 days intervals until serum cortisol falls within normal resting range.

Begin maintenance when desired cortisol concentrations are documented by ACTH stimulation testing. Mitotane given initially at 35–50 mg/kg per week in 2–3
Induction therapy uses higher doses of mitotane that are intended to induce remission (Bruyette 2002). For treatment of Cushing’s disease, mitotane therapy is given at 25 mg/kg PO divided twice daily for 25 consecutive days. The dose is then tapered every 2–3 days until a maintenance dose of 75–100 mg/kg PO is achieved. Once a maintenance dose is established, mitotane is continued until the ACTH stimulation test is normal or the patient is euthyroid (Kintzer, P. 2007).

c) Initial dose of 50 mg/kg q 12h. Glucocorticoids are not usually administered concurrently, but a small supply of prednison should be made available to the owner for emergencies. Continue until water consumption decreases to <100 mL/kg/day, or until a decreased appetite, depression, diarrhea, or vomiting are observed. The time for clinical response is quite variable but most dogs respond within 3–7 days. At this point the dog should be reevaluated and an ACTH stimulation test performed. Prednisone treatment (0.2 mg/kg) should be initiated in patients that are showing clinical signs of hypocortisolemia, until the results of the ACTH stimulation test are known. In patients that are not polydipsic prior to therapy, patients where water consumption cannot be monitored, and in patients whose polydipsia is due to another cause (e.g., diabetes mellitus), mitotane should be administered for a maximum of 5–7 days prior to ACTH stimulation testing. The goal of treatment is to have both the pre- and post-cortisol measurement in the normal resting range (2–6 micrograms/dL). Maintenance therapy (50 mg/kg every 7–10 days) is started once the ACTH stimulation test shows adequate suppression and prednisone therapy (if necessary) has been discontinued. Failure to use maintenance therapy will result in re-growth of the adrenal cortex and recurrence of clinical signs. Efficacy of maintenance therapy is monitored by an ACTH stimulation test after one month of maintenance treatment and then every 3 months. The dose of mitotane required for long term maintenance is very variable (26–330 mg/kg/week). (Scott-Moncrieff 2010)

d) Intentionally causing complete destruction of the adrenal cortex as an alternative to the traditional mitotane treatment: Mitotane at 75–100 mg/kg per day for 25 consecutive days, given in 3–4 doses per day with food. Lifelong prednisone at 0.1–0.5 mg/kg PO twice daily initially and mineralocorticoid therapy is begun at the start of mitotane therapy. Prednisone dose is tapered after completion of the 25-day protocol. Relapse is common and periodic ACTH stimulation testing is necessary. May be considerably more expensive than traditional therapy because of the expense associated with treating Addisonian dogs. (Nelson 2003)

e) For total adrenal ablation for management of Cushing’s: Mitotane 100 mg/kg/day divided twice daily for 30 days. Supplemental cortisone acetate 2 mg/kg/day divided twice daily and fludrocortisone acetate 0.1 mg/10 lb of body weight PO once daily are begun on day 1 of mitotane therapy. Diet is supplemented with 1–5 grams of sodium chloride per day. One week after induction phase with mitotane, cortisone acetate is reduced to 1 mg/kg/day. Electrolytes and ACTH stimulation test are performed at end of induction, every 6 months, and at any time animal demonstrates signs compatible with either hypo- or hyperadrenocorticism. This form of management requires close patient monitoring and life-long daily therapy. Close attention during stress and non-adrenal illnesses required. (Bruyette 2002)

For palliative medical treatment of adrenal carcinomas or medical treatment of adrenal adenomas:

Initially, 50–75 mg/kg PO in daily divided doses for 10–14 days. May supplement with prednisolone at 0.2 mg/kg/day. Stop therapy and evaluate dog if adverse effects occur. After initial therapy run ACTH-stimulation test (do not give prednisolone the morning of the test). If basal or post-ACTH serum cortisol values are decreased, but still above the therapeutic end-point (<1 micrograms/dL), repeat therapy for an additional 7–14 days and repeat testing. If post-ACTH serum cortisol values remain greatly elevated or unchanged, increase mitotane to 100 mg/kg/day and repeat ACTH-stimulation test at 7–14 day intervals. If ACTH continues to remain greatly elevated, increase dosage by 50 mg/kg/day every 7–14 days until response occurs or drug intolerance ensues. Adjust dosage as necessary as patient tolerates or ACTH-responsive dictates. Once undetectable or low-normal post-ACTH cortisol levels are attained, continue mitotane at 100–200 mg/kg/week in divided doses with glucocorticoid supplementation (prednisolone 0.2 mg/kg/day). Repeat ACTH-stimulation test in 1–2 months. Continue at present dose if cortisol remains below 1 micrograms/dL. Should cortisol increase to 1–4 micrograms/dL, increase maintenance dose by 50%. If basal or post-ACTH cortisol goes above 4 micrograms/dL, restart daily treatment (50–100 mg/kg/day) as outlined above. Once patient is stabilized, repeat ACTH-stimulation tests at 3–6 month intervals. (Kintzer, P.P. & Peterson 1989)

**FERRETS:**

For medical treatment of hyperadrenocorticism where surgery has not been performed or tumor has not been fully resected:

a) 50 mg per ferret PO once daily for one week, then 50 mg PO 2–3 times per week. Have a compounding pharmacy make 50 mg capsules. Capsules can be easily administered if coated with a substance such as Nutrical. (Rosenthal & Peterson 2000)

**Monitoring**

Initially and as needed (see doses above):

- Physical exam and history (including water and food consumption, weight)
- BUN, CBC, Liver enzymes, Blood glucose, ACTH response test, serum electrolytes (Na+/K+)

**Client Information**

- Clients must be clearly instructed in the adverse effects of the drug and the clinical signs of acute hyperadrenocorticism
- This medication is best administered immediately after a meal
- Because of the potential severe toxicity associated with this agent, clients should be instructed to wear gloves or wash their hands after administering and to keep the tablets out of reach of children or pets.

**Chemistry/Synonyms**

Mitotane, also commonly known in veterinary medicine as o,p’-DDD, is structurally related to the infamous insecticide, chlorphenothane (DDT). It occurs as a white, crystalline powder with a slightly aromatic odor. It is practically insoluble in water and soluble in alcohol.

Mitotane may also be known as: CB-313, o,p’DDD, NSC-38721, WR-13045, and Lisodren®.

**Storage/Stability**

Mitotane tablets should be stored at room temperature (15–30°C), in tight, light resistant containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Mitotane Tablets (scored): 500 mg; Lysodren® (Bristol-Myers Squibb Oncology); (Rx)

**References**

MITOXANTRONE HCL
(mye-toe-an-trone) Novantrone®

ANTINEOPLASTIC

Prescriber Highlights

- Antineoplastic that may be useful for a variety of neoplastic diseases
- Contraindications (relative): Myelosuppression, concurrent infection, impaired cardiac function; those who have received prior cytotoxic drug or radiation exposure
- Caution: Sensitivity to drug, hyperuricemia or hyperuricuria, impaired hepatic function
- Adverse Effects: Dose-dependent GI distress, bone marrow depression, lethargy, & seizures (cats)
- Relatively expensive
- Renal clearance of drug is minimal

Uses/Indications
Mitoxantrone may be useful in the treatment of several neoplastic diseases in dogs and cats, including lymphosarcoma mammary adenocarcinoma, squamous cell carcinoma, renal adenocarcinoma, fibroid sarcoma, thyroid or transitional cell carcinomas, and hemangiopericytoma.

Because renal clearance of the drug is minimal (10%), it may be administered to cats with renal insufficiency much more safely than doxorubicin.

Pharmacology/Actions
By intercalation between base pairs and a nonintercalative electrostatic interaction, mitoxantrone binds to DNA and inhibits both DNA and RNA synthesis. Mitoxantrone is not cell-cycle phase specific, but appears to be most active during the S phase.

Pharmacokinetics
Mitoxantrone is rapidly and extensively distributed after intravenous infusion. Highest concentrations of the drug are found in the liver, heart, thyroid, and red blood cells. In humans, it is approximately 78% bound to plasma proteins. Mitoxantrone is metabolized in the liver, but the majority of the drug is excreted unchanged in the urine. Half-life of the drug in humans averages about 5 days as a result of the drug being taken up, bound by, and then slowly released by tissues.

Contraindications/Precautions/Warnings
Mitoxantrone is relatively contraindicated (weigh risk vs. benefit) in patients with myelosuppression, concurrent infection, impaired cardiac function, or those who have received prior cytotoxic drug or radiation exposure. It should be used with caution in patients with sensitivity to mitoxantrone, hyperuricemia or hyperuricuria, or impaired hepatic function.

Adverse Effects
In dogs and cats, effects include dose-dependent GI distress (vomiting, anorexia, diarrhea) and bone marrow depression (sepsis). Non-regenerative anemias may be detected and white cell nadirs generally occur on day 10. Some evidence exists that by giving recombinant granulocyte-colony stimulating factor bone marrow depression severity and duration may be reduced. Lethargy may also be noticed. Some cats receiving this drug have developed seizures.

Unlike doxorubicin, cardiotoxicity has not yet been reported in dogs and only rarely occurs in humans. Other adverse effects less frequently or rarely noted in humans and, potentially possible in dogs, include conjunctivitis, jaundice, renal failure, seizures, allergic reactions, thrombocytopenia, irritation or phlebitis at injection site. Tissue necrosis associated with extravasation has only been reported in a few human cases.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Mitoxantrone is excreted in maternal milk and significant concentrations (18 ng/mL) have been reported for 28 days after the last administration to humans. Because of the potential for serious adverse reactions in offspring, it is recommended to use milk replacer if mitoxantrone is administered.

Overdosage/Acute Toxicity
Because of the potential serious toxicity associated with this agent, dosage determinations must be made carefully.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving mitoxantrone and may be of significance in veterinary patients:

- **DOXORUBICIN, DAUNORUBICIN, or RADIATION THERAPY:** Cardiotoxicity risks may be enhanced in patients that have previously received doxorubicin, daunorubicin, or radiation therapy to the mediastinum
Mitoxantrone HCl should be stored at room temperature. While the manufacturer recommends not to freeze, one study (Mauldin 2002) demonstrated that the drug maintained its cytotoxic effects when frozen and thawed at various intervals for a 12-month period. Do not mix or use the same IV line with heparin infusions (precipitate may form). At present, it is recommended to not mix with other IV drugs.

**Doses**

**Note:** Because of the potential toxicity of this drug to patients, and potentially, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring, and safety guidelines often change, the following dosages should be used only as a general guide and not as a dosage protocol. When using mitoxantrone as part of chemotherapy protocols, consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is strongly recommended.

**DOGS:**

As an alternative agent for the treatment of a variety of neoplastic diseases (see Indications above):

a) For transitional cell carcinoma: 5 mg/m² IV every 21 days with piroxicam (0.3 mg/kg PO once daily). (Chun 2007)

b) For lymphoma, squamous cell carcinoma, transitional cell carcinoma, mammary gland tumors, etc.: Effective dose is 6 mg/m² IV every 2–3 weeks (Ogilvie 2003)

c) As a single rescue agent for lymphoma: 5.5–6 mg/m² IV every 3 weeks (Meleo 2003)

d) As a rescue agent for canine lymphoma: 6 mg/m² IV every 2–3 weeks. Check CBC on day 7 after treatment and the protocol can be repeated on day 14 or 21 if the dog attains complete or partial response. Combining with DTIC (dacarbazine) may improve the response rate for dogs with refractory lymphoma, but there are no available studies. (Rassnick 2006)

e) For transitional cell carcinoma after laser ablation of the primary tumor: Mitoxantrone at 5 mg/m² IV every 3 weeks for 4 treatments. Piroxicam was given at a dosage of 0.3 mg/kg PO once daily for the remaining life of the dog. (Upton et al. 2006)

**CATS:**

a) For soft-tissue sarcomas: 6–6.5 mg/m² IV every 3–4 weeks for 4–6 treatments. (Keller & Helfand 1994)

b) Effective dose: 6.5 mg/m² IV every 2–3 weeks (Ogilvie 2003)

c) As a single rescue agent for lymphoma: 6–6.5 mg/m² IV every 3 weeks (Meleo 2003)

**Monitoring**

- CBC with differential and platelets (see Adverse Effects section)
- Efficacy
- Chest radiographs, ECG or other cardiac function tests if cardiac symptomatology present
- Liver function tests if jaundice or other clinical signs of hepatotoxicity present
- Serum uric acid levels for susceptible patients

**Client Information**

- Clients should understand the potential costs and toxicities associated with therapy
- A blue-green color to urine or a bluish color to sclera may be noted but is of no concern
- Have clients report any clinical signs associated with toxicity immediately to veterinarian
- Mitoxantrone or its metabolites may be detected in urine up to 6 days, and in feces up to 7 days after administration. Use appropriate precautions when cleaning up animal waste.

**Chemistry/Synonyms**

Mitoxantrone HCl is a synthetic anthracenedione antineoplastic. It occurs as a dark-blue powder and is sparingly soluble in water, practically insoluble in acetone, acetonitrile, and chloroform, and slowly soluble in methyl alcohol.

Mitoxantrone may also be known as: L-232315, DHAD, dihydroxyanthracenedione dihydrochloride, mitoxantroni hydrochloridum, NSC-301739, Formyxan®, Genefadeone®, Micraleve®, Misostol®, Mitoxal®, Mitoxogen®, Mitroxone®, Neotalem®, Novantron®, Novantrone®, Oncotron®, Oncotrite®, or Pralifan®.

**Storage/Stability**

Mitoxantrone HCl should be stored at room temperature. While the manufacturer recommends not to freeze, one study (Mauldin 2002) demonstrated that the drug maintained its cytotoxic effects when frozen and thawed at various intervals over a 12-month period. Do not mix or use the same IV line with heparin infusions (precipitate may form). At present, it is not recommended to mix with other IV drugs.

**Compatibility/Compounding Considerations**

Do not mix or use the same IV line with heparin infusions (precipitate may form). At present, it is recommended to not mix with other IV drugs.
Reports of human adults and children receiving doses as high as 1,000 mg have been reported and the majority of overdoses had no adverse effects. The most frequent
Montelukast is relatively safe in overdose situations. Rats and mice survived oral doses of approximately 230X and 335X and 230X of the usual human adult dose.

Overdosage/Acute Toxicity
no evidence of risk in later trimesters
has designated it as a category
Montelukast appears safe to use during pregnancy. No teratogenicity was observed in rats at oral dosages of up to 100X, or rabbits at 110X the human dose. The FDA
Reproductive/Nursing Safety
cholestatic hepatitis and allergic granulomatous angiitis have been reported.
No adverse effects were noted for cats but the drug has not been extensively studied or used in cats.

Adverse Effects
Leukotriene inhibitor; potentially may be useful in cats for feline asthma, IBD, upper respiratory disease, and heartworm-associated respiratory disease syndrome
Good evidence not yet available to support use in cats
No significant adverse effects reported in cats to date

Uses/Indications
In veterinary medicine, montelukast has been used primarily in cats. Potential indications include: feline asthma, upper respiratory disease, inflammatory bowel disease and heartworm disease. Its use in treating feline asthma has been disappointing, and few recommend it for this purpose. At the time of writing, only anecdotal evidence exists for efficacy for this class of drugs in cats. A small trial in horses with RAO did not show efficacy (Robinson 2010).

In humans, montelukast is FDA-approved for allergic rhinitis and asthma. It is used off-label for atopic dermatitis, urticaria (chronic and NSAID-induced), and eosinophilic esophagitis.

Pharmacology/Actions
Montelukast is a leukotriene antagonist that inhibits at the cysteinyl leukotriene (CysLT1) receptor. The cysteinyl leukotrienes (LTC4, LTD4, LTE4) are pro-inflammatory products of arachidonic acid metabolism released from certain cells, including mast cells and eosinophils.

Pharmacokinetics
No pharmacokinetic data was located.
In humans, oral bioavailability is 64% and peak levels occur 3-4 hours after dosing. The presence of food does not affect bioavailability. Montelukast is highly bound (99+%) to human plasma proteins. It is extensively metabolized in the liver via cytochrome P450 isoenzymes CYP3A4, CYP2A6, and CYP2C9. Based on in vitro studies in human liver microsomes, therapeutic plasma concentrations of montelukast do not inhibit CYP-450 isoenzymes 3A4, 2C9, 1A2, 2A6, 2C19, or 2D6. Metabolites are excreted primarily in the bile and eliminated in the feces. In healthy young adults, plasma half-life averages around 4 hours.

Contraindications/Precautions/Warnings
Montelukast is contraindicated in patients hypersensitive to it or to any component of the product. Humans are warned not use it to attempt to reverse acute bronchospasm.

Adverse Effects
No adverse effects were noted for cats but the drug has not been extensively studied or used in cats.
In humans, the drug is usually well tolerated with minimal adverse effects reported. Rarely, behavioral effects (aggression, suicidal thoughts), palpitations, cholestatic hepatitis and allergic granulomatous angiitis have been reported.

Reproductive/Nursing Safety
Montelukast appears safe to use during pregnancy. No teratogenicity was observed in rats at oral dosages of up to 100X, or rabbits at 110X the human dose. The FDA has designated it as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)
While studies in rats have shown that montelukast is excreted in milk, it is likely safe to use during nursing.

Overdosage/Acute Toxicity
Montelukast is relatively safe in overdose situations. Rats and mice survived oral doses of approximately 230X and 335X and 230X of the usual human adult dose. Reports of human adults and children receiving doses as high as 1,000 mg have been reported and the majority of overdoses had no adverse effects. The most frequent
Reports of human adults and children receiving doses as high as 1,000 mg have been reported and the majority of overdoses had no adverse effects. The most frequent adverse experiences observed in humans are: headache, vomiting, psychomotor hyperactivity, thirst, somnolence, mydriasis, hyperkinesia, and abdominal pain. Treatment is basically supportive.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans receiving montelukast and may be of significance in veterinary patients:

- **CYP-450 ENZYME INDUCERS** (e.g., phenobarbital, rifampin): May reduce the montelukast plasma concentrations and efficacy
- **PREDNISONE, PREDNISOLONE:** Severe peripheral edema has been reported in a human receiving both drugs, presumably due to increased renal tubular sodium and fluid retention. After prednisone was discontinued, edema resolved; clinical significance is not clear.

**Laboratory Considerations**

- None

**Doses**

**CATS:**

- For feline asthma: There are some anecdotal reports of efficacy of montelukast at 0.5–1 mg/kg PO once daily (q24h) and zafirlukast (1–2 mg/kg PO q12h) in the treatment of feline asthma, but more conclusive evidence is needed before these agents can be used regularly. (Martín-Jiménez 2010)
- For adjunctive treatment of the chronic “snuffler”: 0.25–0.5 mg/kg PO q24h (i.e., 1/4th of a 10 mg Singulair® tablet). (Scherk 2010)
- For IBD: For mild cases of IBD involving eosinophils and lymphocytes, leukotriene antagonists should be considered; either montelukast at 0.5–1 mg/kg PO once daily or zafirlukast (0.15 to 0.2 mg/kg orally PO once daily). Alternatively, these drugs might be used in combination with other drugs in any stage. (Boothe 2009)
- For adjunctive treatment of feline heartworm: There is anecdotal evidence that anti-leukotrienes (e.g., montelukast) at 2 mg total dose (PO) once daily may help to thwart an acute, fatal lung injury when an adult worm dies. (Nelson 2008)

**Monitoring**

- Clinical efficacy

**Client Information**

- May be given with or without food
- This drug is not for the immediate treatment of asthma or other signs or symptoms
- This drug has not been used often in animals; report any adverse effects to the veterinarian immediately

**Chemistry/Synonyms**

Montelukast is a cyclopropeneacetic acid derivative leukotriene inhibitor. It is freely soluble in ethanol, methanol, and water. Montelukast may also be known as MK-476, L-706631, or montelukastum.

**Storage/Stability**

Store tablets or granules at room temperature; excursions are permitted to 15°–30°C (59°–86°F). Protect from moisture and light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Montelukast Sodium Oral Tablets: 4 mg (chewable), 5 mg (chewable), 10 mg; oral granules 4 mg/packet; Singulair® (Merck); (Rx)

**MORANTEL TARTRATE**

(mor-an-tel) Rumatel®

**ANTIPARASITIC AGENT**

**Prescriber Highlights**

- Infrequently used anthelmintic for ruminants
- Contraindications: None
- Adverse Effects: Large safety margin; clinical signs of OD include increased respiratory rates, profuse sweating, ataxia or other cholinergic effects

**Uses/Indications**

Infrequently used anthelmintic for ruminants
Morantel is labeled for the removal of the following parasites in cattle: Mature forms of: *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Nematodirus* spp., *Cooperia* spp. and *Oesophagostomum radiatum*. It is also used in other ruminant species.

**Pharmacology/Actions**
Like pyrantel, morantel acts as a depolarizing neuromuscular blocking agent in susceptible parasites, thereby paralyzing the organism. The drug possesses nicotine-like properties and acts similarly to acetylcholine. Morantel also inhibits fumarate reductase in *Haemonchus* spp.

Morantel is slower than pyrantel in its onset of action, but is approximately 100 times as potent.

**Pharmacokinetics**
After oral administration, morantel is absorbed rapidly from the upper abomasum and small intestine. Peak levels occur about 4–6 hours after dosing. The drug is promptly metabolized in the liver. Within 96 hours of administration, 17% of the drug is excreted in the urine with the remainder in the feces.

**Contraindications/Precautions/Warnings**
There are no absolute contraindications to using this drug.

**Adverse Effects**
At recommended doses, adverse effects are not commonly seen. For more information, see Overdosage section below.

**Reproductive/Nursing Safety**
Morantel is considered generally safe to use during pregnancy.

**Overdosage/Acute Toxicity**
Morantel tartrate has a large safety margin. In cattle, dosages of up to 200 mg/kg (20 times recommended dose) resulted in no toxic reactions. The LD50 in mice is 5 grams/kg. Clinical signs of toxicity that might possibly be seen include increased respiratory rates, profuse sweating (in species with sweat glands), ataxia or other cholinergic effects.

Chronic toxicity studies have been conducted in cattle and sheep. Doses of 4 times recommended were given to sheep with no detectable deleterious effects. Cattle receiving 2.5 times recommended dose for 2 weeks showed no toxic signs.

**Drug Interactions**
- **BENTONITE**: Do not add to feeds containing bentonite.
- **LEVAMISOLE, PYRANTEL**: Because of similar mechanisms of action (and toxicity), morantel is not recommended for use concurrently with pyrantel or levamisole.
- **ORGANOPHOSPHATES, DIETHYLCARBAMAZINE**: Observation for adverse effects should be intensified if used concomitantly with an organophosphate or diethylcarbamazine.
- **PIPERAZINE**: Has antagonistic mechanism of action; do not use with morantel.

**Doses**

**CATTLE:**  
For susceptible parasites:  
a) 9.68 mg/kg PO (Paul 1986)  
b) Feed at the rate of 0.44 grams of morantel tartrate per 100 lbs of body weight. 10 lbs of premix per ton of food per 100 lbs of body weight. (Label Directions; *Rumatel®*—Philbro)  
c) 8.8 mg/kg PO (Roberson 1988)

**SHEEP & GOATS:**  
For susceptible parasites:  
a) **Goats**: As a single therapeutic treatment at 0.44 grams morantel tartrate per 100 lb. body weight. Fresh water should be available at all times. Conditions of constant worm exposure may require retreatment in 2–4 weeks. (Label directions; *Goat Care-2X®*—Durvet)  
b) **Sheep**: 10 mg/kg PO (Roberson 1988)  
c) **Goats**: 10 mg/kg PO (de la Concha 2002)

**Chemistry/Synonyms**
A tetrahydropyrimidine anthelmintic, morantel tartrate occurs as a practically odorless, off-white to pale yellow, crystalline solid that is soluble in water. It has a melting range of 167–171°C. The tartrate salt is equivalent to 59.5% of base activity.

Morantel tartrate may also be known as: CP-12009-18, moranteli hydrogenotartras, or UK-2964-18, *Goat Care-2X®* and *Rumatel®*.

**Storage/Stability**
Morantel tartrate products should be stored at room temperature (15–30°C, 59–86°F) and protected from light unless otherwise instructed by the manufacturer.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
Morantel Tartrate Medicated Pellets: 0.194% (880 mg/lb) in 3 lb (treats 12–50 lb goats) and 10 lb. (treats 40–50 lb. goats). *Goat Care-2X®* (Durvet); (OTC); No withdrawal time noted on label. Do not mix in feeds containing bentonite.

Morantel Tartrate Medicated Premix: 88 grams morantel tartrate per lb. in 25 lb bags; *Rumatel® Medicated Premix-88* (Philbro); (OTC). FDA-approved for use in beef or dairy cattle. Milk withdrawal (at labeled doses) = none; Slaughter withdrawal (at labeled doses) = 14 days.
HUMAN-LABELED PRODUCTS: None

References

MORPHINE SULFATE

(mor-fen)

OPIATE AGONIST

Prescriber Highlights

- Classic opiate analgesic
- Contraindications: Hypersensitivity to morphine, diarrhea caused by a toxic ingestion
- Extreme Caution: Respiratory disease or from acute respiratory dysfunction
- Caution: Hypothyroidism, severe renal insufficiency (acute uremia), adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure, & acute abdominal conditions (e.g., colic)
- Adverse Effects: Histamine release, respiratory depression, bronchoconstriction, CNS depression, physical dependence (chronic use), hyperthermia (cattle, goats, horses & cats), hypothermia (dogs, rabbits); GI Gastrointestinal effects may include: (nausea, vomiting, & decreased intestinal peristalsis), defecation (dogs)
- C-II controlled substance

Uses/Indications

Morphine is used for the treatment of acute pain in dogs, cats, horses, swine, sheep, and goats. It may be used as a preanesthetic agent in dogs and swine. Additionally, it has been used as an antitussive, antidiarrheal, and as adjunctive therapy for some cardiac abnormalities (see doses) in dogs. Due to its poor oral bioavailability in dogs, oral morphine is not recommended in canines.

Intra-articular administration of morphine as part of a balanced analgesic protocol, may be beneficial in horses (and other species) for synovitis or after joint surgery.

Pharmacology/Actions

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

When administered intra-articularly in horses with experimentally-induced synovitis, morphine demonstrated antiinflammatory effects (reduced swelling, reduced synovial total protein, serum amyloid and white blood cell counts) (Lindegaard et al. 2010).

Morphine’s CNS effects are irregular and are species specific. Cats, horses, sheep, goats, cattle, and swine may exhibit stimulatory effects after morphine injection, while dogs, humans, and other primates exhibit CNS depression. Both dogs and cats are sensitive to the emetic effects of morphine, but significantly higher doses are required in cats before vomiting occurs. This effect is a result of a direct stimulation of the chemoreceptor trigger zone (CTZ). Other species (horses, ruminants, and swine) do not respond to the emetic effects of morphine. Like meperidine, morphine can affect the release of histamine from mast cells.

Morphine is an effective centrally acting antitussive in dogs. Following morphine administration, hypothermia may be seen in dogs and rabbits, while hyperthermia may be seen in cattle, goats, horses, and cats. Morphine can cause miosis (pinpoint pupils) in humans and rabbits. While miosis is listed as a pharmacologic effect of morphine in dogs, in a recent study in normal dogs, intravenous doses of morphine (dose not specified), did not significantly affect pupil size or intraocular pressure (Pirie et al. 2008).

While morphine is considered a respiratory depressant, respirations are stimulated initially in dogs. Panting may ensue which may be a result of increased body temperature. Often however, body temperature may be reduced due to a resetting of the “body’s thermostat.” As CNS depression increases and the hyperthermia resolves, respirations can become depressed. Morphine can cause moderate to high doses can also cause bronchoconstriction in dogs.

The cardiovascular effects of morphine in dogs are in direct contrast to its effects on humans. In dogs, morphine causes coronary vasoconstriction with resultant increase in coronary vascular resistance, and a transient decrease in arterial pressure. Both bradycardias and tachycardias have been reported in dogs. While morphine has been used for years as a sedative/analgesic in the treatment of myocardial infarction and congestive heart failure in humans, its effects on dogs make it a less than optimal choice in canine patients with clinical signs of cardiopulmonary failure.

The effects of morphine on the gastrointestinal (GI) tract consist primarily of a decrease in motility and secretions. The dog, however, will immediately defecate following an injection of morphine, then exhibit the signs of decreased intestinal motility and, ultimately, constipation can result. Both biliary and gastric secretions are reduced following administration of morphine, but gastric secretion of HCl will later be compensated by increased (above normal) acid secretion.

Initially, morphine can induce micturition, but with higher doses (>2.4 mg/kg IV) urine secretion can be substantially reduced by an increase in anti-diuretic hormone (ADH) release. Morphine may cause bladder hypertonia which can lead to increased difficulty in urination.

Pharmacokinetics

Morphine is absorbed when given by IV, IM, SC, and rectal routes. Although absorbed when given orally, bioavailability is reduced, probably because of a high first-pass effect. Very low oral bioavailability (<20%) in dogs, limits the clinical usefulness of orally administered morphine in canines. Morphine concentrates in the kidney, liver, and lungs; lower levels are found in the CNS. Although at lower levels then in the parenchymatous tissues, the majority of free morphine is found in the CNS. Although at lower levels, the majority of free morphine is found in the CNS.
Drug Interactions

additive effects on respiratory depression. In cases of severe respiratory depression.

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals.

Overdosage/Acute Toxicity

Taking into account the importance of the drug to the mother.

respiratory secretions may all have a detrimental effect on a susceptible patient. Bronchoconstriction (secondary to histamine release?) following IV doses has been

At usual doses, the primary concern is the effect the opioids have on respiratory function. Decreased tidal volume, depressed cough reflex, and the drying of

Gastrointestinal effects may include: nausea, vomiting, and decreased intestinal peristalsis. Dogs will usually defecate after an initial dose of morphine, but this is not

The CNS effects of morphine are dose and species specific. Animals that are stimulated by morphine may elucidate changes in behavior, appear restless and, at very

Body temperature changes may be seen. Cattle, goats, horses, and cats may exhibit signs of hyperthermia, while rabbits and dogs may develop hypothermia.

Chronic administration may lead to physical dependence.

Reproductive/Nursing Safety

Placental transfer of opiates is rapid. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Morphine appears in maternal milk, but effects on offspring may not be significant when used for short periods. Withdrawal symptoms have occurred however in breastfeeding infants when maternal administration of an opioid-analgesic stopped. Decide whether to accept the risks, discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Overdosage/Acute Toxicity

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Parenteral doses greater than 100 mg/kg are thought to be fatal in dogs. Other toxic effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Some species such as horses, cats, swine, and cattle may demonstrate CNS excitability (hyperreflexia, tremors) and seizures at high doses or if given rapidly intravenously. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated. Animals should be closely observed as naloxone’s effects might diminish before sub-toxic levels of morphine are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression.

Pentobarbital has been suggested as a treatment for CNS excitement and seizures in cats. Extreme caution should be used as barbiturates and narcotics can have additive effects on respiratory depression.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving morphine and may be of significance in veterinary patients:

CNS DEPRESSANTS, OTHER (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.): May cause increased CNS or respiratory depression when used with morphine

DIURETICS: Opiates may decrease efficacy in CHF patients

MONAMINE OXIDASE (MAO) INHIBITORS (e.g., amitraz, possibly selegiline): Use MAOI’s with morphine with extreme caution as meperidine (a related opiate) is contraindicated in human patients receiving monamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.

MUSCLE RELAXANTS, SKELETAL: Morphine may enhance neuromuscular blockade

TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Morphine may exacerbate the effects of tricyclic antidepressants.
TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Morphine may exacerbate the effects of tricyclic antidepressants.

WARFARIN: Opiates may potentiate anticoagulant activity.

Laboratory Considerations
As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses
For additional doses/protocols for using morphine in combination with other drugs (e.g., ketamine, lidocaine, dexmedetomidine) for pain/sedation in dogs or cats, see the doses and their accompanying references in the dexmedetomidine, ketamine, and lidocaine monographs.

**DOGS:**
For analgesia (acute pain):
- a) For post-op pain: 0.25–2 mg/kg IM, SQ; or as a CRI at 0.05–0.2 mg/kg/hr. (Grubb 2007)
- b) As a CRI for acute pain: 0.05–0.2 mg/kg/hr. Morphine tends to produce increased sedation and side effects when used at a dosage of >0.1 mg/kg/h for more than 12 hours; therefore, the infusion rate must often be reduced by that time. (Hansen, B. 2008)
- c) 0.5–2.2 mg/kg SC, IM q 4–6h; 0.1–0.2 mg/kg IV q1–2h (Gaynor 2007)
- d) 0.2–0.5 mg/kg IM, SC or IV (slowly because of histamine release). Easily titrated to effect. Morphine is given every 4 hours to dogs or as required at author’s hospital. (Self 2008)
- e) As a CRI for pain: Give a loading dose of 0.3 mg/kg slowly over 2-3 minutes IV, then a CRI of 0.1–0.2 mg/kg/hour. (Grint 2008)

Epidural administration for pain control:
- a) 0.1 mg/kg preservative free morphine; duration of action 12–24 hours (Thomas 2000)
- b) Using regular morphine injection: 0.1 mg/kg once; using preservative-free morphine: epidural at 0.1–0.2 mg/kg q8h; spinal at 0.05 mg/kg q8h. (Hansen, B. 2007)
- c) Epidural: Morphine (use preservative-free if possible): 0.1 mg/kg in 0.3 mL/kg (max of 6 mL). Opioids provide analgesia without loss of hind limb function or muscle tone. Analgesia has a fairly long duration and can be maintained with an epidural catheter (although placement and maintenance of the catheter may be difficult). One advantage of epidural morphine is that the analgesia will migrate cranially and be effective up to about 18 hrs. (Matthews 2008)

As a preanesthetic:
- a) As a premedicant with acepromazine: acepromazine 0.05 mg/kg IM; morphine 0.5 mg/kg IM (Pablo 2003)
- b) In a healthy large breed dog acepromazine at 0.03 mg/kg IM, with morphine at 0.5 mg/kg IM (onset of action 40 minutes after dose); can induce heavy sedation. Giving the acepromazine 20 minutes before morphine (or hydromorphone) can significantly reduce vomiting.

Severe sedation and sedation/analgesia sufficient for minor surgical procedures can be achieved by IM administration of an opioid. If using morphine: 0.02–0.05 mg/kg with medetomidine (20–40 micrograms/kg), and either ketamine (4.4 mg/kg) or Telazol® (4 mg/kg). (Trim 2008)
- c) In critical patients: 0.5–2 mg/kg IM. Use with diazepam, midazolam, or acepromazine. Caution with IV use due to histamine release. (Raffe 2008)

For adjunctive treatment of cardiogenic pulmonary edema:
- a) 0.05–1 mg/kg IV q1–4 hours, or 0.1–0.5 mg/kg hr IV infusion, or 0.2–2 mg/kg IM or SC q2–4hr (Hansen, B 2003)

For treatment of hypermotile diarrhea:
- a) 0.25 mg/kg (Jones 1985)

As an antitussive:
- a) 0.1 mg/kg q6–12h SC (Roudebush 1985)

**CATS:**
For analgesia:
- a) For post-op pain: 0.1–0.3 mg/kg IM, SC (Grubb 2007)
- b) 0.1–0.2 mg/kg IM, SC or IV (slowly because of histamine release). Easily titrated to effect. Morphine is given every 4 hours to cats or as required at author’s hospital. (Self 2008)
- c) 0.1–0.4 mg/kg IM, SC q3–6h; concomitant tranquillization recommended (Hendrix & Hansen 2000)
- d) 0.02–0.1 mg/kg IV q1–4hrs; 0.2–0.5 mg/kg IM, SC q3–4h; 0.2–0.5 mg/kg PO q6–8h. (Hansen, B 2007)

Epidural administration for pain control:
- a) Using preservative-free morphine: epidural at 0.1–0.2 mg/kg q8h; spinal at 0.05 mg/kg q8h. (Hansen, B 2007)

As a preanesthetic:
- a) In critical patients: 0.5–2 mg/kg IM. Use with diazepam or midazolam in cats. Caution with IV use due to histamine release. (Raffe 2008)

For adjunctive treatment of cardiogenic pulmonary edema:
- a) 0.02–0.1 mg/kg IV q1–4 hours, or 0.2–0.5 mg/kg IM or SC q3–4hr (Hansen, B 2003)

**RABBITS, RODENTS, SMALL MAMMALS:**
- a) Rabbits: 2–5 mg/kg IM or SC q2–4h for sedation and analgesia (Ivey & Morrisey 2000)

**HORSES:** (Note: ARCI UCGFS Class 1 Drug)
Note: Narcotics may cause CNS excitement in the horse. Some clinicians recommend pretreatment with acepromazine, detomidine, or xylazine to reduce the behavioral changes these drugs can cause. **Warning:** Narcotic analgesics can mask the behavioral and cardiovascular clinical signs associated with mild colic.

For analgesia:
- a) 0.1 mg/kg IM q4h; this dose reduces morphine’s impact on GI motility, but patients must be observed for problems following morphine use. To cover the excitatory effects of morphine, small doses of acepromazine (0.011–0.022 mg/kg IM, or 5–10 mg/450 kg) are generally included with the morphine injection.
Excitatory effects of morphine, small doses of acepromazine (0.011–0.022 mg/kg IM, or 5–10 mg/450 kg) are generally included with the morphine injection. (Abrahamsen 2007)

For epidural: Adult horses: 0.1–0.2 mg/kg using conventional morphine injection (15 mg/mL). Use a freshly opened vial. Suggest diluting with saline to a total volume of 0.04 mL/kg or 20 mL/450 kg. (Abrahamsen 2007)

Foals: Using preservative free morphine at 0.1 mg/kg. If no preservative free morphine available, dilute to a volume of 0.2 mL/kg. (Abrahamsen 2007)

Morphine may be used IV (0.012–0.66 mg/kg) as an analgesic agent in combination with alpha2 agonists. When used IV as a sole analgesic agent, it may result in profound excitation. Anecdotally, IM morphine use is not associated with CNS excitation and this may represent an under-appreciated analgesic option. Epidural: Morphine may be administered epidurally on its own or in combination with detomidine (0.03–0.06 mg/kg) to provide effective analgesia of the caudal half of the body. Morphine is typically used at doses of 0.1 to 0.2 mg/kg diluted to 10–20 mL with 0.9% saline (total volume of 0.04 mL/kg body weight). Analgesic effects are seen within 20-30 minutes and may last 8-24 hours without adverse effects on motor function. (Sellon 2007)

**SWINE:**
As a preanesthetic/analgesic (prior to chloralose, barbiturate):

a) 0.2–0.9 mg/kg IM. **Note:** may cause undesirable stimulation. (Booth 1988)

As an analgesic:

a) 0.2 mg/kg up to 20 mg total dose IM (Jenkins 1987)

**SHEEP & GOATS:**
As an analgesic:

a) Up to 10 mg total dose, IM (Jenkins 1987)

**CAMELIDS:**

a) Epidural: 0.1–0.3 mg/kg of preservative-free morphine diluted to 12 mL. (Cebra 2009)

**ZOO, EXOTIC, WILDLIFE SPECIES:**
For use of morphine in zoo, exotic and wildlife medicine refer to specific references, including:

c) Restraint and Handling of Wild and Domestic Animals. Fowler, M (ed.), Iowa State University Press, 1995

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

**Monitoring**

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity

**Client Information**

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

**Chemistry/Synonyms**
The sulfate salt of a natural (derived from opium) occurring opiate analgesic, morphine sulfate occurs as white, odorless, crystals. Solubility: 1 gram in 16 mL of water (62.5 mg/mL), 570 mL (1.75 mg/mL) of alcohol. It is insoluble in chloroform or ether. The pH of morphine sulfate injection ranges from 2.5–6.

Morphine sulfate may also be known as morphini sulfas, Astramorph PF®, Avinza®, DepoDur®, Infumorph®, Kadian®, MSIR®, MS Contin®, Oramorph SR, RMS®, and Roxanol®.

**Storage/Stability**
Oral morphine products should be stored at in tight, light-resistant containers at room temperature unless otherwise labeled. Morphine injection should be stored at room temperature, protected from light; do not freeze. Morphine gradually darkens in color when exposed to light; protect from prolonged exposure to bright light. Morphine does not appear to adsorb to plastic or PVC syringes, tubing or bags.

**Compatibility/Compounding Considerations**
Morphine sulfate has been shown to be physically compatible at a concentration of 16.2 mg/L with the following intravenous fluids: Dextrose 2.5%, 5%, 10% in water; Ringer’s injection and Lactated Ringer’s injection; Sodium Chloride 0.45% and 0.9% for injection. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

The following drugs have been shown to be physically incompatible when mixed with morphine sulfate: aminophylline, chlorothiazide sodium, heparin sodium, meperidine, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, sodium bicarbonate, and thiopental sodium. Morphine sulfate has been demonstrated to be generally physically compatible when mixed with the following agents: Atropine sulfate, benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, diphenhydramine HCl, dobutamine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, metoclopramide, pentazocine lactate, promazine HCl, scopolamine HBr, and succinylcholine chloride.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.
**HUMAN-LABELED PRODUCTS:**

Morphine Sulfate for Injection: 1 mg/mL, 2 mg/mL, 4 mg/mL, 5 mg/mL, 8 mg/mL, 10 mg/mL, 15 mg/mL, 25 mg/mL, 50 mg/mL in amps, vials, syringes, and prefilled IV bags in sizes that range from 1 mL to 250 mL depending on manufacturer and concentration. (Rx; C-II)

Morphine Sulfate Liposomal Extended-release Injection: 10 mg/mL in 1 mL, 1.5 mL, & 2 mL single-use vials; DepoDur® (Endo); (Rx, C-II)

Morphine Sulfate for Injection (preservative-free): 0.5 mg/mL; 2 mL amps, & 10 mL amps and vials; 1 mg/mL: 10 mL amps and vials; 10 mg/mL (200 mg) in 20 mL amps; 25 mg/mL (500 mg) in 20 mL amps; Infumorph® (Baxter); Astramorph PF® (AstraZeneca); (Rx, C-II)

Morphine Sulfate Soluble Tablets for Injection: 10 mg, 15 mg & 30 mg; generic; (Ranbaxy); (Rx, C-II)

Morphine Sulfate Oral Tablets: 15 mg & 30 mg; generic; (Rx, C-II)

Morphine Sulfate Extended/Controlled Release Tablets: 15 mg, 30 mg, 60 mg, 100 mg & 200 mg; MS Contin® (Purdue Frederick); Oramorph SR® (aaiPharma); generic; (Rx, C-II)

Morphine Sulfate Extended/Release Capsules: 20 mg, 30 mg, 45 mg, 50 mg, 60 mg, 75 mg, 80 mg, 90 mg, 100 mg, 120 mg & 200 mg; Avinza® (King Pharmaceuticals); Kadian® (Actavis); (Rx, C-II)

Morphine Sulfate Oral Solution: 2 mg/mL in 100 mL, 500 mL and UD 5 mL & 10 mL; 4 mg/mL in 100mL, 120 mL & 500 mL; 20 mg/mL (concentrate) in 15 mL, 30 mL, 120 mL & 240 mL/calibrated dropper or spoon; MSIR® (Purdue Frederick); Morphine Sulfate ( Roxane); Roxanol®, -T, & -100 (aaiPharma); generic; (Rx, C-II)

Morphine Sulfate Rectal Suppositories: 5 mg, 10 mg, 20 mg, & 30 mg; RMS® (Upsher-Smith); generic; (various); (Rx, C-II)

**Note:** All morphine products are Rx and a Class-II controlled substance. Very accurate record keeping is required as to use and disposition of stock.

**MOXIDECTIN**

(mox-i-dek-tin) Cydectin®, ProHeart®, Advantage® Multi

**AVERMECTIN ANTI-INFECTIVE**

**Prescriber Highlights**

- **Avermectin antiparasitic with products FDA-approved for cattle, dogs, cats, sheep, & horses**
- **Labeling and use of ProHeart® is presently dynamic; get most current info from label/manufacturer**
- **Contraindications (oral; topical): Dogs: Hypersensitive to drug; Cattle: Female dairy cattle of breeding age; Horses: Intended for food purposes or in foals younger than 4 months of age**
- **Adverse Effects (oral; topical): Dogs (potentially): Lethargy, vomiting, ataxia, anorexia, diarrhea, nervousness, weakness, increased thirst, & itching. Cattle: Adverse effects minimal. Horses: At labeled doses, appear minimal.**
- **Apparent safe to use in ABC1-1Δ (formerly MDR1-allele) gene mutation dog breeds at labeled doses; higher doses may cause neurotoxicity in these dogs**

**Uses/Indications**

In dogs and cats, moxidectin with lufenuron is indicated as a once a month topical preventative for the prevention of heartworm, flea, and tick control for hookworms, roundworms, and whipworms (dogs). It has also been successfully used as a treatment for generalized demodicosis.

In dogs, a 6 month injectable product (ProHeart®) is FDA-approved for use (in the USA) for use in dogs six months of age and older for the prevention of heartworm disease caused by Dirofilaria immitis and for the treatment of existing larval and adult hookworm (Ancylostoma caninum and Uncinaria stenocephala) infections. At the time of writing (2010), this product is currently available only through a restricted distribution program, this is likely to change in forthcoming months.

In cattle, moxidectin is indicated for the treatment and control of the following internal [adult and fourth stage larvae (L4)] and external parasites: Gastrointestinal parasites: Strongylus rufus, Cooperia oncophora, Cooperia punctata, Bunostomum phlebotomum, Oesophagostomum radiatum, Nematodirus helvetianus, Ancylostoma caninum, Bauchosoma bovis, Haemonchus placei, Ostertagia ostertagi (adult and L4), including inhibited larvae, and Haemonchus placei (adult), Trichostrongylus axei (adult and L4), Trichostrongylus colubritos (adult), Cooperia oncophora (adult), Cooperia punctata (adult), Haemonchus placei (adult), B. phlebotomum (adult), Oesophagostomum radiatum (adult), Nematodirus helvetianus (adult); Lungworm: Dictyocaulus viviparus (adult and L4); Cattle Gnubs: Hypoderma bovis, Hypoderma lineatum Mites: Chorioptes botritis, Psoroptes ovis.
ataxia, seizures, vomiting and hyperesthesia. Common findings in cats recorded included recumbency.

Dogs: The drug apparently has a very wide margin of safety in dogs when administered orally at the appropriate dosage. Dosages of up to 300X (1120 mg/kg) have been reported. Adverse reactions in dogs are rare and, when they occur, are generally minimal. The most commonly reported adverse reaction is transient diarrhea. Other adverse reactions have included vomiting, ataxia, lethargy, and inappetence. In horses, moxidectin may have a period of action of up to 12 weeks.

Cattle & Horses: Reproductive studies performed thus far have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring. Cattle: No adverse effects have been reported following the intramuscular administration of moxidectin to adult cattle at the labeled dosage. Horses: Thus far at labeled doses, adverse effects appear to be nonexistent or minimal. A case report where three foals developed CNS depression and coma after receiving high dosages has been reported. Two of these three animals were less than 2 weeks of age and all received much higher than labeled dosages.

Contraindications/Precautions/Warnings

Dogs: Contraindicated in dogs hypersensitive to it. The manufacturer warns to only use the oral product in dogs tested negative for heartworm infection. Adult heartworms and microfilaria should be removed prior to therapy. If more than two months pass between dosages of this or other once a month heartworm preventative medications, the dog should be tested for heartworm infection before receiving the next dose. Oral formulation doses (3 mg/kg/month) and topical formulation heartworm prevention doses (2500 micrograms/kg/month) are safe for all ABCB1 genotypes (Mealey 2008). For the 6-month injectable product (ProHeart®6; June 2010): Contraindicated in patients previously found hypersensitive to the drug, or are sick, debilitated, underweight or who have a history of weight loss. Use with caution in dogs with pre-existing allergic disease, including food allergy, atopy, and flea allergy dermatitis. Caution should be used when administering concurrently with vaccinations. Adverse reactions, including anaphylaxis, have been reported following the concomitant use of ProHeart®6 and vaccinations. Caution should be used when administering to heartworm positive dogs; prior to administration, dogs should be tested for existing heartworm infections. Safety and effectiveness has not been evaluated in dogs less than 6 months of age.

Cattle: Not for use in female dairy cattle of breeding age. Horses: Not for horses intended for food purposes and is not labeled for use in foals younger than 4 months of age. Animals with very low body fat (neonates, cachexia) could be more prone to develop adverse reactions.

Adverse Effects

Dogs: The topically applied product (w/imidacloprid) appears to be very well tolerated in dogs, regardless of their ABCB1 genotype. The injectable product (ProHeart®6) has been implicated in serious adverse effects in the past. In 2004, at the request FDA, the manufacturer instituted a voluntary recall of ProHeart®6, after reports of serious adverse events in dogs that included anaphylaxis, liver disease, autoimmune hemolytic disease, convulsions and death. After evaluation of additional data and changes in the manufacturing process, a risk minimization plan (RISKmap) was instituted by the manufacturer. In a 2010 review of the adverse effect data associated with the RISKmap, adverse effect rates were very low. Anaphylaxis/anaphylactoid reactions were the prevalent ADRs reported, but at a rate of 1.24 cases per 10,000 doses administered. The RISKmap plan is at present (summer 2010) still in effect, but may be altered in the future. Contact the manufacturer (Pfizer Animal Health) for more information.

When used orally at demodicosis doses (0.2–0.4 mg/kg PO once daily), vomiting, ataxia, lethargy, and inappetence can be seen. Cattle: Thus far at labeled doses, adverse effects appear to nonexistent or minimal. Horses: Thus far at labeled doses, adverse effects appear to be nonexistent or minimal. A case report where three foals developed CNS depression and coma after receiving high doses has been reported. Two of these three animals were less than 2 weeks of age and all received much higher than labeled dosages.

Reproductive/Nursing Safety

Dogs: Reproductive studies have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring. Cattle: Reproductive studies performed thus far have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring in cattle or horses treated.

Overdosage/Acute Toxicity

Dogs: The drug apparently has a very wide margin of safety in dogs when administered orally at the appropriate dosage. Dosages of up to 300X (1120 micrograms/kg) demonstrated little or no effects. In ABCB1 wild-type dogs, a single oral dose of 200 mg/kg did not cause neurologic toxicity. At 90 micrograms/kg, dogs with the ABCB1 (mutant/mutant) genotype have shown signs of neurologic toxicity. Dogs administered inadvertent overdoses during a clinical study treating demodicosis showed signs of dysorexia, hypersalivation, mydriasis, and fasciculations of the pelvic limbs.

There were 172 exposures to moxidectin reported to the ASPCA Animal Poison Control Center (APCC) during 2005–2006. In these cases, 171 were dogs with 42 showing clinical signs and the remaining case was 1 cat that showed clinical signs. Common findings in dogs recorded in decreasing frequency included tremors, ataxia, seizures, vomiting and hyperventilation. Common findings in cats recorded included hyperemesis.
Cattle: In studies done on cattle, application of the pour-on solution at 5X the recommended dose for five consecutive days, 10X for two consecutive days and 25X for one day did not produce any significant adverse clinical or pathological effects.

Horses: In one study, three of eight foals given the 3X dose became depressed or ataxic after one treatment. The author has received an anecdotal report of a miniature horse developing seizures after receiving a full tube of Quest®.

Intravenous fat emulsion has been used to treat toxicity associated with macrocyclic lactones and other highly lipid soluble drugs.

Drug Interactions

While no specific drug interactions for moxidectin have been reported, the following drug interactions have either been reported or are theoretical in humans or animals receiving ivermectin (a related compound) and may be of significance in veterinary patients:

- **BENZODIAZEPINES**: Effects may be potentiated by moxidectin; use together not advised in humans

Caution is advised if using other drugs that can inhibit p-glycoprotein. Those dogs at risk for ABCB1-1Δ (formerly MDR1-allele) mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”) should probably not receive moxidectin with the following drugs, unless tested “normal”. Drugs and drug classes involved include:

- AMIODARONE
- CARVEDILOL
- CLARITHROMYCIN
- CYCLOSPORINE
- DILTIAZEM
- ERYTHROMYCIN
- ITRACONAZOLE
- KETOCONAZOLE
- QUINIDINE
- SPIRONOLACTONE
- TAMOXIFEN
- VERAPAMIL

Doses

**DOGS:**

a) For labeled indications (prevention of heartworm disease, adult fleas, adult and immature hookworms, adult roundworms, and adult whipworms) for Advantage Multi®: Recommended minimum dose is 10 mg/kg imidacloprid with 2.5 mg/kg moxidectin once a month by topical administration (Note: See package insert for specific instructions on application and safety). For dogs 3–9 lb = 0.4 mL; 9.1–20 lb = 1 mL; 20.1–55 lb = 2.5 mL, 55.1–88 lb = 4 mL; dogs over 88 lb should be treated with appropriate combination for their weight. (Label directions; Advantage Multi® for Dogs—Bayer)

b) For labeled indications (heartworm prevention, hookworms) Note: Current as of June 2010; see actual package insert for most up-to-date information): Owners should be given the Client Information Sheet for ProHeart®6 to read before the drug is administered and should be advised to observe their dogs for potential drug toxicity described in the sheet.

The recommended subcutaneous dose is 0.05 mL of the constituted suspension/kg body weight. This provides 0.17 mg moxidectin/kg bodyweight. To ensure accurate dosing, calculate each dose based on the dog’s weight at the time of treatment. Do not overdose growing puppies in anticipation of their expected adult weight. A dosage chart is found in the package insert that may be used as a guide. Injection Technique: The two-part sustained release product must be mixed at least 30 minutes prior to the intended time of use. Once constituted, swirl the bottle gently before every use to uniformly resuspend the microspheres. Withdraw 0.05 mL of suspension/kg body weight into an appropriately sized syringe fitted with an 18G or 20G hypodermic needle. Dose promptly after drawing into dosing syringe. If administration is delayed, gently roll the dosing syringe prior to injection to maintain a uniform suspension and accurate dosing. Using aseptic technique, inject the product subcutaneously in the left or right side of the dorsum of the neck cranial to the scapula. No more than 3 mL should be administered in a single site. The location(s) of each injection (left or right side) should be noted so that prior injection sites can be identified and the next injection can be administered on the opposite side. Frequency of Treatment: ProHeart® 6 prevents infection by *D. immitis* for six months. It should be administered within one month of the dog’s first exposure to mosquitoes. Follow-up treatments may be given every six months if the dog has continued exposure to mosquitoes and continues to be healthy without weight loss. When replacing another heartworm preventive product, ProHeart® 6 should be given within one month of the last dose of the former medication. (Label Information; ProHeart®6—Pfizer)

c) For scabicideal therapy: Where Cydectin® is available for injection: 0.25 mg/kg SC every 7 days for three treatments. If using oral therapy 0.4 mg/kg PO every 3–4 days for 3–6 weeks. (Foil 2003) Note: These doses may cause toxicity in ABCB1 mutant genotype dogs.

d) For generalized demodicosis: 0.2–0.4 mg/kg PO once a day. Clinical cure averages 75 days; parasitic cure averages 112 days. (Carlotti 2008; Merchant 2000) Note: These doses may cause toxicity in ABCB1 mutant genotype dogs.

**CATS:**

a) For labeled indications (prevention of heartworm disease, adult fleas, ear mites, adult and immature hookworms, and adult roundworms: Recommended minimum dose is 10 mg/kg imidacloprid/1 mg/kg moxidectin once a month by topical administration (Note: See package insert for specific instructions on application and safety). For cats 2.5–5 lb = 0.23 mL; 5.1–9 lb = 0.4 mL; 9.1–18 lb = 0.8 mL; cats over 18 lb should be treated with appropriate combination for their weight. (Label directions; Advantage Multi® for Cats—Bayer)

b) For feline Aelurostrongylosis (*Aelurostrongylus abstrusus*): One to three topical applications of 1 mg/kg moxidectin (in combination with imidacloprid) appeared to be effective in the treatment of eight cats infected with *A. abstrusus*. (Conboy 2009)

**CATTLE:**

a) For labeled indications: 1 mL (5 mg)/10 kg (22 lb) bodyweight applied directly to the hair and skin along the top of the back from the withers to the base of the tail. Application should be made to healthy skin avoiding mange scabs, skin lesions or extraneous foreign matter. (Label Directions; Cydectin® Pour-On—Forty 1999; Bayer 2009)
Advantage Multi
Moxidectin 2.5% (25 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 6—0.4mL tubes, 6—1mL tubes, 6—2.5 mL tubes, & 6—4mL tubes;
advised for use in horse or ponies not intended for food purposes.

Oral Gel containing 20 mg/mL moxidectin and 125 mg/mL of praziquantel in 11.6 gram syringes (sufficient to treat one 1150 lb horse);
dairy cattle of breeding age, veal calves, and calves less than 8 weeks of age. Meat withdrawal = 21 days.

Moxidectin Oral Gel containing 20 mg/mL in 11.3 gram syringes (sufficient to treat one 1150 lb horse);

Moxidectin 0.5% (5 mg/mL) Pour-On for Cattle in 500 mL, 1 L, 2.5 L, 5 L, and 10 L containers;

weeks or older. See the package insert for the most up-to-date information for this product.

VETERINARY-LABELED PRODUCTS:

Moxidectin 1% (10 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 3—0.23mL tubes, 6—0.4mL tubes & 6—0.8mL tubes;

Moxidectin 10 mg/mL Injectable Solution in 200 mL and 500 mL;

Moxidectin 10% Sustained-Release (microspheres) Injectable 598 mg/vial with 17 mL diluent vial:

b) For mucosal stages of small strongyles: 400 micrograms/kg PO (Lyons & Drudge 2000)

CAMELIANS (NWC):

a) Oral treatment with ivermectin or moxidectin at 0.2 mg/kg is generally felt to be the regimen of choice for gastrointestinal helminthes. (Wolff 2009)

Chemistry/Synonyms

An avermectin-class antiparasitic agent, moxidectin is a semi-synthetic methoxime derivative of nemadectin.

Moxidectin may also be known as CL-301423, Advantage Multi®, ComboCare®, Cydectin®, and Quest®.

Storage/ Stability

For the sustained-release injection (ProHeart®6), store the unconstituted product at or below 25°C (77°F). Do not expose to light for extended periods of time. After

constitution, the product is stable for 4 weeks stored under refrigeration at 2-8°C (36°-46°F).

The commerciall available injection and the oral drench for sheep should be stored at, or below 77°F (25°C) and protected from light.

The topical solution for cattle should be stored at or below room temperature. Do not allow prolonged exposure to temperatures above 77°F. If product becomes

frozen, thaw completely and shake well before using.

The oral gel for horses should be stored at or near room temperature (59°F–86°F); avoid freezing. If product becomes frozen, thaw completely before using.

Partially used syringes should have the cap tightly secured.

Compatibility/Compounding Considerations

When constituting the sustained-release injectable product (ProHeart®6) the provided diluent must be used and there are very specific direction for proper preparation. Refer to the package insert for more information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Moxidectin 10% Sustained-Release (microspheres) Injectable 598 mg/vial with 17 mL diluent vial: ProHeart®6 (Pfizer); (Rx). FDA-Approved for use in dogs 6 weeks or older. See the package insert for the most up-to-date information for this product.

Moxidectin 0.5% (5 mg/mL) Pour-On for Cattle in 500 mL, 1 L, 2.5 L, 5 L, and 10 L containers; Cydectin® (BIVI); (OTC). FDA-approved for use in cattle; not to be used in veal calves. No meat or milk withdrawal times required, but FDA has established tolerances of 50 ppb and 200 ppb for parent moxidectin in muscle and liver, respectively, for cattle.

Moxidectin 10 mg/mL Injectable Solution in 200 mL and 500 mL; Cydectin® Injectable Solution (BIVI); (OTC). FDA-approved for cattle. Not to be used in female dairy cattle of breeding age, veal calves, and calves less than 8 weeks of age. Meat withdrawal = 21 days.

Moxidectin 1 mg/mL Oral Drench Solution in 1 L and 4 L; Cydectin® Oral Drench for Sheep (BIVI); (OTC). FDA-approved for sheep. Not to be used in female sheep providing milk for human consumption. Meat withdrawal = 7 days.

Moxidectin Oral Gel containing 20 mg/mL in 11.3 gram syringes (sufficient to treat one 1150 lb horse); Quest® (Pfizer); (OTC). FDA-approved for use in horse or ponies not intended for food purposes.

Oral Gel containing 20 mg/mL moxidectin and 125 mg/mL of praziquantel in 11.6 gram syringes (sufficient to treat one 1150 lb horse); Quest Plus®(Pfizer). FDA-approved for use in horse or ponies not intended for food purposes.

Moxidectin 1% (10 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 3—0.23mL tubes, 6—0.4mL tubes & 6—0.8mL tubes; Advantage Multi® for Cats (Bayer); (Rx). FDA-approved for use on cats 9 weeks of age or greater, and more than 2 lb body weight.

Moxidectin 2.5% (25 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 6—0.4mL tubes, 6—1mL tubes, 6—2.5 mL tubes, & 6—4mL tubes; Advantage Multi® for Dogs (Bayer); (Rx). FDA-approved for use on dogs 7 weeks of age or greater, and more than 3 lb body weight.

HUMAN-LABELED PRODUCTS: None

References

Prescriber Highlights

- Biologic used in dogs as a locally infiltrated injection for immunotherapy treatment of mixed mammary tumor & mammary adenocarcinomas
- In horses, used for immunotherapy treatment of sarcoids (local infiltration), ERCD (IV) or as an aid in the treatment of equine metritis caused by *Streptococcus zooepidemicus* (IV, IU)
- Adverse effects include: Transient fever, depression, decreased appetite, localized pain. Hypersensitivity & systemic inflammatory reactions possible.
- Efficacy for systemic use is not well established

Uses/Indications

Although not labeled indications, *Equimune*-IV has reportedly been used in horses as an adjuvant for EPM treatment and as an adjuvant for herpesvirus vaccines when injected IM at a separate site from the vaccine. Documentation of efficacy for these uses was not located.

Pharmacology/Actions

Mycobacterial fractionated compounds require a functional immune system for efficacy. They have a non-specific immune stimulatory primarily on cell-mediated immune mechanisms and macrophage activation. Interleukin-1 release from macrophages is thought to be the primary mediator for their actions.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

These drugs should not be used in patients with prior hypersensitivity to mycobacterial cell wall compounds or those with mycobacterial infections.

The manufacturer warns that patients receiving cortisone or ACTH may not respond to treatment; in case of an anaphylactic reaction, administer epinephrine.

Adverse Effects

Horses: Adverse effects include fever, drowsiness and diminished appetite for 1–2 days after injection. Local infiltrations can cause pain and tenderness at injection site. Anaphylaxis and severe respiratory inflammatory reactions have also been reported.

Dogs: Adverse effects include fever, drowsiness and diminished appetite for 1–2 days after injection. Local infiltrations can cause pain and tenderness at injection site. Later necrosis and draining may occur. Anaphylaxis or hypersensitivity reactions are possible.

Reproductive/Nursing Safety

The manufacturer states that *Regressin*-V and *Equimune*-I.V. are safe to use in pregnant mares. No other information was located.

Overdosage/Acute Toxicity

No information was located.

Drug Interactions

■ *CORTICOSTEROIDS, ACTH, IMMUNOSUPPRESSIVE DRUGS* (e.g., cyclosporine): May reduce the effectiveness of mycobacterial cell wall immunostimulants

Laboratory Considerations

■ None identified

Doses

■ **DOGS:**

  a) Using *Regressin*-V for immunotherapy of mixed mammary tumor and mammary adenocarcinoma: Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dosage varies with tumor size, but 1 mL should be considered a minimum dose. Be certain the emulsion is mixed thoroughly and inject quickly as emulsion can separate rapidly (see Stability information for more information on mixing.) As pain may occur, additional anesthetics or analgesics may be used. Tumors may be treated once, 2–4 weeks before surgery. If surgery is not to be used, repeat treatment every 1–3 weeks. If no response after 4 treatments, discontinue. (Label information; *Regressin*-V—Bioniche)

■ **HORSES:**

  a) Using *Regressin*-V for immunotherapy of sarcoids: Large pedunculated sarcoids should be de-bulked by partial excision prior to treatment. Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dosage varies with tumor size, but 1 mL should be considered a minimum dose. Be certain the emulsion is mixed thoroughly and inject quickly as emulsion can separate rapidly (see Stability information for more information on mixing.) As pain may occur, additional anesthetics or analgesics may be used. Repeat treatment every 1–3 weeks. If no response after 4 treatments, discontinue. (Label information; *Regressin*-V—Bioniche)
b) Using *Equimune® I.V.* as an immunotherapeutic agent for the treatment of Equine Respiratory Disease Complex (ERDC): 1.5 mL (one syringe) IV into the jugular vein. May be repeated in 1–3 weeks. (Label information; *Equimune® I.V.*—Bioniche)

c) Using *Settle®* as an aid in the treatment of equine metritis caused by *Streptococcus zooepidemicus*: Intravenous use: 1.5 mL (one syringe) IV into the jugular vein during the early estrus period. Or administer via intrauterine instillation: Dilute 1.5 mL of *Settle®* in sterile LRS, normal saline, water for injection or semen extender to provide a final volume of 25–50 mL. Aseptically administer the diluted solution into the uterus using a sterile catheter. (Label information; *Settle®*—Bioniche)

**Monitoring**

- Clinical Efficacy (tumor size, metritis improvement, or respiratory infection improvement)
- Adverse Effects (fever, local reactions, appetite)

**Client Information**

- Intratumoral injection may cause pain or tenderness at the injection site. Tumors may drain or become necrotic indicating effectiveness; if this occurs and is bothersome, contact veterinarian for further instructions on management.
- Treated animals may be depressed, develop fever, or have reduced appetite for a few days after treatment; if these persist or are severe, contact veterinarian

**Chemistry/Synonyms**

*Regressin®-V, Equimune® I.V.* and *Settle®* are oil-in-water emulsions containing purified cell wall fractions obtained from Mycobacteria (species not described) that are non-pathogenic. Concentration is not listed for either product. *Regressin®-V* also contains procaine HCl 0.2% w/v as a local anesthetic and a green tracking dye solution (not identified) 0.1% w/v used to indicate area infiltrated.

Mycobacterial cell wall fraction may also be known as mycobacterial cell wall extract, bacillus Calmette-Guerin, or BCG, *Equimune®, Regressin®, and Settle®*.

**Storage/Stability**

These products should be stored refrigerated (2–7°C), but not frozen. Unused product from vials not labeled for multi-dose use should be discarded after use.

The emulsion “breaks” upon standing and the product must be re-emulsified before administration. To re-emulsify to a milky appearance, shake vial, roll syringe between hands, or heat in hot water (150°F, 65°C).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Mycobacterial Cell Wall Fraction Immunomodulator for IV Injection in 1.5 mL single use vials and 4.5 mL multi-dose vials; *Equimune® I.V.* (Bioniche). Labeled for use in horses.

Mycobacterial Cell Wall Fraction Immunomodulator for IV injection of Intrauterine instillation in 1.5 mL single use vials; *Settle®* (Bioniche). Contains gentamicin as a preservative. Labeled for use in horses.

Mycobacterial Cell Wall Fraction Immunomodulator for Tumor Infiltration in 10 mL vials; *Regressin®-V* (Bioniche). Also contains procaine and a green dye. Labeled for use in horses and dogs.

**Note:** These products are USDA-licensed biologics and are not FDA-approved products. *Equimune® I.V.* and *Regressin®-V* are not to be used in food producing animals. The label for *Settle®* states that it should not be administered to horses within 21 days of slaughter.

**HUMAN-LABELED PRODUCTS:** None

---

**MYCOPHENOLATE MOFETIL**

*(my-koh-fen-oh-layt) Cellcept®, MMF*

**IMMUNOSUPPRESSANT**

**Prescriber Highlights**

- Immunosuppressive drug that may be useful for treating dogs with IMHA, glomerulonephritis, myasthenia gravis, pemphigus foliaceous or inflammatory bowel disease in dogs; potentially useful in cats, but little information available on safety or efficacy
- Very limited experience in veterinary medicine
- Gastrointestinal effects (diarrhea, vomiting, anorexia) most likely adverse effects & can be severe
- Treatment may be very expensive

**Uses/Indications**

While there has been very limited experience using mycophenolate in veterinary medicine, it potentially could be useful in the treatment of a variety of autoimmune diseases, including immune-mediated hemolytic anemia (IMHA), myasthenia gravis, glomerulonephritis, and pemphigus foliaceous. While mycophenolate has been suggested for use in treating inflammatory bowel disease in dogs, the drug’s primary adverse effects in dogs are gastritis, diarrhea, and intestinal inflammation. Mycophenolate is also used in anti-rejection protocols for organ transplants in animals.

In humans, although it is used “off label” for a variety of autoimmune disease indications, the drug is only labeled for use to prevent transplant rejection.

**Pharmacology/Actions**
Mycophenolate mofetil (MMF) is a prodrug that must be converted (hydrolyzed) *in vivo* to mycophenolic acid (MPA) for it to be pharmacologically active. MPA non-competitively, but reversibly, inhibits inosine monophosphate dehydrogenase (IMPDHA). This is the rate-limiting enzyme in *de novo* synthesis of guanosine nucleotides. As T- and B-cells are dependent on *de novo* synthesis of purines (*e.g.*, guanosine) and unlike other cells cannot use salvage pathways, proliferative responses of T- and B-cells are inhibited and suppression of B-cell formation of antibodies occur. Via its effects, MPA can inhibit leukocyte recruitment to inflammatory sites and allotransplant tissues.

### Pharmacokinetics

After oral administration mycophenolate mofetil is absorbed, but limited bioavailability studies in dogs have shown both a wide inter-patient and inter-dose variation. One study done in a single dog showed bioavailabilities of 54%, 65%, and 87% after doses of 10, 15, and 20 mg/kg of MMF were administered (Lupu *et al.* 2006). In humans, oral bioavailability averages 94%; food reduces peak levels of MPA by up to 40%. After absorption, MMF is rapidly hydrolyzed to mycophenolic acid.

In a study in dogs comparing mycophenolic acid’s (MPA) pharmacokinetic parameters with its pharmacodynamic effects on inosine monophosphate dehydrogenase activity in lymphocytes (Langman *et al.* 1996), volume of distribution at steady-state was approximately 5 L/kg, but there was wide inter-patient variability (±4.5). Elimination half-life for MPA was about 8 hours (±4 hours). Mycophenolic acid is primarily excreted in the urine, both unchanged (approximately 5%) and as the glucuronide metabolite (approximately 90%). In this study, the authors concluded that the pharmacokinetic/pharmacodynamic profile of MMF in dogs suggests that an every 8-hour dosing schedule would be required for optimization of immunosuppressive efficacy.

### Contraindications/Precautions/Warnings

Do not use in patients with documented hypersensitivity reactions to mycophenolate. Patients with severe renal dysfunction may require dosage adjustment.

- In humans, the active metabolite, MPA is primarily excreted as the MPA-glucuronide metabolite. As cats are deficient in this metabolic process, it should be used with caution in this species.
- For humans, mycophenolate has a “black box” warning regarding potential increased risk for lymphoma associated with its use.

### Adverse Effects

Because of the limited numbers of veterinary patients who have received this drug, the adverse effect profile is not well established. The primary adverse effects reported in dogs thus far include diarrhea, vomiting, anorexia, lethargy/reduced activity, lymphopenia, and increased rates of dermal infections. Because of the drug’s immunosuppressive actions, increased systemic infection and malignancy rates are possible.

A study (Chanda *et al.* 2002) comparing adverse effects in dogs with mycophenolate mofetil capsules and mycophenolate sodium enteric-coated tablets demonstrated significantly greater occurrences and severity of diarrhea, weight loss and hypo-activity in the dogs that received the sodium salt enteric-coated tablets.

In humans, the most common adverse effects include GI effects (constipation, diarrhea, nausea, vomiting) and headache. Hypertension and peripheral edema occur in about 30% of patients. Leukopenia has been reported in 25–45% of patients taking the medication. Other effects that occur more rarely include: GI bleeding, severe neutropenia, cough, confusion, tremor, infection and malignant lymphoma (0.4–1%).

### Reproductive/Nursing Safety

At doses significantly lower than those used in humans, increased resorptions and malformations were noted in rabbits and rats; it is recommended that the drug be avoided, if at all possible, during pregnancy.

Mycophenolic acid is distributed in rat milk. It is unknown if it is safe to use during nursing.

### Overdosage/Acute Toxicity

In oral acute studies performed in mice and monkeys, no deaths occurred in dosages up to 4,000 mg/kg and 1,000 mg/kg, respectively. In small animals, acute GI disturbances could be expected. Treat supportively, if required.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mycophenolate mofetil and may be of significance in veterinary patients:

- **ACYCLOVIR:** Increased serum concentrations of acyclovir and the phenolic glucuronide of mycophenolic acid
- **ANTACIDS (aluminum or magnesium containing):** Decreased absorption of mycophenolate; separate dosing by at least 2 hours
- **ASPIRIN (or other salicylates):** Potentially increased concentrations of free mycophenolic acid
- **AZATHIOPRINE:** Increased risk for bone marrow suppression; use together not recommended in humans
- **IRON (oral):** Decreased absorption of mycophenolate; separate dosing by at least 2 hours
- **PROBENECID:** Potentially increased serum levels of mycophenolic acid and the phenolic glucuronide of mycophenolic acid
- **VACCINES (live virus):** May be less effective; avoid use

### Laboratory Considerations

- No issues noted

### Doses

**DOGS:**

For immune-mediated hemolytic anemia:

a) 12–17 mg/kg PO once daily or divided twice daily. Given with prednisolone (at 2 mg/kg q12–24h). Dogs also received ranitidine and sucralfate in the study. (Nielsen *et al.* 2005)

b) Limited use has shown a beneficial response in dogs with IMHA, myasthenia gravis or glomerulonephritis: 12–17 mg/kg PO once daily or divided twice daily. Given with prednisone (at 2.2 mg/kg q12–24h). (Macintire 2006)

c) Dose is unknown, and extrapolated from human medicine, with reports of starting dosages of 400–600 mg/m² orally twice daily. Gastrointestinal side effects are common and dose limiting. (Noonan 2009)
d) For adjunctive treatment of glomerulonephritis: 10–20 mg/kg PO q12h. Immunosuppressive treatment is controversial. Other immunosuppressive drugs suggested include: glucocorticoids, cyclophosphamide, azathioprine, and cyclosporine. Trial of single drug therapy for 3–4 weeks recommended. (Labato 2006)

For pemphigus foliaceus:

a) For pemphigus foliaceus: 22–39 mg/kg/day divided into 3 daily doses. Success rates (limited use) of approximately 50%; most dogs require glucocorticoids to control signs. (Rosenkranz 2004)
b) For pemphigus foliaceus: 20–40 mg/kg/day PO divided q8h; steroid-sparing only. (Scott 2008)

Miscellaneous indications:

a) For adjunctive treatment of glomerulonephritis: 10–20 mg/kg PO q12h. Immunosuppressive treatment is controversial. Other immunosuppressive drugs suggested include: glucocorticoids, cyclophosphamide, azathioprine, and cyclosporine. Trial of single drug therapy for 3–4 weeks recommended. (Labato 2006)
b) From a case report for treating aplastic anemia: 10 mg/kg PO q12h. The first effects (improvements in hematocrit) were observed 2 weeks later, and complete remission of all blood cell counts were obtained in approximately 3 weeks. (Yuki et al. 2007)
c) From a case report in 3 dogs as a rescue agent for generalized myasthenia gravis: Initially, dogs received 500 mg (15-20 mg/kg) diluted and given IV over 2–4 hours. Dogs were given daily IV treatments for 1–3 days until they could adequately swallow oral meds. They were then switched to oral mycophenolate at doses between 10–11 mg/kg PO q12h. Subsequently, doses were adjusted based upon clinical response and AChR titers. (Abelson et al. 2009)

**CATS:**

a) For IMHA: 10 mg/kg PO q12h. (Macintire 2009)

**Monitoring**

- **Efficacy**
- **CBC, renal and hepatic function, serum electrolytes; baseline and periodically (frequency depending on reason for treatment)**
- **Gastrointestinal effects (weight, client’s report)**

**Client Information**

- Preferably give on an empty stomach; if vomiting or lack of appetite occurs, give with food to see if it improves.
- Because of concerns that this drug can cause birth defects, the manufacturer recommends that tablets or capsules not be crushed, split, or opened.
- If diarrhea persists or is severe, contact veterinarian

**Chemistry/Synonyms**

Mycophenolate mofetil occurs as a white or almost white, crystalline powder. It is practically insoluble in water and sparingly soluble in alcohol.

Mycophenolate mofetil may also be known as: RS-61443 or MMF. International trade names include: CellCept®, Cellmune®, Imuxgent®, Munotras®, Mycept®, Myfortic®, and Refrat®.

**Storage/Compatibility**

Mycophenolate mofetil tablets and capsules should be stored between 15–30°C and protected from light.

Mycophenolate mofetil powder for oral suspension should be stored between 15–30°C; preferably at 25°C. Once reconstituted with 94 mL of water it may be stored at room temperature or in the refrigerator; do not freeze. Unused drug should be discarded after 60 days.

The injectable product should be stored between 15–30°C; preferably at 25°C. Each vial should be reconstituted with 14 mL of 5% dextrose injection; final volume is approximately 15 mL. Gently agitate to dissolve the powder. For human use, the manufacturer recommends further diluting with dextrose 5% to a concentration of 6 mg/mL for IV administration. This would be an additional 70 mL of dextrose 5% per vial. Mycophenolate injection should not be mixed or given with any other medication or diluent.

The drug is also recommended to administer within 6 hours of dilution. The drug must be administered over at least two hours and is not to be given as an IV bolus or via rapid IV infusion.

**Compatibility/Compounding Considerations**

Mycophenolate injection should not be mixed or given with any other medication or diluent.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Mycophenolate Mofetil Oral Capsules: 250 mg; CellCept® (Roche); generic (Rx)
- Mycophenolate Mofet Oral Tablets: 500 mg; CellCept® (Roche); (Rx)
- Mycophenolate Mofet Powder for Oral Suspension: 200 mg/mL (reconstituted) in 225 mL bottles; CellCept® (Roche); (Rx)
- Mycophenolate Mofet Lyophilized Powder for Injection: 500 mg in 20 mL vials; CellCept® (Roche); (Rx)

Mycophenolate Mofetil is also available as the sodium salt in oral, delayed-release tablets in 180 mg and 360 mg strengths. Trade name is Myfortic® (Novartis); (Rx). It does not appear that this dosage form will be useful for veterinary patients.

**References**

Uses/Indications
Naloxone is used in veterinary medicine almost exclusively for its opiate reversal effects, but the drug is being investigated for treating other conditions (e.g., septic, hypovolemic or cardiogenic shock). Naloxone may also be employed as a test drug to see if endogenous opiate blockade will result in diminished tail chasing or other self-mutilating behaviors. It, potentially, could be useful for treating overdoses of clonidine or the CNS effects of benzodiazepines (ivermectin?), but more research is necessary before recommending its use.

Pharmacology/Actions
Naloxone is considered a pure opiate antagonist and it has no analgesic activity. The exact mechanism for its activity is not understood, but it is believed that the drug acts as a competitive antagonist by binding to the mu, kappa, and sigma opioid receptor sites. The drug apparently has its highest affinity for the mu receptor.

Naloxone reverses the majority of effects associated with high-dose opiate administration (respiratory and CNS depression). In dogs, naloxone apparently does not reverse the emetic actions of apomorphine.

Naloxone may be useful in treating adverse effects associated with overdoses of propoxyphene, pentazocine, buprenorphine and loperamide, but larger naloxone doses may be required.

Naloxone has other pharmacologic activity at high doses, including effects on dopaminergic mechanisms (increases dopamine levels) and GABA antagonism.

Pharmacokinetics
Naloxone is only minimally absorbed when given orally as it is rapidly destroyed in the GI tract. Much higher doses are required if using this route of administration for any pharmacologic effect. When given IV, naloxone has a very rapid onset of action (usually 1–2 minutes). If given IM, the drug generally has an onset of action within 5 minutes of administration. The duration of action usually persists from 45–90 minutes, but may act for up to 3 hours.

Naloxone is distributed rapidly throughout the body with high levels found in the brain, kidneys, spleen, skeletal muscle, lung, and heart. The drug also readily crosses the placenta.

Naloxone is metabolized in the liver, principally via glucuronidative conjugation, with metabolites excreted into the urine. In humans, the serum half-life is approximately 60–100 minutes.

Contraindications/Precautions/Warnings
Naloxone is contraindicated in patients hypersensitive to it. It should be used cautiously in animals that have preexisting cardiac abnormalities or that may be opioid dependent. The veterinary manufacturer of the product once marketed for veterinary use states to use the drug “… cautiously in animals who have received exceedingly large doses of narcotics … it may produce an acute withdrawal syndrome and smaller doses should be employed.” (Package Insert; P/M® Naloxone HCl Injection—Mallinckrodt)

In humans, naloxone is reportedly not effective for reversing meperidine-induced seizures. Benzodiazepines and/or barbiturates may be necessary.

In a case of a dog that received an overdose (10X) of meperidine, naloxone administration elicited CNS excitement. The authors recommend that naloxone (and butorphanol) should be avoided when normeperidine (active metabolite of meperidine) excitotoxicty is suspected, unless severe respiratory depression is present without a method of ventilatory support (Golder et al. 2010).

Naloxone has not been shown to be an effective therapy to reverse apnea of newborns and its routine use is not recommended. However, if the dam received opiates during parturition, it may reverse opiate-induced respiratory depression. Naloxone is not a good reversal agent for buprenorphine. Doses of 100X-usual have been required to reverse effects in a normal dog.

Adverse Effects
At usual doses, naloxone is relatively free of adverse effects in non-opioid dependent patients; however, when using to reverse opiates’ effects, it can also reverse any analgesic activity of the opiate.

Because the duration of action of naloxone may be shorter than that of the narcotic being reversed, animals that are being treated for opioid intoxication or with clinical signs of respiratory depression should be closely monitored as additional doses of naloxone and/or ventilatory support may be required.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

It is not known whether the drug is excreted in maternal milk. Use caution when administering to nursing patients.

Overdosage/Acute Toxicity
Naloxone is considered a very safe agent with a very wide margin of safety, but very high doses have initiated seizures (secondary to GABA antagonism?) in a few patients.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving naloxone and may be of significance in veterinary patients:

**OPSIOD PARTIAL-AGONISTS (e.g., butorphanol, pentazocine, or nalbuphine):** Naloxone may also antagonize the effects these agents (respiratory depression, analgesia). It should not be relied upon to treat respiratory depression caused by buprenorphine.

**CLONIDINE:** Naloxone may reduce the hypotensive and bradycardic effects of clonidine; potentially useful for clonidine overdoses

**YOHIMBINE:** Naloxone may increase the CNS effects of yohimbine (anxiety, tremors, nausea, palpitations) and increase plasma cortisol levels

Doses

**DOGS/CATS:**
- For opioid reversal:
  a) 0.01–0.02 mg/kg IM, IV, or SC. (Trim 2008)
  b) Dogs: 0.04 mg/kg IV, IM or SC (Package Insert; P/M® Naloxone HCl Injection—Mallinckrodt), (Kirk 1989)
  c) For dysphoria associated with post-surgical opioids: If the patient is clearly dysphoric or returns to a whining state shortly after additional opioid administration, or if suspicion exists related to the use of high doses of opioid during surgery, a slow titration of naloxone can be given to effect (4 micrograms/kg diluted to 10 mL and given in 1-mL increments every minute). (Dyson 2008)
  d) Following caesarian sections when puppies or kittens are sedated or have respiratory depression from the expected placental transfer of the opioid: 1 drop of naloxone (0.4 mg/mL from a 1-mL syringe) can be administered under the tongue, and repeat doses can be sent home with the owner if longer acting opioids are involved. (Dyson 2008)

  For adjunctive treatment of pulseless electrical activity (PEA) in CPR:
  a) 0.02–0.04 mg/kg IV may be effective in augmenting cardiac output by blocking endogenous endorphins or exogenous narcotics. (Scroggin & Quandt 2009)

  For adjunctive treatment of hyperthermia in cats:
  a) Authors have treated cats with body temperatures exceeding 41.1°C (106° F) following anesthesia with naloxone at 0.01 mg/kg IM or SC and have seen body temperature return to normal range in <30 minutes. (Posner et al. 2010)

**RABBITS, RODENTS, SMALL MAMMALS:**
- For opioid reversal in rodents: 0.01–0.1 mg/kg SC or IP as needed (Huerkamp 1995)
- Rabbits: 0.005–0.1 mg/kg IM or IV (Ivey & Morrisey 2000)
- Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: 0.01–0.1 mg/kg SC, IP (Adamcak & Otten 2000)

**HORSES:** (Note: ARCI UCGFS Class 3 Drug)
- For opioid reversal:
  a) 0.01–0.022 mg/kg to reverse sedative and excitatory effects of narcotic agonists (Clark & Becht 1987)
  b) 0.01 mg/kg IV to limit increases in locomotor activity secondary to narcotic agonists (Muir 1987)
  c) For treatment of opioid gastrointestinal tract dysfunction: 10–50 micrograms/kg (route not specified, assume IV—Plumb) will induce movement and passage of contents. (Boscan 2009)

Monitoring
- Respiratory rate/depth
- CNS function
- Pain associated with opiate reversal

Client Information
- Should be used with direct professional supervision only

Chemistry/Synonyms
An opiate antagonist, naloxone HCl is structurally related to oxymorphone. It occurs as a white to slightly off-white powder with a pKₐ of 7.94. Naloxone is soluble in water and slightly soluble in alcohol. The pH ranges of commercially available injectable solutions are from 3–4.5.

Naloxone HCl may also be known as: N-allylnoroxymorphone, naloxona, EN-15304, naloxoni and by the trade name, Narcan®.

Storage/Stability
Naloxone HCl for injection should be stored at room temperature (15–30°C) and protected from light.

Sterile water for injection is the recommended diluent for naloxone injection. When given as an IV infusion, either D₅W or normal saline should be used.

Compatibility/Compounding Considerations
Naloxone HCl injection should not be mixed with solutions containing sulfites, bisulfites, long-chain or high molecular weight anions or any solutions at alkaline pH.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.
Naltrexone is an orally available narcotic antagonist. It competitively binds to opiate receptors in the CNS, thereby preventing both endogenous opiates (e.g., endorphins) and exogenously administered opiate agonists or agonist/antagonists from occupying the site. Naltrexone may be more effective in blocking the euphoric aspects of the opiates and less effective at blocking the respiratory depressive or miotic effects.

Naltrexone may also increase plasma concentrations of luteinizing hormone (LH), cortisol, and ACTH. In dogs with experimentally-induced hypovolemic shock, naltrexone (like naloxone) given IV in high dosages increased mean arterial pressure, cardiac output, stroke volume, and left ventricular contractility.

Contraindications/Precautions/Warnings
