Naltrexone is contraindicated in patients physically dependent on opiate drugs, in hepatic failure, or with acute hepatitis. The benefits of the drug versus its risks should be weighed in patients with hepatic dysfunction or with a history of allergic reaction to naltrexone or naloxone.

Adverse Effects
At usual doses, naltrexone is relatively free of adverse effects in non-opioid dependent patients. Some human patients have developed abdominal cramping, nausea and vomiting, nervousness, insomnia, joint or muscle pain, skin rashes, & pruritus. Dose-dependent hepatotoxicity is possible.

Uses/Indications
Naltrexone might be useful in determining if adverse behaviors (e.g., self-mutilating or tail-chasing) in dogs or cats have a significant endorphin component. Its relative expense and other more accepted treatments have largely supplanted the use of this drug in animals for treatment of behavioral disorders.

References

Overdosage/Acute Toxicity
Naltrexone appears to be relatively safe even after very large doses. The LD_{50} in dogs after subcutaneous injection has been reported to be 200 mg/kg. Oral LD_{50}'s in species tested range from 1.1 grams/kg in mice to 3 grams/kg in monkeys (dogs or cats not tested). Deaths at these doses were a result of respiratory depression and/or tonic-clonic seizures. Massive overdoses should be treated using gut-emptying protocols when warranted and giving supportive treatment.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving naltrexone and may be of significance in veterinary patients:

**OPioid Partial-Agonists** *(e.g., butorphanol, pentazocine, or nalbuphine)*: Naloxone may also antagonize the effects these agents (respiratory depression, analgesia).

**Clonidine**: Naltrexone may reduce the hypotensive and bradycardic effects of clonidine

**Yohimbine**: Naltrexone may increase the CNS effects of yohimbine (anxiety, tremors, nausea, palpitations) and increase plasma cortisol levels

Laboratory Considerations
- Naltrexone reportedly does not interfere with TLC, GLC, or HPLC methods of determining *urinary opiates*, or quinine, but can interfere with some enzymatic assays
- Naltrexone may cause increases in *hepatic function tests* *(e.g., AST, ALT)* (see Adverse Effects above).

Doses
**DOGS**
- As adjunctive therapy in behavior disorders:
  - a) For tail chasing or excessive licking: First give 0.01 mg/kg SC of naloxone to determine if narcotic antagonists may be effective, if so give naltrexone PO at 1–2 mg/kg daily. Long-term therapy may be required. (Crowill-Davis 1992)
  - b) 2–5 mg/kg, PO once daily (Line 2000)
  - c) 1–2.2 mg/kg, PO q8–12h (Crowell-Davis 1999)
- For the adjunctive treatment of acral pruritic dermatitis:
  - a) 2.2 mg/kg, PO once daily for one-month trial. Some dogs exhibit drowsiness and minor changes in behavior. 50–60% of patients have benefited. Expense is of concern. (Rosychuck 1991)

**CATS**
- As adjunctive therapy in behavior disorders:
  - a) 25–50 mg/cat PO q24h. Note: has a bitter taste (Crowell-Davis 1999)

**ZOo, Exotic, Wildlife SPECIES**
- For use of naltrexone in zoo, exotic and wildlife medicine refer to specific references, including:
  e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJSe

Monitoring
- Efficacy
- Liver enzymes if using very high dose with prolonged therapy

Client Information
- Stress the importance of compliance with prescribed dosing regimen
- Additional behavior modification techniques may be required to alleviate clinical signs

Chemistry/Synonyms
A synthetic opiate antagonist, naltrexone HCl occurs as white crystals having a bitter taste. 100 mg are soluble in one mL of water.

Naltrexone may also be known as EN-1639A, ReVia®, and Vivitrol®.

Storage/Stability
Naltrexone tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

**Veterinary-Labeled Products**: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**Human-Labeled Products**:
Naltrexone HCl Oral Tablets: 50 mg; ReVia® (Duramed); generic; (Rx)
Naltrexone HCl Oral Tablets: 50 mg; ReVia® (Duramed); generic; (Rx)

Naltrexone HCl Powder for Suspension Extended-Release Injection: 380 mg/vial in single-use vials w/4 mL diluent; Vivitrol® (Alkermes); (Rx)

References

NANDROLONE DECANOATE
(nan-dro-e-lone) Deca-Durabolin®
PARENTERAL ANABOLIC STEROID

Prescriber Highlights

- Injectable anabolic steroid; may be useful to stimulate erythropoiesis or to stimulate appetite. Rarely recommended or used today.
- Contraindications: Hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, & during the nephrotic stage of nephritis
- Adverse Effects: Sodium, calcium, potassium, water, chloride, & phosphate retention; hepatotoxicity, behavioral (androgenic) changes, & reproductive abnormalities (oligospermia, estrus suppression)
- Known teratogen
- Drug Interactions
- C-III Controlled Substance. No FDA-approved products marketed in USA; may be available from compounding pharmacies.

Uses/Indications
The principle use of nandrolone in veterinary medicine has been to stimulate erythropoiesis in patients with certain anemias (e.g., secondary to renal failure, aplastic anemias). It has also been suggested for use as an appetite stimulant. Anabolic steroids are rarely recommended or used today in veterinary medicine.

Pharmacology/Actions
Nandrolone exhibits similar actions as other anabolic agents. In the presence of adequate protein and calories, anabolic steroids promote body tissue building processes and can reverse catabolism. As these agents are either derived from or closely related to testosterone, the anabolics have varying degrees of androgenic effects. Endogenous testosterone release may be suppressed by inhibiting luteinizing hormone (LH). Large doses can impede spermatogenesis by negative feedback inhibition of FSH.

Anabolic steroids can stimulate erythropoiesis. The mechanism for this effect may occur by stimulating erythropoietic stimulating factor. Anabolics can cause nitrogen, sodium, potassium, and phosphorus retention and decrease the urinary excretion of calcium. Many veterinary and human clinicians feel that nandrolone is clinically superior to other anabolics in its ability to stimulate erythropoiesis. It is believed that nandrolone may enhance red cell counts by directly stimulating red cell precursors in the bone marrow, increasing red cell 2,3-diphosphoglycerate and erythropoietin production in the kidney.

Pharmacokinetics
No specific information was located for this agent. It is generally recommended for both small animals and humans to be dosed on a weekly basis.

Contraindications/Precautions/Warnings
No specific recommendations were located for this agent in veterinary species.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, in selected patients with breast carcinoma, benign prostatic hypertrophy, and during the nephrotic stage of nephritis.

Adverse Effects
Potential (from human data) adverse reactions of the anabolic agents in dogs and cats include: sodium, calcium, potassium, water, chloride, and phosphate retention; hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (oligospermia, estrus suppression).

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) Anabolic steroids can cause masculinization of the fetus.

It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, decide whether to discontinue nursing or the drug.

Overdosage/Acute Toxicity
No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving nandrolone and may be of significance in veterinary medicine.

- C-III Controlled Substance. No FDA-approved products marketed in USA; may be available from compounding pharmacies.
The following drug interactions have either been reported or are theoretical in humans or animals receiving nandrolone and may be of significance in veterinary patients:

- **ANTICOAGULANTS (warfarin):** Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR and dosage adjustment of the anticoagulant (if necessary) are recommended.

- **CORTICOSTEROIDS, ACTH:** Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy.

- **INSULIN:** Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements.

**Laboratory Considerations**

- Concentrations of **protein bound iodine (PBI)** can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important.

- Androgen/anabolic agents can decrease amounts of **thyroxine-binding globulin** and decrease total T<sub>4</sub> concentrations and increase **resin uptake of T<sub>3</sub> and T<sub>4</sub>**: free thyroid hormones are unaltered and, clinically, there is no evidence of dysfunction.

- Both **creatinine** and **creatinine excretion** can be decreased by anabolic steroids.

- **Anabolic steroids can increase the urinary excretion of 17-ketosteroids.**

- **Androgenic/anabolic steroids may alter blood glucose levels.**

- **Androgenic/anabolic steroids may suppress clotting factors II, V, VII, and X.**

- **Anabolic agents can affect liver function tests** (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase).

**Doses**

**DOGS:**

For adjunctive treatment of chronic idiopathic myelofibrosis:

- a) Prednisolone at 2–3 mg/kg PO once daily for 3–4 weeks, then every other day with a tapering of the dose as the anemia resolves. Nandrolone decanoate may be used at 2 mg/kg IM weekly for 3 weeks. If anemia does not respond to initial treatments, azathioprine at 2 mg/kg PO every other day can be given. (Raskin 2006)

For disuse muscle atrophy secondary to immobilization:

- a) 1.5 mg/kg IM once weekly from the day of surgery/immobilization for up to 8 weeks. (Yun et al. 2005)

For treatment of anemia in patients with chronic renal failure:

- a) 1–1.5 mg/kg IM once weekly; may require 2–3 months to achieve beneficial effects. Evidence to support use is poor. (Polzin, D. et al. 1992; Polzin, D.J. & Osborne 1985)

- b) 5 mg/kg IM (maximum of 200 mg/week) every 2–3 weeks (Ross et al. 1989)

For treatment of metabolic and endocrine anemias:

- a) 5 mg/kg IM once weekly (maximum of 200 mg); most resolve with correction of underlying disease process (Maggio-Price 1988)

For aplastic anemia:

- a) 1–3 mg/kg IM weekly (Weiss 1986)

As an appetite stimulant:

- a) 5 mg/kg IM (max. 200 mg/week) weekly (Macy & Ralston 1989)

**CATS:**

For FeLV-induced anemia or as a general bone marrow stimulant:

- a) 10–20 mg IM once weekly (is of questionable benefit) (Maggio-Price 1988)

For chronic anemia secondary to feline cardiomyopathy:

- a) 50 mg IM weekly (Harpster 1986)

**REPTILES:**

To reduce protein catabolism in renal disease of lizard species:

- a) 1 mg/kg IM every 7–28 days (de la Navarre 2003)

**Monitoring**

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- Red blood cell count, indices, if indicated
- Weight, appetite

**Client Information**

- Because of the potential for abuse of anabolic steroids by humans, this agent is a controlled (C-III) drug. It should be kept in a secure area and out of the reach of children.

**Chemistry/Synonyms**

An injectable anabolic steroid, nandrolone decanoate occurs as a white, to creamy white, crystalline powder. It is odorless or may have a slight odor and melts between...
Naproxen is a nonsteroidal anti-inflammatory agent (NSAID) that is approved for use in horses in the United States. It is used to treat the signs of inflammation and associated pain associated with various musculoskeletal diseases. However, its use is largely superseded by newer, less GI-toxic NSAIDs in dogs and by other NSAIDs in horses as the equine product is no longer marketed in the USA.

Adverse Effects: Relatively uncommon in Horses: Possible GI (distress, diarrhea, ulcers), hematologic (hypoproteinemia, decreased hematocrit), renal (fluid retention), & CNS (neuropathies). Dogs: GI ulcers & perforation, renal effects (nephritis/nephrotic syndrome), & hepatic (increased liver enzymes) effects.

Drug Interactions

Uses/Indications

The former manufacturer listed the following indications: “...for the relief of inflammation and associated pain and lameness exhibited with myositis and other soft tissue diseases of the musculoskeletal system of the horse.” (Package Insert; Equiproxen®—Syntex). It has also been used as an antiinflammatory/analgesic in dogs for the treatment of osteoarthritis and other musculoskeletal inflammatory diseases (see adverse reactions below).

Pharmacology/Actions

Like other NSAIDs, naproxen exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase with resultant impediment of prostaglandin synthesis.

Pharmacokinetics

In horses, the drug is reported to have a 50% bioavailability after oral dosing and a half-life of approximately 4 hours. Absorption does not appear to be altered by the presence of food. It may take 5–7 days to see a beneficial response after starting treatment. Following a dose, the drug is metabolized in the liver. It is detectable in the urine for at least 48 hours in the horse after an oral dose.

In dogs, absorption after oral dosing is rapid and bioavailability is between 68–100%. The drug is highly bound to plasma proteins. The average half-life in dogs is very long at 74 hours.

In humans, naproxen is highly bound to plasma proteins (99%). It crosses the placenta and enters milk in levels of about 1% of those found in serum.

Contraindications/Precautions/Warnings

Naproxen is relatively contraindicated in patients with a history of or preexisting hematologic, renal, or hepatic disease. It is contraindicated in patients with active GI ulcers, or with a history of hypersensitivity to the drug. It should be used cautiously in patients with a history of GI ulcers, or heart failure (may cause fluid retention). Animals suffering from inflammation secondary to concomitant infection, should receive appropriate antimicrobial therapy.

Adverse Effects

Adverse effects are apparently uncommon in horses. The possibility exists for GI (distress, diarrhea, ulcers), hematologic (hypoproteinemia, decreased hematocrit, renal (fluid retention), and CNS (neuropathies) effects.
Reports of GI ulcers and perforation associated with naproxen have occurred in dogs. Dogs may also be overly sensitive to the adverse renal (nephritis/nephrotic syndrome) and hepatic effects (increased liver enzymes) of naproxen. Because of the apparently very narrow therapeutic index and the seriousness of the potential adverse reactions that can be seen in dogs, many clinicians feel that the drug should not be used in this species.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In studies in rodents and in limited studies in horses, no evidence of teratogenicity or adverse effects in breeding performance have been detected following the use of naproxen. Weigh the potential benefits of therapy against the potential risks of its use in pregnant animals.

Most NSAIDs are excreted in maternal milk. Naproxen appears at approximately 1% of maternal serum concentration.

Overdosage/Acute Toxicity
There is very limited information regarding acute overdoses of this drug in humans and domestic animals. The reported oral LD50 in dogs is >1000 mg/kg. In dogs, PO ingestions of >5 mg/kg can cause gastrointestinal signs and GI ulceration; >25 mg/kg (some dogs as low as 10 mg/kg) can cause significant renal damage, and >50 mg/kg can result in neuro signs.

One report of a dog that received 5.6 mg/kg for 7 days has been published (Gilmour and Walshaw 1987). The dog presented with clinical signs of melena, vomiting, depression, regenerative anemia, and pale mucous membranes. Laboratory indices of note included neutrophilia with a left shift, BUN of 66 mg/dL, serum creatinine of 2.1 mg/dL, serum protein to albumin ratio of 4.0:2.1 grams/dL. The dog recovered following treatment with fluids/blood, antibiotics, vitamin/iron supplementation, oral antacids, and cimetidine.

There were 817 exposures to naproxen reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 764 were dogs with 335 dogs showing clinical signs, 49 cats with 13 showing clinical signs, 2 rodents with 1 showing clinical signs and the remaining 2 cases were 1 bird and 1 bovine showing no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, anorexia, bloody vomitus, diarrhea, melena, and anemia. Common findings in cats recorded in decreasing frequency included vomiting, lethargy, and anorexia.

As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants, including misoprostol and sucralfate should be considered. GI protectant treatment is generally recommended for 10-14 days post-exposure. If renal effects are also expected, fluid diuresis should be considered. Supportive treatment should be instituted as necessary. Monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving naproxen and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc.): Increased risk for nephotoxicity
- **ANTICOAGULANTS** (heparin, LMWH, warfarin): Increased risk for bleeding possible
- **ASPIRIN**: When aspirin is used concurrently with naproxen, plasma levels of naproxen could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with naproxen cannot be recommended.
- **BISPHOSPHONATES** (alendronate, etc.): May increase risk for GI ulceration
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **FUROSEMIDE**: Naproxen may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (e.g., phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, and the sulfonylurea antidiabetic agents): Because naproxen is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern, clinically, use together with caution.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.
- **PROMBENECID**: May cause a significant increase in serum levels and half-life of naproxen.

**Doses**

- **DOGS**:
  
  **Note**: Because of the difficulty in accurately dosing naproxen and its potential for adverse effects, the use of this drug in dogs should only be considered when FDA-approved and safer NSAIDs have been ineffective.

  a) 2 mg/kg PO every other day (q48h). (Hansen 2003; Hardie & Grauer 2007; Hardie et al. 2003)

- **RABBITS, RODENTS, SMALL MAMMALS**:

  a) Rabbits: For septic arthritis pain; inflammation: 2.4 mg/mL in drinking water for 21 days (Ivey & Morrissey 2000)

- **HORSES** (Note: ARCl UCGFS Class 4 Drug)

  a) 5 mg/kg by slow IV, then 10 mg/kg, PO (top dressed in feed) twice daily for up to 14 days or 10 mg/kg, PO (top dressed in feed) twice daily for up to 14 consecutive days. (Package Insert; Equiproxen®—Syntex Animal Health; **Note**: No longer commercially available)

  b) 10 mg/kg PO daily (Trumble & Kawcak 2003)

**Monitoring**

- Analgesic/antiinflammatory efficacy
- GI: appetite, feces (occult blood, diarrhea)
- PCV (packed cell volume), hematocrit if indicated or on chronic therapy
- WBC's if indicated or on chronic therapy
Uses/Indications

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. Dogs and humans may develop miosis, while hypotension and syncope may occur.

Stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic effects (constipation/defecation). Secondary pharmacologic effects include, mu receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Kappa receptors are located primarily in the deep layers of the cerebral cortex and spinal cord. They are responsible for analgesia, sedation, and miosis. Sigma receptors are thought to be responsible for the dysphoric effects (struggling, whining), hallucinations, respiratory and cardiac stimulation, and mydriatic effects of opiates. Delta receptors, located in the limbic areas of the CNS, and epsilon receptors have also been described, but their actions have not been well explained at this time.

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle. Opiate receptors are further broken down into five main sub-groups. Mu receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Kappa receptors are located primarily in the deep layers of the cerebral cortex and spinal cord. They are responsible for analgesia, sedation, and miosis. Sigma receptors are thought to be responsible for the dysphoric effects (struggling, whining), hallucinations, respiratory and cardiac stimulation, and mydriatic effects of opiates. Delta receptors, located in the limbic areas of the CNS, and epsilon receptors have also been described, but their actions have not been well explained at this time.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include, CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthonastic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis. For more information see the individual monographs for each agent.
Uses/Indications
N-butylscopolammonium bromide (NBB) injection is indicated (per the label) for control of abdominal pain (colic) associated with spasmodic colic, flatulent colic, and simple impactions in horses. It may also be of benefit in horses in combination with oxytocin to treat esophageal obstruction (choke), and as an aid to performing rectal exams, including colonoscopy.

Pharmacology/Actions
N-butylscopolammonium reduces gastrointestinal peristalsis and rectal pressure via its anti-cholinergic actions by competitively inhibiting muscarinic receptors on smooth muscle. N-butylscopolammonium has shorter duration of action than atropine. It appears to have brief (15-20 minutes) visceral colorectal distention antinociceptive effects in horses (Sanchez et al. 2008).

Pharmacokinetics
Limited information is available for horses. After an intravenous dose, the drug is eliminated within 48 hours in urine and feces equally. Estimated elimination half-life is approximately 6 hours.

Contraindications/Precautions
N-butylscopolammonium is labeled as contraindicated in horses with impaction colics associated with ileus or those with glaucoma.
This medication is not to be used in horses intended for food purposes.
The manufacturer has not studied the safety of IM administration.

Adverse Effects
Adverse effects include transient tachycardia and decreased borborygmal sounds that last for approximately 20-30 minutes after IV dosing. Transient pupil dilation can be noted. Other effects include decreased secretions and dry mucous membranes.
Because this drug can cause increases in heart rate, heart rate cannot be used as a valid pain indicator for 30 minutes after injection.
When used for labeled indications, a lack of response may indicate a more serious problem that may require surgery or more aggressive care (White 2005).

Reproductive/Nursing Safety
As no data is available to document safety, the manufacturer does not recommend use in nursing foals or pregnant or lactating mares.

Overdosage/Acute Toxicity
Dosages up to 10X (3 mg/kg) were administered to horses as part of pre-approval studies. Clinical effects noted included dilated pupils (returned to normal in 4–24 hours), tachycardia (returned to normal within 4 hours) and dry mucous membranes (returned to normal in 1–2 hours). Gut motility was inhibited, but returned to baseline within 4 hours and normal feces were seen within 6 hours. Two of the four horses treated at 10X dosage developed mild signs of colic which resolved without further treatment.

Drug Interactions
The following drug interactions have either been reported or are theoretical in animals receiving N-butylscopolammonium bromide and may be of significance in veterinary patients:

- **ATROPINE or other anticholinergic agents**: May cause additive effects if used with N-butylscopolammonium
- **METOCLOPRAMIDE and other drugs that have cholinergic-like actions on the GI tract**: These drugs and N-butylscopolammonium may counteract one another’s actions on GI smooth muscle

Laboratory Considerations
- No specific concerns noted.

Doses

**HORSES:**
- For labeled indications:
  a) 0.3 mg/kg (30 mg or 1.5 mL per 100 kg of body weight) via slow IV, one time (Label Dosage; Buscopan®—B1)
  b) To treat esophageal obstruction: 0.3 mg/kg IV once with oxytocin (0.11–0.22 Units/kg IV once). Oxytocin use should be avoided in mares, or dose significantly reduced. Do not use in pregnant mares. (Beard 2008)

Monitoring
- Heart rate (Note: heart rate cannot be used as indicator for pain for the first 30 minutes after administration)
- GI motility via gut sounds and feces output

Client Information
- Because an accurate patient assessment must be performed prior to the use of this medication and intravenous administration and subsequent monitoring are required, this drug should only be administered by veterinarians

Chemistry/Synonyms
N-butylscopolammonium bromide, a derivative of scopolamine, is a synthetic, quaternary ammonium antispasmodic-anticholinergic agent. It occurs as a white crystalline substance that is soluble in water.
N-butylscopolammonium bromide may also be known as: butylscopolamine bromide, hysocine butylbromide, hysocine N-butylbromide, scopolaminibutylbromidum, hyoscini butylbromidum, Buscopan® or Buscapina®.

Storage/Stability
The commercially available injection should be stored at room temperature (15–30°C).
NEOMYCIN SULFATE

(nee-o-my-e-sin) Biosol®, Neomix®

AMINOGLYCOSIDE ANTIBIOTIC

Prescriber Highlights

- Aminoglycoside antibiotic usually used orally (gut “sterilization”) or in topical formulations
- Contraindications: Oral: Hypersensitive to aminoglycosides, intestinal blockage; rabbits
- Adverse Effects: Parenteral use can be very toxic (nephrotoxic) & is not recommended. Chronic use can lead to GI superinfections. Rarely, oral neomycin may cause ototoxicity, nephrotoxicity, severe diarrhea, & intestinal malabsorption
- Minimal amounts absorbed via GI (if intact)

Uses/Indications

Because neomycin is more nephrotoxic and less effective against several bacterial species than either gentamicin or amikacin, its use is generally limited to topical formulations for skin, eyes, and ears, oral treatment of enteric infections, to reduce microbe numbers in the colon prior to colon surgery, and oral or enema administration to reduce ammonia-producing bacteria in the treatment of hepatic encephalopathy. Doses for parenteral administration are listed below, but should be used only with extreme caution due to the drug’s toxic potential.

Pharmacology/Actions

Neomycin has a mechanism of action and spectrum of activity (primarily gram-negative aerobes) similar to the other aminoglycosides, but in comparison to either gentamicin or amikacin, it is significantly less effective against several species of gram-negative organisms, including strains of Klebsiella, E. coli, and Pseudomonas. However, most strains of neomycin-resistant bacteria of these species remain susceptible to amikacin. More detailed information on the aminoglycosides mechanism of action and spectrum of activity is outlined in the amikacin monograph.

Pharmacokinetics

Approximately 3% of a dose of neomycin is absorbed after oral or rectal (retention enema) administration, but this can be increased if gut motility is slowed or if the bowel wall is damaged. Therapeutic levels are not attained in the systemic circulation after oral administration.

After IM administration, therapeutic levels can be attained with peak levels occurring within 1 hour of dosing. The drug apparently distributes to tissues and is eliminated like the other aminoglycosides (refer to Amikacin monograph for more details). Orally administered neomycin is nearly all excreted unchanged in the feces.

Contraindications/Precautions/Warnings

Oral neomycin is contraindicated in the presence of intestinal obstruction or if the patient is hypersensitive to aminoglycosides.

In neonates, orally administered neomycin can yield high systemic levels; avoid use in neonatal patients.

Chronic usage of oral aminoglycosides may result in bacterial or fungal superinfections.

Because aminoglycosides can cause irreversible ototoxicity when administered parenterally, they should be used with caution in “working” dogs.

Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, when administered parenterally they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals. When neomycin is given orally, only perhaps 3% of a dose is absorbed, but use with caution in patients with renal dysfunction.

Aminoglycosides are generally considered contraindicated in rabbits/hares, as they adversely affect the GI flora balance in these animals. Oral neomycin has been associated with antibiotic-associated diarrhea (enterocolitis) in horses and it is not commonly used in this species.

Adverse Effects

Refer to the amikacin monograph for more information regarding these topics with parenteral neomycin; however, parenterally administered neomycin is much more nephrotoxic than is amikacin.

Rarely, oral neomycin may cause ototoxicity, nephrotoxicity, severe diarrhea, and intestinal malabsorption.
Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Neomycin is excreted in cow’s milk following a single IM injection. If used orally, it is unlikely neomycin poses significant systemic risk to nursing offspring, but may negatively alter gut flora and cause diarrhea.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral neomycin and may be of significance in veterinary patients:

- **DIGOXIN**: Oral neomycin with orally administered digoxin may result in decreased absorption. Separating the doses of the two medications may not alleviate this effect. Some human patients (<10%) metabolize digoxin in the GI tract and neomycin may increase serum digoxin levels in these patients. It is recommended that enhanced monitoring be performed if oral neomycin is added or withdrawn from the drug regimen of a patient stabilized on a digitalis glycoside.

- **METHOTREXATE**: Absorption may be reduced by oral neomycin but is increased by oral kanamycin (found in Amforal®)

- **OTOTOXIC, NEPHROTOXIC DRUGS**: Although only minimal amounts of neomycin are absorbed after oral or rectal administration, the concurrent use of other ototoxic or nephrotoxic drugs with neomycin should be done with caution

- **PENICILLIN VK (oral)**: Oral neomycin should not be given concurrently with oral penicillin VK as malabsorption of the penicillin may occur

- **WARFARIN**: Oral neomycin may decrease the amount of vitamin K absorbed from the gut; this may have ramifications for patients receiving oral anticoagulants

Refer to the amikacin monograph for more information regarding drug interactions with parenteral neomycin.

Laboratory Considerations

No specific concerns noted

Doses

**DOGS:**

- For treatment of hepatic encephalopathy:
  a) A check list for acute management of hepatic encephalopathy includes: 1) Lactulose (orally, or by enema if stupor or seizures); 2) NPO for 12 to 24 hours; 3) If no response, add metronidazole orally at 15 mg/kg/day; 4) If no response, add neomycin orally at 20 mg/kg PO three times daily. 5) Provide IV fluids with potassium (and dextrose for patients with portosystemic shunts or severe cirrhosis). 6) Add anti-ulcer therapy (GI bleeding is a protein load in hepatic encephalopathy), and add vitamin K₁ if jaundiced. 7) Withhold any glucocorticoids until encephalopathy is resolved! 8) Give as much dietary protein as tolerated; increase the lactulose dosage if needed. (Trepanier 2008)
  b) For adjunctive management of portosystemic shunts: 10–20 mg/kg PO two to three times a day. (Twedt 2009)
  c) Animals that are neurologically and systemically stable should be treated with orally-administered nonabsorbable antibiotics in order to decrease the numbers of urease-producing bacteria within the gastrointestinal tract. If using neomycin: 20 mg/kg PO q12h. Avoid neomycin if any evidence of intestinal bleeding, ulcerations, or renal failure. The use of oral lactulose therapy, in conjunction with or as an alternative to antibiotics, is also beneficial in neurologically stable animals. The combination of neomycin and lactulose may be synergistic. (Silverstein 2009)
  d) 15 mg/kg as an enema every 6 hours after a cleansing enema or 10–20 mg/kg, PO every 6 hours. May be used with lactulose. (Johnson 1986)

For GI tract infections:
  a) For campylobacteriosis: 20 mg/kg PO q12h (Willard 2003)
  b) For systemic therapy (Caution: Very nephrotoxic):
     a) 3.5 mg/kg IV, IM or SC q8h (Kirk 1989)

**CATS:**

For treatment of hepatic encephalopathy:
  a) See “A check list for acute management of hepatic encephalopathy” in Dog dose section above.
  b) 22 mg/kg q8h PO (Cornelius, Bartges et al. 2000)
  c) Lactulose at 0.5–1 mg/kg PO q8h with or without neomycin at 20 mg/kg PO q8–12h. (Marks 2004)
  d) Animals that are neurologically and systemically stable should be treated with orally-administered nonabsorbable antibiotics in order to decrease the numbers of urease-producing bacteria within the gastrointestinal tract. If using neomycin: 20 mg/kg PO q12h. Avoid neomycin if any evidence of intestinal bleeding, ulcerations, or renal failure. The use of oral lactulose therapy, in conjunction with or as an alternative to antibiotics, is also beneficial in neurologically stable animals. The combination of neomycin and lactulose may be synergistic. (Silverstein 2009)

For GI tract infections: For campylobacteriosis:
  a) 20 mg/kg PO q12h (Willard 2003)
  b) For systemic therapy (Caution: Very nephrotoxic):
     a) 3.5 mg/kg IV, IM or SC q8h (Kirk 1989)

**FERRETS:**

For susceptible enteric infections:
  a) 10–20 mg/kg, PO twice to four times daily (Williams 2000)

**RODENTS, SMALL MAMMALS:**

Note: Contraindicated in rabbits/frogs...
Note: Contraindicated in laboratory rabbits.

**CATTLE:**
For oral administration to treat susceptible enteral infections:
- a) 4–7.5 grams/day PO divided 2–4 times daily at regular intervals. Calves: 2–3 grams/day, PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander et al. 1982)
- b) 10–20 mg/kg q12h (general guideline only). (Jenkins 1986)
- c) 7–12 mg/kg, PO q12h (Howard 1986)
- d) Feed at levels of 70–140 grams/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg or mix with reconstituted milk replacers to provide 200–400 mg/gallon. (Label directions; Neomix Ag® 325—Upjohn)

**HORSES:**
For oral administration to treat susceptible enteral infections:
- a) Adults: 4–7.5 grams/day PO divided 2–4 times daily at regular intervals. Foals: 2–3 grams/day PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander et al. 1982)
- b) 5–15 mg/kg PO once daily (Robinson 1987)
- For intrauterine infusion:
  - a) Neomycin alone: 3–4 grams. Combination of neomycin (2 grams) and procaine penicillin G (3,000,000 IU), Combination of Neomycin (1 grams) and Polymyxin B (40,000 IU), Furaltadone (600 mg) and penicillin G (Sodium or potassium, 3,000,000–5,000,000 IU). Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

**SWINE:**
For oral administration to treat susceptible enteral infections:
- a) Young pigs: 0.75–1 grams/day, PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander, Pugh, and Bywater 1982)
- b) 7–12 mg/kg, PO q12h (Howard 1986)

**SHEEP & GOATS:**
For oral administration to treat susceptible enteral infections:
- a) Lambs: 0.75–1 grams/day PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander et al. 1982)
- b) Feed at levels of 70–140 grams/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg or mix with reconstituted milk replacers to provide 200–400 mg/gallon. (Label directions; Neomix Ag® 325—Upjohn)

**BIRDS:**
For bacterial enteritis:
- a) Chickens, turkeys, ducks: Feed at levels of 70–140 grams/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg (Label directions; Neomix Ag® 325—Upjohn)

**SNAKES:**
For susceptible infections:
- a) For bacterial gastritis: gentamicin 2.5 mg/kg IM every 72 hours with oral neomycin 15 mg/kg plus oral live lactobacillus (Burke 1986)

**Monitoring**
For oral use:
- Clinical efficacy
- Systemic and GI adverse effects with prolonged use.
For parenteral use: Refer to Amikacin monograph

**Client Information**
- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication when used parenterally.

**Chemistry/Synonyms**
An aminoglycoside antibiotic obtained from *Streptomyces fradiae*, neomycin is actually a complex of three separate compounds, neomycin A (neamine; inactive), neomycin C, and neomycin B (framycetin). The commercially available product almost entirely consists of the sulfate salt of neomycin B. It occurs as an odorless or almost odorless, white to slightly yellow, hygroscopic powder or cryodessicated solid. It is freely soluble in water and very slightly soluble in alcohol. One mg of pure neomycin sulfate is equivalent to not less than 650 Units. Oral or injectable (after reconstitution with normal saline) solutions of neomycin sulfate have a pH from 5–7.5.

Neomycin sulfate may also be known as: fradiomycin sulfate, neomycin sulphate, or neomycini sulfas, Neo-325®, Neo-fradin®, Neo-Sol 50®, and Neovet®.

**Storage/Stability**
Neomycin sulfate oral solution should be stored at room temperature (15–30°C) in tight, light-resistant containers. Unless otherwise instructed by the manufacturer, oral tablets/boluses should be stored in tight containers at room temperature. The sterile powder should be stored at room temperature and protected from light.

In the dry state, neomycin is stable for at least 2 years at room temperature.
VETERINARY-LABELED PRODUCTS:

Neomycin Sulfate Oral Liquid: 200 mg/mL (140 mg neomycin base/mL); generic; (OTC). Depending on labeling FDA-approved for use in cattle, swine, sheep, goats, turkeys, laying hens, and broilers. Check labels for slaughter withdrawals; may vary with product. General withdrawal times (when used as labeled): Cattle = 1 day; Sheep = 2 days and swine and goats = 3 days. Withdrawal period has not been established in pre-ruminating calves. Do not use in calves to be processed for veal. A milk discard period has not been established in lactating dairy cattle. Do not use in female dairy cattle 20 months of age or older.

Neomycin Sulfate Soluble Powder: 325 grams/bottle; Neo-325® Soluble Powder (Bimeda); Neover® 325/100 & NeoVet® 325 AG Grade (includes turkey label); (AgriPharm) Neo-Sol 50® (Alpharma); (OTC). FDA-approved for use in cattle and goats (not veal calves), swine, sheep, goats and turkeys (some products). Check labels for slaughter withdrawals; may vary with product. General slaughter withdrawal times (when used as labeled): Cattle = 1 day; Turkeys = 0 days; Sheep = 2 days; Swine and Goats = 3 days.

HUMAN-LABELED PRODUCTS:

Neomycin Sulfate Tablets: 500 mg; generic; (Rx)
Neomycin Sulfate Oral Solution: 25 mg/mL in 480 mL; Neo-fradin® (Pharma-Tek); (Rx)

References

NEOSTIGMINE BROMIDE
NEOSTIGMINE METHYLSULFATE
(parasympathomimetic (cholinergic)

Prescriber Highlights

- Parasympathomimetic used to initiate peristalsis, empty the bladder, & stimulate skeletal muscle contractions. Also for diagnosis & treatment of myasthenia gravis & treatment of non-depolarizing neuromuscular blocking agents (curare-type) overdose; has been used for treating massive ivermectin overdoses in cats
- Contraindications: Peritonitis, mechanical intestinal or urinary tract obstructions, late stages of pregnancy, hypersensitivity to this class of compounds, or if treated with other cholinesterase inhibitors
- Adverse Effects: Cholinergic in nature & dose related (nausea, vomiting, diarrhea, excessive salivation & drooling, sweating, miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiomyopathy, bronchoconstriction, urinary constriction, miosis and bradycardia. Neostigmine also has a direct cholinomimetic effect on skeletal muscle.
- Cholinergic crisis & myasthenic crisis must not be confused

Uses/Indications
Neostigmine is indicated for rumen atony, initiating peristalsis, emptying the bladder, and stimulating skeletal muscle contractions in cattle, horses, sheep, and swine (Package insert; Stiglyn® 1:500-P/M—Mallinckrodt). It has been used in the diagnosis and treatment of myasthenia gravis and in treating non-depolarizing neuromuscular blocking agents (curare-type) overdoses in dogs. Neostigmine has also been used to treat massive ivermectin overdoses in cats.

Pharmacology/Actions
Neostigmine competes with acetylcholine for acetylcholinesterase. As the neostigmine-acetylcholine complex inactivates, acetylcholine will accumulate with a resultant exaggeration and prolongation of its effects. These effects can include increased tone of gastrointestinal and skeletal musculature, stimulation of salivary and sweat glands, bronchoconstriction, ureter constriction, miosis and bradycardia. Neostigmine also has a direct cholinomimetic effect on skeletal muscle.

In horses, neostigmine may decrease jejunal activity and delay gastric emptying. Its use in treating colon impactions and ileus is controversial.

Pharmacokinetics
Information on the pharmacokinetics of neostigmine in veterinary species was not located. In humans, neostigmine bromide is poorly absorbed after oral administration with only 1–2% of the dose absorbed. Neostigmine effects on peristaltic activity in humans begin within 10–30 minutes after parenteral administration and can persist for up to 4 hours.

Neostigmine is 15–25% bound to plasma proteins. It has not been detected in human milk nor would it be expected to cross the placenta when given at usual doses. In humans, the half-life of the drug is approximately one hour. It is metabolized in the liver and hydrolyzed by cholinesterases to 3-OH PTM, which is weakly active. When administered parenterally, approximately 80% of the drug is excreted in the urine within 24 hours, with 50% excreted unchanged.
Contraindications/Precautions/Warnings
Neostigmine is contraindicated in patients with peritonitis, mechanical intestinal or urinary tract obstructions, in animals hypersensitive to this class of compounds, or treated with other cholinesterase inhibitors.
Use neostigmine with caution in patients with epilepsy, peptic ulcer disease, bronchial asthma, cardiac arrhythmias, hyperthyroidism, vagotonia, or megacolon.

Adverse Effects
Adverse effects of neostigmine are dose-related and cholinergic in nature. See overdosage section below.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)
Because it is ionized at physiologic pH, neostigmine would not be expected to be excreted in maternal milk.

Overdosage/Acute Toxicity
Overdosage of neostigmine can induce a cholinergic crisis. Clinical signs can include: nausea, vomiting, diarrhea, excessive salivation and drooling, sweating (in animals with sweat glands), miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiomyopathy, bronchospasm, hypotension, muscle cramps and weakness, agitation, restlessness, or paralysis. In patients with myasthenia gravis, it may be difficult to distinguish between a cholinergic crisis and myasthenic crisis. A test dose of edrophonium should differentiate between the two.

Treat cholinergic crisis by temporarily ceasing neostigmine therapy and instituting treatment with atropine (doses are listed in the Atropine monograph). Maintain adequate respirations using mechanical assistance if necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving neostigmine and may be of significance in veterinary patients:

★ATROPINE: Atropine will antagonize the muscarinic effects of neostigmine and some clinicians routinely use the two together, but concurrent use should be used cautiously as atropine can mask the early clinical signs of cholinergic crisis

★CORTICOSTEROIDS: May decrease the anticholinesterase activity of neostigmine; after stopping corticosteroid therapy, neostigmine may cause increased anticholinesterase activity

★DEXPANTHENOL: Theoretically, dexpanthenol may have additive effects when used with neostigmine

★MAGNESIUM: Anticholinesterase therapy may be antagonized by administration of parenteral magnesium therapy, as it can have a direct depressant effect on skeletal muscle

★MUSCLE RELAXANTS: Neostigmine may prolong the Phase I block of depolarizing muscle relaxants (e.g., succinylcholine, decamethonium) and edrophonium antagonizes the actions of non-depolarizing neuromuscular blocking agents (e.g., pancuronium, tubocurarine, gallamine, vecuronium, atracurium, etc.)

Doses

★DOGS:
a) For treatment of myasthenia gravis: 0.04 mg/kg IM q6h to bypass the problem of oral medication in actively regurgitating animals (Inzana 2000)
b) For diagnosis of myasthenia gravis: 0.05 mg/kg IM (diagnostic for MA if clinical improvement occurs in 15–30 minutes; pre-treat with atropine) (LeCouteur 1989)
c) For treatment of curare overdoses: 0.001 mg/kg SC, follow with IV injection of atropine (0.04 mg/kg) (Bailey 1986)

★CATS:
For treatment of myasthenia gravis:
a) 0.04 mg/kg IM q6h to bypass the problem of oral medication in actively regurgitating animals (Inzana 2000)

★CATTLE:
a) 1 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; Stiglyn® 1:500-P/M—Mallinckrodt)

★HORSES: (Note: ARCI UCGFS Class 3 Drug)
a) 1 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; Stiglyn® 1:500-P/M—Mallinckrodt)
For treatment of ileus:
a) 0.022 mg/kg IV or 0.044 mg/kg SC, IM. This drug has no therapeutic value for small intestinal ileus. (White 2007)
b) For ileus with marked colonic distension in foals secondary to C. perfringens type C: 1–2 mg (2 mg for foals greater than 250 lb) SC, 2–3 doses at 1–hour intervals then as needed. (Slovis 2003)
c) 0.025 mg/kg SC q2–6h (Hassel 2005)
d) May be beneficial for treatment of small intestinal ileus at 2 mg per 500 kg adult horse administered SC or IV every 30 to 60 minutes to a maximum dose of 10 mg. Side effects include colic signs. (Hallowell 2008)

★SWINE:
a) 2–3 mg/100 lbs of body weight IM; repeat as indicated (Package Insert; Stiglyn® 1:500-P/M—Mallinckrodt)
b) 0.03 mg/kg (Davis 1986)

★SHEEP:
a) 1–1.5 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; Stiglyn® 1:500-P/M—Mallinckrodt)
b) 0.01–0.02 mg/kg (goats also) (Davis 1986)
Monitoring
Dependent on reason for use.
- Adverse reactions (see Adverse Effects and Overdosage above)
- Clinical efficacy

Client Information
- This product should only be used by professionals in locations where the drug’s effects can be monitored.

Chemistry/Synonyms
Synthetic quaternary ammonium parasympathomimetic agents, neostigmine bromide and neostigmine methylsulfate both occur as odorless, bitter-tasting, white, crystalline powders that are very soluble in water and soluble in alcohol. The melting point of neostigmine methylsulfate is from 144–149°. The pH of the commercially available neostigmine methylsulfate injection is from 5–6.5.

Neostigmine methylsulfate may also be known as: neostigmine metilsulfate, neostigmine methylsulfate, neostigmini metilsulfas, proserinum, Glycostigmin®, Intrastigmina®, Neostig-Reu®, Normastigmin®, Prostigmin®, Prostigmina®, Prostigmine®, Stiglyn®, or Tilistigmin®.

Storage/Stability
Neostigmine bromide tablets should be stored at room temperature in tight containers. Neostigmine methylsulfate injection should be stored at room temperature and protected from light; avoid freezing.

Neostigmine methylsulfate injection is reportedly physically compatible with the commonly used IV replacement solutions and the following drugs: glycopyrrolate, pentobarbital sodium, and thiopental sodium.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Neostigmine Methylsulfate Injection: 1:1000 (1 mg/mL) in 10 mL vials, 1:2000 (0.5 mg/mL) in 1 mL amps & 10 mL vials, 1:4000 (0.25 mg/mL) in 1 mL amps; Prostigmin® (ICN); generic; (Rx)
- Neostigmine Bromide Oral Tablets: 15 mg; Prostigmin® (Valeant Pharmaceuticals); (Rx)

References

NIACINAMIDE (NICOTINAMIDE)
(nye-a-sin-a-mide)
IMMUNOMODULATOR; NUTRITIONAL

Prescriber Highlights

- Used in canine medicine in combination with tetracycline for treatment of discoid lupus erythematosus; may be useful in other immune-mediated dermatologic conditions such as sterile pyogranulomas, idiopathic onychodystrophy, pemphigus foliaceous, & pemphigus erythematosus. Not believed to be effective (w/tetracycline) for atopic dermatitis.
- Possible Contraindications: Liver disease, active peptic ulcers, or hypersensitivity to it
- Adverse Effects: Anorexia, vomiting, & lethargy; occasionally increases in liver enzymes seen
- Improvement may be gradual & take 6–8 weeks
- Inexpensive

Uses/Indications

When used in conjunction with tetracycline in dogs, niacinamide may be useful in controlling discoid lupus erythematosus (subacute cutaneous lupus) and pemphigus erythematosus in 25% to 65% of affected dogs. Can also be used for adjunctive therapy for pemphigus foliaceus (with prednisone and azathioprine). May also be used in other dermatoses such as: vesicular cutaneous lupus erythematosus, lupoid onychodystrophy, dermatomyositis, German Shepherd Dog metatarsal fistulae, sterile granulomatous and/or pyogranulomatous dermatitis and/or panniculitis, vasculitis, cutaneous histiocytosis, sebaceous adenitis, and arteritis of the nasal phillum (Bruner 2006). It may make take 1–2 months before efficacy is noted.

Pharmacology/Actions

While niacinamide is an essential nutrient in humans (necessary for lipid metabolism, tissue respiration, and glycoenolysis) its primary pharmacologic use (in veterinary medicine) is as an immunomodulator/antinflammatory in the treatment of cutaneous lupus erythematosus.
While niacinamide is an essential nutrient in humans (necessary for lipid metabolism, tissue respiration, and glycogenolysis) its primary pharmacologic use (in combination with tetracycline for discoid lupus erythematosus) in dogs is secondary to its action of blocking IgE-induced histamine release and degranulation of mast cells. When used with tetracycline, niacinamide may suppress leukocyte chemotaxis secondary to complement activation by antibody-antigen complexes. It also inhibits phosphodiesterases and decreases the release of proteases. In combination with tetracycline’s immunomodulating and antiinflammatory effects, efficacy has been noted in up to two-thirds of dogs treated for DLE. While niacinamide and niacin act identically as vitamins, niacinamide does not affect blood lipid levels or the cardiovascular system.

**Pharmacokinetics**
Niacinamide is absorbed well after oral administration and widely distributed to body tissues. Niacinamide is metabolized in the liver to several metabolites that are excreted into the urine. At physiologic doses, only a small amount of niacinamide is excreted into the urine unchanged, but as dosages increase, larger quantities are excreted unchanged.

**Contraindications/Precautions/Warnings**
In humans, niacinamide therapy is contraindicated in patients with liver disease, active peptic ulcers, or hypersensitivity to the drug. Use niacinamide/tetracycline with caution in dogs with a seizure history.

**Adverse Effects**
Adverse effects of niacinamide in dogs are uncommon, but may include anorexia, vomiting, and lethargy. Occasionally, increases in liver enzymes may be noted. There have been some anecdotal reports of increased seizure frequencies in dogs.

**Reproductive/Nursing Safety**
While niacinamide alone should be safe to use in pregnant and lactating animals, its use in combination with tetracycline may not be safe.

**Overdosage/Acute Toxicity**
There is unlikely to be a problem with niacinamide overdoses other than acute GI distress.

**Drug Interactions**
Niacinamide and tetracycline treatment does not interfere with antibody production associated with routine vaccinations in dogs. Also see the tetracycline monograph for additional drug interactions if using combination therapy.

The following drug interactions have either been reported or are theoretical in humans or animals receiving niacinamide and may be of significance in veterinary patients:

- **INSULIN/ORAL ANTIDIABETIC AGENTS:** In diabetic humans, dosage adjustments for insulin or oral antidiabetic agents have sometimes been necessary after initiating niacinamide therapy.

**Doses**

- **DOGS:**
  - For discoid lupus erythematosus:
    - a) For dogs weighing 10 kg or more: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing from 5–10 kg: 250 mg of each drug PO q8h. For dogs weighing less than 5 kg: 100 mg of each drug PO q8h. Improvement is usually noted within 6 weeks. (White 2000))
    - b) Dogs weighing more than 10 kg: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing less than 10 kg: 250 mg of each PO q8h. May use in combination with corticosteroids and Vitamin E. If adverse effects become a problem, reduce dose of niacinamide first. May also try this regimen for pemphigus foliaceous or pemphigus erythematosus (approximately (Campbell 1999)
  - For various immune-mediated diseases (discoid lupus erythematosus, pemphigus erythematosus, pemphigus foliaceous, vasculitis, sterile pyelgranuloma, dermatomyositis, and lupoid onychodystrophy):
    - a) For dogs less than 10 kg: 250 mg each of niacinamide and tetracycline PO three times daily.
    - For dogs larger than 10 kg: 500 mg each of niacinamide and tetracycline PO three times daily. May substitute doxycycline for tetracycline at 5 mg/kg PO once a day. (Tapp 2002)
    - b) For pemphigus foliaceous: Doses as above (with prednisone and azathioprine). Dogs that show improvement with this therapy do so within the first one or two months of therapy. Once remission has occurred the dose may be gradually tapered to once daily administration. (Marsella 2008)
    - c) For adjunctive therapy for pemphigus or discoid lupus erythematosus: 100 mg of each for dogs <5kg; 250 mg of each for dogs 5-10 kg; 500 mg of each for dogs >10 kg PO three times daily until resolve (90-120 days), then decrease by one dose per day per month (three times daily to two times daily to once daily and eventually to every other day for 30–60 days.) (Yu 2008)

**Monitoring**
- **Efficacy**
- **Adverse effects (baseline and occasional monitoring of liver enzymes is suggested)**

**Client Information**
- Give as directed. Improvement may not be noted for 6–8 weeks.
- If dog’s condition deteriorates or if adverse effects are a problem, contact veterinarian.

**Chemistry/Synonyms**
Niacinamide, also commonly known as nicotinamide, occurs as a white crystalline powder. It is odorless or nearly odorless and has a bitter taste. It is freely soluble in water or alcohol.

Niacinamide may also be known as: nicotinamide, nicotinamidum, nicotinic acid amide, nicotylamide, Vitamin B(3), or Vitamin PP.

**Storage/Stability**

---

While the text briefly mentions the involvement of niacinamide in various physiologic processes and its use in treating several skin diseases in dogs, the primary focus is on understanding its pharmacokinetics, contraindications, adverse effects, drug interactions, and dosages. The inclusion of specific dosing recommendations for different conditions highlights the importance of precise administration to achieve effective treatment outcomes. Additionally, the cautionary notes regarding the use of niacinamide in combination with corticosteroids underscore the need for careful consideration of potential drug interactions. The text concludes with a discussion on monitoring for efficacy and adverse effects, emphasizing the importance of regular surveillance to ensure safe and effective treatment.
Store niacinamide tablets in tight containers at room temperature unless otherwise labeled. Niacinamide is incompatible with alkalis or strong acids.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Niacinamide (Nicotinamide) Tablets: 100 mg & 500 mg; generic; (OTC)

**References**

**NITAZOXANIDE**

(nty-tah-ox-ah-nide) Navigator®

**ANTIPARASITIC AGENT**

**Prescriber Highlights**

- Drug that has activity against a variety of protozoa, nematodes, bacteria, & trematodes, including *Sarcocystis neurona*, giardia, cryptosporidia, & *Helicobacter pylori*
- Was approved for use in horses (EPM), but veterinary paste no longer marketed
- Interest in using in other companion animals (e.g., dogs, cats), but data is lacking to support use
- Adverse effects in dogs (GI, hypersalivation) may be therapy limiting; but very well tolerated in humans

**Uses/Indications**

Nitazoxanide may be useful as an alternative treatment for cryptosporidia in cats. In humans, nitazoxanide is FDA-approved for use in treating diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia* in pediatric patients from ages 1 to 11 years old. Because of the drug’s spectrum of activity and apparent safety, there is considerable interest in using it in a variety of companion animal species, but data is lacking for specific indications and dosages.

Nitazoxanide oral paste was approved for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*, but is no longer marketed in the USA.

**Pharmacology**

While the precise mechanism of action of nitazoxanide is unknown, its active metabolites tizoxanide and tizoxanide glucuronide, are thought to inhibit the pyruvate:ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reactions essential to anaerobic energy metabolism. Nitazoxanide has activity against a variety of protozoa, nematodes, bacteria, and trematodes, including *Sarcocystis neurona*, giardia, cryptosporidia, and *Helicobacter pylori*.

**Pharmacokinetics**

Following oral administration in horses, nitazoxanide is absorbed and rapidly converted to tizoxanide (desacetyl-nitazoxanide). Peak levels of tizoxanide are attained between 2–3 hours and are not detectable by 24 hours post dosing. In humans, nitazoxanide is not detectable in plasma, but peak levels of tizoxanide and tizoxanide glucuronide occur about 3–4 hours post dose. More than 99% of tizoxanide is bound to plasma proteins. Tizoxanide is excreted in the urine, bile, and feces; the glucuronide metabolite is secreted in the urine and bile.

**Contraindications/Precautions/Warnings**

In horses, the drug was labeled as contraindicated in horses less than one year of age and those that are sick or debilitated for reasons other than EPM. The drug should be used with caution in stallions and other horses predisposed to developing laminitis. Safety for use in animals with compromised renal or hepatic function has not been established; use with caution. The manufacturer has not evaluated nitazoxanide in horses weighing more than 545 kg (1200 lbs).

**Adverse Effects**

In horses, the following adverse effects are most commonly reported: fever, reduced appetite/anorexia, and lethargy/depression. Other adverse effects include decreased gut sounds, scant feces, loose/malodorous or discolored feces/diarrhea, colic, laminitis, increased water consumption, discolored urine, head and/or limb edema, or weight loss. The manufacturer states that stallions may be more prone to developing laminitis than either geldings or mares.

Nitazoxanide may disrupt normal flora in the horse leading to enterocolitis. If patient develops any of the following: a high fever (>103°F), scant or loose feces, diarrhea, colic, or signs of laminitis, nitazoxanide treatments should be stopped immediately and appropriate veterinary care be initiated.

A so-called “treatment crisis” may develop, particularly early in therapy (first two weeks) and is thought to be caused by CNS inflammation secondary to death or dying protozoa. Common signs include neurological deficits, fever, lethargy, and decreasing appetite. Treatment with antiinflammatory agents may be indicated. Treatment may continue if horse is closely monitored for other adverse reactions (e.g., anorexia, diarrhea, colic, laminitis).

In a study using nitazoxanide in dogs with naturally occurring *Giardia* spp. infections, 5 of 9 in the study developed excessive salivation, vomiting, or diarrhea that resulted in removal from the study (Lappin et al. 2008).

In humans, nitazoxanide appears to be well tolerated and adverse effect rates are similar to placebo. Rarely, sclera may turn yellow secondary to drug disposition, but return to normal after drug discontinuation.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Niacinamide (Nicotinamide) Tablets: 100 mg & 500 mg; generic; (OTC)
Reproductive/Nursing Safety

The reproductive safety of nitazoxanide has not been determined in breeding stallions or in breeding or lactating mares. In pregnant humans, nitazoxanide is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Nitazoxanide did not affect male or female fertility in rats given approximately 66 times the human dose. It did not cause fetal harm in pregnant rats or rabbits given 48 times and 3 times the human dose, respectively. It is unknown if tizoxanide is excreted into milk.

Overdosage/Acute Toxicity

There is limited information available on the acute toxicity of nitazoxanide. It has been reported that overdoses of 2.5X in horses has been associated with fatalities. The oral LD₅₀ for cats and dogs is greater than 10 grams/kg. Repeated doses of 450 mg/kg in rats caused intense salivation and increased liver and spleen weights. In horses given approximately 5 times the labeled dose, all developed anorexia, diarrhea, and lethargy, and testing was halted after 4 days of study. Human volunteers have taken doses of up to 4 grams without significant adverse effects occurring. In the event of an overdose, it is suggested to observe the patient closely and treat adverse effects in a supportive manner.

Drug Interactions

No specific drug interactions have been noted to date, but the veterinary and human manufacturers warn to use with caution if the patient is receiving other drugs that are highly protein bound and with a narrow therapeutic index.

Laboratory Considerations

- No specific laboratory interactions or considerations noted.

Doses

HORSES:

For equine protozoal myeloencephalitis (EPM) caused by Sarcocystis neurona:

a) For a 28 day course of therapy: Days 1–5: 25 mg/kg (11.36 mg/lb) PO once daily; Days 6–28: 50 mg/kg (22.72 mg/lb) PO once daily. See directions for use in client information section that follows. (Package insert; Navigator®—Idexx). Note: Product has been withdrawn from the US market.

b) As a potentially effective therapy for relapsing EPM: Extend the treatment regimen from 28 to 56 days. (MacKay 2008)

CATS:

For cryptosporidia-associated diarrhea:

a) 25 mg/kg PO q12-24h. No drug is consistently effective. In cats, Cryptosporidium spp. associated diarrhea sometimes resolves after administration of tylosin, paromomycin, or nitazoxanide. (Lappin 2008)

Monitoring

- Clinical efficacy
- Weekly body weight
- Adverse reactions; if adverse reactions occur, the manufacturer recommends performing a physical exam, CBC, serum albumin, total serum protein and body weight.

Client Information

- For use in small animals, clients should understand that this drug has not been commonly used in dogs or cats and adverse effects may occur.

Chemistry/Synonyms

A nitrothiazolyl-salicylamide derivative antiparasitic agent, nitazoxanide occurs as a light yellow powder. It is slightly soluble in ethanol and practically insoluble in water.

Nitazoxanide may also be known as: PH-5776, Alinia®, Daxon®, Heliton®, and Navigator®.

Storage/Stability

The human-approved powder for oral suspension should be stored at 25°C (77°F); excursions permitted to 15–30°C (59–86°F). Once suspended with tap water, the oral suspension should be kept in tightly closed containers at room temperature and discarded after 7 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None. Nitazoxanide oral paste (32%); Navigator® was FDA-approved in the USA for horses, but the drug is no longer manufactured or marketed and approval has been withdrawn.

HUMAN-LABELED PRODUCTS:

Nitazoxanide Oral Tablets: 500 mg; Alinia® (Romark Laboratories); (Rx)

Nitazoxanide Powder for Oral Suspension: 20 mg/mL (100 mg/5 mL after reconstitution) in 60 mL; Alinia® (Romark Laboratories); (Rx)

References

Prescriber Highlights

- Oral insecticide used primarily as a flea adulticide in dogs & cats; may also have efficacy for other conditions (e.g., maggots)
- Very safe
- Not effective alone for flea eggs or other immature forms
- Over-the-counter

Uses/Indications
Nitenpyram is indicated as a flea adulticide in dogs and cats. It does not kill ticks, flea eggs, larvae or immature fleas. Nitenpyram may be effective for treating fly larvae (maggots) of various species. Fleas begin to fall from treated animals about 30 minutes after dosing and a single dose can protect animals for 1–2 days.

Pharmacology/Actions
Nitenpyram is in the class of neonicotinoid insecticides. It enters the systemic circulation of the adult flea after consuming blood from a treated animal. It binds to nicotinic acetylcholine receptors in the postsynaptic membranes and blocks acetylcholine-mediated neuronal transmission causing paralysis and death of the flea. Nitenpyram is 3500 times more selective for insect alpha-4beta-2 nicotinic receptors than in vertebrate receptors. It does not inhibit acetylcholinesterase. Efficacy appears to be greater than 99% (kill rate) in dogs or cats within 3-6 hours of treatment. When combined with an insect growth regulator (e.g., lufenuron), immature stages of fleas may also be controlled.

Pharmacokinetics
Nitenpyram is rapidly and practically completely absorbed after oral administration. Peak levels occur about 80 minutes after dosing in dogs; about 40 minutes in cats. Elimination half-lives are about 3 hours for dogs; 8 hours for cats. Nitenpyram is excreted primarily unchanged in the urine. In dogs, about 3% of a dose is excreted in the feces; in cats about 5% is excreted in the feces.

Contraindications/Precautions/Warnings
Nitenpyram is not labeled to be used in animals under 2 pounds of body weight or under 4 weeks of age.

Adverse Effects
Nitenpyram is tolerated well. As fleas begin to die, animal may begin scratching. This effect is temporary and due to the fleas and not the medication.

Reproductive/Nursing Safety
Nitenpyram is probably safe to use in breeding, pregnant, or lactating animals.

Overdosage/Acute Toxicity
Nitenpyram is relatively safe in high dosages to mammals. The oral LD50 in rats is approximately 1.6 grams/kg. Cats or dogs given 10 times the usual dose for 14 days showed no untoward effects. In the circumstance of a massive overdose, contact an animal poison control center for additional guidance.

Drug Interactions
No specific drug interactions were located. Nitenpyram has reportedly been used safely with a variety of other medications and other flea products.

Laboratory Considerations
- No specific laboratory interactions or considerations noted.

Doses
**DOGS:**

- As a flea adulticide:
  - a) For dogs weighing 2–25 lb. (0.9–11.36 kg): Give one 11.4 mg tablet PO. May be given as often as once per day. For dogs weighing 25–125 lb. (11.36–56.8 kg): Give one 57 mg tablet PO. May be given as often as once per day. May be given with or without food. (Label directions; Capstar®—Novartis)

**CATS:**

- As a flea adulticide:
  - a) For cats weighing 2–25 lb. (0.9–11.36 kg): Give one 11.4 mg tablet PO. May be given as often as once per day. May be given with or without food. (Label directions; Capstar®—Novartis)

**REPTILES:**

- a) For maggots: crush one 11.4 mg tablet into powder and give PO, as an enema, or on wound one time. (Klaphake 2005)

Monitoring

- Efficacy

Client Information

- All animals in household should be treated.

Best dosed after a meal to increase absorption
Best dosed after a meal to increase absorption
Because nitenpyram does not kill immature fleas, eggs, etc., it is usually used in combination with other products that will control those forms of fleas.
Keep tablets out of reach of children.

Chemistry/Synonyms
A neonicotinoid insecticide, nitenpyram occurs as a pale yellow crystalline powder and is very soluble in water (840 mg/mL)  
Nitenpyram may also be known as: TI-304, (E)-Nitenpyram, Bestguard®, and Capstar®.

Storage/Stability
Commercially available nitenpyram tablets should be stored at room temperature (15–30°C; 59–86°F). Shelf life is reported to be 3 years if stored below 25°C (76°F).

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Nitenpyram Oral Tablets: 11.4 mg and 57 mg in boxes containing blister packs of 6 tablets; Capstar® (Novartis); (OTC); FDA-approved for use in dogs and cats. Also available in combination packs with Lufenuron [Program® Flavor Tabs and Capstar® Flea Management System for Dogs and Program® Flavor Tabs (OTC); and Capstar® Flea Management System for Cats (OTC)] and in combination with milbemycin and lufenuron [Sentinel® Flavor Tabs and Capstar® Flea Management System for Dogs (Rx)].

**HUMAN-LABELED PRODUCTS:** None

References

---

**NITROFURANTOIN**
(nye-tree-foor-an-toyn) Macrodantin®, Macrobid®

**URINARY ANTIMICROBIAL**

**Prescriber Highlights**

- Antibacterial used for susceptible UTI’s
- Contraindications: Renal impairment; hypersensitivity to it
- Adverse Effects: Gastrointestinal disturbances & hepatopathy of most concern; may cause infertility in males or peripheral neuropathy
- Potentially teratogenic, may be toxic to neonates

---

**Uses/Indications**
Considered a urinary tract antiseptic, nitrofurantoin is used primarily in small animals, but also occasionally in horses in the treatment of lower urinary tract infections caused by susceptible bacteria. It is not effective in treating renal cortical or perinephric abscesses or other systemic infections.

**Pharmacology/Actions**
Nitrofurantoin usually acts as a bacteriostatic antimicrobial, but it may be bactericidal depending on the concentration of the drug and the susceptibility of the organism. The exact mechanism of action of nitrofurantoin has not been fully elucidated, but the drug apparently inhibits various bacterial enzyme systems, including acetyl coenzyme A. Nitrofurantoin has greater antibacterial activity in acidic environments.

Nitrofurantoin has activity against several gram-negative and some gram-positive organisms, including many strains of *E. coli*, Klebsiella, Enterobacter, Enterococci, *Staphylococcus aureus* and *epidermidis*, Enterobacter, Citrobacter, Salmonella, Shigella, and Corynebacterium. It has little or no activity against most strains of Proteus, Serratia, or Acinetobacter and has no activity against *Pseudomonas* spp.

**Pharmacokinetics**
Nitrofurantoin is rapidly absorbed from the GI tract and the presence of food may enhance the absorption of the drug. Macrocystalline forms of the drug may be absorbed more slowly with less GI upset. Because of its slower absorption, urine levels of the drug may be prolonged.

Therapeutic levels in the systemic circulation are not maintained due to the rapid elimination of the drug after absorption. Approximately 20–60% of the drug is bound to serum proteins. Peak urine levels occur within 30 minutes of dosing. The drug crosses the placenta and only minimal quantities of the drug are found in milk. Approximately 40–50% of the drug is eliminated into urine unchanged via both glomerular filtration and tubular secretion. Some of the drug is metabolized, primarily in the liver. Elimination half-lives in humans with normal renal function average 20 minutes.

**Contraindications/Precautions/Warnings**
Nitrofurantoin is contraindicated in patients with renal impairment as the drug is much less efficacious and the development of toxicity is much more likely. The drug is also contraindicated in patients hypersensitive to it.

Rats can develop neurotoxicity when given nitrofurantoin; avoid use.

**Adverse Effects**
In dogs and cats, gastrointestinal disturbances (primarily vomiting) and hepatopathy can occur with this drug. Rarely, reversible myasthenic-like effects have been seen in dogs. Neuropathies, chronic active hepatitis, hemolytic anemia, and pneumonitis have been described in humans, but are believed to occur very rarely in animals.
Reproductive/Nursing Safety

In humans, the drug is contraindicated in pregnant patients at term and neonates as hemolytic anemia can occur secondary to immature enzyme systems. Safe use of the drug during earlier stages of pregnancy has not been determined. Nitrofurantoin has been implicated in causing infertility in male dogs. Use only when the benefits of therapy outweigh the potential risks.

Nitrofurantoin is excreted into maternal milk in very low concentrations. Safety for use in the nursing mother or offspring has not been established.

Overdosage/Acute Toxicity

No specific information was located. Because the drug is rapidly absorbed and excreted, patients with normal renal function should require little therapy when mild overdoses occur. If the ingestion was relatively recent, massive overdoses should be handled by emptying the gut using standard protocols; patient should then be monitored for adverse effects (see above).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitrofurantoin and may be of significance in veterinary patients:

- **FLUOROQUINOLONES** (*e.g.*, enrofloxacin, ciprofloxacin): Nitrofurantoin may antagonize the antimicrobial activity of the fluoroquinolones and concomitant use is best avoided.
- **FOOD or ANTICHOLINERGIC DRUGS** may increase the oral bioavailability of nitrofurantoin.
- **MAGNESIUM TRISILICATE CONTAINING ANTACIDS**: May inhibit the oral absorption of nitrofurantoin.
- **PROBENECID**: May inhibit the renal excretion of nitrofurantoin potentially increasing its toxicity and reducing its effectiveness in urinary tract infections.

Laboratory Considerations

- Nitrofurantoin may cause false-positive **urine glucose** determinations if using cupric-sulfate solutions (Benedict’s reagent, **Clinitest®**). Tests using glucose oxidase methods (**Tes-Tape®**, **Clinistix®**) are not affected by nitrofurantoin.
- Nitrofurantoin may cause decreases in **blood glucose**, and increases in **serum creatinine, bilirubin** and **alkaline phosphatase**.

Doses

**DOGS:**

For susceptible bacterial urinary tract infections:

- a) For prevention of re-infections with gram-negative organisms: nitrofurantoin 4 mg/kg PO once a day immediately before bedtime after the dog has urinated. May rarely cause drug-induced hepatopathy and liver enzymes should be evaluated if any adverse effects are suspected. Preventative therapy for repeated reinfection (> 2 per 6 months) should only be utilized after an extensive search for any underlying cause. This approach will not resolve existing UTI and should only be used after effective treatment using full therapeutic doses. (Adams 2009)
- b) For recurrent UTI: Conventional dose: 4 mg/kg, PO q8h; Prophylactic dose: 3–4 mg/kg, PO q24h (should be given at night after micturition and immediately before bedtime) (Polzin & Osborne 1985)
- c) 4 mg/kg PO q6–8h (Brovida 2003)
- d) 5 mg/kg PO q8h (Dowling 2007; Dowling 2009)
- e) 4.4 mg/kg PO three times daily (Senior 2005)

**CATS:**

For susceptible bacterial urinary tract infections:

- a) 5 mg/kg PO q8h (Dowling 2007; Dowling 2009)
- b) For recurrent UTI: Conventional dose: 4 mg/kg, PO q8h; Prophylactic dose: 3–4 mg/kg, PO q24h (should be given at night after micturition and immediately before bedtime) (Polzin & Osborne 1985)
- c) 4 mg/kg PO q6–8h (Brovida 2003)

**HORSES:**

For susceptible urinary tract infections:

- a) 2.5–4.5 mg/kg, PO three times daily (Robinson 1987)
- b) 10 mg/kg, PO daily (Huber 1988)

Monitoring

- Clinical efficacy
- Adverse effects
- Periodic liver function tests should be considered with chronic therapy

Chemistry/Synonyms

A synthetic, nitrofuran antibacterial, nitrofurantoin occurs as a bitter tasting, lemon-yellow, crystalline powder with a pKa of 7.2. It is very slightly soluble in water or alcohol.

Nitrofurantoin may also be known as: furadoninium or nitrofurantoinum, **Furadantin®**, **Macrobid®**, and **Macrodantin®**.

Storage/Stability

Nitrofurantoin preparations should be stored in tight containers at room temperature and protected from light. The oral suspension should not be frozen. Nitrofurantoin will decompose if it comes into contact with metals other than aluminum or stainless steel.
VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Nitrofurantoin Macrocrystals Oral Capsules: 25 mg, 50 mg & 100 mg (as macrocrystals) and 100 mg (as monohydrate/macrocrystals); Macrodantin® and Macrobid® (Procter & Gamble); generic; (Rx)

Nitrofurantoin Oral Suspension: 5 mg/mL (25 mg/5 mL) in 470 mL; Furadantin® (Sciele); (Rx)

References

NITROGLYCERIN, TOPICAL

(ye-true-gli-ser-in) NTG, Nitro-bid®, Minitran®

VENODILATOR

Prescriber Highlights

- Topical, oral, & injectable venodilator; occasionally used topically in veterinary medicine for CHF or hypertension
- Contraindications: anemia or hypersensitivity to nitrates. Caution: cerebral hemorrhage or head trauma, diuretic-induced hypovolemia, or other hypotensive conditions.
- Continuous use results in tolerance after 48–72 hours
- Adverse Effects: rashes at the application sites & orthostatic hypotension; transient headaches common in humans & may be a problem for some animals
- Rotate application sites
- Wear gloves when applying; avoid human skin contact

Uses/Indications

Topical nitroglycerin (NTG) in small animal medicine is used primarily as an adjunctive vasodilator in heart failure and cardiogenic edema. Because of questionable efficacy and rapid development of tolerance, nitroglycerine is not commonly used as an outpatient drug in veterinary medicine today. In humans, NTG is also used as an anti-anginal agent, antihypertensive (acute), and topically to treat Raynaud’s disease.

Pharmacology/Actions

Nitroglycerin relaxes vascular smooth muscle primarily on the venous side, but a dose related effect on arterioles is possible. Preload (left end-diastolic pressure) is reduced from the peripheral pooling of blood and decreased venous return to the heart. Because of its arteriolar effects, depending on the dose, afterload may also be reduced. Myocardial oxygen demand and workload are reduced and coronary circulation can be improved.

Pharmacokinetics

Nitroglycerin topical ointment is absorbed through the skin, with an onset of action usually within 1 hour and duration of action of 2–12 hours. It is generally dosed in dogs and cats q6–8 hours (three to four times a day). The transdermal patches have a wide inter-patient bioavailability. Nitroglycerin has a very short half-life (1–4 minutes in humans) and is metabolized in the liver. At least two metabolites have some vasodilator activity and have longer half-lives than NTG.

Contraindications/Precautions/Warnings

Nitrates are contraindicated in patients with severe anemia or those hypersensitive to them. They should be used with caution (if at all) in patients with cerebral hemorrhage or head trauma, diuretic-induced hypovolemia or other hypotensive conditions.

Adverse Effects

Most common side effects seen are rashes at the application sites and orthostatic hypotension. If hypotension is a problem, reduce dosage. Transient headaches are a common side effect seen in humans and may be a problem for some animals.

Continuous use (48–72 hours) of nitroglycerin results in the rapid development of tolerance to the effects of the drug.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

It is not known whether nitrates are excreted in maternal milk; use with caution in nursing animals.

Overdosage/Acute Toxicity
Overdosage/Acute Toxicity
If severe hypotension results after topical administration, wash the site of application to prevent any more absorption of ointment. Fluids may be administered if necessary. Epinephrine is contraindicated as it is ineffective and may complicate the animal’s condition.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroglycerin and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS, OTHER**: Use of nitroglycerin with other antihypertensive drugs may cause additive hypotensive effects
- **PHENOTHIAZINES**: May increase hypotensive effects
- **SILDENAFIL (and other PDE INHIBITORS)**: May profoundly increase risk for hypotension

Doses

**Note**: For the treatment of heart failure, nitroglycerin is not generally used alone.

**DOGS**:

For adjunctive treatment of heart failure:

a) If nitroprusside not used, 2% NTG at ¼ to 1 inch q6–12h; apply to hairless area in the axilla or groin. (Macintire 2006)
b) Using the 2.5–10 mg/24hr transdermal patch: 12 hours on, 12 hours off (Fox 2003)
c) For adjunctive treatment of pulmonary edema: ¼–2 inches every 8 hours is applied cutaneously or directly to mucous membranes every 8 hours during the first 48 hours (all animals tolerate the paste given orally). (Lichtenberger 2009)
d) For any patient with cardiogenic pulmonary edema that is headed for oxygen: ¼ inch for small dogs up to 1 inch for large dogs on the inner ear pinnae, groin or axilla as needed q8h for the first 24 hours. Wear gloves to apply. (DeFrancesco 2006)
e) As a venodilator for the adjunctive treatment of systolic heart failure: ¼ inch per 5 kg of body weight of the 2% ointment applied topically three times daily for the first 24 hours. (Atkins 2007)

**CATS**:

For adjunctive treatment of heart failure:

a) Topical nitroglycerin might be beneficial in cats with severe pulmonary edema secondary to feline HCM; however, no studies have examined any effects of this drug in this species and its efficacy is suspect. But it is safe and some benefit may occur with its administration in some cats. ⅛th to ¼ inch of a 2% cream applied to a hairless area (e.g., inside the earflap) every 4–6 hours for the first 24 hours as long as furosemide is being administered concomitantly. Never rely on NTG to produce a beneficial effect and use is by no means mandatory. Tolerance develops rapidly in other species and probably does so in the cat, so prolonged administration is probably of even lesser benefit. Person applying should use gloves and avoid contact with the product. (Kittleson 2009).
b) To enhance resolution of pulmonary edema: ¼ to ½ inch topically q6h; to reduce nitrate tolerance, alternate 12 hrs with and 12 hrs without nitroglycerin therapy. (Fox 2007)
c) Using the 2.5–5 mg/24hr transdermal patch: 12 hours on, 12 hours off (Fox 2003)
d) For adjunctive treatment of pulmonary edema: ¼ inch every 8 hours is applied cutaneously or directly to mucous membranes every 8 hours during the first 48 hours (all animals tolerate the paste given orally). (Lichtenberger 2009)
e) For any patient with cardiogenic pulmonary edema that is headed for oxygen: ¼ inch on the inner ear pinnae, groin or axilla as needed q8h for the first 24 hours. Wear gloves to apply. (DeFrancesco 2006)

For adjunctive treatment of hypertension:

a) ¼ inch applied to pinna q6–8h (Norsworthy 2007)

**FERRETS**:

For adjunctive therapy for heart failure:

a) ⅛th inch strip applied to inside of pinna q12h for the first 24 hours of therapy (Hoeffer 2000)
b) For dilative cardiomyopathy: ⅛th of an inch applied to shaved skin once to twice daily. Apply to ear pinna or skin of thigh. May cause hypotension. (Williams 2000)

Monitoring

- Clinical efficacy
- Sites of application for signs of rash
- Blood pressure, particularly if hypotensive effects are seen

Client Information

- Dosage is measured in inches of ointment; use papers supplied with product to measure appropriate dose. Wear gloves (non-permeable) when applying.
- Do not pet animal where ointment has been applied
- Rotate application sites. Recommended application sites include: groin, inside the ears, and thorax. Rub ointment into skin well. If rash develops, do not use that site again until cleared.
- Contact veterinarian if rash persists or animal’s condition deteriorates
- There is no danger of explosion or fire with the use of this product

Chemistry/Synonyms

Famous as an explosive, nitroglycerin (NTG) occurs undiluted as a thick, volatile, white-pale yellow flammable, explosive liquid with a sweet, burning taste. The undiluted drug is soluble in alcohol and slightly soluble in water. Because of obvious safety reasons, nitroglycerin is diluted with lactose, dextrose, propylene glycol, and other inert ingredients.
Nitroprusside is an immediate acting intravenous hypotensive agent that directly causes peripheral vasodilation (arterial and venous) independent of autonomic innervation. It produces a lowering of blood pressure, an increase in heart rate, a mild decrease in cardiac output, and a significant reduction in total peripheral resistance. The use of nitroprusside in small animal medicine is practically limited to the use of topical ointment or transdermal patches, those other dosage forms are not listed here.

### Uses/Indications
In human medicine, nitroprusside is indicated for the management of hypertensive crises, acute heart failure secondary to mitral regurgitation, and severe refractory CHF (often in combination with dopamine or dobutamine). In patients with dilated cardiomyopathy, administering dobutamine first to improve contractility and increase cardiac output can offset the hypotensive effects of sodium nitroprusside (Erling & Mazzaferro 2008). Its use in veterinary medicine is generally reserved for the treatment of critically ill patients with those conditions only when constant blood pressure monitoring can be performed.

### Pharmacology/Actions
Nitroprusside is an immediate acting intravenous hypotensive agent that directly causes peripheral vasodilation (arterial and venous) independent of autonomic innervation. It produces a lowering of blood pressure, an increase in heart rate, a mild decrease in cardiac output, and a significant reduction in total peripheral resistance. Preload, afterload and left ventricular end-diastolic pressures are reduced. Unlike the organic nitrates, tolerance does not develop to nitroprusside.

### Pharmacokinetics
After starting an IV infusion of nitroprusside, reduction in blood pressure and other pharmacologic effects begin almost immediately. Blood pressure will return to pretreatment levels within 1-10 minutes following cessation of therapy.

Nitroprusside is metabolized non-enzymatically in the blood and tissues to cyanogen (cyanide radical). Cyanogen is converted in the liver to thiocyanate where it is eliminated in the urine, feces, and exhaled air. The half-life of cyanogen is 2.7-7 days if renal function is normal, but prolonged in patients with impaired renal function.

### DOSAGE FORMS/REGULATORY STATUS

#### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

**Note:** Many dosage forms of nitroglycerin are available for human use, including sublingual tablets, buccal tablets, lingual spray, extended-release oral capsules and tablets, and parenteral solutions for IV infusion. Because the use of nitroglycerin in small animal medicine is practically limited to the use of topical ointment or transdermal patches, those other dosage forms are not listed here.

**Nitroglycerin Topical Ointment:** 2% in a lanolin-white petrolatum base in 30 gram & 60 gram tubes and UD 1 gram; **Nitro-bid®** (Savage); generic; **(Rx)**

Nitroglycerin Transdermal Systems (patches): 0.1 mg/hr, 0.2 mg/hr, 0.3 mg/hr, 0.4 mg/hr, 0.6 mg/hr & 0.8 mg/hr; **Minitrán®** (3M); **Nitro-Dur®** (Key); **Nitrok®** (Bertek); generic; **(Rx)**

**Note:** Various products contain differing quantities of nitroglycerin and patch surface area size, but release rates of drug are identical for a given mg/hr.

### NITROPRUSSIDE SODIUM
(nye-troe-gras-ide) Nitropress®, Sodium Nitropresside

#### VASODILATOR

#### Prescriber Highlights

- **Vascular, smooth muscle relaxant used for acute/severe hypertension; acute heart failure secondary to mitral regurgitation & in combination with dopamine for refractory CHF**
- **Contraindications:** Compensatory hypertension, inadequate cerebral circulation, or during emergency surgery in patients near death. Caution: Geriatric patients, hepatic insufficiency, severe renal impairment, hyponatremia, or hypothyroidism.
- **Adverse effects:** Hypotensive effects; potentially: nausea, retching, restlessness, apprehension, muscle twitching, dizziness
- **May be irritating at the infusion site; avoid extravasation.**
- **Continued use may lead to potential thiocyanate & cyanide toxicity**
- **Use only in an ICU setting; monitoring essential**

#### Uses/Indications
In human medicine, nitroprusside is indicated for the management of hypertensive crises, acute heart failure secondary to mitral regurgitation, and severe refractory CHF (often in combination with dopamine or dobutamine). In patients with dilated cardiomyopathy, administering dobutamine first to improve contractility and increase cardiac output can offset the hypotensive effects of sodium nitroprusside (Erling & Mazzaferro 2008). Its use in veterinary medicine is generally reserved for the treatment of critically ill patients with those conditions only when constant blood pressure monitoring can be performed.
Nitroprusside is contraindicated in patients with compensatory hypertension (e.g., AV shunts or coarctation of the aorta; Cushing’s reflex), inadequate cerebral circulation, or during emergency surgery in patients near death.

Nitroprusside must be used with caution in patients with hepatic insufficiency, severe renal impairment, hyponatremia, or hypothyroidism. When nitroprusside is used for controlled hypotension during surgery, patients may have less tolerance to hypovolemia, anemia, or blood loss. Geriatric patients may be more sensitive to the hypotensive effects of nitroprusside.

Adverse Effects
Most adverse reactions from nitroprusside are associated with its hypotensive effects, particularly if blood pressure is reduced too rapidly. Clinical signs such as nausea, retching, restlessness, apprehension, muscle twitching, and dizziness have been reported in humans. These effects disappear when the infusion rate is reduced or stopped. Nitroprusside may be irritating at the infusion site; avoid extravasation.

Continued use may lead to potential thiocyanate and cyanide toxicity (see Overdosage section).

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

It is not known whether nitroprusside and its metabolites are excreted in maternal milk.

Overdosage/Acute Toxicity
Acute overdosage is manifested by a profound hypotension. Treat by reducing or stopping the infusion and giving fluids. Monitor blood pressure constantly.

Excessive doses, prolonged therapy, a depleted hepatic thiosulfate (sulfur) supply, or severe hepatic or renal insufficiency may lead to profound hypotension, cyanogen, or thiocyanate toxicity. Acid/base status should be monitored to evaluate therapy and to detect metabolic acidosis (early sign of cyanogen toxicity). Tolerance to therapy is also an early sign of nitroprusside toxicity. Hydroxocobalamin (Vitamin B12a) may prevent cyanogen toxicity. Thiocyanate toxicity may be exhibited as delirium in dogs. Serum thiocyanate levels may need to be monitored in patients on prolonged therapy, especially in those patients with concurrent renal dysfunction. Serum levels >100 micrograms/mL are considered toxic. It is suggested to refer to other references or contact an animal poison control center for further information should cyanogen or thiocyanate toxicity be suspected.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroprusside and may be of significance in veterinary patients:

**ANESTHETICS, GENERAL:** The hypotensive effects of nitroprusside may be enhanced by concomitant administration of general anesthetics (e.g., halothane, enflurane), or other circulatory depressants

**DOBUTAMINE:** Synergistic effects (increased cardiac output and reduced wedge pressure) may result if dobutamine is used with nitroprusside

**HYPOTENSIVE AGENTS, OTHER:** Patients receiving other hypotensive agents (e.g., beta-blockers, ACE inhibitors, etc.) may be more sensitive to the hypotensive effects of nitroprusside

Doses
Directions for preparation of infusion: Add 2–3 mL D3W to 50 mg vial to dissolve powder. Add dissolved solution to 1000 mL of D5W and promptly protect solution from light (using aluminum foil or other opaque covering). Resultant solution contains 50 micrograms/mL of nitroprusside. Higher concentrations may be necessary in treating large animals. The administration set need not be protected from light. Solution may have a slight brownish tint, but discard solutions that turn to a blue, dark red or green color. Solution is stable for 24 hours after reconstitution. Do not add any other medications to IV running nitroprusside. Avoid extravasation at IV site. If using a Mini-Drip IV set (for small animals) (60 drops 1 mL; 1 drop contains approximately 0.83 micrograms of nitroprusside). Use an accurate flow control device (pump, controller, etc.) for administration.

**DOGS:**

For hypertensive crisis (systolic arterial BP >200 mm Hg):

a) Initiate dose at 1–2 micrograms/kg/minute; increase dosage incrementally every 3–5 minutes until a predetermined target BP is attained. Reduce BP 25% over 4-hour period to allow readaptation of cerebral blood vessels. (Proulx & Dhupa 2000)

For adjunctive treatment of heart failure (cardiogenic shock; fulminant pulmonary edema):

a) Goal is to decrease or maintain mean arterial pressure to support vital organ functions—approx. 70 mmHg): Dose as above (in “a”); concurrent use of dobutamine (5–10 micrograms/kg/min) often indicated. (Proulx & Dhupa 2000)

b) 0.5–10 micrograms/kg/min IV at a low fluid rate (1 to 2 mL/kg/hr) using D5W or other low sodium fluid. Usually start at 2 micrograms/kg/min and increase the base concentration by 1 microgram/kg every 20–30 minutes until there is an improvement in respiratory effort and thoracic auscultation. The patient is maintained on the effective dose for 48 hours. Monitor blood pressure; cyanide poisoning can occur if infusion lasts more than 3 days. After stabilized, drip is tapered as therapy with enapril is initiated. (Macintire 2006)

c) For catastrophic pulmonary edema: As a CRI initiated at 1 microgram/kg/min and carefully titrated to effect by increasing by 1 microgram/kg/min increments every 15 minutes as long as BP remains stable and until perfusion and pulmonary function improves (usually requires between 2–5 micrograms/kg/min with the upper limit being 8–10 micrograms/kg/min). Maintain most effective dose for 12–15 hours until respiratory distress resolves, lungs clear, and the patient is stable with a normal blood pressure, pink mucous membranes, normal capillary refill time, and normal heart rate. Most animals at our clinic require 12 hours of treatment. The systolic blood pressure must remain greater than 90 mm Hg. If hypotension develops, the CRI should be stopped. Blood pressure will return to pretreatment levels within 1–10 minutes of discontinuing treatment and administration can be reinstated at the previous lower dose. Administer with dobutamine to treat or prevent hypotension if severe myocardial failure is present based on an echocardiogram evaluation. Wear sodium nitroprusside over 6 hours first and then dobutamine over 6 hours. ACE inhibitor is added after tapering the infusions over 3–6 hours. (Lichtenberger 2006)
Nitroprusside sodium powder for injection should be stored protected from light and moisture and kept at room temperature (15–30°C). Nitroprusside solutions exposed to light will cause a reduction of the ferric ion to the ferrous ion with a resultant loss in potency and a change from a brownish-color to a blue color. Degradation is enhanced with nitroprusside solutions in Viaflex® (Baxter) plastic bags exposed to fluorescent light. After reconstitution, protect immediately by covering vial or infusion bag with aluminum foil or other opaque material. Discard solutions that turn to a blue, dark red, or green color. Solutions protected from light will remain stable for 24 hours after reconstitution. IV infusion tubing need not be protected from light while the infusion is running. It is not recommended to use IV covering vial or infusion bag with aluminum foil or other opaque material. Discard solutions that turn to a blue, dark red, or green color. Solutions protected from light will remain stable for 24 hours after reconstitution. IV infusion tubing need not be protected from light while the infusion is running. It is not recommended to use IV covering vial or infusion bag with aluminum foil or other opaque material. Discard solutions that turn to a blue, dark red, or green color. Solutions protected from light will remain stable for 24 hours after reconstitution.

Compatibility/Compounding Considerations
It is not recommended to use IV infusion solutions other than D₃W or to add any other medications to the infusion solution.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Nitroprusside Sodium Powder for Injection: 50 mg/vial in 2 mL Flitopv vials and 5 mL vials; Nitropress® (Hospira); generic; (Rx)

References

NIZATIDINE
(ni-za-tide) Axid®
H₂-RECEPTOR ANTAGONIST; PROKINETIC

Prescriber Highlights
• H₂ receptor antagonist similar to ranitidine; used primarily for its prokinetic activity; may be useful in preventing hemorrhagic necrosis in cats with
H₂ receptor antagonist similar to ranitidine; used primarily for its prokinetic activity; may be useful in preventing hemorrhagic necrosis in cats with pancreatitis. Not frequently used in veterinary medicine.

- Caution: Geriatric patients or those with hepatic or renal insufficiency
- Adverse Effects are rare

**Uses/Indications**

While nizatidine acts similarly to cimetidine and ranitidine as an H₂ blocker to reduce gastric acid secretion in the stomach, in small animal medicine its use has been primarily for its prokinetic effects. It may be useful to treat delayed gastric emptying, pseudo-obstruction of the intestine and constipation. H₂ blockers may be useful in preventing hemorrhagic necrosis in feline pancreatitis.

**Pharmacology/Actions**

At the H₂ receptors of the parietal cells, nizatidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, amino acids, pentagastrin, histamine, or insulin.

While nizatidine may cause gastric emptying times to be delayed, it more likely will stimulate GI motility by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors). It may also have direct agonist effects on M₃ muscarinic receptors. Lower esophageal sphincter pressures may be increased by nizatidine. By decreasing the amount of gastric juice produced, nizatidine decreases the amount of pepsin secreted.

**Pharmacokinetics**

In the dog, oral absorption is rapid and nearly complete with minimal first pass effect. Food can enhance the absorption of nizatidine, but this is not considered clinically important. The drug is only marginally bound to plasma proteins. It is unknown if it enters the CNS. Nizatidine is metabolized in the liver to several metabolites, including at least one that has some activity. In animals with normal renal function over half the drug is excreted in the urine unchanged.

**Contraindications/Precautions/Warnings**

Nizatidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and, possibly, at reduced dosage in patients with diminished renal function. Nizatidine has caused increased serum ALT levels in humans receiving high IV doses for longer than 5 days. The manufacturer recommends that in high dose, chronic therapy, serum ALT values be monitored.

**Adverse Effects**

Nizatidine appears to be very well tolerated. Very rarely, anemia has been reported in humans taking the drug. CNS effects have been noted (headache, dizziness) but incidence is similar to those taking placebo. Rash and pruritus have also been reported in a few humans taking nizatidine.

**Reproductive/Nursing Safety**

Doses of up to 275 mg/kg per day in pregnant rabbits did not reveal any teratogenic or fetotoxic effects. Safety during pregnancy not firmly established, so use only when clearly warranted. In humans, the FDA categorizes this drug as category B for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Nizatidine is excreted in maternal milk in a concentration of 0.1% of the oral dose in proportion to plasma concentrations and unlikely to cause significant effects in nursing offspring.

**Overdosage/Acute Toxicity**

Single oral doses of up to 800 mg/kg were not lethal in dogs. Adverse effects could include cholinergic effects (lacrimation, salivation, emesis, miosis and diarrhea); suggest treating supportively and symptomatically.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving nizatidine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS** (atropine, propantheline etc.): May negate the prokinetic effects of nizatidine

- **ASPIRIN**: Nizatidine may increase salicylate levels in patients receiving high doses of aspirin (or other salicylates)

**Laboratory Considerations**

- False positive tests for urobilinogen may occur with patients receiving nizatidine

**Doses**

- **DOGS:**
  - As a prokinetic agent:
    a) 2.5–5 mg/kg PO once daily (Hall & Washabau 2000)
  - As an H₂ blocker to reduce gastric acid production:
    a) 5 mg/kg PO once daily (dosage not well established). (Leib 2008)

- **CATS:**
  - As a colonic prokinetic agent:
    a) 2.5–5 mg/kg PO once daily (Washabau & Holt 2000)
  - In combination with cisapride: nizatidine 2.5–5 mg/kg PO q12h (Scherk 2003)

**Monitoring**

...
**Clinical efficacy** (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.

**Client Information**
- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; clinical signs may reoccur if dosages are missed.

**Chemistry/Synonyms**
Nizatidine occurs as an off-white to buff-colored crystalline powder. It has a bitter taste and a slight sulfur-like odor. Nizatidine is sparingly soluble in water.
Nizatidine may also be known as: LY-139037, nizatidinum, and Axid®.

**Storage/Stability**
Nizatidine oral tablets and capsules should be stored in tight, light-resistant containers at room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**
- Nizatidine Tablets: 75 mg; Axid® AR (Wyeth Consumer); (OTC)
- Nizatidine Capsules: 150 mg & 300 mg; Axid® Pulvules (GlaxoSmithKline); generic; (Rx)
- Nizatidine Oral Solution: 15 mg/mL in 480 mL; Axid® (Braintree); (Rx)

**References**

---

**NOVOBIOCIN SODIUM**
*(noe-ve-oh-sin) Albaplex®*

**Prescriber Highlights**
- Antibiotic primarily effective against some gram-positive cocci
- Contraindications: hypersensitivity to it; Extreme caution: hepatic or hematopoietic dysfunction
- Adverse Effects: Systemic use: Fever, GI (nausea, vomiting, diarrhea), rashes, & blood dyscrasias

**Uses/Indications**
Novobiocin is FDA-approved in combination with penicillin G for use in dry dairy cattle as a mastitis tube. Novobiocin is available in combination with tetracycline and prednisolone for oral use in dogs.

**Pharmacology/Actions**
Novobiocin is believed to act in several ways in a bactericidal manner. It inhibits bacterial DNA gyrase, interfering with protein and nucleic acid synthesis and also interferes with bacterial cell wall synthesis. Activity of the drug is enhanced in an alkaline medium.

The spectrum of activity of novobiocin includes some gram-positive cocci (Staphs, Streptococcus pneumonia, and some group A streps). Activity is variable against other streptococci and weak against the Enterococci. Most gram-negative organisms are resistant to the drug, but some *Haemophilus spp.*, *Neisseria spp.*, and *Proteus* spp. may be susceptible.

**Pharmacokinetics**
After oral administration, novobiocin is well absorbed from the GI tract. Peak levels occur within 1–4 hours. The presence of food can decrease peak concentrations of the drug.

Novobiocin is only poorly distributed to body fluids with concentrations in synovial, pleural, and ascitic fluids less than those found in plasma. Only minimal quantities of the drug cross the blood-brain barrier, even when meninges are inflamed. Highest concentrations of novobiocin are found in the small intestine and liver. The drug is approximately 90% protein bound and is distributed into milk.

Novobiocin is primarily eliminated in the bile and feces. Approximately 3% is excreted into the urine; urine levels are usually less than those found in serum.

**Contraindications/Precautions/Warnings**
Novobiocin is contraindicated in patients hypersensitive to it. Additionally, the drug should be used with extreme caution in patients with preexisting hepatic or hematopoietic dysfunction.

**Adverse Effects**
Adverse effects reported with the systemic use of this drug include fever, GI disturbances (nausea, vomiting, diarrhea), rashes, and blood dyscrasias. In humans, occurrences of hypersensitivity reactions, hepatotoxicity, and blood dyscrasias have significantly limited the use of this drug.

**References**
Reproductive/Nursing Safety
Safety during pregnancy has not been established; use only when clearly indicated.

Overdosage/Acute Toxicity
Little information is available regarding overdoses of this drug. It is suggested that large oral overdoses be handled by emptying the gut following standard protocols; monitor and treat adverse effects symptomatically if necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving novobiocin and may be of significance in veterinary patients:

**BETA-LACTAM ANTIBIOTICS:** Novobiocin reportedly acts similarly to probenecid by blocking the tubular transport of drugs. Although the clinical significance of this is unclear, the elimination rates of drugs excreted in this manner (e.g., penicillins, cephalosporins) could be decreased and half-lives prolonged.

Laboratory Considerations
- Novobiocin can be metabolized into a yellow-colored product that can interfere with serum bilirubin determinations.
- Novobiocin may interfere with the determination BSP (bromosulfophthalein, sulfobromophthalein) uptake tests by altering BSP uptake or biliary excretion.

Doses
**DOGS:**
- For susceptible infections using the combination product (with tetracycline and prednisolone): 22 mg/kg of each antibiotic and 0.55 mg prednisolone PO q12h for 48 hours (Package insert; *Delta Albaplex*®—Upjohn)

**CATTLE:**
- For treatment of subclinical mastitis in dry cows: Infuse contents of one syringe into each quarter at the time of drying off; not later than 30 days prior to calving. Shake well before using. (Package directions; *Albadry Plus*®—Pharmacia & Upjohn)

Monitoring
- Clinical efficacy
- Adverse effects
- Periodic liver function tests and CBC’s are recommended if using long-term systemically.

Client Information
- Shake mastitis tubes well before using
- Do not exceed dosage recommendations or length of treatment

Chemistry/Synonyms
An antibiotic obtained from *Streptomyces niveus* or *spheroides*, novobiocin sodium occurs as white to light yellow, crystalline powder and is very soluble in water.

Novobiocin or novobiocin sodium may also be known as: crystallinic acid, PA-93, streptonivicin, U-6591, novobiocinum natricum, sodium novobiocin, *Albadry Plus*®, *Albamycin*®, *Biodry*® and *Delta Albaplex*®.

Storage/Stability
Novobiocin should be stored at room temperature in tight containers unless otherwise directed.

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:**
Novobiocin Combination Products:
- Novobiocin (as the sodium salt): 400 mg and Penicillin G Procaine 200,000 Units per 10 mL *Plaster® Syringe. Albadry Plus*® (Pfizer); (OTC). FDA-approved for use in dry cows only. Do not use 30 days prior to calving. Milk must not be used for 72 hours after calving. Slaughter withdrawal (at labeled doses) = 30 days.
- Novobiocin Sodium 60 mg, Tetracycline HCl 60 mg and Prednisolone 1.5 mg tablets; Novobiocin Sodium 180 mg, Tetracycline HCl 180 mg and Prednisolone 4.5 mg tablets; *Delta Albaplex*® and *Delta Albaplex*® 3X (Pfizer); (Rx). FDA-approved for use in dogs.

**HUMAN-LABELED PRODUCTS:** None

---

**NYSTATIN (ORAL)**
*Nilstat®, Mycostatin®*

**ANTIFUNGAL (CANDIDA)**

**Prescriber Highlights**
- Oral & topical antifungal (Candida); not absorbed systemically after PO
- Adverse Effects: GI effects possible at high dosages; hypersensitivity possible
Uses/Indications
Orally administered nystatin is used primarily for the treatment of oral or gastrointestinal tract Candida infections in dogs, cats, and birds; it has been used less commonly in other species for the same indications.

Pharmacology/Actions
Nystatin has a mechanism of action similar to that of amphotericin B. It binds to sterols in the membrane of the fungal cell altering the permeability of the membrane allowing intracellular potassium and other cellular constituents to “leak out.” When given orally, the drug must come into contact with the organism to be effective. Nystatin has activity against a variety of fungal organisms, but is clinically used against topical, oropharyngeal, and gastrointestinal Candida infections.

Pharmacokinetics
Nystatin is not measurably absorbed after oral administration and almost entirely excreted unchanged in the feces. The drug is not used parenterally because it is reportedly extremely toxic to internal tissues.

Contraindications/Precautions/Warnings
Nystatin is contraindicated in patients with known hypersensitivity to it.

Adverse Effects
Occasionally, high dosages of nystatin may cause GI upset (anorexia, vomiting, diarrhea). Rarely, hypersensitivity reactions have been reported in humans.

Reproductive/Nursing Safety
Although the safety of the drug during pregnancy has not been firmly established, the lack of appreciable absorption or case reports associating the drug with teratogenic effects appear to make it safe to use. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) It is not known whether nystatin is excreted in maternal milk, but because the drug is not absorbed after oral administration it is unlikely to be of concern.

Overdosage/Acute Toxicity
Because the drug is not absorbed after oral administration, acute toxicity after an oral overdose is extremely unlikely, but transient GI distress may result.

Drug Interactions
No significant interactions reported for oral nystatin.

Doses

**DOGS:**
For oral treatment of Candidal infections:
  a) 100,000 Units PO q6h (Kirk 1989)
  b) 50,000–150,000 Units PO q8h (Jenkins & Boothe 1987)
  c) 22,000 Units/kg/day (Huber 1988)

**CATS:**
For oral treatment of Candidal infections:
  a) 100,000 Units PO q6h (Kirk 1989)

**HORSES:**
For intrauterine infusion:
  a) 250,000–1,000,000 IU; Mix with sterile water; precipitates in saline. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

**BIRDS:**
For crop mycosis and mycotic diarrhea (*Candida albicans*) in chickens and turkeys:
  a) Feed at 50 grams per ton (*Mycostatin®-20*) or at 100 grams/ton for 7–10 days. (Label directions; *Mycostatin®-20*—Solvay)
For enteric yeast (*Candidal*) infections:
  a) 200,000–300,000 Units/kg PO q8–12h. Relatively large volume must be administered (2–3 mL). May also be used prophylactically to prevent yeast infection in nestling birds treated with broad-spectrum antibiotics. Oral lesions may be missed if bird is tubed. (Flammer 2003)
  b) For neonates on antibiotic therapy: Crush one fluconazole 100 mg tablet and mix with 20 mL of nystatin 100,000 Units/mL oral suspension. Dose at 0.5 mL/1000g of body weight PO twice daily for duration of antibiotic therapy. (Wissman 2003)
  c) For treatment of candidiasis after antibiotic or in conjunction with antibiotics: One mL of the 100,000 Units/mL suspension per 300 grams body weight PO 1–3 times daily for 7–14 days. If treating mouth lesions do not give by gavage. Hand-fed babies should receive antifungal therapy if being treated with antibiotics. (Clubb 1986)
  d) Ratites: 250,000–500,000 Units/kg PO twice daily (Jenson 1998)

**REPTILES:**
For susceptible infections:
  a) For turtles with enteric yeast infections: 100,000 Units/kg PO once daily for 10 days (Gauvin 1993)
  b) All species: 100,000 Units/kg PO once daily (Jacobson 1999)
Chemistry/Synonyms
A polyene antifungal antibiotic produced by *Streptomyces noursei*, nystatin occurs as a yellow to light tan, hygroscopic powder having a cereal-like odor. It is very slightly soluble in water and slightly to sparingly soluble in alcohol. One mg of nystatin contains not less than 4400 Units of activity. According to the USP, nystatin used in the preparation of oral suspensions should not contain less than 5000 Units per mg.

Nystatin may also be known as: fungicidin, nistatina, or nystatinum, Mycostatin®, and Nilstat®.

Storage/Stability
Nystatin tablets and oral suspension should be stored at room temperature (15–30°C) in tight, light-resistant containers. Avoid freezing the oral suspension or exposing to temperatures greater than 40°C.

Nystatin deteriorates when exposed to heat, light, air or moisture.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
None, for oral use. For topical use, see the topical dermatologic section in the appendix.

**HUMAN-LABELED PRODUCTS:**
Nystatin Oral Suspension: 100,000 Units/mL in 5 mL, 60 mL, 473 mL and 480 mL; Nilstat® (Lederle); generic; (Rx)
Nystatin Bulk powder: 50 million Units, 150 million Units, 500 million Units, 1 billion Units, 2 billion Units & 5 billion Units; generic; (Paddock); Nilstat® (Lederle); (Rx)
Nystatin Oral Tablets: 500,000 Units; Mycostatin® (Bristol-Myers Squibb), generic; (Rx)
Also available in oral troches, vaginal tablets, topical creams, powders and ointments.

**OCTREOTIDE ACETATE**

*(ok-trye-ok-tide)* Sandostatin®

**SOMATOSTATIN ANALOG**

**Prescriber Highlights**

- Injectable long acting somatostatin analog that may be useful for adjunctive treatment of insulinomas & gastrinomas
- Limited experience, but appears safe
- Multiple daily SC injections are required
- No information for veterinary use of depot IM form
- Expensive (especially in large dogs)
- May affect GI fat absorption

---

**Uses/Indications**

Octreotide may be useful in the adjunctive treatment of hyperinsulinenia in patients with insulinomas (especially dogs, ferrets). Response is variable, presumably dependent on whether the tumor cells have receptors for somatostatin. Octreotide may also be useful in the diagnosis and symptomatic treatment of gastrinomas in dogs or cats. It may be of use in the treatment of acute pancreatitis, but more research is needed before it can be recommended for this use in veterinary patients.

Octreotide has not been effective in reducing growth hormone levels or enhancing insulin sensitivity in cats with acromegaly.

**Pharmacology/Actions**

Octreotide is a synthetic long acting analog of somatostatin. It inhibits the secretion of insulin (in both normal and neoplastic beta cells), glucagon, secretin, gastrin and motilin. In humans, octreotide may bind to any of 5 subtypes of somatostatin receptors found on neoplastic beta cells, but dogs only have one subtype. This, or octreotide’s inhibition of glucagon and growth hormone secretion, may explain the variable response dogs have to treatment.
Pharmacokinetics

Octreotide is absorbed and distributed rapidly from the injection site after SC administration. Half lives in humans average about 2 hours with duration of effect up to 12 hours. Treated dogs or ferrets generally require 2–3 injections per day to maintain blood glucose. About 32% of a dose is excreted unchanged in the urine and patients with severe renal dysfunction may need dosage adjustment.

Contraindications/Precautions/Warnings

Octreotide is contraindicated in patients hypersensitive to it. It should be used with caution in patients with biliary tract disorders.

Adverse Effects

Very limited experience in domestic animals, although it appears to be well tolerated thus far. GI effects (including biliary tract effects) are most commonly noted in human patients, particularly acromegalis.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) It is not known whether this drug is excreted in maternal milk.

Overdosage/Acute Toxicity

Serious adverse effects are unlikely. Human subjects have received up to 120 mg IV over 8 hours with no untoward effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving octreotide and may be of significance in veterinary patients:

- **BETA-BLOCKERS**: Octreotide may cause additive bradycardic effects
- **BROMOCRIPTINE**: Octreotide may increase oral bioavailability
- **CALCIUM-CHANNEL BLOCKERS**: Octreotide may cause additive bradycardic effects
- **CYCLOSPORINE**: Octreotide may reduce cyclosporine levels
- **DIURETICS (and other agents that affect fluid/electrolyte balance)**: Octreotide may enhance fluid/electrolyte imbalances
- **FOOD**: Octreotide may reduce fat absorption
- **INSULIN, ORAL HYPOGLYCEMICS**: Octreotide may inhibit insulin
- **QUINIDINE**: Octreotide may reduce the quinidine clearance

Doses

**DOGS:**

For medical treatment of insulinoma (beta cell tumor) particularly in patients refractory to or unable to tolerate other medical or surgical therapy:

a) 10–40 micrograms (total dose per dog) SC 2–3 times a day. Used in combination with dietary, glucocorticoid, and diazoxide treatment. (Nelson 2007)

b) Further studies needed to determine octreotide’s efficacy and safety; has been administered at 2–4 micrograms/kg SC q8–12h (Hess 2005)

For adjunctive treatment of gastrinoma:

a) 2–20 micrograms/kg SC three times daily; with omeprazole. (Simpson 2005)

For adjunctive treatment of chylothorax:

a) 10–20 micrograms/kg SC three times a day for 2–3 weeks; prolonged treatment should be discouraged because people treated for longer than 4 weeks are at risk for gallstones. (Fossom 2006)

**CATS:**

For adjunctive treatment of chylothorax:

a) 10–20 micrograms/kg SC three times a day for 2–3 weeks; prolonged treatment should be discouraged because people treated for longer than 4 weeks are at risk for gallstones. (Fossom 2006)

**FERRETS:**

For medical treatment of insulinoma (particularly in patients refractory to or unable to tolerate other medical or surgical therapy):

a) 1–2 micrograms/kg SC 2–3 times a day (Meleo & Caplan 2000)

Monitoring

- Blood glucose (for insulinoma treatment)
- Clinical efficacy

Client Information

- There is very limited experience with this medication in dogs and ferrets and therapy must be considered experimental.
- Injections must be given 2–3 times a day per veterinarian instructions
- The expense associated with this medication can be considerable.

Chemistry/Synonyms

Octreotide acetate is a synthetic polypeptide related to somatostatin. It is commercially available in injectable forms for subcutaneous or IV injection, and as an extended release suspension for IM administration.
Octreotide acetate may also be known as: SMS-201-995, Longastatina®, Samilstin®, Sandostatin®, Sandostatina®, or Sandostatine®.

Storage/Stability
When stored at room temperature and protected from light, octreotide acetate injection remains stable for 14 days. For long-term storage, keep refrigerated. If injectable solution has been in the refrigerator, allow it to come to room temperature in the syringe before injecting. Do not use artificial warming techniques. It is recommended to use multidose vials within 14 days of initial use.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- **Octreotide Acetate for Injection:** 0.05 mg/mL (50 micrograms/mL), 0.1 mg/mL (100 micrograms/mL), 0.2 mg/mL (200 micrograms/mL), 0.5 mg/mL (500 micrograms/mL) & 1 mg/mL (1,000 micrograms/mL) in 1 mg amps, single-dose vials and 5 mL multi-dose vials; Sandostatin® (Novartis); generic (Sicor); (Rx)
- **Octreotide Acetate Powder for Injectable Suspension:** 10 mg/5 mL, 20 mg/5 mL & 30 mg/5mL in single-use kits; Sandostatin® LAR Depot (Novartis); (Rx)

References

OLSALAZINE SODIUM
(ols-al-a-zeen) Dipentum®
ANTINFLAMMATORY (LOCAL GI TRACT)

Prescriber Highlights

- Used for treatment of chronic colitis in dogs that either are unresponsive to or cannot tolerate sulfasalazine; limited experience
- Keratoconjunctivitis sicca (KCS) has been reported in some dogs
- Converted to 2 molecules of 5-ASA (mesalamine) in colon
- Expensive when compared to sulfasalazine

Uses/Indications

Olsalazine is used for treatment of dogs with chronic colitis that either cannot tolerate the adverse effects associated with sulfasalazine or the response to sulfasalazine has been ineffective.

Pharmacology/Actions

Olsalazine is cleaved in the intestine into 5-aminosalicylic acid (5-ASA, mesalamine) by bacteria in the gut. While its exact mechanism is unknown, mesalamine is thought to have efficacy for chronic colitis secondary to its antiinflammatory activity.

Pharmacokinetics

Olsalazine is poorly absorbed; approximately 98% of a dose reaches the colon intact and what drug is absorbed is rapidly eliminated. Serum half-life is about one hour.

Contraindications/Precautions/Warnings

Olsalazine is contraindicated in patients hypersensitive to it or to salicylates. Use with caution in animals with renal disease as renal toxicity has developed, though rarely, in human patients.

Adverse Effects

While keratoconjunctivitis sicca (KCS) is occasionally reported in dogs receiving olsalazine, it probably occurs less frequently than with sulfasalazine therapy. In humans, approximately 17% of patients developed more serious diarrhea (then they had prior to treatment) after receiving olsalazine.

Reproductive/Nursing Safety

In high dose rat studies, some fetal abnormalities were seen. Use during pregnancy only when benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Oral olsalazine given to lactating rats in doses 5–20 times the human dose produced growth retardation in their pups. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Overdosage in dogs may cause vomiting, diarrhea and decreased motor activity; treat symptomatically and supportively. Dosages up to 2 grams/kg were not lethal in dogs.

Drug Interactions

The following drug interaction has either been reported or are theoretical in humans or animals receiving olsalazine and may be of significance in veterinary patients:
WARFARIN: Olsalazine may increase prothrombin times in patients receiving warfarin

Laboratory Considerations
- Olsalazine may cause increases in ALT or AST

Doses
- **DOGS:**
  a) For dogs who cannot tolerate sulfasalazine: 10–20 mg/kg PO three times daily (Leib 2000)
  b) 10–20 mg/kg PO q8h has had limited use in dogs without causing apparent side effects. (Marks 2007)
  c) 10–15 mg/kg PO q8–12h (Hall 2004)
  d) Initially at 5–10 mg/kg PO three times daily, then reduce gradually. (Allensbach 2005; Allenspach 2009)

Monitoring
- Clinical efficacy
- Adverse effects

Client Information
- Should be given with food in evenly spaced doses (if possible)
- If diarrhea worsens or dogs eyes become dry, contact veterinarian

Chemistry/Synonyms
Olsalazine sodium occurs as a yellow crystalline powder that is soluble in water and stable under physiologic acidic and alkaline conditions. It is basically 2 molecules of mesalamine (5-ASA) connected at the azo bonding site.

- Olsalazine sodium may also be known as: azodisal sodium, dimesalamine, CI mordant yellow 5, CI No. 14130, CJ-91B, olsalazinum natricum, sodium azidosalicylate, Dipentum® or Rasal®.

Storage/Stability
Store capsules at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
- Olsalazine Sodium Oral Capsules: 250 mg; Dipentum® (UCB Pharma); (Rx)

References
- OMEPRAZOLE
  (oh-meh-prah-zahl) Gastrogard®, Prilosec®

PROTON PUMP INHIBITOR

Prescriber Highlights
- Proton pump inhibitor used for GI ulcers & erosions
- May need to adjust dosage with hepatic or renal disease
- Adverse Effects: Horses: Unlikely; potential hypersensitivity. Small Animals: Appears to be well tolerated. Potentially: GI distress (anorexia, colic, nausea, vomiting, flatulence, diarrhea), hematologic abnormalities, urinary tract infections, proteinuria, or CNS disturbances

Uses/Indications
Omeprazole is potentially useful in treating both gastroduodenal ulcer disease and to prevent or treat gastric erosions caused by ulcerogenic drugs (e.g., aspirin). Omeprazole was superior to famotidine when used to prevent exercise-induced gastritis in racing Alaskan sled dogs (Williamson et al. 2010). An oral paste product is labeled for the treatment and prevention of recurrence of gastric ulcers in horses.

Pharmacology/Actions
Omeprazole is a substituted benzimidazole gastric acid (proton) pump inhibitor. In an acidic environment, omeprazole is activated to a sulphenamide derivative that binds irreversibly at the secretory surface of parietal cells to the enzyme, H⁺/K⁺ ATPase. There it inhibits the transport of hydrogen ions into the stomach. Omeprazole
reduces acid secretion during both basal and stimulated conditions. There is a lag time between administration and efficacy. Omeprazole also inhibits the hepatic cytochrome P-450 mixed function oxidase system (see Drug Interactions below).

**Pharmacokinetics**

Omeprazole is rapidly absorbed from the gut; the human commercial product is in an enteric-coated granule form as the drug is rapidly degraded by acid. The equine paste is not enteric coated. In humans, peak serum levels occur within 0.5–3.5 hours and onset of action within 1 hour. Omeprazole is distributed widely, but primarily in gastric parietal cells. In humans, approximately 95% is bound to albumin and alpha1-acid glycoprotein. It is unknown whether omeprazole enters maternal milk.

Omeprazole is extensively metabolized in the liver to at least six different metabolites. These are excreted principally in the urine, but also via the bile into feces. Significant hepatic dysfunction will reduce the first pass effect of the drug. In humans and dogs with normal hepatic function, serum half-life averages about 1 hour, but the duration of therapeutic effect may persist for 24–72 hours or more. Effects on acid production in horses can last up to 27 hours, depending upon dose.

**Contraindications/Precautions/Warnings**

Omeprazole is contraindicated in patients hypersensitive to it. In patients with hepatic or renal disease, the drug’s half-life may be prolonged and dosage adjustment may be necessary if the disease is severe.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving omeprazole and may be of significance in veterinary patients:

- **BENZODIAZEPINES (e.g., diazepam):** Omeprazole may potentially alter benzodiazepine metabolism and prolong CNS effects

- **CLARITHROMYCIN:** Increased levels of omeprazole, clarithromycin and 14-hydroxyclarithromycin are possible

- **CYANOCOBALAMIN (oral):** Omeprazole may decrease oral absorption

- **CYCLOSPORINE:** Omeprazole may reduce cyclosporine metabolism

- **DRUGS REQUIRING DECREASED GASTRIC PH FOR OPTIMAL ABSORPTION (e.g., ketoconazole, itraconazole, iron, ampicillin esters):**
  - Omeprazole may decrease drug absorption

- **WARFARIN:** Omeprazole may increase anticoagulant effect

**Laboratory Considerations**

- Omeprazole may cause increased liver enzymes

- Omeprazole will increase serum gastrin levels early in therapy

**Doses**

Dose dependent on formulation, equine paste and human oral forms may not be interchangeable. Be wary of compounded formulations; bioequivalence is not assured.

**DOGS:**

- For GI ulcer management/prevention:
  - a) 0.5–1 mg/kg PO once daily (Davenport 1992)(Haskins 2000)(Trepanier 2010)
  - b) For adjunctive treatment of uremic gastropathy: 0.5–1 mg/kg PO q24h; dosage may need to be modified in moderate or severe renal failure. (Vaden 2007)
  - c) To prevent exercise-induced gastritis in racing Alaskan sled dogs: In the study, dogs were dosed at approx. 0.85 mg/kg (one 20 mg tablet) once daily approximately 30 minutes before being fed. Dosing began approximately 48 hours before exercise. (Williamson et al. 2010)
  - d) For adjunctive treatment of esophagitis or gastric ulcers: 0.5–1 mg/kg PO q24h (Sellon 2007a; Sellon 2007b)
  - e) For some animals with gastrinomas or esophagitis (often H-2 receptor antagonists are adequate): 0.7–1.5 mg/kg PO q24h, but if severe esophagitis or gastrinomas may use up to 2 mg/kg PO q12h (Willard 2006)
  - f) 0.7 mg/kg PO q24h (20 mg/dog). (Marks 2008)

**Horses:**

- g) For esophagitis: 0.7 mg/kg PO twice daily. (Simpson 2008)
For esophagitis: 0.7 mg/kg PO twice daily. (Simpson 2008)

h) For adjunctive treatment of uremic vomiting: 0.7 mg/kg PO q12h. (Washabau 2009)

i) For Helicobacter infection/gastritis: Omeprazole 0.7 mg/kg PO once daily (or an H2 blocker), amoxicillin 15 mg/kg PO twice daily, metronidazole 10 mg/kg PO twice daily, and Pepto Bismol ¼–2 tablets PO twice daily. All are given for 2 weeks. Other suggestions include omeprazole with either azithromycin 10–20 mg/kg PO once daily or clarithromycin 7.5 mg/kg PO twice daily. (Leib 2008)

**CATS:**

For GI ulcer management/prevention:

a) For adjunctive treatment of esophagitis or gastric ulcers: 0.5–1 mg/kg PO q24h (Sellon 2007a; Sellon 2007b; Trepanier 2010)

b) 0.7–1.5 mg/kg PO q12–24h (Willard 2003)

c) For adjunctive treatment of uremic gastropathy: 0.7 mg/kg PO q24h; dosage may need to be modified in moderate or severe renal failure. (Vaden 2007)

**FERRETS:**

a) For short-term treatment of gastroenteritis: 0.7 mg/kg PO q24h. (Johnson-Delaney 2009)

**HORSES:** *(Note: ARCI UCGFS Class 5 Drug)*

For gastric ulcers:

a) For treatment of gastric ulcers: 4 mg/kg PO once daily for 4 weeks; to prevent recurrence treat for at least another 4 weeks at 2 mg/kg PO once daily (Label Directions; *Gastrogard®*)

b) **Foals:** Preventative dose: 1 mg/kg PO q24h; Treatment dose: 4 mg/kg PO q24h. Will reduce gastric pH in a few hours. There has been a recent shift to not administering prophylactic antiulcer medication routinely to sick foals. (Stewart 2008)

c) For treatment or prophylaxis of gastric ulcers in foals: 4 mg/kg PO once daily for treatment, 1–2 mg/kg PO once daily for prophylaxis (Wilkins 2004)

d) **Foals:** 4 mg/kg PO q24h. Commonly foals will be started on ranitidine (1.5 mg/kg IV q8h; 6.6 mg/kg PO q8h) and omeprazole together. The ranitidine is quick acting histamine-2 antagonist and begins to alkalinate the gastric pH quickly. (Paradis 2008)

**SWINE:**

For ulcer management:

a) 40 mg of PO daily for two days; fasted for 48 hours (DeMint 1999)

**Monitoring**

- Efficacy
- Adverse effects

**Client Information**

- Give before meals, preferably in the morning

**Chemistry/Synonyms**

A substituted benzimidazole proton pump inhibitor, omeprazole has a molecular weight of 345.4 and pKa’s of 4 and 8.8. Omeprazole may also be known as: H-168/68, or omeprazolum, *Gastrogard®, Prilosec®, Ulcergard®* and Zegerid®.

**Storage/Stability**

Omeprazole oral paste should be stored below 86°F. Transient exposure to temperatures up to 104°F is permitted. Omeprazole tablets should be stored at room temperature in light-resistant, tight containers. Omeprazole pellets found in the capsules are fragile and should not be crushed. If needed to administer as a slurry, it has been suggested to mix the pellets carefully with fruit juices, not water, milk or saline.

**Compatibility/Compounding Considerations**

Use caution when using compounded omeprazole products; bioequivalence has been an issue with some compounded preparations. Omeprazole capsules or tablets should not be crushed or chewed. If reducing the dose of the commercially available capsules, the capsule contents should be re-inserted into a gelatin capsule so they cannot be chewed.

**Compounded preparation stability:** Omeprazole oral suspension compounded from the commercially available powder packets has been published (Johnson *et al.*, 2007). Dissolving one (1) omeprazole 20 mg powder packet *qs ad* 10 ml in sterile water yields 2 mg/mL omeprazole oral suspension that retains >98% potency for 45 days when stored at 4°C; however, the resulting low concentration and strawberry flavoring may not be suitable for administration to veterinary patients. The efficacy of omeprazole 40 mg/mL oral suspension compounded by diluting commercially available equine paste 1:9 with sesame oil for use in dogs has been published (Tolbert *et al.*, 2011). While the long term stability of this preparation has not yet been assayed, it meets the default beyond-use-date criteria of 180 days for non-aqueous oral suspensions.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Omeprazole Oral Paste, 2.28 g per syringe; *Gastrogard®* (Merial), (Rx); *Ulcergard®* (Merial), (OTC)

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Omeprazole Oral Delayed-Release Capsules: 10 mg, 20 mg (tablets & capsules) & 40 mg; *Prilosec®* (AstraZeneca); *Prilosec® OTC* (Losec® in Canada; Procter & Gamble); generic; (Rx & OTC)

Omeprazole/Sodium Bicarbonate Oral Capsules (Immediate Release): 20 mg omeprazole/1,100 mg sodium bicarbonate; 40 mg omeprazole/1,100 mg sodium bicarbonate; Zegerid® (Santarus); (Rx)
Ondansetron is a 5-HT3 receptor antagonist for severe vomiting. It is suggested to be well tolerated in dogs. Generic dosage forms are now available, prices are much lower than previously.

**Uses/Indications**
Used as an antiemetic when conventional antiemetics are ineffective, such as when administering cisplatin or for other causes of intractable vomiting. The use of ondansetron in cats is somewhat controversial and some state it should not be used in this species.

**Pharmacology/Actions**
Ondansetron is a 5-HT3 receptor antagonist. 5-HT3 receptors are found peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone (CTZ). It is not clear if ondansetron's effects are mediated centrally, peripherally or both.

**Pharmacokinetics**
No veterinary species data was located for ondansetron pharmacokinetics. In humans, ondansetron is well absorbed from the GI tract, but exhibits some first pass hepatic metabolism. Bioavailability is about 50-60%. Peak plasma levels occur about 2 hours after an oral dose. Ondansetron is extensively metabolized in the liver. Elimination half-lives are about 3–4 hours, but are prolonged in elderly patients.

**Contraindications/Precautions/Warnings**
Ondansetron is contraindicated in patients hypersensitive to it or other agents in this class. Ondansetron may mask ileus or gastric distention; it should not be used in place of nasogastric suction. Use with caution in patients with hepatic dysfunction as half-life may be prolonged.

**Adverse Effects**
Ondansetron appears to be well tolerated. Constipation, sedation, extrapyramidal clinical signs (head shaking), arrhythmias and hypotension are possible (incidence in humans <10%).

**Reproductive/Nursing Safety**
Safety in pregnancy not clearly established, but high dose studies in rodents did not demonstrate overt fetal toxicity or teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy. There are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters. Ondansetron is excreted in the maternal milk of rats. Exercise caution when administering ondansetron to dogs with the MDR1 mutation.

**Overdose/Acute Toxicity**
Overdoses of up to 10X did not cause significant morbidity in human subjects. If an overdose occurs, treat supportively. Ondansetron demonstrates a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters (FDA). Demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters (FDA). Overdoses of up to 10X did not cause significant morbidity in human subjects. If an overdose occurs, treat supportively.

**Drug Interactions/Laboratory Considerations**

- **APOMORPHINE**: A human patient that received ondansetron and apomorphine developed severe hypotension. In humans, use together is contraindicated.
- **DRUGS AFFECTING QT INTERVAL**: (e.g., amiodarone, cisapride, halothane, isoflurane, sotalol): Theoretically, ondansetron may have additive effects on QTc interval; possible serious arrhythmias may result.
- **TRAMADOL**: In humans, use together may reduce the efficacy of both drugs. Veterinary significance is not known.

**Doses**
- **DOGS**:
  a) 0.1–0.3 mg/kg IV given as a slow push every 8 to 12 hours (based on patient response). Has produced dramatic results in either controlling or at least significantly decreasing the frequency of vomiting in dogs with frequent or severe vomiting, including dogs with severe parvo virus enteritis or pancreateitis. (Tams 2007)
  b) For chemotherapy-related vomiting: 0.5–1 mg/kg PO q8-12h; 0.1–0.5 mg/kg IV over 15 minutes q8h or 30 minutes before cisplatin infusion. (Kent 2009)
  c) For adjunctive therapy of acute diarrhea: 0.5–1 mg/kg PO twice daily. Antagonizes neuronal 5-HT3 receptors and inhibits Cl- and HCO3- secretion from intestinal epithelial cells. (Washabau 2007)
  d) As an antiemetic: 0.1–0.2 mg/kg IV q6-12h or 0.1–1 mg/kg PO q12-24h (Otto 2005)
  e) As an antiemetic for adjunctive treatment of uremia: 0.6–1 mg/kg PO or IV q12/24h; usually combined with metoclopramide. (Polzin 2005)
- **CATS**:
  a) Empiric dose: 0.5 mg/kg IV or PO twice daily. (Trepnair 2010)
  b) As an anti-emetic for intractable vomiting: 0.1–0.15 mg/kg slow IV push q6-12h as needed (Scherk 2003)
  c) As an antiemetic for adjunctive treatment of severe parvovirus: 0.1–1 mg/kg PO or IV q12-24h (Armstrong 2007)
Orbifloxacin, like other fluoroquinolones, can cause arthropathies in immature, growing animals. Because dogs appear to be more sensitive to this effect, the manufacturer states that the drug is contraindicated in immature dogs.

Contraindications/Precautions/Warnings
- Orbifloxacin has weak activity against most anaerobes and is not a good choice when treating known or suspected anaerobic infections.
- Orbifloxacin is a concentration-dependent bactericidal agent. It acts by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis. The net result is disruption of bacterial cell replication.
- Orbifloxacin has good activity against many gram-negative and gram-positive bacilli and cocci, including most species and strains of Klebsiella spp., Staphylococcus intermedius or aureus, E. coli, Enterobacter, Campylobacter, Shigella, Proteus, Pasteurella species. Some strains of Pseudomonas aeruginosa and Pseudomonas spp. are resistant to orbifloxacin and most Enterococcus spp. are resistant. Like other fluoroquinolones, orbifloxacin has weak activity against most anaerobes and is not a good choice when treating known or suspected anaerobic infections.

Pharmacokinetics
- After oral administration in dogs or cats, orbifloxacin is apparently nearly completely absorbed. The drug is distributed well (Vd=1.5 L/kg in dogs and 1.4 L/kg in cats) and only bound slightly to plasma proteins (8% dogs; 15% cats). Orbifloxacin is eliminated primarily via the kidneys. Approximately 50% of the drug is excreted unchanged. Serum half-life is about 6 hours in both dogs and cats. Urine levels remain well above MIC’s for susceptible organisms for at least 24 hours after dosing.
- In horses, orbifloxacin is well absorbed after oral administration (bioavailability is about 70%) and distributes in many body fluids and endometrial tissue. Protein binding is relatively low (approx. 20%). Elimination half-life is approximately 6 hours.

Contraindications/Precautions/Warnings
- Orbifloxacin, like other fluoroquinolones, can cause arthropathies in immature, growing animals. Because dogs appear to be more sensitive to this effect, the manufacturer states that the drug is contraindicated in immature dogs.

Compatibility/Compounding Considerations
- Drugs reported to be compatible with ondansetron when combined in a syringe and administered via a Y-site, include: alfentanil, atropine, fentanyl, glycopyrrolate, metoclopramide, midazolam, morphine, naloxone, neostigmine, and propofol.
- Ondansetron is reported compatible with the following drugs when administered via a Y-site: amikacin, azithromycin, bleomycin, carboplatin, carmustine, ceftazidime, cefuroxime, cisplatin, clindamycin, cyclophosphamide, cytarabine, dacarbazine, dactinomycin, daunorubicin, dexmethylasone sodium phosphate, dexmedetomidine, diphenhydramine, dopamine, doxorubicin HCl (also liposome form), doxycycline, famotidine, firlaglimat, fluconazole, gentamicin, heparin, hydrocortisone, hydroxyzine, ifosfamide, imipenem-cilastatin, mexitil, mesna, methotrexate, methylprednisolone sodium succinate, metoclopramide, mitoxantrone, morphone, pipercillin-tazobactam, potassium chloride, prochlorperazine, promethazine, ranitidine, vancomycin, vinblastine, vincristine, and zidovudine.

References

Drug Interactions
- Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

HUMAN-LABELED PRODUCTS:
- Ondansetron HCl Tablets: 4 mg, 8 mg, 16 mg & 24 mg; Zofran® (GlaxoSmithKline), generic; (Rx)
- Ondansetron Orally Disintegrating Tablets: 4 mg & 8 mg (as base); Zofran® ODT (GlaxoSmithKline), generic (Sandoz); (Rx)
- Ondansetron HCl Oral Solution: 0.8 mg/ml (4 mg/5 mL) in 50 mL; Zofran® (GlaxoSmithKline), generic; (Rx)
- Ondansetron HCl Injection: 2 mg/ml in 2 mL single-dose & 20 mL multi-dose vials; and 32 mg/50 mL (premixed; preservative free) in 50 mL single-dose containers; Zofran® (GlaxoSmithKline); generic; (Rx)
- Zofran® (GlaxoSmithKline), generic; (Rx)
- Ondansetron HCl dihydrate occurs as a white to off-white powder that is soluble in water.
- Ondansetron HCl may also be known as: GR-38032F or ondansetroni hydrochloridum, and ondansetron hydrochloride.
Orbifloxacin Oral Suspension: 30mg/mL in 20 mL btls; cats. Federal law prohibits the use of the drug in food-producing animals.

Orbifloxacin Oral Tablets: 5.7 mg (yellow) in btls of 250; 22.7 mg (green; E-Z Break) in btls of 250; 68 mg (blue; E-Z Break) in btls of 100;

An orbifloxacin 22.7 mg tablet crushed and mixed with mollases, dark corn syrup, water from canned tuna, Kame fish sauce, and Ora-Plus® to a chewable tablet was still effective after 7 days. The commercially available tablets should be stored between 2–30°C (36–86°F) and protected from excessive moisture.

Chemistry/Synonyms
Orbifloxacin may also be known as marufloxacin or Orbax®. Orbifloxacin may also be known as marufloxacin or Orbax®.

Overdosage/Acute Toxicity
Dogs and cats receiving up to 5X (37.5 mg/kg) for 30 days did not result in any significant adverse effects. Cats receiving the higher dosages exhibited soft feces and decreased body weight gains.

Adverse Effects
Doses
DOGS/CATS:
For susceptible infections:
Tablets: Dogs and cats: 2.5 mg/kg–7.5 mg/kg, once daily PO. Higher end of the dosing range may be necessary in hospitalized patients, those with underlying disease (e.g., malignancy) or structural alterations (e.g., burns, complicated urinary tract infections, foreign body infections), infections associated with vascular compromise and infections caused by “problem” pathogens. (Package Insert; Orbax® —Schering)

Suspension: Dogs: For the treatment of urinary tract infections (cystitis) in dogs caused by susceptible bacteria; and for the treatment of skin and soft tissue infections (wounds and abscesses) in dogs caused by susceptible bacteria (see package insert for actual species): 2.5–7.5 mg/kg PO once daily.

Cats: For the treatment of skin infections (wounds and abscesses) in cats caused by susceptible strains of S. aureus, E. coli, and P. multocida: 7.5 mg/kg PO once daily. (Package insert; Orbax® Suspension—Intervet S-P)

HORSES:
For susceptible infections:
a) 5 mg/kg, once daily PO (Davis et al. 2006).
b) 7.5 mg/kg PO once daily (Haines et al. 2001)

Monitoring/Client Information
Efficacy is the most important monitoring parameter.

Clients should be instructed on the importance of giving the medication as instructed and not to discontinue it on their own.

Chemistry/Synonyms
A 4-fluoroquinolone antibiotic, orbifloxacin is slightly soluble in water at neutral pH. Solubility increases in either an acidic or basic medium.

Orbifloxacin may also be known as marufloxacin or Orbax®.

Storage/Stability
The commercially available tablets should be stored between 2–30°C (36–86°F) and protected from excessive moisture.

The oral suspension should be stored between 2-25°C (36-77°F). It does not require refrigeration. Store upright. Shake well before use.

Compatibility/Compounding Considerations
An orbifloxacin 22.7 mg tablet crushed and mixed with molasses, dark corn syrup, water from canned tuna, Kame fish sauce, Ora-Plus®, Syrplate® or simple syrup was relatively stable (>85% expected value) for up to 7 days when stored unrefrigerated, but protected from light. Mixing with oral supplements that contain calcium or magnesium (e.g., Lisintin®) showed significant inactivation of orbifloxacin by 4 days (Kukanich & Papich 2003).

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
Orbifloxacin Oral Tablets: 5.7 mg (yellow) in btls of 250; 22.7 mg (green; E-Z Break) in btls of 250; 68 mg (blue; E-Z Break) in btls of 100; Orbax® (Intervet Schering-Plough); (Rx). FDA-approved for use in dogs and cats. Federal law prohibits the use of the drug in food-producing animals.

Orbifloxacin Oral Suspension: 30mg/ml in 20 mL btls; Orbax® Suspension (Intervet Schering-Plough); (Rx). FDA-approved for use in dogs and cats. Federal law prohibits the use of the drug in food-producing animals.
Drug Interactions

Oseltamivir has relatively low toxic potential. In humans, overdoses of up to 1000 mg have caused only nausea and vomiting.

Overdosage/Acute Toxicity

studies in humans Oseltamivir appears to be relatively safe during pregnancy. In rabbits, doses of 150 and 500 mg/kg (13X, 100X) caused dose-dependent increases of minor skeletal abnormalities. In humans, the FDA categorizes

Reproductive/Nursing Safety

vertigo. Bronchitis has been reported, but may be an artifact associated with influenza infection. Gastrointestinal effects are usually transient and may be alleviated by giving the medication with food.

Adverse effect profile in animals is not known. In the study mentioned above performed in horses, no adverse effects were noted. In humans, oseltamivir can cause gastrointestinal effects (nausea, vomiting), insomnia and vertigo. Bronchitis has been reported, but may be an artifact associated with influenza infection. Gastrointestinal effects are usually transient and may be alleviated by giving the medication with food.

Ormetoprim–see Niflumic acid

Uses/Indications

Oseltamivir has been suggested as a treatment for canine parvovirus infections. A recently published prospective, randomized, blinded, placebo-controlled clinical trial study, treated dogs showed statistically significant differences versus untreated dogs in weight gain and maintenance of white blood cell count (untreated dogs WBC’s decreased). No major adverse effects were noted in the treated group. The authors concluded that while a clear advantage to oseltamivir treated dogs was not established, and the true role of oseltamivir for the treatment of parvoviral enteritis remains speculative, further investigation is warranted (Savigny & MacIntire 2010). Oseltamivir may be of benefit for adjunctive treatment of other viral infections, particularly those with associated secondary bacterial components, but research or experience is lacking. A recent study performed in horses, experimentally infected with equine influenza A (H3N8), documented some efficacy in the attenuation of clinical signs (pyrexia), viral shedding, and secondary bacterial pneumonias (Yamanaka, T et al. 2006).

Because oseltamivir is the primary antiviral agent proposed for treatment or prophylaxis for an H5N1 influenza (“bird flu”) pandemic in humans, its use in veterinary patients is controversial, particularly due to concerns of adequate drug supply for the human population and the potential for influenza virus resistance development. In 2006, the FDA banned the extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys and ducks.

Pharmacology/Actions

Oseltamivir phosphate is a prodrug that is converted after absorption into oseltamivir carboxylate, the active form of the drug. Oseltamivir carboxylate competitively inhibits influenza virus neuraminidase, an enzyme that is required for viral replication, release of virus from infected cells and the prevention of formation of viral aggregates after release from cells. Resistance to oseltamivir has been induced in the laboratory and from post-treatment isolates from infected humans. Oseltamivir or oseltamivir carboxylate do not act as substrates or inhibitors for any CYP-450 isoenzymes.

It has been postulated that oseltamivir may limit the ability of canine parvovirus to pass through intestinal mucosa and infect intestinal crypt cells. There is evidence that oseltamivir has this effect (increased mucous production) on influenza viruses in the respiratory tract of humans. Additionally, it may reduce GI bacteria colonization, translocation and toxin production.

Pharmacokinetics

No information was located for the pharmacokinetic profiles of oseltamivir in dogs or cats.

In horses, oseltamivir and oseltamivir carboxylate (active metabolite) pharmacokinetics were evaluated after NG administration of 2 mg/kg. The drug was rapidly absorbed and peak levels were attained between 1-2 hours post-dose. Elimination half-lives were approximately 2 hours for oseltamivir and 2.5 hours of the carboxylate. When dosed at 2 mg/kg, the authors concluded that to maintain levels above the inhibitory concentrations against equine influenza A viruses administration intervals should be less than 10 hrs (Yamanaka, T et al. 2007).

In humans, oseltamivir phosphate is readily absorbed and converted into the carboxylate (active) form predominantly via liver esterases. The bioavailability of oseltamivir carboxylate is about 75%; it is minimally bound to plasma proteins. Elimination of oseltamivir carboxylate is primarily via renal mechanisms, both glomerular filtration and tubular secretion. Elimination half-life is about 6–10 hours in patients with normal renal function. Up to 20% of a dose may be eliminated in the feces.

Contraindications/Precautions/Warnings

Oseltamivir should not be used in patients with documented hypersensitivity to it. For efficacy, treatment must begin as early as possible. Delay in treatment beyond 40 hours after the onset of clinical signs in humans with influenza is associated with minimal efficacy. Dosages may need adjustment in patients with severe renal insufficiency.

Studies where neonatal rats were administered 1 gram/kg levels of the prodrug in the brain were 1500X greater and the active metabolite was 3 times higher than those found in adult rats. Potentially, newborn puppies could exhibit similar findings; neurotoxicity is a possibility.

In 2006, the FDA banned the extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys and ducks.

Adverse Effects

Adverse effect profile in animals is not known. In the study mentioned above performed in horses, no adverse effects were noted. In humans, oseltamivir can cause gastrointestinal effects (nausea, vomiting), insomnia and vertigo. Bronchitis has been reported, but may be an artifact associated with influenza infection. Gastrointestinal effects are usually transient and may be alleviated by giving the medication with food.

Reproductive/Nursing Safety

Oseltamivir appears to be relatively safe during pregnancy. In rabbits, doses of 150 and 500 mg/kg (13X, 100X) caused dose-dependent increases of minor skeletal abnormalities. In humans, the FDA categorizes oseltamivir as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Oseltamivir and oseltamivir carboxylate have been detected in the milk of lactating rats. Safety during nursing cannot be guaranteed, but it is unlikely to pose significant risk in nursing veterinary patients.

Overdosage/Acute Toxicity

Oseltamivir has relatively low toxic potential. In humans, overdoses of up to 1000 mg have caused only nausea and vomiting.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oseltamivir and may be of significance in veterinary patients:

Probenecid: May increase 2-fold the exposure to oseltamivir (active metabolite) by reducing tubular secretion. This could potentially be useful in reducing drug dosages or dosing frequency, or increasing serum concentrations at the usual dosage, however, supporting data is not readily available. Because of the implications associated with treating H5N1 influenza in humans, expect more information to be published on this interaction in the future. See the Probenecid monograph for more information.

Vaccines, influenza (live): Oseltamivir may potentially reduce the immune response to live influenza virus vaccines. There does not appear to be any effect on inactivated (killed) vaccines.
Oxacillin sodium is resistant to acid inactivation in the gut, but is only partially absorbed after oral administration. The bioavailability after oral administration in humans has been reported to range from 30–35%, and, if

Pharmacokinetics

choices. The penicillinase-resistant penicillins are inactive against Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses. This class of penicillins does have activity against some other gram-positive and gram-negative aerobes and anaerobes, other antibiotics (penicillins and otherwise) are usually better

staphylococcal penicillins. There are documented strains of Staphylococcus that are resistant to these drugs (so-called methicillin-resistant or oxacillin-resistant Staph), but these strains have only begun to be a significant

spectrum of activity than the natural penicillins. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly staphylococcal species. They are sometimes called anti-

Cloxacillin, dicloxacillin and oxacillin have nearly identical spectrums of activity and can be considered therapeutically equivalent when comparing

rapid elimination with required frequent dosing, and the present unavailability of solid oral dosage forms, it is infrequently used.

The veterinary use of these agents has been primarily in the treatment of bone, skin, and other soft tissue infections in small animals when penicillinase-producing Staphylococcus species have been isolated. Because of its

Must dose orally quite often (6-8h); owner compliance may be an issue

Uses/Indications

The veterinary use of these agents has been primarily in the treatment of bone, skin, and other soft tissue infections in small animals when penicillinase-producing Staphylococcus species have been isolated. Because of its rapid elimination with required frequent dosing, and the present unavailability of solid oral dosage forms, it is infrequently used.

Pharmacokinetics

Oxacillin sodium is resistant to acid inactivation in the gut, but is only partially absorbed after oral administration. The bioavailability after oral administration in humans has been reported to range from 30–35%, and, if given with food, both the rate and extent of absorption is decreased. After IM administration, oxacillin is rapidly absorbed and peak levels generally occur within 30 minutes.

The drug is distributed to the lungs, kidneys, bone, bile, pleural fluid, synovial fluid, and ascitic fluid. The volume of distribution is reportedly 0.4 L/kg in human adults and 0.3 L/kg in dogs. As with the other penicillins, only minimal amounts are distributed into the CSF, but levels are increased with meningeal inflammation. In humans, approximately 89–94% of the drug is bound to plasma proteins.

Oxacillin is partially metabolized to both active and inactive metabolites. These metabolites and the parent compound are rapidly excreted in the urine via both glomerular filtration and tubular secretion mechanisms. A
Dosage Forms/Regulatory Status

Oxacillin sodium injection is reportedly physically incompatible with the following fluids/drugs: dextrose 5% and 10% in water, dextrose 5% and 10% in sodium chloride 0.9%, lactated Ringer's injection, sodium chloride 9%, ampicillin sodium, cefprozil sodium, cephalosporins, ceftriaxone sodium, cefuroxime sodium, cefazolin sodium, and dicloxacillin sodium. Oxacillin sodium injection is reportedly compatible with the following fluids/drugs: saline solution, dextrose, lactated Ringer's injection, and sodium bicarbonate.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefazolin, and carbenicillin).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence. Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or fulminant anaphylaxis. In humans, it is estimated that 1–15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class A (Probably safe. Although specific studies may not have proved safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.).

Penicillins are excreted in maternal milk in low concentrations; use may cause diarrhea, candidiasis, or allergic response in nursing offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxacillin and may be of significance in veterinary patients:

- **Aminoglycosides**: In vitro evidence of synergism with oxacillin against S. aureus strains
- **Cyclosporine**: Oxacillin may reduce levels
- **Probenecid**: Competitively blocks the tubular secretion of oxacillin, thereby increasing serum levels and serum half-lives
- **Tetracyclines**: Theoretical antagonism; use together usually not recommended
- **Warfarin**: Oxacillin may cause decreased warfarin efficacy

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate aminoglycosides in vitro (and in vivo in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Doses

**Note**: Oxacillin is only available commercially in the USA for use as a parenteral injection and an oral suspension. For oral therapy, dicloxacillin capsules may be substituted for oxacillin.

**Dogs/Cats**

For susceptible infections:

- **a)** 22–40 mg/kg PO, SC, IM, or IV q6h (Lappin 2003)

**Horses**

For susceptible infections:

- **a)** 20–30 mg/kg IV q6–8h (Dose extrapolated from adult horse data; use lower dose or longer interval in premature foals or those less than 7 days old.) (Brumbaugh 1999; Caprile & Short 1987)
- **b)** 25–50 mg/kg IM, IV twice daily (Robinson 1987)

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Unless otherwise instructed by the veterinarian, this drug should be given to an animal with an empty stomach, at least 1 hour before feeding or 2 hours after.
- Keep oral solution in the refrigerator and discard any unused suspension after 14 days.

Chemistry/Synonyms

An isoxazolyl-penicillin, oxacillin sodium is a semi-synthetic penicillinase-resistant penicillin. It is available commercially as the monohydrate sodium salt, which occurs as a fine, white, crystalline powder that is odorless or has a slight odor. It is freely soluble in water and has a pH of about 2.8. One mg of oxacillin sodium contains not less than 815–950 micrograms of oxacillin. Each gram of the commercially available powder for injection contains 2.8–3.1 mEq of sodium.

Oxacillin sodium may also be known as: sodium oxacillin, methylphenyl isoxazolyl penicillin (5-methyl-3-phenyl-4-isoxazolyl) penicillin sodium, oxacillinum natricum, oxacillinum natrium, P-12, or SQ-16423.

Storage/Stability

Oxacillin sodium powder for oral solution, and powder for injection should be stored at room temperature (15–30°C) in tight containers. After reconstituting with water, refrigerate and discard any remaining oral solution after 14 days. If kept at room temperature, the oral solution is stable for 3 days.

After reconstituting the sterile powder for injection with sterile water for injection or sterile sodium chloride 0.9%, the resultant solution with a concentration of 167 mg/ml is stable for 3 days at room temperature or 7 days if refrigerated. The manufacturer recommends using different quantities of diluent depending on whether the drug is to be administered IM, IV directly, or IV (piggyback). Refer to the package insert for specific instructions.

Compatibility/Compounding Considerations

Oxacillin sodium injection is reportedly physically compatible with the following fluids/drugs: dextrose 5% and 10% in water, dextrose 5% and 10% in sodium chloride 0.9%, lactated Ringer's injection, sodium chloride 0.9% ampicillin sodium, cephaloridine sodium, propranolol hydrochloride, phenylpropanolamine hydrochloride, and verapamil.

Oxacillin sodium injection is reportedly physically incompatible with the following fluids/drugs: oxytetracycline HCl and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.
Laboratory Considerations

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxazepam and may be of significance in veterinary patients:

**Drug Interactions**

Oxazepam may potentially be used in life-threatening overdoses. Binding the drug (if taken orally) in the gut, and supportive systemic measures. The use of analeptic agents, (CNS stimulants such as caffeine, amphetamines, etc.) are generally not recommended. Flumazenil could be used in cases of oxazepam overdose where benzodiazepines are involved.

**Overdosage/Acute Toxicity**

When used alone, oxazepam overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Treatment of significant overdoses consists of standard protocols for removing and/or diluting the drug in the gut, supportive systemic measures, use of analeptics, and supportive care.

**References**

- **Benzodiazepines** may decrease the thyroidal uptake of 
  - Oxazepam (C-IV Controlled substance)
  - Oxazepam is used most frequently in small animal medicine as an appetite stimulant in cats, but it may also be useful to treat behavior problems in dogs or cats.
  - Contraindications: Known benzodiazepine hypersensitivity, acute narrow angle glaucoma. Caution: Myasthenia gravis, hepatic dysfunction, seizure disorders.
  - Adverse Effects: Primarily sedation & occasionally, ataxia.
  - Possibly teratogenic
  - Use in feline patients with liver dysfunction is somewhat controversial.

**Pharmacokinetics**

Oxazepam is absorbed from the GI tract, but it is one of the more slowly absorbed oral benzodiazepines. Oxazepam, like other benzodiazepines is widely distributed; it is highly bound to plasma proteins (97% in humans).

**Pharmacology/Actions**

The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by oxazepam and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of gamma-aminobutyric acid (GABA) and/or facilitation of GABA activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

**Uses/Indications**

Oxazepam is used most frequently in small animal medicine as an appetite stimulant in cats, but it may also be useful to treat behavior problems in dogs or cats. Like lorazepam, it does not have any active metabolites so it may be a good choice for treating geriatric patients and those with liver dysfunction. Use in feline patients with liver dysfunction is somewhat controversial, as it has been anecdotally reported that oxazepam has been associated with fulminant hepatic failure in cats.

**Dosage Forms/Regulatory Status**

- **Oxazepam Powder for Oral Solution:** 250 mg/5 mL when reconstituted in 100 mL; generic; (Rx)
- **Oxazepam Powder for Oral Solution:** 250 mg/5 mL when reconstituted in 100 mL; generic; (Rx)

- Oxazepam (ox-a-ze-pam) Serax®

**Adverse Effects**

- Primarily sedation & occasionally, ataxia.
- Possibly teratogenic
- Use in feline patients with liver dysfunction is somewhat controversial, as it has been anecdotally reported that oxazepam has been associated with fulminant hepatic failure in cats.

**Contraindications/Precautions/Warnings**

- Known benzodiazepine hypersensitivity, acute narrow angle glaucoma. Caution: Myasthenia gravis, hepatic dysfunction, seizure disorders.
- Use in feline patients with liver dysfunction is somewhat controversial, as it has been anecdotally reported that oxazepam has been associated with fulminant hepatic failure in cats.

**Dose/Use in Acute Toxicity**

When used alone, oxazepam overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Treatment of significant overdoses consists of standard protocols for removing and/or diluting the drug in the gut, and supportive systemic measures. The use of analeptics, (CNS stimulants such as caffeine, amphetamines, etc.) are generally not recommended. Flumazenil could be used in cases of oxazepam overdose where benzodiazepines are involved.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxazepam and may be of significance in veterinary patients:

- **CNS DEPRESSANT DRUGS**: If oxazepam administered with other CNS depressant agents (barbiturates, narcotics, anesthetics, etc.) additive effects may occur.
- **PHENYTOIN**: May decrease oxazepam concentrations.
- **PROBENECID**: May impair glucuronide conjugation (in dogs) and prolong effects.
- **RIFAMPIN**: May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines.
- **ST. JOHN’S WORT**: May decrease oxazepam effectiveness.
- **THEOPHYLLINES**: May decrease oxazepam effectiveness.

**Laboratory Considerations**

- Benzodiazepines may decrease the thyroidal uptake of I\(^{131}\) or I\(^{123}\)
Benzodiazepines may decrease the thyroidal uptake of $\text{I}^{123}$ or $\text{I}^{131}$.

**DOGS:**

For treating fears and phobias:
- a) 0.2–0.5 mg/kg PO q12–24h (Siebert 2003)
- b) 0.2–1 mg/kg PO q12–24h (Virga 2002; Virga 2007)
- c) 0.2–1 mg/kg one to two times a day (Landsberg 2005)
- d) 0.04–0.5 mg/kg PO q6h. The lowest dose and longest frequency between doses that alleviate the fear should be used. (Crowell-Davis 2008)

**CATS:**

As an appetite stimulant:
- a) 2 mg per cat (total dose) every 12 hours (Hartke et al. 1992)(Hodgkins & Franks 1991)
- b) In cats with hepatic lipidosis, if cat has a small interest in eating: 0.1–0.3 mg/kg PO q12–24h (Twedt 2005)
- c) 0.25–0.5 mg/kg PO one to two times daily. (Sparkes 2005)

For behavior-related conditions:
- a) For treating fears and phobias: 1–2.5 mg per cat (total dose) PO every 12 hours (Siebert 2003)
- b) For treating fears and phobias 0.2–0.5 mg/kg PO q12–24h (Virga 2002; Virga 2007)
- c) For feline urine marking: 0.2–0.5 mg/kg PO once to twice a day. (Landsberg 2007)
- d) For spraying or overgrooming: 0.2–0.5 mg/kg PO q12–24h (Seksel 2006)
- e) For fears and phobicias: 0.2–1 mg/kg PO q12h PO q6h. The lowest dose and longest frequency between doses that alleviate the fear should be used. (Crowell-Davis 2008)

**Monitoring**

- **Efficacy**
- **Adverse effects**

**Client Information**

- Caution clients not to discontinue medication or adjust dosage without first checking with veterinarian.
- Efficacy for anorexia may be improved if given just prior to feeding as effects are generally seen within 30 minutes.

**Chemistry/Synonyms**

A benzodiazepine, oxazepam occurs as a creamy white to pale yellow powder. It is practically insoluble in water.

Oxazepam may also be known as: oxazepamum, Wy-3498, and Serax®.

**Storage/Stability**

Store oxazepam capsules and tablets at room temperature in well-closed containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

**References**

**OXFENDAZOLE**

*ox-fer-da-za-ole* Synanthic®

**ANTIPARASITIC AGENT (ANTHELMINTIC)**

**Prescriber Highlights**

- Benzimidazole anthelmintic used primarily in cattle
- Contraindications: Not for use in female dairy cattle of breeding age
- Caution: Debilitated or sick horses; 7 day slaughter withdrawal in cattle
- Adverse Effects: Unlikely; hypersensitivity possible

**Uses/Indications**

Oxfendazole (Synanthic®) is indicated in cattle for the removal and control of lungworms, roundworms (including inhibited forms of *Ostertagia ostertagi*) and tapeworms.

Oxfendazole as *Benzelmin®* was indicated (no longer marketed in the USA) for the removal of the following parasites in horses: large roundworms (*Parascaris equorum*), large strongyles (*S. edentatus, S. equinus, S. vulgaris*), small strongyles, and pinworms (*Oxyuris equi*).

Oxfendazole has also been used extra-label in sheep, goats, and swine; see Dosage section for more information.

**Pharmacology/Actions**

Benzimidazoles are benzene derivatives containing an imidazole moiety. They exert their activity through a direct interaction with a key enzyme involved in the biosynthesis of the cellular nucleic acid. The primary target is tubulin, a major component of microtubules, which are structural components of the cell. The inhibition of tubulin synthesis results in the arrest of parasite development in the gastrointestinal tract.
Benzimidazole anthelmintic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics

Limited information is available regarding this compound’s pharmacokinetics. Unlike most of the other benzimidazole compounds, oxfendazole is absorbed more readily from the GI tract. The elimination half-life has been reported to be about 7.5 hours in sheep and 5.25 hours in goats. Absorbed oxfendazole is metabolized (and vice-versa) to the active compound, fenbendazole (sulfoxide) and the sulfone.

After a single oral dose of 50 mg/kg to dogs, oxfendazole levels peaked at 8 hours. Elimination half-lives for the parent compound and the sulfoxide metabolite (active) were both about 5.5 hours. In dogs, oxfendazole plasma concentrations were significantly higher and resident times longer than that of either fenbendazole or albendazole following single oral administration at the same dose (50 mg/kg) (Gokbulut et al. 2007).

Contraindications/Precautions/Warnings

Not for use in female dairy cattle of breeding age. A 7 day slaughter withdrawal is required when using at labeled doses.

There are no contraindications to using this drug in horses, but it is recommended to use oxfendazole cautiously in debilitated or sick horses.

Adverse Effects

When used as labeled, it is unlikely any adverse effects will be noted. Hypersensitivity reactions secondary to antigen release by dying parasites are theoretically possible, particularly at high dosages.

Reproductive/Nursing Safety

Oxfendazole may be safely used in pregnant mares and foals.

Overdosage/Acute Toxicity

Doses of 10 times those recommended elicited no adverse reactions in horses tested. It is unlikely that this compound would cause serious toxicity when given alone.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxfendazole and may be of significance in veterinary patients:

BROMOSALAN FLUKICIDES (dibromsalan, tribromsalan): Oxfendazole should not be given concurrently with these agents; abortions in cattle and death in sheep have been reported after using these compounds together

Doses

**DOGS:**
- a) For *Oslerus ostleri*: 10 mg/kg PO once daily for 28 days. (Bowman 2006)

**HORSES:**
- a) For susceptible parasites: 10 mg/kg PO (Roberson 1988), (Package insert; Benzemint®—Fort Dodge)

**CATTLE:**
- a) For susceptible parasites: 4.5 mg/kg either PO or via intraruminal injection (22.5% only). May repeat in 4-6 weeks. Dose of the 9.06% suspension is 2.5 mL per 100 lb (50 kg) of body weight PO. Dose of the 22.5% suspension is 1 mL per 100 lb (50 kg) of body weight either PO or via intraruminal injection. See package label for specific directions if giving by intraruminal injection. (Package inserts; Synanthic® 9.06% and 22.5%—Fort Dodge)

**SWINE:**
- a) For susceptible parasites: 3–4.5 mg/kg PO (Roberson 1988)

**SHEEP:**
- a) For susceptible parasites: 5 mg/kg PO (Brander et al. 1982; Roberson 1988)

**GOATS:**
- a) For susceptible parasites: 7.5 mg/kg PO (Roberson 1988)

Monitoring

- Efficacy

Client Information

- Not to be used in horses intended for food purposes
- Shake suspension well
- Slaughter withdrawal in cattle is 7 days; not FDA-approved for lactating dairy cattle

Chemistry/Synonyms

A benzimidazole anthelmintic, oxfendazole occurs as white or almost white powder possessing a characteristic odor. It is practically insoluble in water. Oxfendazole is the sulfoxide metabolite of fenbendazole. Oxfendazole may also be known as RS 8858; there are many international trade names.

Storage/Stability

Unless otherwise directed by the manufacturer, oxfendazole products should be stored at room temperature and protected from light. The manufacturer recommends discarding any unused suspension 24 hours after it has been reconstituted.

Dosage Forms/Preparations/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Oxfendazole Oral Suspension: 9.06% in 1 liter and 4 liter; Synanthic® (BIVI); (OTC). FDA-approved for use in beef cattle and in female dairy cattle not of breeding age. Because a withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

Oxfendazole Oral Suspension: 22.5% in 500 mL and 1 liter; Synanthic® (BIVI); (Rx). FDA-approved for use in beef cattle and in female dairy cattle not of breeding age. Because a withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

References

Prescriber Highlights

- Benzimidazole anthelmintic used primarily in horses
- Resistance development an ongoing issue
- Contraindications: Severely debilitated horses or in horses suffering from colic, toxemia or infectious disease.
- Adverse Effects: Unlikely; hypersensitivity possible

Uses/Indications
Oxibendazole is indicated (labeled) for the removal of the following parasites in horses: large roundworms (*Parascaris equorum*), large strongyles (*S. edentatus, S. equinus, S. vulgaris*), small strongyles, threadworms, and pinworms (*Oxyuris equi*). Resistance to antiparasitic agents is an ongoing problem. It is recommended to perform fecal egg count reduction testing (FECRT) for strongyle nematodes. A value of less than 90% in 5-10 horses is the suggested cut-off for determining resistance on a given farm (Kaplan & Nielsen 2010).

Oxibendazole has also been used in cattle, sheep, and swine; see Dosage section for more information.

Pharmacology/Actions
Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics
No information was located.

Contraindications/Precautions/Warnings
Oxibendazole is stated by the manufacturer to be contraindicated in severely debilitated horses or in horses suffering from colic, toxemia, or infectious disease.

Adverse Effects
When used in horses at recommended doses, it is unlikely any adverse effects would be seen. Hypersensitivity reactions secondary to antigen release by dying parasites are theoretically possible, particularly at high dosages.

Oxibendazole in combination with diethylcarbamazine (*Filaribits Plus*) was implicated in causing periportal hepatitis in dogs when it was marketed (1980s).

Reproductive/Nursing Safety
Oxibendazole is considered safe to use in pregnant mares.

Overdosage/Acute Toxicity
Doses of 60 times those recommended elicited no adverse reactions in horses tested. It is unlikely that this compound would cause serious toxicity when given alone to horses.

Drug Interactions
- No significant interactions have been reported

Doses

**HORSES:**
- For susceptible parasites:
  a) 10 mg/kg PO; 15 mg/kg PO for strongyloides; horses maintained on premises where reinfection is likely to occur should be retreated in 6–8 weeks. (Package insert; *Anthelcide EQ®*—Pfizer)
  b) 10 mg/kg, PO (Roberson 1988; Robinson 1987)

**CATTLE:**
- For susceptible parasites:
  a) 10–20 mg/kg PO (Brander *et al.* 1982)

**SWINE:**
- For susceptible parasites:
  a) 15 mg/kg, PO (Roberson 1988)

**SHEEP:**
- For susceptible parasites:
  a) 10–20 mg/kg PO (Brander *et al.* 1982)

Monitoring
- Efficacy

Client Information
- Protect suspension from freezing
- Shake suspension well before using
- Not for use in horses intended for food

Chemistry/Synonyms
A benzimidazole anthelmintic, oxibendazole occurs as a white powder that is practically insoluble in water.

Oxibendazole may also be known as SKF-30310 and *Anthelcide EQ®* and in the U.K. by the proprietary names: *Div®* (Alan Hitchings), *Equidin®* (Univet), *Equitac®* (SKF) or *Loditac®* (SKF).

Storage/Stability
Unless otherwise directed by the manufacturer, oxibendazole products should be stored at room temperature; protect from freezing.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Oxibendazole Suspension: 100 mg/mL (10%) in gallons. *Anthelcide EQ® Suspension* (Pfizer); (Rx). FDA-approved for use in horses not used for food.
Oxibendazole Oral Paste: 227 mg/gram (22.7%) in 24-gram syringes. Anthelcide EQ® Paste (Pfizer); (OTC). FDA-approved for use in horses not used for food.

HUMAN-LABELED PRODUCTS: None

OXYBUTYXIN CHLORIDE

(ox-ib-byo-tin) Ditropan®, Oxytrol®

GENITOURINARY SMOOTH MUSCLE RELAXANT

Prescriber Highlights

- Urinary antispasmodic potentially useful in dogs or cats
- Cautions (risk vs. benefit): Obstructive GI tract disease or intestinal atony/paralytic ileus, angle closure glaucoma, hiatal hernia, cardiac disease (particularly associated with mitral stenosis, associated arhythmias, tachycardia, CHF, etc.), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, severe ulcerative colitis, urinary retention, or other obstructive uropathies
- Adverse Effects: Diarrhea, constipation, urinary retention, hypersalivation, & sedation

Uses/Indications

Oxybutynin may be useful for the adjunctive therapy of detrusor hyperreflexia in dogs and in cats with FeLV-associated detrusor instability.

Pharmacology/Actions

Considered a urinary antispasmodic, oxybutynin has direct antimuscarinic (atropine-like) and spasmyloytic (papaverine-like) effects on smooth muscle. Spasmolytic effects appear to be most predominant on the detrusor muscle of the bladder and small and large intestine. It does not have appreciable effects on vascular smooth muscle. Studies done in patients with neurogenic bladders showed that oxybutynin increased bladder capacity, reduced the frequency of uninhibited contractions of the detrusor muscle and delayed initial desire to void. Effects were more pronounced in patients with uninhibited neurogenic bladders than in patients with reflex neurogenic bladders. Other effects noted in lab animal studies include moderate antihistaminic, local anesthetic, mild analgesic, very low mydriatic, and antialagogue effects.

Pharmacokinetics

Oxybutynin is apparently rapidly and well absorbed from the GI tract. Studies done in rats show the drug distributed into the brain, lungs, kidneys, and liver. While elimination characteristics have not been well documented, oxybutynin apparently is metabolized in the liver and excreted in the urine. In humans, the duration of action is from 6–10 hours after a dose.

Contraindications/Precautions/Warnings

Because of the drug’s pharmacologic actions, oxybutynin should be used when its benefits outweigh its risks if the following conditions are present: obstructive GI tract disease or intestinal atony/paralytic ileus, angle closure glaucoma, hiatal hernia, cardiac disease (particularly associated with mitral stenosis, associated arhythmias, tachycardia, CHF, etc.), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, severe ulcerative colitis, urinary retention or other obstructive uropathies.

Adverse Effects

While use in small animals is limited, diarrhea, constipation, urinary retention, hypersalivation, and sedation have been reported. Other adverse effects reported in humans, and potentially seen in animals, primarily result from the drug’s pharmacologic effects, including: dry mouth or eyes, tachycardia, anorexia, vomiting, weakness, or mydriasis.

Reproductive/Nursing Safety

While safety during pregnancy has not been firmly established, studies in a variety of lab animals have demonstrated no teratogenic effect associated with the drug. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known whether this drug is excreted in maternal milk. While oxybutynin may inhibit lactation, no documented problems associated with its use in nursing offspring have been noted.

Overdosage/Acute Toxicity

Overdosage may cause CNS effects (e.g., restlessness, excitement, seizures), cardiovascular effects (e.g., hyper- or hypotension, tachycardia, circulatory failure), fever, nausea or vomiting. Massive overdoses may lead to paralysis, coma, respiratory failure and death. Treatment of overdoses should consist of general techniques to limit absorption of the drug from the GI tract and supportive care as required; intravenous physostigmine may be useful. See the monograph for more information on the use of physostigmine.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxybutynin and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS** (e.g., atropine, propantheline, scopolamine, isopropanide, glycopyrrolate, hyoscymine, tricyclic antidepressants, disopyramide, procainamide, antihistamines, etc.): May intensify oxybutynin’s anticholinergic effects
- **AZOLE ANTIFUNGALS** (ketoconazole, etc.): May increase oxybutynin levels
- **CNS DEPRESSANTS**: Other sedating drugs may exacerbate the sedating effects of oxybutynin
- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May increase oxybutynin levels

**Doses**

**Dogs:**

- To decrease bladder contractility (detrusor hyperreflexia):
  a) 0.2 mg/kg PO q8–12h; most dogs are dosed at 1.25–3.75 mg (total dose) q12h. Juvenile animals may require a prolonged dosing interval. (Lane 2000)
  b) 1.25–5 mg (total dose) PO q8–12h (Bartges 2003; Bartges 2009)
  c) 2–5 mg (total dose) PO q8–12h (Vernau 2006)

**Cats:**

- To decrease bladder contractility (detrusor hyperreflexia):
  a) 0.5–1 mg (total dose) PO q8–12h. Juvenile animals may require a prolonged dosing interval. (Lane 2000)
  b) 0.5–1.25 mg per cat PO q8–12h (Osborne et al. 2000; Bartges 2003; Polzin 2005)
Oxymorphone should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and in geriatric or severely debilitated patients. Oxymorphone is contraindicated in patients with a known sensitivity to it.

**Pharmacokinetics**

Oxymorphone is absorbed when given by IV, IM, SC, and rectal routes. Although absorbed when given orally, bioavailability is reduced, probably from a high first-pass effect. After IV administration, analgesic efficacy usually occurs within 3–5 minutes. After 0.1 mg/kg IM administration to dogs, onset of action is about 15 minutes and duration of effect, 2-4 hours.

**Adverse Effects**

Oxymorphone may cause more panting in dogs than morphine, while in dogs the opposite appears to be true. At the usual doses employed, oxymorphone alone has good sedative qualities in the dog. Respiratory depression can occur especially in debilitated, neonatal or geriatric patients. Bradycardia, as well as a slight decrease in cardiac contractility and blood pressure, may also be seen. Like morphine, oxymorphone does initially increase the respiratory rate (panting in dogs) while actual oxygenation may be decreased and blood CO2 levels may increase by 10 mmHg or more. Oxymorphone may cause more panting in dogs than morphine. Gut motility is decreased with oxymorphone.

**Receptors for opiate analgesics** are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antinociceptive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. In a study done in dogs, morphine, oxymorphone was comparable to hydromorphone in potency and efficacy for pain control. Patients receiving hydromorphone vomited more than when oxymorphone was used, but hydromorphone was significantly less expensive (Bateman et al. 2008).

**Pharmacology/Actions**

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the mu receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antinociceptive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. In a study done in dogs, morphine, oxymorphone was comparable to hydromorphone in potency and efficacy for pain control. Patients receiving hydromorphone vomited more than when oxymorphone was used, but hydromorphone was significantly less expensive (Bateman et al. 2008).

Oxymorphone is used in dogs and cats as a sedative/restraining agent, analgesic, and preanesthetic; occasionally in horses as an analgesic and anesthesia induction agent. It may also be used in swine as an adjunctive agent with ketamine/xylazine anesthesia and small rodents as an analgesic/anesthetic for minor surgical procedures.

Oxymorphone is effective for moderate to severe pain and its effects on the cardiovascular system are usually not clinically significant. It causes less histamine release than morphine.

In a study done in dogs, oxymorphone was comparable to hydromorphone in potency and efficacy for pain control. Patients receiving hydromorphone vomited more than when oxymorphone was used, but hydromorphone was significantly less expensive (Bateman et al. 2008).

**Pharmacokinetics**

Oxymorphone is absorbed when given by IV, IM, SC, and rectal routes. Although absorbed when given orally, bioavailability is reduced, probably from a high first-pass effect. After IV administration, analgesic efficacy usually occurs within 3–5 minutes. After 0.1 mg/kg IM administration to dogs, onset of action is about 15 minutes and duration of effect, 2-4 hours.

Like morphine, oxymorphone concentrates in the kidney, liver, and lungs; lower levels are found in the CNS. Oxymorphone crosses the placenta and narcotized newborns can result if mothers are given the drug before giving birth, but these effects can be rapidly reversed with naloxone.

The drug is metabolized in the liver; primarily by glucuronidation. Because cats are deficient in this metabolic pathway, half-lives in cats are probably prolonged. The kidneys excrete the glucurononidated metabolite.
**Doses**

For sedation for minor procedures:

a) Up to 0.2 mg/kg IM or IV; initially a maximum of 5 mg total dose (Combine with acepromazine 0.05–0.1 mg/kg IM or IV) (Shaw et al. 1986)

b) 0.05–0.1 mg/kg IV or 0.1–0.2 mg/kg IM, SC (Morgan 1988)

For analgesia (acute pain):

a) 0.1–0.2 mg/kg IM, IV, or SC q1–3h (Hendrix & Hansen 2000)

b) For animals with cardiovascular disease: 0.05–0.1 mg/kg IV, IM or SC q2–4h (Hansen 2003)

c) Epidural administration: 0.05 mg/kg. Recommend to dilute with sterile saline to a volume not to exceed 0.3 mL/kg to a maximum of 6 mL. Use of preservative-free opioids is best. (Matthews 2008)

d) 0.1–0.2 mg/kg IM or SC q3–4h for acute pain. (Gaynor 2007)

e) 0.05–0.4 mg/kg IV, IM, or SC q2–4h (Wagner 2002)

For premedication to anesthesia in healthy dogs:

a) 0.05–0.1 mg/kg IM, IV; 0.2 mg/kg for extra heavy sedation. Maximum initial dose: 5 mg. (Trim 2008)

**Cats:**

As a preanesthetic/analgesic:

a) 0.05–0.1 mg/kg IM; may cause dysphoria or excitement, add sedative. (Trim 2008)

As an analgesic (acute pain):

a) 0.05–0.1 mg/kg IM, SC or IV q1–3h; concomitant tranquilization recommended (Hendrix & Hansen 2000)

b) For animals with cardiovascular disease: 0.05–0.1 mg/kg IV, IM or SC q2–4h (Hansen 2003)

c) 0.025–0.1 mg/kg IV (IM or SC) q2–6h (Scherk 2003)

d) 0.02–0.1 mg/kg IM, IV, or SC q3–4h (Wagner 2002)

**Ferrets:**

a) 0.05–0.2 mg/kg IV or IM 2–4 times daily (Williams 2000)

b) 0.05–0.2 mg/kg SQ or IM q8–12 hrs (Hernandez-Divers 2008)

**Rabbits, Rodents, Small Mammals:**

a) Rabbits: 0.2 mg/kg IM q2–4h (Ivey & Morrisey 2000)

b) Anesthetic/analgesic for minor surgical procedures: 0.15 mg/kg IM (for a hamster-sized animal) (Shaw et al. 1986)

c) Hamsters, Gerbils, Mice, Rats, Guinea Pigs: 0.2–0.5 mg/kg SC, IM q6–12h for analgesia (Adamk & Otten 2000)

d) Rabbits, Rats, Mice, Gerbils, Guinea Pigs, Hamsters, Chinchillas: 0.05–0.2 mg/kg SQ (or IM for rabbits only) q8–12 hrs (Hernandez-Divers 2008)

**Horses:**

*Note: ARCI UCGFS Class 1 Drug*

**Laboratory Considerations**

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxymorphone and may be of significance in veterinary patients:

- **Buprenorphine, Buprenorphine, Nalbuphine:** Potentially could antagonize opiate effects
- **Monoamine Oxidase Inhibitors:** Use MAOIs with oxymorphone with extreme caution as meperidine (a related opiate) is contraindicated in human patients receiving monoamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.
- **Muscle Relaxants, Skeletal:** Oxymorphone may enhance effects
- **Phenothiazines:** Some phenothiazines may antagonize anesthetic effects and increase risk for hypotension
- **Tricyclic Antidepressants:** Oxymorphone may exacerbate the effects of tricyclic antidepressants
- **Warfarin:** Oxymorphone may potentiate anticoagulant activity

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Most opioids appear in maternal milk, but effects on offspring may not be significant. Withdrawal symptoms have occurred in breastfeeding human infants when maternal administration of an opioid-analgesic is stopped. Mechanical respiratory support should be considered in cases of severe respiratory depression.

**Overdosage/Acute Toxicity**

Massive overdoses may produce profound respiratory and/or CNS depression in most species. Other effects may include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as naloxone’s effects sometimes diminish before sub-toxic levels of oxymorphone are attained. Protective respiration should be considered in cases of severe respiratory depression.

**Adverse Effects**

Oxymorphone may cause respiratory depression and bradycardia (see above). Panting is commonly seen in dogs. When used in cats at high dosages, oxymorphone may cause ataxia, hyperthermia, and behavioral changes such as hyperexcitability or aggression (without concomitant tranquilization). Decreased GI motility with resultant constipation has been described.

**Note:** This drug should be used cautiously in patients with hypothyroidism, severe renal insufficiency, severe hepatic disease, or concurrent administration of monoamine oxidase inhibitors (MAOIs), and in geriatric, or severely debilitated patients. Oxymorphone is contraindicated in patients hypersensitive to narcotic analgesics, those receiving monoamine oxidase inhibitors (MAOIs), or with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract.

Oxymorphone should be used with extreme caution in patients with head injuries, increased intracranial pressure or acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions, and suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

In horses, opiates may cause CNS excitement and pretreatment with drugs such as xylazine are usually administered to reduce the behavioral changes these drugs can cause.

**Opiate analogues** are also contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus Ewing* and *C. gertschi Stahnke* as it may potentiate these venoms.
Note: Opiates (oxymorphone included) may cause CNS excitement in the horse. Some clinicians recommend pretreatment with acepromazine (0.02–0.04 mg/kg IV), or xylazine (0.3–0.5 mg/kg IV) to reduce the behavioral changes these drugs can cause.

Warning: Opiate analgesics can mask the behavioral and cardiovascular clinical signs associated with mild colic.

As an analgesic:

a) 0.01–0.02 mg/kg IV (Muir 1987)

b) 0.01–0.02 mg/kg IV; up to 15 mg total (divide dose into 3–4 increments and give several minutes apart (Shaw et al. 1986)

c) 0.02–0.03 mg/kg IM (Robinson 1987)

d) 0.015–0.03 mg/kg IV (Thurmon & Benson 1987)

Anesthetic induction in severely compromised horses:

a) 0.01–0.02 mg/kg IV (after approx. 45 minutes, may be necessary to “top off” with another ⅓ of the original dose) (Shaw et al. 1986)

SWINE:

a) To increase analgesia when used with ketamine (2 mg/kg)/xylazine (2 mg/kg): 0.075 mg/kg IV (duration of anesthesia and recumbency: 20–30 minutes) (Shaw et al. 1986)

ZOO, EXOTIC, WILDLIFE SPECIES:

For use of oxymorphone in zoo, exotic and wildlife medicine refer to specific references, including:

c) Restraint and Handling of Wild and Domestic Animals. Fowlser, M (ed.). Iowa State University Press, 1995

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

Monitoring

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity
- Cardiac rate

Client Information

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

Chemistry/Synonyms

A semi-synthetic phenanthrene narcotic agonist, oxymorphone HCl occurs as odorless white crystals or white to off-white powder. It will darken in color with prolonged exposure to light. One gram of oxymorphone HCl is soluble in 4 mL of water; it is sparingly soluble in alcohol or ether. The commercially available injection has a pH of 2.7–4.5.

Oxymorphone HCl may also be known as: 7,8-Dihydro-14-hydroxymorphinone hydrochloride, or oximorphone hydrochloride, Numorphan® and Opana®.

Storage/Stability

The injection should be stored protected from light and at room temperature (15–30°C); avoid freezing. The commercially available suppositories should be stored at temperatures between 2–15°C.

Compatibility/Compounding Considerations

The injection should be compatible when mixed with acepromazine, atropine, glycopyrrolate, and ranitidine. It is physically incompatible when mixed with barbiturates or diazepam.

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Oxymorphone HCl Oral Tablets: 5 mg & 10 mg; Opana® (Endo); (Rx, C-II)

Oxymorphone HCl Extended-Release Oral Tablets: 5 mg, 7.5 mg, 10 mg, 15 mg, 20 mg, 30 mg & 40 mg; Opana® ER (Endo); (Rx, C-II)

Oxymorphone HCl for Injection: 1 mg/mL in 1 mL amps; Opana® (Endo); (Rx, C-II)

Note: Oxymorphone is a Class-II controlled substance. Very accurate record keeping is required as to use and disposition of stock.

References

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytetracycline and may be of significance in veterinary patients:

**Adverse Effects:** GI distress, staining of developing teeth & bones, superinfections, photosensitivity; long-term use may cause uroliths. Can do not tolerate very well. Horses: if stressed may break with diarrheas (oral use). Ruminants: high oral doses can cause ruminal microflora depression & ruminoreticular stasis. Rapid IV of undiluted propylene glycol-based products can cause intravascular hemolysis & cardiodepressant effects. IM: local reactions, yellow staining & necrosis may be seen at the injection site.

---

### Uses/Indications

Oxytetracycline products are FDA-approved for use in dogs and cats (no known products are being marketed, however), calves, non-lactating dairy cattle, beef cattle, swine, fish, and poultry. For more information, refer to the Doses section, below.

### Pharmacology/Actions

Tetracyclines generally act as bacteriostatic antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, preventing binding to those ribosomes of aminocyclinol transfer-RNA. Tetracyclines also are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can also inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococci and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines, include *Actinomyces spp.*, *Bacillus anthracis*, *Clostridium perfringens* and tetani, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have in vitro and in vivo activity include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasteurella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, Enterobacter, *Proteus* and *Pseudomonas aeruginosa* are resistant to the tetracyclines. While most strains of *Pseudomonas aeruginosa* show in vitro resistance to tetracyclines, those compounds containing high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism.

Oxytetracycline and tetracyclines share nearly identical spectrums of activity and patterns of cross-resistance. A tetracycline susceptibility disk is usually used for in vitro testing for oxytetracycline susceptibility. In horses, oxytetracycline appears to be a potent inhibitor of matrix metalloproteinase-9 and a modest inhibitor of matrix metalloproteinase-2 (Fugler et al. 2009).

### Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailabilities are approximately 60–80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration of oxytetracycline (not long-acting), peak levels may occur in 30 minutes to several hours, depending on the volume and site of injection. The long-acting product (LA-2000) has significantly slower absorption after IM injection.

Tetracyclines as a class are widely distributed in the body, including to the heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aequous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF and therapeutic levels may not be attainable. While all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation, and are distributed into milk. The volume of distribution of oxytetracycline is approximately 2.1 L/kg in small animals, 1.4 L/kg in horses, and 0.8 L/kg in cattle. In the amount of plasma protein binding is approximately 10%–40% for oxytetracycline. Oxytetracycline tissue concentrations are higher in diseased lung than in healthy lung and concentrations in milk are higher than serum when mammary glands are inflamed.

Both oxytetracycline and tetracycline are eliminated unchanged primarily via glomerular filtration. Patients with impaired renal function can have prolonged elimination half-lives and may accumulate the drug with repeated dosing. These drugs apparently are not metabolized, but are excreted into the GI tract via both biliary and nonbiliary routes and may become inactive after chelation with fecal materials. The elimination half-life of oxytetracycline is approximately 4–6 hours in dogs and cats, 4.3–9.7 hours in cattle, 10.5 hours in horses, 6.7 hours in swine, and 3.6 hours in sheep.

### Contraindications/Precautions/Warnings

Oxytetracycline is contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolored deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, oxytetracycline and tetracycline must be used cautiously. Lower than normal dosages are recommended with enhanced monitoring of renal and hepatic function.

Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs with tetracyclines. Monitoring of serum levels should be considered if long-term therapy is required.

### Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause a yellow, brown, or gray discoloration of bones and teeth. High dosages or chronic administration may delay bone growth and healing. Tetracyclines in high levels can exert an antiabolic effect, which can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiodepressant effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well, and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs, but this is thought to occur very rarely.

Horses, who are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrheas after receiving tetracyclines (especially with oral administration). Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity).

Tetracyclines are excruted in maternal milk. Milk to plasma ratios varies between 0.25 to 1.5. Because of the potential for serious adverse reactions, decide whether to discontinue nursing or discontinue the drug.

### Overdosage/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytetracycline and may be of significance in veterinary patients:

- **ATOVUQONE:** Tetracyclines have caused decreased atovaquone levels
- **BETA-LACTAM or AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides; there is some controversy regarding the actual clinical significance of this interaction, however.
- **DIGOXIN:** Tetracyclines may increase the bioavailability of digoxin in a small percentage of human patients and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **DIVALENT or TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products.
- **METHOXYFLURANE:** Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline is not recommended
Laboratory Considerations

**CATTLE:**
- RABBITS, RODENTS, SMALL MAMMALS:
- CATS:
  - Tetracyclines (not minocycline) may cause falsely elevated values of urine catecholamines when using flurometric methods of determination. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (Clinistix®, Tes-Tape®).
  - f) For proliferative enteropathy (Neorickettsia helminthoea): 7 mg/kg IV every 8 h for 3–5 days. (Headley et al.)
  - d) As a chelating antibiotic for medial canthus syndrome (tear staining): 25–50 mg (total dose) PO once per day 2 weeks on and off and on. (Krohne 2008)
  - e) For diagnosis and treatment of idiopathic antibiotic-responsive diarrhea: 10–20 mg/kg PO q8h. (Allenbach 2009)

**DOGS:**
- For susceptible infections:
  - a) For systemic infections: 22 mg/kg PO q8h for 7–14 days or 20 mg/kg IM (using reconstituted form) every 7 days as needed. (Greene et al. 2006)
  - b) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995)
  - c) For adjunctive treatment of Salmon poisoning (Neorickettsia helminthoea): 7 mg/kg IV every 8 h for 3–5 days. (Headley et al.)
  - d) As a chelating antibiotic for medial canthus syndrome (tear staining): 25–50 mg (total dose) PO once per day 2 weeks on and off and on. (Krohne 2008)
  - e) For diagnosis and treatment of idiopathic antibiotic-responsive diarrhea: 10–20 mg/kg PO q8h. (Allenbach 2009)

**CATS:**
- Tetracyclines (not minocycline) may cause falsely elevated values of urine catecholamines when using flurometric methods of determination. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (Clinistix®, Tes-Tape®).
  - f) For proliferative enteropathy (Neorickettsia helminthoea): 7 mg/kg IV every 8 h for 3–5 days. (Headley et al.)
  - d) As a chelating antibiotic for medial canthus syndrome (tear staining): 25–50 mg (total dose) PO once per day 2 weeks on and off and on. (Krohne 2008)
  - e) For diagnosis and treatment of idiopathic antibiotic-responsive diarrhea: 10–20 mg/kg PO q8h. (Allenbach 2009)

**RABBITS, RODENTS, SMALL MAMMALS:**
- a) RABBITS: 15 mg/kg SC, IM q8h; 15–50 mg/kg PO once daily; 1 mg/mL in drinking water (Ivey & Morrissey 2000)
- b) For E. canaliculatus infections in rabbits: 20 mg/kg SC once daily. (Bryan 2009)
- c) Chinchillas: 50 mg/kg PO q12h (Hayes 2000); (Adamcak & Otten 2000)
- d) Gerbils: 10 mg/kg PO q8h or 20 mg/kg SC q24h; Guinea Pigs: 50 mg/kg, PO q12h; Hamsters: 16 mg/kg, SC q24h; Mice: 10–20 mg/kg PO q8h; Rats: 10–20 mg/kg PO q8h or 6–10 mg/kg IM q12h (Adamcak & Otten 2000)

**CATTLE:**
- a) For susceptible infections:
  - Using Liqueamycin LA-200®: For bacterial pneumonia caused by Pasteurella spp. (shipping fever) in calves and yearlings, where retreatment is impractical due to husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable, or infectious bovine keratoconjunctivitis (pink eye) caused by (M. bovis): 9 7–13 mg/kg (20–30 mg/kg) IM or SC once. Can be given as 3–5 mg/lb (6.6–11 mg/kg) IM, SC, or IV once daily. In the treatment of severe footrot and advanced cases of other indicated diseases, a dosage level of 5 mg/lb (11 mg/kg) per day is recommended. Treatment should be continued 24–48 hours following remission of disease signs; however, treatment should not exceed a total of 4 consecutive days. (Label information; Liqueamycin LA-200®—Pfizer)
  - b) Using Tetradure-300®: For the control of respiratory disease in cattle at high risk of developing BRD associated with Mannheimia (Pasteurella) haemolytica: 13.6 mg/lb (30 mg/kg) IM or SC once.
- For bacterial pneumonia caused by Pasteurella spp. (shipping fever) in calves and yearlings where treatment is impractical due to husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable, or infectious bovine keratoconjunctivitis (pink eye) caused by Moraxella bovis: 9–13.6 mg/kg (20–30 mg/kg) IM or SC once.
- Other indications (see label): 3–5 mg/lb (6.6–11 mg/kg) IM, SC or IV (IV slowly over a period of at least 5 minutes) once daily. In treatment of foot-rot and advanced cases of other indicated diseases, a dosage level of 5 mg/lb (11 mg/kg) per day is recommended. Treatment should be continued 24 as 48 hours following remission of disease signs, however, not to exceed a total of four consecutive days. If improvement is not noted within 24 to 48 hours of the beginning of treatment, diagnosis and therapy should be re-evaluated.
- Do not administer intramuscularly in the neck of small calves due to lack of sufficient muscle mass. Use extreme care when administering this product by intravenous injection. Perivascular injection or leakage from an intravenous injection may cause severe swelling at the injection site. (Label information; Tetradure-300®—Merial)
  - c) For respiratory tract infections: Using 50 mg/mL product: 11 mg/kg IM or SC q24h or IV q12–24h; Using 100 mg/mL product: 20 mg/kg IM q24h; Using 200 mg/mL product (LA-200®): 20 mg/kg IM q3–4 days; IM or SC doses should be injected into the neck and not more than 10 mL per site. IM route may lead to myositis and abscesses. Rapid IV injection may cause collapse. Phlebitis is possible with IV dosing. (Beech 1987)
  - d) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kaufmann 1986)
  - e) For bovine anaplasmosis:
    - For control: At start of vector season give 6.6–11 mg/kg (if using 50 mg/mL or 100 mg/mL product) or 20 mg/kg (if using depot form — LA®-200) every 21–28 days and extending 1–2 months after vector season ends.
    - To eliminate carrier state: If using 50 mg/mL or 100 mg/mL product: 22 mg/kg IM (not over 10 mL per injection site) or IV (diluted in saline) daily for 10 days or 11 mg/kg as above for 10 days. If using depot form (LA®-200): Give 20 mg/kg for 4 treatments deep IM in two separate injection sites at 3-day intervals.
    - For treatment of sick animals: Preferably using depot form (LA®-200): Give 20 mg/kg one time.
    - For temporary/prorogated protection for rest of herd: If using 50 mg/mL or 100 mg/mL product: 6.6–11 mg/kg IM (not over 10 mL per injection site) at repeat 21–28 days throughout vector season for prolonged protection. If using depot form (LA®-200): Give 20 mg/kg IM as above and repeat at 28-day intervals for prolonged protection. (Richey 1986)
  - f) For pneumonia: If using 50 mg/mL or 100 mg/mL product: 11 mg/kg SC once daily. If using depot form (LA®-200): Give 20 mg/kg IM q48h (Hjerpe 1986)
  - g) For infectious bovine keratoconjunctivitis (M. bovis): 20 mg/kg once or twice followed by 2 grams/calf/day for 10 days. May give either PO or parenterally. (Angelos 2008)
  - h) For listeriosis (L. monocytogenes): Requires administration of very high doses to be effective; recommended oxytetracycline treatment scheme requires doses as high as 10 mg/kg per day for at least five days. (Wiedmann 2007)

**HORSES:**
- a) Fows: 5–10 mg/kg IV q12h diluted and given slowly, or 10–20 mg/kg IV q24h diluted and given slowly. Monitor creatinine and UA. (Bentz 2007)
- b) Drug of choice for equine monocytic or granulocytic leishmaniasis: 6.6 mg/kg IV q24h; to safeguard against adverse effects (muscle tremors, agitation or acute collapse) dilute at least in a 1:1 ratio and give IV slowly, or deliver it as an infusion in 500 mL or 1 liter of fluids. (Bentz 2007)
- c) For Lyme disease: 5–6.6 mg/kg IV q12h for 3–4 weeks is typically regarded as the preferred treatment eliminating persistent B. burgdorferi infection. (Weese 2009)
- d) For Potomac Horse Fever (Neorickettsia risticii) early in the clinical course of the disease: 6.6 mg/kg IV twice a day. Usually no more than 5 days of treatment is necessary. For Equine Granulocytic Leishmaniasis: 7.5 mg/kg once daily for 5–7 days (Madin & Pusler 2006)
  - e) For proliferative enteropathy ([Lausenia intracellularis] in foals: Oxytetracycline 5–6.6 mg/kg IV q12h for 3–7 days followed by doxycycline (10 mg/kg PO q12h for 7–17 days). (Sampieri et al. 2006)
  - f) For proliferative enteropathy ([Lausenia intracellularis]): Our recent clinical experiences suggest the use of metronidazole (10–15 mg/kg PO q8h-12h) combined with either oxytetracycline (10–18 mg/kg slow IV bolus) or doxycycline (Hjerpe 2006).

**WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant) therapy may need dosage adjustment.
Doses usually available in either propylene glycol or povidone-based products. A tetracycline derivative obtained from Chemistry/Synonyms Monitoring RABBITS, RODENTS, SMALL MAMMALS: CATS: Tetracyclines reportedly can cause false-positive monitoring. WARFARIN: METHOXYFLURANE: DIVALENT CATIONS Long-term use or in susceptible patients: periodic renal, hepatic, hematologic evaluations Adverse effects a) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kaufmann 1986) b) For enteritis (E. coli) and pneumonia (P. multocida): 22 mg/kg in water daily for 7 to 14 days. (Fapt 2008) c) For campylobacteriosis in pregnant ewes: In the face of an outbreak, all pregnant ewes should be treated. Long acting oxytetracycline at 20 mg/kg can be used successfully. For large flocks when individual injections may be more difficult, tetracyclines may be added to the feed at a level of 250–300 mg/head/day until lambing is finished. (Menzies 2008) BIRDS: For chlamydirosis (Psittacosis): a) Using 200 mg/mL, product (LA-2008): 50 mg/kg IM once every 3–5 days in birds suspected or confirmed of having disease. Used in conjunction with other forms of tetracyclines. IM injections may cause severe local tissue reactions. (McDonald 1989) b) Using 200 mg/mL, product (LA-2008): 200 mg/kg IM once daily for 3–5 days. Has worked well in treating breeding birds to control outbreak and while getting birds to eat oral forms doxycycline or chlortetracycline. (Clubb 1986) REPTILES: For susceptible infections: a) For turtles and tortoises: 10 mg/kg PO once daily for 7 days (useful in ulcerative stomatitis caused by Vibrio) (Gauvin 1993) Monitoring a) Adverse effects b) Clinical efficacy c) Long-term use or in susceptible patients: periodic renal, hepatic, hematologic evaluations Client Information a) Avoid giving this drug orally within 1–2 hours of feeding, milk, or other dairy products Chemistry/Synonyms A tetracycline derivative obtained from Streptomyces rimosus, oxytetracycline base occurs as a pale yellow to tan, crystalline powder that is very slightly soluble in water and sparingly soluble in alcohol. Oxytetracycline HCl occurs as a bitter-tasting, hygroscopic, yellow, crystalline powder that is freely soluble in water and sparingly soluble in alcohol. Commercially available 50 mg/mL and 100 mg/mL oxytetracycline HCl injections are usually available in either propylene glycol or povidone-based products. Oxytetracycline may also be known as: glomycin, hydroxytetracycline, oxytetracyclinn, riomitsin, terrafungine, Biomycin®, Liquamycin®, Medamycin®, Oxytet®, Oxytet®, and Terramycin®. DIGOXIN: Tetracyclines may increase the bioavailability of digoxin in a small percentage of human patients and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline. DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations): When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products. METHOXYFLURANE: Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline is not recommended WARFARIN: Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment Laboratory Considerations a) Tetracyclines (not minocycline) may cause falsely elevated values of urine catecholamines when using fluorometric methods of determination. b) Tetracyclines reportedly can cause false-positive urine glucose results if using the cupric sulfate method of determination (Benedict’s reagent, Clinistix®, but this may be the result of ascorbic acid, which is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (Clinistix®, Tes-Tape®). Doses a) For systemic infections: 22 mg/kg PO q8h for 7–14 days or 20 mg/kg IM (using repositol form) every 7 days as needed. (Greene et al. 2006) b) 20 mg/kg PO q8-12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995) c) For adjunctive treatment of Salmon poisoning (Neorickettsia helmintheca): 7 mg/kg IV every 8 h for 3–5 days. (Headley et al.) d) As a chelating antibiotic for medial canthus syndrome (tear staining): 25–50 mg (total dose) PO once per day 2 weeks on and off and on. (Krohne 2008) e) For diagnosis and treatment of idiopathic antibiotic-responsive diarrhea: 10–20 mg/kg PO q8h. (Allenspach 2009) CATS: For susceptible infections: a) For hemotropic mycoplasmosis/feline hemoplasmosis: 10–25 mg/kg PO, IV q8h for 5–7 days (Greene et al. 2006). Oxytetracycline does not seem to clear the infection, as parasites may still be present three months after therapy. (Lobetti 2007) b) 20 mg/kg PO q8-12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995) c) As a trial for adjunctive treatment of inflammatory bowel disease: 10–20 mg/kg PO three times daily. (Simpson 2009) RABBITS, RODENTS, SMALL MAMMALS: a) Rabbits: 15 mg/kg SC, IM q8h; 15–50 mg/kg PO once daily; 1 mg/mL in drinking water (Ivey & Morrissey 2000)
For susceptible infections:

a) Using **Liquamycin LA-2000**: For bacterial pneumonia caused by *Pasteurella* spp. (shipping fever) in calves and yearlings, where retreatment is impractical due to husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable, or infectious bovine keratoconjunctivitis (pink eye) caused by (M. bovis) 9 mg/lb (20 mg/kg) SC or IM once. Can also be given at 3–5 mg/lb (6.6–11 mg/kg) IM, SC, or IV once daily. In the treatment of severe footrot and advanced cases of other indicated diseases, a dosage level of 5 mg/lb (11 mg/kg) per day is recommended. Treatment should be continued 24–48 hours following remission of disease signs; however, treatment should not exceed a total of 4 consecutive days. (Label information; **Liquamycin LA-2000—Pfizer**)

b) Using **Tetradure-3000**: For the control of respiratory disease in cattle at high risk of developing BRD associated with *Mannheimia (Pasteurella) haemolytica*: 13.6 mg/lb (30 mg/kg) IM or SC once.

For bacterial pneumonia caused by *Pasteurella* spp. (shipping fever) in calves and yearlings where retreatment is impractical due to husbandry conditions, such as cattle on range, or where their repeated restraint is inadvisable, or infectious bovine keratoconjunctivitis (pink eye) caused by *M. haemolytica*, 9–13.6 mg/lb (20–30 mg/kg) IM or SC once.

For other indications (see label): 3–5 mg/lb (6.6–11 mg/kg) IM, SC or IV (IV slowly over a period of at least 5 minutes) once daily. In treatment of foot-rot and advanced cases of other indicated diseases, a dosage level of 5 mg/lb (11 mg/kg) per day is recommended. Treatment should be continued 24 to 48 hours following remission of disease signs, however, not to exceed a total of four consecutive days.

Do not administer intramuscularly in the neck of small calves due to lack of sufficient muscle mass. Use extreme care when administering this product by intravenous injection. Perivascular injection or leakage from an intravenous injection may cause severe swelling at the injection site. (Label information; **Tetradure-3000—Merial**)

c) For respiratory tract infections: Using 50 mg/mL product: 11 mg/kg IM or SC q24h or IV q12–24h;

Using 100 mg/mL product: 20 mg/kg IM q24h;

Using 200 mg/mL product (LA-2000): 20 mg/kg IM q3–4 days;

IM or SC doses should be injected into the neck and not more than 10 mL per site. IM route may lead to myositis and abscesses. Rapid IV injection may cause collapse. Phlebitis is possible with IV dosing. (Beech 1987)

d) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kauffman 1986)

e) For bovine anaplasmosis:

For control: At start of vector season give 6.6–11 mg/kg (if using 50 mg/mL or 100 mg/mL product) or 20 mg/kg (if using depot form —LA®-200) every 21–28 days and extending 1–2 months after vector season ends.

To eliminate carrier state: If using 50 mg/mL or 100 mg/mL product: 22 mg/kg IM (not over 10 mL per injection site) or IV (diluted in saline) daily for 5 days; or 11 mg/kg as above for 10 days. If using depot form (LA®-200): Give 20 mg/kg for 4 treatments deep IM in two separate injection sites at 3-day intervals.

For treatment of sick animals: Preferably using depot form (LA®-200): Give 20 mg/kg one time.

For temporary/prolonged protection for rest of herd: If using 50 mg/mL or 100 mg/mL product: 6.6–11 mg/kg IM (not over 10 mL per injection site) repeat at 21–28 days intervals throughout vector season for prolonged protection. If using depot form (LA®-200): Give 20 mg/kg IM as above and repeat at 28-day intervals for prolonged protection. (Richey 1986)

f) For pneumonia: If using 50 mg/mL or 100 mg/mL product: 11 mg/kg SC once daily. If using depot form (LA®-200): Give 20 mg/kg IM q48h (Hjerpe 1986)

g) For infectious bovine keratoconjunctivitis (M. bovis): 20 mg/kg one or twice followed by 2 grams/calf/day for 10 days. May give either PO or parenterally. (Angelos 2008)

h) For listeriosis (L. monocytogenes): Requires administration of very high doses to be effective; recommended oxytetracycline treatment scheme requires doses as high as 10 mg/kg per day for at least five days. (Wiedmann 2007)

**HORSES:**

For susceptible infections:

a) Foals: 5–10 mg/kg IV q12h diluted and given slowly, or 10–20 mg/kg IV q24h diluted and given slowly. Monitor creatinine and UA. (Bentz 2007)

b) Drug of choice for equine monocytic or granulocytic ehrlichiosis: 6.6 mg/kg IV q24h; to safeguard against adverse effects (muscle tremors, agitation or acute collapse) dilute at least in a 1:1 ratio and give IV slowly, or deliver it as an infusion in 500 mL or 1 liter of fluids. (Bentz 2007)

c) For Lyme disease: 5–6.6 mg/kg IV q12h for 3–4 weeks is typically regarded as the preferred treatment eliminating persistent *B. burgdorferi* infection. (Weese 2009)

d) For Potomac Horse Fever (Neorickettsia risticii) early in the clinical course of the disease: 6.6 mg/kg IV twice a day. Usually no more than 5 days treatment is necessary.

For Equine Granulocytic Ehrlichiosis: 7 mg/kg once daily for 5–7 days (Madigan & Pusterla 2000)

e) For proliferative enteropathy (*Lawsionia intracellularis*): 7 mg/kg once daily for 5–7 days (Madigan & Pusterla 2000)

f) For proliferative enteropathy (*Lawsionia intracellularis*): Our recent clinical experiences suggest the use of metronidazole (10–15 mg/kg PO q8-12h) combined with either oxytetracycline (10–18 mg/kg slow IV infusion q24h) or chloramphenicol (44 mg/kg PO q24h). (Frazier 2007)

g) For intrauterine infection: 1–5 grams; use pivodone based products only. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

**SWINE:**

For susceptible infections:

a) Using **Tetradure-3000**: For bacterial pneumonia caused by *Pasteurella multocida* where retreatment is impractical due to husbandry conditions or where repeated restraint is inadvisable: 9 mg/lb (20 mg/kg) IM once. May also be used at 3–5 mg/lb (6.6–11 mg/kg) IM once per day. Treatment should be continued 24 to 48 hours following remission of disease signs; however, not to exceed a total of four (4) consecutive days.

If improvement is not noted within 24 to 48 hours of the beginning of treatment, diagnosis and therapy should be re-evaluated. For sows as an aid in the control of infectious enteritis in baby pigs: 3 mg/lb (6.6 mg/kg) IM once approximately eight (8) hours before farrowing or immediately after completion of farrowing.

For swine weighing 25 lbs (11.4 kg) or less, administer undiluted for treatment at 9 mg/lb (20 mg/kg), but should be administered diluted (see label for guidelines) for treatment at 3 or 5 mg/lb (6.6–11 mg/kg). (Label information; **Tetradure-3000—Merial**)

b) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kauffman 1986)

c) 6–11 mg/kg IV or IM; 10–20 mg/kg PO q6h (Howard 1986)

d) If using 50 mg/mL or 100 mg/mL product: 10 mg/kg IM initially, then 7.5 mg/kg IM once daily (Baggot 1983)

**SHEEP & GOATS:**

For susceptible infections:

a) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kauffman 1986)

b) For enteritis (*E. coli*) and pneumonia: 22 mg/kg in water daily for 7 to 14 days. (Fajj 2008)

c) For campylobacteriosis in pregnant ewes: In the face of an outbreak, all pregnant ewes should be treated. Long acting oxytetracycline at 20 mg/kg can be used successfully. For large flocks when individual injections may be more difficult, tetracyclines may be added to the feed at a level of 250–300 mg/head/day until lambing is finished. (Menzies 2008)

**BIRDS:**

For chlamydiosis (Psittacosis):

a) Using 200 mg/mL product (LA-2008): 50 mg/kg IM once every 3–5 days in birds suspected or confirmed of having disease. Used in conjunction with other forms of tetracyclines. IM injections may cause severe local tissue reactions. (McDonald 1989)
b) Using 200 mg/mL, product (LA-2000®): 200 mg/kg IM once daily for 3–5 days. Has worked well in treating breeding birds to control outbreak and while getting birds to eat oral forms doxycycline or oxytetracycline. (Chubb 1986)

REPTILES:
For susceptible infections:

a) For turtles and tortoises: 10 mg/kg PO once daily for 7 days (useful in ulcerative stomatitis caused by Vibrio) (Gauvin 1993)

References
Established residue tolerances: Uncooked edible tissues of swine, cattle, salmonids, catfish and lobsters: 0.10 ppm. Uncooked kidneys of chickens or turkeys: 3 ppm. Uncooked muscle, liver, fat or skin of chickens or calves, and swine. When used as labeled, slaughter withdrawal = 28 days on the actual product, this drug may be FDA-approved for use in swine, cattle, beef cattle, chickens or turkeys. Products may also be labeled for IV, IM, or SC use. Withdrawal times vary with regard to individual products; consult specialized references or a hospital pharmacist for more specific information.

Drugs that are reportedly physically incompatible with oxytetracycline, data conflicts, or compatibility is concentration/time dependent, include: amikacin sulfate, amphotericin B, ampicillin B, calcium chloride/dextrose, carbencillin disodium, cephalothin sodium, cephalixin sodium, chloramphenicol sodium succinate, erythromycin glucophage, heparin sodium, hydrocortisone sodium succinate, iron dextran, methylithion, methotrexate sodium, oxacillin sodium, penicillin G potassium/sodium, penambutol sodium, sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status/

VETERINARY-LABELED PRODUCTS:
Oxytetracycline HCI 50 mg/mL, 100 mg/mL. Injection: There are many FDA-approved oxytetracycline products marketed in these concentrations. Some trade names for these products include: Terramycin®, Liquamycin®, Biomycin® (Bio-Ceutic), Medamycin® (TechAmerica), Bios® (Anthony), Oxytet® (Fermenta), and Oxytet® (BIVI). Some are labeled for Rx (prescription) use only, while some are over-the-counter (OTC). Depending on the actual product, this drug may be FDA-approved for use in swine, cattle, beef cattle, chickens or turkeys. Products may also be labeled for IV, IM, or SC use. Withdrawal times vary with regard to individual products; when used as labeled, slaughter withdrawal times vary in cattle from 15–22 days, swine 20–26 days, and 5 days for chickens and turkeys. Refer to the actual labeled information for the product used for more information.

Oxytetracycline base 200 mg/mL. Injection in 100, 250, and 500 mL bottles; Liquamycin® LA-200 (Pfizer); (OTC). FDA-approved for use in swine and cattle. When used as labeled, slaughter withdrawal = 28 days for swine and cattle; Milk withdrawal = 96 hours

Oxytetracycline base 300 mg/mL. Injection in 100 mL, 250 mL, and 500 mL vials; Tetradure®-300 (Merial); (Rx) FDA-approved for use in beef cattle, non-lactating dairy cattle, calves, including pre-ruminating (veal) calves, and swine. When used as labeled, slaughter withdrawal = 28 days

Oxytetracycline Oral Tablets (Boluses) 250 mg tablet; Terramycin® Scours Tablets (Pfizer); (OTC). FDA-approved for use in non-lactating dairy and beef cattle. Slaughter withdrawal (at labeled doses) = 7 days.

Oxytetracycline is also available in feed additive, premix, opthalmic, and intramammary products.

Established residue tolerances: Uncooked edible tissues of swine, cattle, salmonids, catfish and lobsters: 0.10 ppm. Uncooked kidneys of chickens or turkeys: 3 ppm. Uncooked muscle, liver, fat or skin of chickens or turkeys: 1 ppm.

HUMAN-LABELED PRODUCTS: None

Drug Summary

HORMONAL AGENT

Prescriber Highlights

- Hypothalamic hormone used for induction or enhancement of uterine contractions at parturition, postpartum retained placenta & metritis, uterine involution after manual correction of prolapsed uterus in dogs, & agalactia.
- Contraindications: Known hypersensitivity, dystocia due to abnormal presentation of fetus(es) unless correction is made. When used prepartum, oxytocin should be used only when the cervix is relaxed naturally or by the prior administration of estrogen.
Uses/Indications
In veterinary medicine, oxytocin has been used for induction or enhancement of uterine contractions at parturition, treatment of postpartum retained placenta and metritis, uterine involution after manual correction of prolated uterus in dogs, and in treating agalactia.

Pharmacology/Actions
By increasing the sodium permeability of uterine myofibris, oxytocin stimulates uterine contraction. The threshold for oxytocin-induced uterine contraction is reduced with pregnancy duration, in the presence of high estrogen levels and in patients already in labor.

Oxytocin can facilitate milk ejection, but does not have any galactopoietic properties. While oxytocin only has minimal antiadiperic properties, water intoxication can occur if it is administered at too rapid a rate and/or if excessively large volumes of electrolyte-free intravenous fluids are administered.

Pharmacokinetics
Oxytocin is destroyed in the GI tract and, therefore, must be administered parenterally. After IV administration, uterine response occurs almost immediately. Following IM administration, the uterus responds generally within 3–5 minutes. The duration of effect in dogs after IV or IM/SC administration has been reported to be 13 minutes and 20 minutes, respectively. While oxytocin can be administered intranasally, absorption can be erratic. Oxytocin is distributed throughout the extracellular fluid. It is believed that small quantities of the drug cross the placenta and enter the fetal circulation.

In humans, plasma half-life of oxytocin is about 3–5 minutes. In goats, this value has been reported to be about 22 minutes. Oxytocin is metabolized rapidly in the liver and kidneys and a circulating enzyme, oxytocinase can also destroy the hormone. Very small amounts of oxytocin are excreted in the urine unchanged.

Contraindications/Precautions/Warnings
Oxytocin is considered contraindicated in animals with dystocia due to abnormal presentation of fetuses(es), unless correction is made. When used prepartum, oxytocin should be used only when the cervix is relaxed naturally (and are less hazardous to the bitch (uterine rupture) and to the fetuses (placental compromise). Hypersensitivity reactions are a possibility in non-synthetically produced products. Repeated bolus injections of oxytocin may cause uterine cramping and discomfort.

Acute Overdose/Acute Toxicity
Effects of overdose on the uterus depend on the stage of the uterus and the position of the fetus(es). Hypertonic or tetanic contractions can occur leading to tumultuous labor, uterine rupture, fetal injury, or death.

Water intoxication can occur if large doses are infused for a long period, especially if large volumes of electrolyte-free intravenous fluids are concomitantly being administered. Early clinical signs can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures and eventually death. Treatment for mild water intoxication is stopping oxytocin therapy and restricting water access until resolved. Severe intoxication may require the use of osmotic diuretics (mannitol, urea, dextrose) with or without furosemide.

Reproductive/Nursing Safety
In humans, oxytocin is contraindicated in patients with significant cephalopelvic disproportion, unfavorable fetal positions, in obstetrical emergencies when surgical intervention is warranted, severe toxemia, or when vaginal delivery is contraindicated. Nasally administered oxytocin is contraindicated in pregnancy.

Adverse Effects
When used appropriately at reasonable dosages, oxytocin rarely causes significant adverse reactions. Most adverse effects are a result of using the drug in inappropriate individuals (adequate physical exam and monitoring of patient are essential) or at too high doses (see Overdosage below). Most of the older dosage recommendations for dogs or cats are obsolete as mini doses have been found to improve the frequency of uterine contractility,

When used appropriately adverse effects are rare. Common adverse effects include tetanic, ineffective uterine contractions that can further compromise fetal oxygen supply by placental compression. The frequency of oxytocin administration is dictated by the labor pattern, and it is generally not given more frequently than hourly. (Davidson 2009a)

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytocin and may be of significance in veterinary patients:

Doses

**DOGS:**

To augment uterine contractions during parturition:

- **0.5–3 Units SC or IM every 30–60 minutes, best based upon the results of tokodynamometry.** (Davidson 2004)

For uterine inertia:

- a) For uterine inertia if no fetuses in birth canal, cervix is dilated, and fetal and maternal obstruction have been ruled out: Oxytocin at 5–20 Units (depending on size of animal) IM or as an IV drip (10 Units/liter) beginning as a slow drip and gradually increasing until effective contractions are observed. If no response to IM injection in 30 minutes, may repeat along with 10% dextrose IV slowly. If no response again in 30 minutes, repeat IM again. Some tests recommend giving calcium gluconate (2–10 mL slowly IV while monitoring ECG for bradycardia or arrhythmias). If no response to this medical management, perform Caesarean section. (Macintire 2006)

- b) Use uterine and fetal monitors to guide oxytocin and calcium gluconate therapy. Generally, the administration of oxytocin increases the frequency of uterine contractions, while the administration of calcium increases their strength. Calcium is given before oxytocin in most cases, improving contraction strength before increasing frequency. Additionally, the action of oxytocin appears to be improved when given 15 minutes after calcium. Calcium gluconate 10% solution (0.465 mg/kg of calcium/mL) is given SC at 1 mL/5.5 kg of body weight BW as indicated by the strength of uterine contractions, generally no more frequently than every 4–6 hours. Oxytocin is effective at mini-doses, starting with 0.25 Units (total dose) SC or IM to a maximum dose of 4 Units per bitch or queen. Higher doses of oxytocin or intravenous boluses can cause tetanic, ineffective uterine contractions that can further compromise fetal oxygen supply by placental compression. The frequency of oxytocin administration is dictated by the labor pattern, and it is generally not given more frequently than hourly. (Davidson 2009a)

To induce milk let-down:

- a) In bitches with adequate milk production and who tolerate nursing: Oxytocin nasal spray (Synocin®): 5–10 minutes prior to nursing three times daily (Loar 1989)

- b) For secondary agalactia: oxytocin 0.25–1 Unit (total dose) SC q2h. Neonates are removed for 30 minutes post-injection, and then encouraged to suckle, or gentle stripping of the glands performed. Metoclopramide is given at 0.1–0.2 mg/kg SC q12h (dopamine antagonist) to promote milk production. Therapy is usually rewarding within 24 hours. (Davidson 2009b)

For adjunctive treatment of acute metritis:

- a) Dan started on a broad-spectrum antibiotic with good tissue penetration into the reproductive tract, while waiting for the culture and sensitivity results. Institute fluid therapy if patient is dehydrated or in shock. Oxytocin at 0.5–5 Units (total dose) IM may be used if birth has occurred less than 24 hours prior to dinoprostone (0.25 mg/kg SQ) may be used at any time to promote evacuation of the uterus. (Traas & O’Conner 2009)

- To promote uterine involution after uterine prolapse manual reduction:
To control post-extraction cervical and uterine bleeding after internal manipulations:

- a) 5–10 Units IM 3–4 times a day for 2–3 days (Hameida et al. 2009a)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)

**CATS:**

To promote uterine involution after uterine prolapse manual reduction:

- a) See the dog doses above.
- a) To treat primary uterine inertia:
  - b) See the dog doses above.

For adjunctive treatment of metritis:

- a) Dam started on a broad-spectrum antibiotic with good tissue penetration into the reproductive tract, while waiting for the culture and sensitivity results. Institute fluid therapy if patient is dehydrated or in shock.
- b) Oxytocin at 0.5–5 Units IM may be used if birth has occurred less than 24 hours prior or dinoprostone (0.25 mg/kg SQ) may be used at any time to promote evacuation of the uterus. (Traas & O’Connor 2009)

To induce milk let-down:

- a) For secondary agalactia: oxytocin 0.25–1 Unit (total dose) SC q2h. Neonates are removed for 30 minutes post injection, and then encouraged to suckle, or gentle stripping of the glands performed. Metoclopramide is given at 0.1–0.2 mg/kg SC q12h (dopamine antagonist) to promote milk production. Therapy is usually rewarding within 24–48 hours. (Davidson 2009b)

**RABBITS, RODENTS, SMALL MAMMALS:**

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.2–3 Units/kg IV, IM or SC (Adamcak & Otten 2000)

**CATTLE:**

For retained placenta in patients

- a) 40–60 Units oxytocin q2h (often used in conjunction with intravenous calcium therapy) as necessary. Of limited value after 48 hours postpartum as uterine sensitivity is reduced. (McClyr 1986)
- b) To reduce incidence of retained placenta: 20 Units IM immediately following calving and repeated 2–4 hours later (Hameida et al. 1986)

For mild to moderate cases of acute post-partum metritis:

- a) 20 Units IM 3–4 times a day for 2–3 days (Hameida et al. 1986)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)

To augment uterine contractions during parturition:

- a) 30 Units IM; repeat no sooner than 30 minutes if necessary (Wheaton 1989)
- b) For obstetrical use in cows: 100 Units IV, IM or SC (Package Insert; Oxytocin Injection—Anthony Products)

For milk let-down in cows:

- a) 10–20 Units IV (Package Insert; Oxytocin Injection—Anthony Products)

**HORSES:**

To augment or initiate uterine contractions during parturition in properly evaluated mares:

- a) For induction: 2.5–5 Units IV, every 15–20 minutes until foal is born (McCue 2003)
- b) To prevent lateonyx:
- c) To prolong corpus luteum lifespan, oxytocin is given from day 7 to day 14 post-ovulation at a dose of 60 Units (3 ml) IM once daily. Mares have stayed out of heat for up to 45–60 days with this protocol. The negative aspect to using oxytocin in this manner is that ovulation must be documented (or estimated really closely). (Dascanio 2009)

For evacuation of uterine fluid:

- a) 20 Units IV or IM one to three times a day (McCue 2003)
- b) Oxytocin: 20 Units IV or IM given every hour beginning 2–3 hours after foaling. Repeat as needed. (McCue 2003)

For mild to moderate cases of acute post-partum metritis:

- a) 20 Units IM 3–4 times a day for 2–3 days (Hameida et al. 1986)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)

To treat primary uterine inertia:

- a) See the dog doses above.

**SWINE:**

For adjunctive treatment of agalactia syndrome (MMA) in sows:

- a) 30–40 Units per sow at 3–4 hours (Powe 1986)
- b) 20–50 Units IM or 5–10 Units IV (Einarsen 1986)

For retained placenta in patients with uterine atony:

- a) 20 Units IM; repeat no sooner than 30 minutes if necessary (Wheaton 1989)
- b) To reduce incidence of retained placenta: 20 Units IM immediately following calving and repeated 2–4 hours later (Hameida et al. 1986)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)

To prevent luteolysis:

- a) For induction: 2.5–5 Units IV, every 15–20 minutes until foal is born (McCue 2003)
- b) To prevent lateonyx:
- c) To prolong corpus luteum lifespan, oxytocin is given from day 7 to day 14 post-ovulation at a dose of 60 Units (3 ml) IM once daily. Mares have stayed out of heat for up to 45–60 days with this protocol. The negative aspect to using oxytocin in this manner is that ovulation must be documented (or estimated really closely). (Dascanio 2009)

For evacuation of uterine fluid:

- a) 20 Units IV or IM one to three times a day (McCue 2003)
- b) Oxytocin: 20 Units IV or IM given every hour beginning 2–3 hours after foaling. Repeat as needed. (McCue 2003)

For mild to moderate cases of acute post-partum metritis:

- a) 20 Units IM 3–4 times a day for 2–3 days (Hameida et al. 1986)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)

To promote uterine involution after uterine prolapse manual reduction:

- a) See the dog doses above.
- a) To treat primary uterine inertia:
  - b) See the dog doses above.

For adjunctive treatment of metritis:

- a) Dam started on a broad-spectrum antibiotic with good tissue penetration into the reproductive tract, while waiting for the culture and sensitivity results. Institute fluid therapy if patient is dehydrated or in shock.
- b) Oxytocin at 0.5–5 Units IM may be used if birth has occurred less than 24 hours prior or dinoprostone (0.25 mg/kg SQ) may be used at any time to promote evacuation of the uterus. (Traas & O’Connor 2009)

To induce milk let-down:

- a) For secondary agalactia: oxytocin 0.25–1 Unit (total dose) SC q2h. Neonates are removed for 30 minutes post injection, and then encouraged to suckle, or gentle stripping of the glands performed. Metoclopramide is given at 0.1–0.2 mg/kg SC q12h (dopamine antagonist) to promote milk production. Therapy is usually rewarding within 24–48 hours. (Davidson 2009b)

**SHEEP & GOATS:**

For retained placenta in patients with uterine atony:

- a) 10–20 Units oxytocin. Of limited value after 48 hours postpartum as uterine sensitivity is reduced. If signs of metritis develop, treat with antibiotics. (McClyr 1986)
- b) Anesthetize patient and apply sterile lubricant liberally to the exposed tissue. The uterine horn is flushed with sterile saline under pressure. Mannitol or hypertonic saline can be used to reduce edema if necessary before attempting reduction. Once the uterus is replaced, give 5–10 Units (total dose) of oxytocin IM to cause uterine involution. If the uterus stays in for 24 hours, further risk of prolapse is unlikely because the cervix should be closed. (Shaw 2007)
HUMAN-LABELLED PRODUCTS:
beef cattle, sheep, swine, cats, and dogs. There are no milk or meat withdrawal times specified for oxytocin. Oxytocin for Injection: 20 USP Units/mL in 10 mL, 30 mL, and 100 mL vials; available labeled generically from several manufacturers; (Rx). Oxytocin products are labeled for several species, including horses, dairy cattle,

VETERINARY-LABELLED PRODUCTS:

PAMIDRONATE DISODIUM
(pal-mil-dro-sate) Aredia®
BISPHosphONATE
Prescriber Highlights

- Bisphosphonate used IV for treating hypercalcemia associated with Vitamin D-analog toxicity or hypercalcemia of malignancy; being investigated for adjuvant treatment of osteosarcoma
- Must be given IV in saline over several hours
- Potentially can cause electrolyte abnormalities, anemias, or renal toxicity
- Expense may be an issue, but generic forms now available
Uses/Indications
Pamidronate may be useful in treating hypercalcemia associated with vitamin D-related toxicoses or hypercalcemia of malignancy. There is ongoing research on the use of this drug to determine if it has clinical usefulness in directly treating “micro-metastases” in osteosarcomas.

Pharmacology/Actions
Bisphosphonates at therapeutic levels inhibit bone resorption and do not inhibit bone mineralization via binding to hydroxyapatite crystals. They impede osteoclast activity, and induce osteoclast apoptosis. Pamidronate has approximately 100 times greater relative antiresorptive potency when compared to etidronate.

Bisphosphonates in vitro have direct cytotoxic or cytostatic effects on human osteosarcoma cell lines. They may also have antiangiogenic effects and inhibit cell migration in certain cancers.

Pharmacokinetics
After intravenous infusion in rats, 50-60% of the dose is rapidly absorbed by bone. Bone uptake is highest in areas of rapid bone turnover. The kidneys very slowly eliminate the drug. Terminal half-life is on the order of 300 days in rats.

Contraindications/Precautions/Warnings
Pamidronate is contraindicated in patients hypersensitive to it or any of the bisphosphonate drugs. It should be used with caution in patients with impaired renal function; the drug has been associated with renal toxicity. In humans, it has not been tested in patients with serum creatinine levels greater than 5 mg/dL.

Adverse Effects
Electrolyte abnormalities may occur with pamidronate therapy. One case of a dog developing hypomagnesemia and arrhythmias after pamidronate has been reported (Kadar et al. 2004). Pamidronate potentially can cause renal toxicity in dogs, but it is thought this can be minimized or avoided by infusing the drug over at least 2 hours. In humans, ophthalmic syndromes (e.g., scleritis), transient bone pain, hypocalcemia, anemia, thrombocytopenia and granulocytosis have been reported.

Reproductive/Nursing Safety
In pregnant humans, the FDA lists pamidronate as a category D drug (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Pamidronate has produced both maternal and embryo/fetal toxicity in laboratory animals when given at dosages therapeutically used in human patients. If it is used in pregnant veterinary patients, informed consent by the owner accepting the risks to both mother and offspring is recommended.

It is unknown if pamidronate is excreted into milk. Use with caution in nursing mothers.

Overdosage/Acute Toxicity
Overdosage of pamidronate may cause hypocalcemia, including tetany. Should this occur, treat with short-term, intravenous calcium.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pamidronate and may be of significance in veterinary patients:

- **CALCIIUM-AFFECTING DRUGS** (e.g., furosemide, corticosteroids): Pamidronate must be used carefully (with monitoring) when used in conjunction with other drugs that can affect calcium
- **NEPHROTOXIC DRUGS** (e.g., cisplatin, aminoglycosides): Use with caution, potential for increased risk for nephrotoxicity

Laboratory Considerations
- No specific laboratory interactions or considerations noted.

Doses

- **DOGS:**
  - a) For refractory hypercalcemia: 1 mg/kg IV given over 2 hours in 250 mL of normal saline every 4 weeks. (Chun 2007)
  - b) For control of hypercalcemia: Treat each patient individually and if possible remove the underlying cause. If parenteral saline, furosemide and corticosteroids do not resolve the issue then bisphosphonates can be considered for more chronic control of hypercalcemia. Pamidronate 1.3–2 mg/kg in 150 mL of 0.9% saline with a 2 hour IV infusion; can repeat in 1–3 weeks. (Chew et al. 2003)
  - c) For treatment of cholecalciferol-induced toxicosis: 0.65–2 mg/kg in 0.9% NaCl on days 1 and 4 post-ingestion (Rumbelhia et al. 2000)
  - d) For attempting to reduce bone pain associated with osteosarcoma in combination with an NSAID: 1–2 mg/kg; diluted into 250 mL of 0.9% sodium chloride and administered as a CRI over 2 hours every 28 days. (Fan & de Lorimier 2003), (Fan et al. 2007)
  - e) For pain associated with skeletal neoplasias: 1–2 mg/kg IV over 2 hours every 21–28 days. Pamidronate has been shown to provide pain relief in ~50% of dogs with skeletal neoplasia. (Posner & papich 2009)
  - f) For calcipotriene toxicosis: 1.3–2 mg/kg slow IV infusion. In most cases, a single dose will lower calcium levels back to normal levels. Recommended to monitor calcium levels daily for at least 10 days after they have returned to normal. (Gwatney-Brant 2003)
  - g) For control of hypercalcemia: 1.05–2 mg/kg IV over 4 hours (from a retrospective study of 7 dogs). (Hostutler et al. 2005)

- **CATS:**
  - a) For control of hypercalcemia: 1.5–2 mg/kg IV over 4 hours (from a retrospective study of 2 cats). (Hostutler et al. 2005)

Monitoring
- Renal function (serum creatinine, etc.) and hydration status should be monitored before treating and prior to each dose
- Serum calcium, phosphate, magnesium, potassium
- CBC; baseline and continued if ongoing treatment
- Urinalysis

Client Information
- The medication must be given in an inpatient setting.
- Clients should understand the costs for the medication, care, and monitoring associated with its use.

Chemistry/Synonyms
Pamidronate disodium a bisphosphonate inhibitor of bone resorption occurs as a white, crystalline powder that is soluble in water and practically insoluble in organic solvents.

- Pamidronate may also be known as: ADP sodium, AHP/BP sodium, GCP-2339A, Aminomux®, Areosol®, Aredotrel®, Ostepam®, or Pamidran®.

Storage/Stability
Do not store at temperatures greater than 30°C (86°F).

Once the lyophilized powder for injection is reconstituted (10 mL) with sterile water for injection, it may be stored in the refrigerator for 24 hours. Be sure drug is completely dissolved before withdrawing into syringe.

Compatibility/Compounding Considerations
Do not mix pamidronate with any intravenous fluid containing calcium (e.g., Ringer’s). It is recommended to use a dedicated IV solution (0.45% or 0.9% NaCl, or D5W) and intravenous line.
Doses

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancrelipase and may be of significance in veterinary patients:

**Overdosage/Acute Toxicity**

In humans, the FDA categorizes this drug as category D for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

**Adverse Effects**

High doses may cause GI distress (diarrhea, cramping, nausea). Concentrated pancreatic enzymes can cause oral or esophageal ulcers; follow dosing with food or water. Oral bleeding has been reported in dogs after receiving pancrelipase (Rutz et al. 2002). Dose reduction and moistening the food pancreatic/powder mix may also decrease the incidence of this adverse effect.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

- These enzymes are unlikely to be excreted in maternal milk or pose risk to offspring.

**Overdosage/Acute Toxicity**

Overdosage may cause diarrhea or other intestinal upset. The effects should be temporary; treat by reducing dosage and supportively if diarrhea is severe.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancrelipase and may be of significance in veterinary patients:

- **ANTACIDS** (magnesium hydroxide, calcium carbonate): May diminish the effectiveness of pancrelipase

**Dogs**

For pancreatic exocrine insufficiency:

a) 1–1.5 teaspoonsful with each meal mixed with food. Mix with food thoroughly and allow to stand for 15–20 minutes before feeding. Dosage should be adjusted as necessary. Best results are usually obtained by feeding small meals frequently (at least 3 times per day). (Package Insert; Viokase®-V Powder—Fort Dodge)

b) Initially, two teaspoons per 20 kg body weight per meal. Oral bleeding has recently been reported in 3 of 25 dogs with EPI treated with pancreatic enzyme supplements. The oral bleeding stopped in all 3 dogs after the dose of pancreatic enzymes was decreased. Moistening the food pancreatic/powder mix may also decrease the incidence of this adverse effect. When clinical signs have resolved, the amount of pancreatic enzymes given can be gradually decreased to the lowest effective dose, which may vary from patient to patient and from batch to batch of the pancreatic supplement. (Steiner 2008)

c) 1–2 teaspoonsful of powder or finely crushed nonenteric-coated tablets to each of two meals of balanced canine ration. It is not necessary to incubate the enzyme preparation before feeding. Tailor regimen to maintain optimal body weight. (Bunch 2003)

d) Maintenance dose is usually 1 teaspoonful per meal. (Westermarck et al. 2005)

**Cats**

Note: Cats reportedly “hate” the taste of the powder and may be more easily dosed using solid dosage forms (enteric-coated tablets or compounded capsules made from powder or crushed tablets). If using these products, be certain that the cat follows the tablets with water or food to reduce the risk for esophageal damage. It has also been reported that some cats will eat food mixed with one brand of veterinary powder and refuse another.

For pancreatic exocrine insufficiency:

a) 0.5–0.75 teaspoonsful with each meal mixed with food. Mix with food thoroughly and allow to stand for 15–20 minutes before feeding. Dosage should be adjusted as necessary. Best results are usually obtained by feeding small meals frequently (at least 3 times per day). (Package Insert; Viokase®-V Powder—Fort Dodge)

b) 1 teaspoonful of powder or finely crushed nonenteric-coated tablets to each of two meals of balanced feline ration. Cats that refuse to eat food treated with powder may be dosed with capsules filled with powder or

**Uses/Indications**

Pancrelipase is used to treat patients with exocrine pancreatic enzyme insufficiency (EPI). It may also be used in the attempt to test for pancreatic insufficiency secondary to chronic pancreatitis.

**Pharmacology/Actions**

The enzymes found in pancrelipase help to digest and absorb fats, proteins, and carbohydrates.

**Contraindications/Precautions/Warnings**

Pancrelipase products are contraindicated in animals that are hypersensitive to pork proteins.

Do not inhale the powder or bronchial/lung irritation can occur. Avoid contact with mucous membranes or skin.

**Adverse Effects**

High doses may cause GI distress (diarrhea, cramping, nausea). Concentrated pancreatic enzymes can cause oral or esophageal ulcers; follow dosing with food or water. Oral bleeding has been reported in dogs after receiving pancrelipase (Rutz et al. 2002). Dose reduction and moistening the food pancreatic/powder mix may also decrease the incidence of this adverse effect.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

- These enzymes are unlikely to be excreted in maternal milk or pose risk to offspring.

**Overdosage/Acute Toxicity**

Overdosage may cause diarrhea or other intestinal upset. The effects should be temporary; treat by reducing dosage and supportively if diarrhea is severe.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancrelipase and may be of significance in veterinary patients:

- **ANTACIDS** (magnesium hydroxide, calcium carbonate): May diminish the effectiveness of pancrelipase

**Cats**

Note: Cats reportedly “hate” the taste of the powder and may be more easily dosed using solid dosage forms (enteric-coated tablets or compounded capsules made from powder or crushed tablets). If using these products, be certain that the cat follows the tablets with water or food to reduce the risk for esophageal damage. Pancuronium bromide
(pən-ku-ro-nee-um broe-mide) Pavulon®
NON-DEPOLARIZING NEUROMUSCULAR BLOCKER

Prescriber Highlights

♦ Non-depolarizing neuromuscular blocker used as an adjunct to general anesthesia

♦ Extreme Caution: Myasthenia gravis

♦ Caution: Renal dysfunction, hepatic or biliary disease; patients where tachycardias may be deleterious

♦ No analgesic or sedative/anesthetic actions

♦ Adverse Effects: Slight elevations in cardiac rate & blood pressure, hypersalivation (if not pretreated with an anticholinergic agent), prolonged or profound muscular weakness, & respiratory depression. Very Rarely: Histamine release with resultant hypersensitivity reaction

♦ Drug Interactions

Uses/Indications

Pancuronium is sometimes used as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation.

Pharmacology/Actions

Pancuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor endplate, inhibiting the effects of acetylcholine. It is considered 5 times as potent as d-tubocurarine and ⅓ as potent as vecuronium (some sources say that pancuronium is equipotent with vecuronium in animals). It has little effect on the cardiovascular system other than increasing heart rate slightly, and only rarely does it cause histamine release.

Pharmacokinetics

After intravenous administration, muscle relaxation sufficient for endotracheal intubation occurs generally within 2–3 minutes, but is dependent on the actual dose administered. Duration of action may persist 30–45 minutes, but this again is dependent on the dose. Additional doses may slightly increase the magnitude of the blockade and will significantly increase the duration of action.

In humans, pancuronium is approximately 87% bound to plasma proteins, but it may be used in hypoalbuminemic patients. Activity is non-affected substantially by either plasma pH or carbon dioxide levels.

References

There are capsules, tablets, and powders available containing lipase, protease, and amylase in varying units available for human consumption from many distributors.

Storage/Stability

Unless otherwise recommended by the manufacturer, store at room temperature in a dry place in tight containers. When present in quantities greater than trace amounts, acids will inactivate pancrelipase.

Dosage Forms/Regulatory Status

Note: There are several dosage forms (both human and veterinary-label) available containing pancrelipase, including oral capsules, oral delayed-release capsules, tablets, and delayed-released tablets. Most small animal practitioners feel that the oral powder is most effective in dogs.

VETERINARY-LABELED PRODUCTS:

Pancrelipase Powder containing (approximately) per teaspoonful (2.8 grams): 71,400 Units lipase; 388,000 Units protease; 460,000 Units amylase; in 8 oz bottle; Viokase®-V Powder (Fort Dodge), Pancrezyme® Powder (Vircab); Pancrepowder Plus® (Butler), PancreZyme® Powder (Vedco), Epizyme® Powder (V.E.T.), Panakare® Plus Powder (Neogen); (Rx). Labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

There are capsules, tablets, and powders available containing lipase, protease, and amylase in varying units available for human consumption from many distributors.

Monitoring

♦ Animal’s weight

♦ Stool consistency, frequency

Client Information

♦ Powder spilled on hands should be washed off or skin irritation may develop; do not allow powder to contact eyes

♦ Avoid inhaling powder; causes mucous membrane irritation and may trigger asthma attacks in susceptible individuals.

Chemistry/Synonyms

Pancrelipase contains pancreatic enzymes, primarily lipase but also amylase and protease, and is obtained from the pancreas of hogs. Each mg of pancrelipase contains not less than 24 USP Units of lipase activity, not less than 100 USP Units of protease activity, and not less than 100 USP Units of amylase activity. When compared on a per weight basis, pancrelipase has at least 4 times the trypsin and amylase content of pancreatin, and at least 12 times the lipolytic activity of pancreatin.

Pancrelipase may also be known as pancrelipasa, Epizyme®, Panakare®, Pancrepowder Plus®, Pancrezyme®, and Viokase®.

RABBITS, RODENTS, SMALL MAMMALS:

For pancreatic exocrine insufficiency (used in birds that are polyphagic “going light”, passing whole seeds, and slow in emptying crops):

a) ¼ tsp per kg. Mix with moistened feed or administer by gavage. Incubate with food for 15 minutes prior to gavage. (Clubb 1986)
Pancuronium is contraindicated in patients hypersensitive to it. It should be used with caution in patients with renal dysfunction, or where tachycardias may be deleterious. Lower doses may be necessary in patients with hepatic or biliary disease. Pancuronium has no analgesic or sedative/anesthetic actions. In patients with myasthenia gravis, neuromuscular blocking agents should be used with extreme caution, if at all.

Adverse Reactions

Adverse reactions seen with pancuronium include: slight elevations in cardiac rate and blood pressure, hypersalivation (if not pretreated with an anticholinergic agent), occasional rash (humans), and prolonged or profound muscular weakness and respiratory depression. Very rarely, pancuronium will cause substantial histamine release with resultant hypersensitivity reactions.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.) It is not known whether these drugs are excreted in maternal milk.

Overdosage/Acute Toxicity

Monitoring muscle twitch response to peripheral nerve stimulation can minimize overdosage possibilities. Increased risks of hypotension and histamine release occur with overdoses, as well as prolonged duration of muscle blockade. Besides treating conservatively (mechanical ventilation, O2, fluids, etc.), reversal of blockade may be accomplished by administering an anticholinesterase agent (edrophonium, physostigmine, or neostigmine) with an anticholinergic (atropine or glycopyrrolate). A suggested dose for neostigmine is 0.06 mg/kg IV after atropine 0.02 mg/kg IV.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancuronium and may be of significance in veterinary patients:

- **AZATHIOPRINE:** May reverse pancuronium’s neuromuscular blocking effects
- **AMINOGlicosides (gentamicin, etc.):** May enhance the neuromuscular blocking activity of pancuronium
- **CALCIUM (IV):** May reverse the effects of nondepolarizing neuromuscular blocking agents
- **LINCOSAMIDES: (clindamycin, etc.):** May enhance the neuromuscular blocking activity of pancuronium
- **MAGNESIUM SULFATE or HCL:** May enhance the neuromuscular blocking activity of pancuronium
- **QUINIDINE:** May enhance the neuromuscular blocking activity of pancuronium
- **SUCCINYLCHOLINE:** Other muscle relaxant drugs may cause a synergistic or antagonistic effect. Succinylcholine may speed the onset of action and enhance the neuromuscular blocking actions of pancuronium. Do not give pancuronium until succinylcholine effects have subsided.
- **THEBOPHILINE:** May inhibit or reverse the neuromuscular blocking action of pancuronium and possibly induce arrhythmias
- **TRICYCLIC ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline):** Increased risk for cardiac arrhythmias when used with halothane anesthesia

Doses

- **DOGS:**
  a. As a paralytic during mechanical ventilation: 0.05–0.1 mg/kg IV; lasts about an hour, must give sedation as well (Carr 2003)
  b. 0.044–0.11 mg/kg IV; higher dose used initially; lower doses required if repeated doses are necessary (Mandsager 1988)
  c. On occasions when anesthesia maintenance with IV or regional techniques are not adequate to prevent spontaneous movement and the addition of inhalational agents results in severe hypotension (not corrected with fluid therapy): 0.02–0.04 mg/kg IV provides 30–45 minutes of muscle relaxation. (Day 2005)

- **CATS:**
  a. 0.044–0.11 mg/kg IV; higher dose used initially; lower doses required if repeated doses are necessary (Mandsager 1988)

- **RABBITS, RODENTS, SMALL MAMMALS:**
  a. Rabbits: 0.1 mg/kg IV (Ivey & Morrisey 2000)

Monitoring

- Level of neuromuscular blockade
- Cardiac rate

Client Information

This drug should only be used by professionals familiar with using neuromuscular blocking agents in a supervised setting with adequate ventilatory support

Chemistry/Synonyms

A synthetic, non-depolarizing neuromuscular blocker, pancuronium bromide occurs as a white, odorless, bitter-tasting, hygroscopic, fine powder. It has a melting point of 215°C and one gram is soluble in 100 mL of water; it is very soluble in alcohol. Acetic acid is used to adjust the commercially available injection to a pH of approximately 4.

Pancuronium bromide may also be known as: NA-97, Org-NA-97, or pancuronii bromidum.

Storage/Stability

Pancuronium injection should be stored under refrigeration (2–8°C), but, according to the manufacturer, it is stable for 6 months at room temperature.

Do not store pancuronium in plastic syringes or containers as it may be adsorbed to plastic surfaces. It may be administered in plastic syringes, however.

Compatibility/Compounding Considerations

It is recommended that pancuronium NOT be mixed with barbiturates, as a precipitate may form, although data conflict on this point. No precipitate was seen when pancuronium was mixed with succinylcholine.

Dosage Forms/Regulatory Status

**VETERINARY-LAbeLED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LAbeLED PRODUCTS:**

Pancuronium Bromide for Injection: 1 mg/mL in 10 mL vials; 2 mg/mL in 2 mL & 5 mL vials & amps; generic; (Rx)

Pantoprazole (pan·to·pra·zol·ə) Protonix®, Pantoloc®
PROTON PUMP INHIBITOR
Prescriber Highlights

- Proton pump inhibitor similar to omeprazole; also available in IV dosage form
- May be useful in treating or preventing gastric acid-related pathologies in dogs, cats, foals & camels
- Relatively limited research & experience in veterinary medicine, particularly when compared with omeprazole
- Appears well tolerated

Uses/Indications
Pantoprazole may be useful in treating or preventing gastric acid-related pathologies in dogs, cats, foals and camels, particularly when the intravenous route is preferred. Pantoprazole is available in both intravenous and oral tablet (delayed-release) formulations. One study (Bersenas et al. 2005) performed in dogs, comparing the gastric pH effects of intravenous pantoprazole with oral omeprazole, intravenous ranitidine, and intravenous famotidine, found at the dosages used, that pantoprazole was more effective than ranitidine, but similar to famotidine, and that oral omeprazole was more effective in maintaining intragastric pH >3 for a longer period than pantoprazole.

Pantoprazole has been shown to directly reduce in vitro counts of H. pylori and is used in some H. pylori treatment protocols for humans.

Pharmacology/Actions
Pantoprazole is a substituted benzimidazole, similar to omeprazole and the other proton pump inhibitors (PPIs). At the secretory surface of gastric parietal cells, pantoprazole forms a covalent bond at two sites of the H+K+ ATPase (proton pump) enzyme system. There it inhibits the transport of hydrogen ions into the stomach. Pantoprazole reduces acid secretion during both basal and stimulated conditions.

Pharmacokinetics
No specific information was located for pantoprazole pharmacokinetics in dogs or cats. In neonatal foals, intragastric (IG) administered pantoprazole bioavailability was 41% and drug was detected in plasma within 5 minutes of administration. Mean hourly gastric pH was increased for 2–24 hours versus untreated foals after either IV or IG administration, but IV administration increased pH significantly greater than IG administration, presumably due to low GI bioavailability (Ryan et al. 2005). In humans, it is rapidly absorbed after oral administration with an oral bioavailability of 77%. Food can reduce the rate of absorption, but does not appear to affect the extent of absorption. On average, 51% of gastric acid secretion is inhibited at 2.5 hours after a single dose and 85% is inhibited after the seventh day of daily administration. Protein binding is 98%, primarily to albumin.

The drug is metabolized in the liver, primarily by CYP2C19 isoenzymes. CYP3A4, 2D6, 2C9, or 1A2 are minor components of pantoprazole biotransformation; pantoprazole does not appear to clinically affect (either induce or inhibit) the metabolism of other drugs using these isoenzymes for biotransformation. Metabolites of pantoprazole do not appear to have pharmacologic activity. Elimination half-life for both oral and IV administration is only about an hour, but the drug’s pharmacologic action can persist for 24 hours or more, presumably due to irreversible binding at the receptor site. About 71% of a dose is excreted as metabolites in the urine, with the remainder in the feces as metabolites and unabsorbed drug.

Contraindications/Precautions/Warnings
Pantoprazole is contraindicated in patients known to be hypersensitive to it or other substituted benzimidazole PPIs.

Parenteral pantoprazole must be administered IV; do not give IM or SQ. Reconstituted injection (4 mg/mL) must be administered intravenously over not less than 2 minutes.

Adverse Effects
Use has been limited in small animals and an adverse effect profile is not well established; however, the drug appears to be tolerated well.

In humans, the most commonly reported adverse effects are diarrhea and headache. Hyperglycemia has been reported in about 1% of patients. Proton pump inhibitors have been associated with an increased risk of developing community-acquired pneumonia in humans. Injection site reactions (thrombophlebitis, abscess) have occurred with IV administration.

Reproductive/Nursing Safety
When pantoprazole was dosed in rats (98X human dose) and rabbits (16X), no affects on fertility or teratogenic effects were noted. In humans, the FDA categorizes pantoprazole as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Pantoprazole and its metabolites have been detected in milk, but it should be relatively safe to use in nursing veterinary patients.

Overdosage/Acute Toxicity
There is limited information available. A single oral dose of 887 mg/kg was lethal in dogs. Acute toxic signs included ataxia, hypo-activity, and tremor. In humans, single oral overdoses of up to 600 mg have been reported without adversity. In the event of a large overdose, it is recommended to contact an animal poison control center for guidance.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pantoprazole and may be of significance in veterinary patients:

- **DRUGS REQUIRING DECREASED GASTRIC PH FOR OPTIMAL ABSORPTION** (e.g., ketoconazole, itraconazole, iron, ampicillin esters): Pantoprazole may decrease drug absorption
- **SUCRALFATE**: May decrease bioavailability of orally administered pantoprazole
- **WARFARIN**: Pantoprazole may increase anticoagulant effect

Laboratory Considerations

- Although not likely to be important for veterinary patients, pantoprazole may cause false-positive results for urine screening tests for THC (tetrahydrocannabinol)

Doses

- **DOGS/CATS:**
  a) Dogs: For intravenous treatment of stress-related mucosal disease: 0.7–1 mg/kg IV once daily. (Butemans 2003)
  b) Dogs, Cats: 0.5–1 mg/kg IV over 15 minutes q24h (once daily). (Marks 2008)
- **HORSES:**
  a) For gastric acid suppression in neonatal foals: 1.5 mg/kg IV once daily. **Note:** From an experimental study evaluating the pharmacokinetics and pharmacodynamics in normal neonatal foals. Further studies are required to investigate the use of this drug in critically ill patients. (Ryan et al. 2005)

Monitoring

- **Efficacy**
- **Adverse effects (vomiting, diarrhea, injection site reactions if used IV)**

PARAPOX OVIS VIRUS IMMUNOMODULATOR
(pair-ah-poks o-viz) Zylexis®

IMMUNOSTIMULANT

Prescriber Highlights

♦ Biologic immunostimulant labeled for use in healthy horses of 4 months of age & older as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 & 4

♦ Limited published information available on safety & efficacy

Uses/Indications
Parapox ovis virus immunomodulator is commercially available in the USA labeled for "use in healthy horses of 4 months of age and older as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 and 4."

A parapoxvirus product (Bovpamulin®) is reportedly available in some European countries for use in small animals.

Pharmacology/Actions
Parapox ovis is the virus responsible for "ort" in sheep, a contagious pustular dermatitis. The virus is inactivated in the commercial product. Parapoxvirus products are so-called "paramunity inducers" and are believed to prevent viral infection by pathogenic viruses via viral interference. By "infecting" host cells with a defective (non-replicating) virus, interference with infection by the pathogenic virus can occur. Postulated mechanisms of action include induction of interferons, cytokines and colony-stimulating factors, and activation of natural killer cells.

Pharmacokinetics
Effects on the immune system are reported to occur 4–6 hours after treating; effects persist for 1–2 weeks.

Contraindications/Precautions/Warnings
Do not be use in patients with prior hypersensitivity to the agent. The manufacturer warns that in the case of an anaphylactic reaction, administer epinephrine or equivalent.

Reproductive/Nursing Safety
No information was located.

Adverse Effects
No adverse effects are listed in the package insert, but anaphylaxis is possible.

Overdosage/Acute Toxicity
No information was located.

Drug Interactions
None noted

Laboratory Considerations
None identified

Doses

HORSES:

a) For an aid in reducing upper airway disease caused by herpesvirus types 1 and 4: After reconstituting with the sterile diluent provided, administer 2 mL IM. Repeat doses on days 2 and 9 following the initial dose. (Label information; Zylexis®—Pfizer)
The following drug interactions have either been reported or are theoretical in humans or animals receiving opiate antidiarrheals and may be of significance in veterinary patients:

**Drug Interactions**

For more information, refer to the meperidine and morphine monographs found in the CNS section. Naloxone may be necessary to reverse the opiate effects.

**Overdose/Acute Toxicity**

Acute overdosage of the opiate antidiarrheals could result in CNS, cardiovascular, GI, or respiratory toxicity. Because the opiates may significantly reduce GI motility, absorption from the GI may be delayed and prolonged.

**Contraindications/Precautions/Warnings**

- Known hypersensitivity to narcotic analgesics
- Patients receiving monoamine oxidase inhibitors (MAOIs)
- Diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract

**Adverse Effects**

- Dogs: Constipation, bloating, and sedation.
- Cats: Use is controversial, may exhibit excitatory behavior.
- Horses: With GI bacterial infection, may delay the disappearance of the microbe from the feces and prolong the febrile state.
- Dose carefully in small animals; do not confuse with opium tincture

**Uses/Indications**

Paregoric is occasionally used as a motility modifier for animals with diarrhea. Opiates as an anti-diarrheal treatment in cats is controversial and many clinicians do not recommend their use in this species.

**Pharmacology/Actions**

The morphine in paregoric is absorbed in a variable fashion from the GI tract. It is rapidly metabolized in the liver and serum morphine levels are considerably less than when morphine is administered parenterally.

**Pharmacokinetics**

The morphine in paregoric is absorbed in a variable fashion from the GI tract. It is rapidly metabolized in the liver and serum morphine levels are considerably less than when morphine is administered parenterally.

**Pharmacokinetics**

The morphine in paregoric is absorbed in a variable fashion from the GI tract. It is rapidly metabolized in the liver and serum morphine levels are considerably less than when morphine is administered parenterally.
The following drug interactions have either been reported or are theoretical in humans or animals receiving opiate antidiarrheals and may be of significance in veterinary patients:

- **CNS DEPRESSANT DRUGS** (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.): May cause increased CNS or respiratory depression when used with opiate antidiarrheal agents

- **MONOAMINE OXIDASE INHIBITORS** (including amitraz, and possibly selegiline): Opiate antidiarrheal agents are contraindicated in human patients receiving monoamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors

### Laboratory Considerations

- Plasma amylase and lipase values may be increased for up to 24 hours following administration of opiates.

### Doses

**DOGS:**

- For acute colitis: 0.06 mg/kg, PO three times daily (DeNovo 1988)
- For malabsorption; antidiarrheal: 0.05–0.06 mg/kg PO two to three times daily (Chiapella 1988), (Johnson 1984)
- As an antidiarrheal: 0.05–0.06 mg/kg PO q12h (Willard 2003)

**CATS:**

- Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.
  - For malabsorption, anti-diarrheal:
    - 0.05–0.06 mg/kg PO two to three times daily (Chiapella 1989), (Johnson 1984)

**CATTLE:**

- Calves: 15–30 mL PO (Cornell 1985)

**HORSES:**

- Foals: 15–30 mL PO; Adults: 15–60 mL PO (Cornell 1985)

### Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea
- CNS effects if using high dosages

### Client Information

- If diarrhea persists or animal appears listless or develops a high fever, contact veterinarian.

### Chemistry/Synonyms

Paregoric contains 2 mg of the equivalent of anhydrous morphine (usually as powdered opium or opium tincture) per 5 mL. Also included (per 5 mL) are 0.02 mL anise oil, 0.2 mL glycerin, 20 mg benzoic acid, 20 mg camphor, and a sufficient quantity of diluted alcohol to make a total of 5 mL. Paregoric should not be confused with opium tincture (tincture of opium), which contains 50 mg of anhydrous morphine equivalent per 5 mL.

Paregoric is also known as camphorated tincture of opium.

### Storage/Stability

Paregoric should be stored in tight, light-resistant containers. Avoid exposure to excessive heat or direct exposure to sunlight.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Paregoric (camphorated tincture of opium): 2 mg of morphine equiv. per 5 mL (45% alcohol) in 473 mL; generic; (Rx; C-III)
  - Note: Do not confuse with opium tincture, which contains 25 times more morphine per mL than paregoric.

### References

### PAROMOMYCIN SULFATE

(pair-oh-moe-my-sin) Humatin®

ORAL AMINOGLYCOSIDE ANTIPARASITIC

**Prescriber Highlights**

- Aminoglycoside used primarily as an alternative for PO treatment of cryptosporidiosis in small animals
- Not appreciably absorbed when gut is intact when dosed orally in humans & dogs
- Some state that the drug is contraindicated in cats secondary to toxicity
- Adverse effects are usually limited to GI effects (N,V,D); cats may be susceptible to renal & ophthalmic toxicity
- Use with caution in patients with intestinal ulceration

### Uses/Indications

Paromomycin may be useful as a secondary treatment for cryptosporidiosis in dogs and cats. It has also been used topically to treat cutaneous Leishmaniasis. In humans, it has been used as an alternative treatment for giardiasis, Dientamoeba fragilis, and hepatic coma.

### Pharmacology/Actions

Paromomycin has an antimicrobial spectrum of activity similar to neomycin, but its primary therapeutic uses are for the treatment of protozoa, including *Leishmania* spp., *Entamoeba histolytica*, and *Cryptosporidium* spp. It also has activity against a variety of tapeworms, but there are better choices available for clinical use.
Paromomycin is contraindicated in patients with known hypersensitivity to the drug, ileus or intestinal obstruction, and GI ulceration. Use with caution in cats. Because of potential toxicity, some clinicians recommend not using the drug in this species. Do not use in animals with blood in the stool as this may signal that the drug could be absorbed and cause nephrotoxicity.

Adverse Effects
Gastrointestinal effects (nausea, inappetence, vomiting, diarrhea) are the most likely adverse effects to be noted with therapy. Because paromomycin can affect gut flora, nonsusceptible bacterial or fungal overgrowths are a possibility. In patients with significant gut ulceration, paromomycin may be absorbed systemically with resultant nephrotoxicity, ototoxicity, or pancreatitis.

Use in cats has been associated with renal dysfunction, ototoxicity and blindness.

Reproductive/Nursing Safety
Because minimal amounts are absorbed when administered orally, paromomycin should be safe to use during pregnancy. It should not be used parenterally during pregnancy.

When used orally, paromomycin should be safe to use during lactation.

Overdosage/Acute Toxicity
Because paromomycin is not absorbed orally, acute overdose adverse effects should be limited to gastrointestinal distress in patients with an intact GI system. Chronic overdoses may lead to systemic toxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving paromomycin and may be of significance in veterinary patients:

- **DIGOXIN**: Paromomycin may reduce digoxin absorption
- **METHOTREXATE**: Paromomycin may reduce methotrexate absorption

Laboratory Considerations

- None were noted.

Doses

- **DOGS**:
  - For treatment of cryptosporidiosis:
    - a) 125–165 mg/kg PO twice daily for 5 days (Blagburn 2003)
    - b) 150 mg/kg PO once a day for 5 days. **Caution**: nephrotoxicity. (Tams 2003)
  - **CATS**: For treatment of cryptosporidiosis: **Note**: Higher dosages of paromomycin have caused renal or otic toxicity and/or blindness in some treated cats. Consider using an alternate treatment first (e.g., azithromycin) or paromomycin at an initially reduced dosage level.
    - a) 125–165 mg/kg PO twice daily for 5 days. (Blagburn 2003)
    - b) 150 mg/kg PO once a day for 5 days. **Caution**: nephrotoxicity. (Tams 2003)
    - c) 150 mg/kg PO q12-24hr. Paromomycin can be nephrotoxic if absorbed. If the cat is responding to the first 7 days of therapy and toxicity has not been noted, continue treatment for 1 week past clinical resolution of diarrhea. (Lappin 2008)
  - **CAMELIDS (NWC)**: For treatment of cryptosporidiosis in crias: 50 mg/kg PO (dosing interval not specified, assume once per day—Plumb) for 5–10 days. (Walker 2009)

- **REPTILES**: For treatment of cryptosporidiosis: 300–800 mg/kg PO q24–48h for 7–14 days or as needed (de la Navarre 2003)

Client Information

- **Efficacy**
- **GI adverse effects**
- **If used in cats, monitor renal function**

Chemistry/Synonyms
An aminoglycoside antibiotic, paromomycin sulfate occurs as an odorless, creamy white to light yellow, hygroscopic, amorphous powder having a saline taste. Paromomycin is very soluble in water (>1 gram/mL).

Paromomycin may also be known as: aminosidin sulphate, aminosidine sulphate, catenulin sulphate, crestomycin sulphate; estomycin sulphate, hydroxymycin sulphate, monomycin A sulphate, neomycin E sulphate, paracynium sulphate, Gabbroral, Gabbroral®. Gabbroral®, Humagen®, Humait®, Kaman®, and Sinost®.

Storage/ Stability
Paromomycin capsules should be stored at room temperature (15–30°C; 59–86°F) in tight containers.
Prescriber Highlights

SELECTIVE SEROTONIN REUPTAKE INHIBITOR (SSRI) ANTIDEPRESSANT

Uses/Indications
Paroxetine may be beneficial for the treatment of canine aggression, and stereotypic or other obsessive-compulsive behaviors. It has been used occasionally in cats as well.

Pharmacology/Actions
Paroxetine is a highly selective inhibitor of the reuptake of serotonin (SSRI) in the CNS, thus potentiating the pharmacologic activity of serotonin. Paroxetine apparently has little effect on other neurotransmitters (e.g., dopamine or norepinephrine).

Pharmacokinetics
No veterinary data was located. In humans, paroxetine is slowly, but nearly completely, absorbed from the GI tract. Because of a relatively high first pass-effect, relatively small amounts reach the systemic circulation unchanged. Food does not impair absorption.

The drug is about 95% bound to plasma proteins. Paroxetine is extensively metabolized, probably in the liver. Half-life in humans ranges from 7–65 hours and averages about 24 hours.

Contraindications/Precautions/Warnings
Paroxetine is contraindicated in patients with known hypersensitivity to it or those receiving monoamine oxidase inhibitors (see Drug Interactions below). Use with caution in patients with seizure disorders, severe cardiac, hepatic, or renal disease. Dosages may need to be reduced in patients with severe hepatic or renal impairment.

If paroxetine is rapidly discontinued, withdrawal reactions can occur. If the patient has been receiving the drug for an extended period, a gradual withdrawal is recommended.

Adverse Effects
In dogs, paroxetine can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously unaggressive dogs has been reported. SSRIs may also cause changes in blood glucose levels and potentially, reduce seizure threshold.

Paroxetine in cats can cause behavior changes (anxiety, irritability, sleep disturbances), anorexia, constipation and changes in elimination patterns.

Reproductive/Nursing Safety
Paroxetine’s safety during pregnancy has not been established. Preliminary studies done in rats demonstrated no overt teratogenic effects. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

The drug is excreted into milk but at low levels; caution is advised in nursing patients.

Overdosage/Acute Toxicity
There is limited information available. Experience with overdoses in humans yields a mixed picture. While not as toxic as the tricyclic antidepressants, fatalities and significant morbidity have occurred after paroxetine overdoses.

There were 114 exposures to paroxetine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 102 were dogs with 20 showing clinical signs, and 12 were cats with 4 showing clinical signs. Common findings in dogs recorded in decreasing frequency included hyperactivity, lethargy, mydriasis, and trembling. Common findings in cats included mydriasis.

In overdoses with small animals, it is recommended to err on the safe side and employ gut evacuation (if not contraindicated) and then treat supportively. Activated charcoal is very effective in binding paroxetine. Phenothiazine and cyproheptadine can be effective in controlling serotonin syndrome. Contact an animal poison control center for additional guidance.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving paroxetine and may be of significance in veterinary patients:

- BUSPIRONE: Increased risk for serotonin syndrome
- CIMETIDINE: May increase paroxetine levels
- CYPROHEPTADINE: May decrease or reverse the effects of SSRIs
- DIGOXIN: Paroxetine (in humans) can decrease digoxin AUC by 15%
- INSULIN: May alter insulin requirements
- ISOPTORDI: Increased risk for serotonin syndrome
- MAO INHIBITORS (including amitraz and potentially, selegline): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing paroxetine and a 2 week washout period if first discontinuing the MAO inhibitor
- PENTAZOCINE: Serotonin syndrome-like adverse effects possible
- PHENOBARBITAL: May decrease paroxetine levels
- PHENYTOIN: Increased plasma levels of phenytoin possible; may decrease paroxetine levels
- PROPANOLOL, METOPROLOL: Paroxetine may increase these beta-blockers’ plasma levels and cause hypotension; atenolol may be safer to use if paroxetine required
- TRAMADOL: SSRIs can inhibit the metabolism of tramadol to the active metabolites decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures).
- TRICYCLIC ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline): Paroxetine may increase TCA blood levels and may increase the risk for serotonin syndrome
- THEOPHYLLINE: Increased plasma levels of theophylline possible
- WARFARIN: Paroxetine may increase the risk for bleeding

Doses
- DOGS:
  a) For compulsive disorders: 1 mg/kg (up to 3 mg/kg) PO once daily (q24h) (Landsberg 2004)
  b) For generalized anxiety disorder: 1–1.5 mg/kg q24h (Crowell-Davis 2009)
  c) For adjunctive treatment of phobias, fears, and anxieties: 0.5–1 mg/kg PO once daily (Moffat 2007a)

- CATS:
  a) For compulsive disorders: 1 mg/kg (up to 2 mg/kg) q24h (Landsberg 2004)
  b) For generalized anxiety disorder: 1 mg/kg q24h (Crowell-Davis 2009)

- TREATMENT:
  a) In refractory cases, it may be beneficial to increase the dose to 2 mg/kg or more q24h (Landsberg 2004)
Penicillamine that is not complexed with either a metal or cystine is thought to be metabolized by the liver and excreted in the urine and feces. In humans, penicillamine is well absorbed after oral administration and peak serum levels occur about one hour after dosing. The drug apparently crosses the placenta but, otherwise, little information is known about its pharmacokinetics.

Penicillamine chelates a variety of metals, including copper, lead, iron, and mercury, forming stable water soluble complexes that are excreted by the kidneys.

Uses/Indications

- Can also be used for the long-term oral treatment of lead, or mercury poisoning or in cystine urolithiasis.
- Penicillamine is used primarily for its chelating ability in veterinary medicine. It is the drug of choice for Copper storage-associated hepatopathies in dogs, but clinical improvement may require weeks to months of therapy. It can also be used for the long-term oral treatment of lead, or mercury poisoning or in cystine urolithiasis.

Chemistry/Synonyms

Penicillamine, also known as: BRL-29060, FG-7051, and Pzill®.

Pharmacology/Actions

- Chelating agent used primarily for copper-storage hepatopathies (dogs). May be considered for lead poisoning or cystine urolithiasis
- Contraindications: History of penicillamine-related blood dyscrasias; lead present in GI tract
- Adverse Effects: Nausea, vomiting, & depression. Can reduce GI dietary mineral (zinc, iron, copper, and calcium) absorption and cause deficiencies; Rarely: Fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy
- Potentially teratogenic
- Preferably given on an empty stomach

Uses/Indications

Penicillamine is used primarily for its chelating ability in veterinary medicine. It is the drug of choice for Copper storage-associated hepatopathies in dogs, but clinical improvement may require weeks to months of therapy. It can also be used for the long-term oral treatment of lead, or mercury poisoning or in cystine urolithiasis.

Because it has anti-fibrotic effects, penicillamine may be of benefit in chronic hepatitis, but doses necessary for effective treatment may be too high to be tolerated.

Pharmacology/Actions

Penicillamine chelates a variety of metals, including copper, lead, iron, and mercury, forming stable water soluble complexes that are excreted by the kidneys.

Penicillamine combines chemically with cystine to form a stable, soluble complex that can be readily excreted.

Penicillamine has antifibrotic activity via inhibition of collagen crosslinking thereby causing collagen to be more susceptible to degradation.

Although penicillamine is a degradation product of penicillins, it has no antimicrobial activity.
Penicillamine is contraindicated in patients with a history of penicillamine-related blood dyscrasias. Penicillamine potentially can cause enhanced absorption of lead from the gastrointestinal tract. If lead is still present in the gut, it should not be administered.

### Adverse Effects
In dogs, the most prevalent adverse effects associated with penicillamine are nausea, vomiting, and depression. If vomiting is a problem, attempt to alleviate by giving smaller doses of the drug on a more frequent basis. Although food probably decreases the bioavailability of the drug, many clinicians recommend mixing the drug with food or giving at mealtimes if vomiting persists. Although thought infrequent or rare, fever, lymphadenopathy, skin hypersensitivity reactions, or immune-complex glomerulonephropathy may occur.

Penicillamine can reduce GI dietary mineral (zinc, iron, copper, and calcium) absorption and cause deficiencies with long-term use.

### Reproductive/Nursing Safety
Penicillamine has been associated with the development of birth defects in offspring of rats given 10 times the recommended dose. There are also some reports of human teratogenicity. In humans, the FDA categorizes this drug as category D for use during pregnancy. (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Lactation safety has not been established.

### Overdosage/Acute Toxicity
No specific acute toxic dose has been established for penicillamine and toxic effects generally occur in patients taking the drug chronically. Any relationship of toxicity to dose is unclear; patients on small doses may develop toxicity.

### Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillamine and may be of significance in veterinary patients:

**Aminoquinoline Drugs** (e.g., chloroquine, quinacrine): Concomitant administration with these agents may increase the risks for severe dermatologic adverse effects.

**CATIONS, ORAL including ZINC, IRON, CALCIUM, MAGNESIUM**: May decrease the effectiveness of penicillamine if given orally together.

**FOOD, ANTACIDS**: The amount of penicillamine absorbed from the GI tract may be reduced by the concurrent administration of food or antacids.

**GOLD COMPOUNDS**: May increase the risk of hematologic and/or renal adverse reactions.

**Immunosuppressant Drugs** (e.g., cyclophosphamide, azathioprine, but not corticosteroids): May increase the risk of hematologic and/or renal adverse reactions.

**Phenybutazone**: May increase the risk of hematologic and/or renal adverse reactions.

### Laboratory Considerations
When using technetium Tc 99m gluceptate to visualize the kidneys, penicillamine may chelate this agent and form a compound that is excreted via the hepatobiliary system resulting in gallbladder visualization that could confuse the results.

### Doses
**Dogs:**
- For copper-associated hepatopathy:
  - a) 10-15 mg/kg PO q12h on an empty stomach. Do not give concurrently with any medication, including zinc or a vitamin-mineral supplement. (Jergens & Willard 2000)
  - b) Reduce copper intake (water, food), use chelation initially if liver copper >1,500 micrograms/gram dry wt, and thereafter may reduce enteric copper uptake with zinc. Chelation: penicillamine 15 mg/kg PO twice daily 30 minutes before meals. Give supplemental pyridoxine. Chelate at least 6 months, and then use a second liver biopsy to determine efficacy and chronic treatment plan. If copper is critically lower, may be worth trying chronic zinc acetate, maintain dietary copper restriction, and watch ALT. If the patient is zinc intolerant, use chronic penicillamine at a dose restriction of 50%. Do not use chelation and zinc together; stagger dosing may still result in penicillamine-zinc chelation. (Center 2008)
  - c) 10-15 mg/kg PO two times a day 30 minutes prior to food. Start low and increase. (Webb 2007)
  - d) 15 mg/kg PO twice daily on an empty stomach. (Twedt 2009)

For cystine urolithiasis:
- a) 15 mg/kg: PO twice daily. If nausea and vomiting occur, mix with food or give at mealtime. Some dogs may need to have the dosage slowly increased to full dose in order to tolerate the drug. (Osborne et al. 1989)
- b) 15 mg/kg: PO twice daily with food (Lage et al. 1988)

For lead poisoning:
- a) After initial therapy regimen with CaEDTA and if continued therapy is desired at home, may give penicillamine at 110 mg/kg/day, PO divided q6-8h for 1–2 weeks. If vomiting, depression, and anorexia occur, may reduce dose to 33–55 mg/kg/day divided q6-8h, which should be better tolerated. (Mount 1989)
- b) As an alternate or adjunct to CaEDTA: 110 mg/kg/day divided q6-8h PO 30 minutes before feeding for 1–2 weeks. If vomiting a problem may premedicate with dimenhydrinate (2–4 mg/kg PO). Alternatively, may give 33–55 mg/kg/day divided as above. Dissolving medication in juice may facilitate administration. (Nicholson 2000)

**Cats:**
- For lead poisoning:
  - a) After initial therapy with CaEDTA and if blood lead is greater than 0.2 ppm at 3–4 weeks post-treatment, may repeat CaEDTA or give penicillamine at 125 mg q12h PO for 5 days. (Reid & Oehme 1989)

**Ruminants:**
- Note: When used in food animals, FARAD recommends a minimum milk withdrawal time of 3 days after the last treatment and a 21-day preslaughter withdrawal. (Haskell et al. 2005)
- a) For copper toxicity in small ruminants: 52 mg/kg daily for 6 days is sometimes successful (Reilly 2004)
- b) For copper toxicity in small ruminants: 26–52 mg/kg PO once daily for 6 days. (Boileau 2009)
- c) For lead or mercury toxicity: 110 mg/kg PO for 1-3 weeks. To prevent continued metal absorption, must clear GI tract of toxic metal before therapy. (Osweiler 2007)

**Birds:**
- For adjunctive treatment of lead poisoning:
  - a) 55 mg/kg PO q12h for 1–2 weeks. It has been suggested that combining CaEDTA and penicillamine for several days until symptoms dissipate followed by a 3–6 week treatment with penicillamine as the best regimen for lead toxicity. (Jones 2007)

### Monitoring
Monitoring of penicillamine therapy is dependent upon the reason for its use; refer to the references in the Dose section above for further discussion on the diseases and associated monitoring of therapy.

### Client Information
This drug should preferably be given on an empty stomach, at least 30 minutes before feeding. If the animal develops problems with vomiting or anorexia, three remedies have been suggested:

1. Give the same total daily dose, but divide into smaller individual doses and give more frequently
2. Temporarily reduce the daily dose and gradually increase to recommended dosage, or
3. Give with a small amount of food (e.g., cheese or bread). Giving with full meals will probably reduce amount of drug absorbed, but may be necessary in some patients.
**Penicillins, General Information**

Penicillins are a class of antibiotics that are derived from the fungus Penicillium. They are the basis of a large group of antibiotics known as the penicillins. Penicillins are used to treat infections caused by bacteria.

### Uses/Indications

Penicillins have been used for a wide range of infections in various species. FDA-approved indications/species, as well as non-FDA-approved uses, are listed in the Uses/Indications and Dosage section for each drug.

### Pharmacology/Actions

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucoprotein synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities of various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The clinically available penicillins encompass several distinct classes of compounds with varying spectrums of activity:

- **Natural Penicillins**: Include penicillin G and V, which are essentially the same antibiotic with V having a more stable chemical structure. They are not only active against many bacteria, but also provide a sterile environment for the body's natural defenses to eliminate the infection.

- **Penicillinase-Resistant Penicillins** (Penicillinase-Resistant Penicillin G and V): These are chemically modified versions of natural penicillins that are resistant to penicillinase, an enzyme produced by some bacteria that can destroy natural penicillins.

- **Extended-Spectrum Penicillins**: Include both alpha-carboxypenicillins (carbenicillin and ticarcillin) and acylaminopenicillins (piperacillin, azlocillin, and mezlocillin). These are effective against a broader range of bacteria than the natural penicillins.

- **Aminopenicillins**: Include ampicillin, amoxicillin, and others. They are active against a variety of gram-negative and gram-positive bacteria, including some strains resistant to other penicillins.

- **β-Lactamase Inhibitors**: Include clavulanate, sulbactam, and tazobactam. These are used in combination with other antibiotics to prevent the breakdown of penicillins by β-lactamases.

### Contraindications/Precautions

- **Hypersensitivity**: Penicillins may cause allergic reactions in some patients, including rashes, fever, angioedema, and anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

- **Contraindications**

- **Pregnancy**: Use cautiously during pregnancy.

### Storage/Stability

Penicillins should be stored at room temperature (15–30°C). The capsules should be stored in tight containers; tablets in well-closed containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Penicillin Titratable Oral Tablets: 250 mg (scored); Depen® (Wallace); (Rx)

Penicillin Oral Capsules: 125 mg & 250 mg; Cuprimine® (Atom Pharma); (Rx)

### References

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) However, use only when the potential benefits outweigh the risks.

Penicillins are excreted in maternal milk in low concentrations; use potentially could cause diarrhea, candidiasis, or allergic response in the nursing offspring.

Overdosage/Acute Toxicity
Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillins and may be of significance in veterinary patients:

- **AminoGlycosides**: In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.

- **Bacteriostatic Antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly as penicillins tend to perform better on actively growing bacteria.

- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations
- Penicillins may cause false-positive urine glucose determinations when using cupric-sulfate solution (Benedict’s Solution, Clinister®). Tests utilizing glucose oxidase (Tes-Tape®, Clinistix®) are not affected by penicillin.
- In humans, clavulanic acid and high dosages of piperacillin have caused a false-positive direct ‘Combs’ test.
- As penicillins and other beta-lactams can inactivate aminoglycosides in vitro, serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Monitoring
- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop.
- Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information
- Owners should be instructed to give oral penicillins on an empty stomach, unless using amoxicillin or GI effects (anorexia, vomiting) occur.
- Compliance with the therapeutic regimen should be stressed.
- Reconstituted oral suspensions should be kept refrigerated and discarded after 14 days, unless labeled otherwise.

**Penicillin G**
(pen-ih-sil-in inj)
**Penicillin Antibiotic**

Prescriber Highlights

- Prototypical penicillin agent used for susceptible gram-positive aerobes & anaerobes; best used parenterally
- Contraindications: Known hypersensitivity (unless no other options)
- Adverse Effects: Hypersensitivity possible. Very high doses may cause CNS effects
- Benzathine penicillin only effective against extremely sensitive agents
- Certain species may be sensitive to procaine penicillin G

Uses/Indications
Natural penicillins remain the drugs of choice for a variety of bacteria, including group A beta-hemolytic streptococci, many gram-positive anaerobes, spirochetes, gram-negative aerobic cocci, and some gram-negative aerobic bacilli. Generally, if a bacteria remains susceptible to a natural penicillin, either penicillin G or V is preferred for treating that infection as long as adequate penetration of the drug to the site of the infection occurs and the patient is not hypersensitive to penicillins.

Pharmacology/Actions
Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria. Penicillins are considered time dependent antibiotics as efficacy depends on the length of time that plasma (or tissue) concentrations exceed the MIC of pathogens.

The natural penicillins (G and K) have similar spectrums of activity, but penicillin G is slightly more active in vitro against most spirochetes and gram-positive and gram-negative aerobic cocci, but not penicillinase producing strains. They have activity against some aerobic and anaerobic gram-positive bacilli such as Bacillus anthracis, Clostridium spp. (not C. difficile), Fusobacterium, and Actinomycetes. The natural penicillins are customarily inactive against most gram-negative aerobic and anaerobic bacilli, and all Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

Pharmacokinetics
Penicillin G potassium is poorly absorbed orally because of rapid acid-catalyzed hydrolysis. When administered on an empty (fasted) stomach, oral bioavailability is only about 15–30%. If given with food, absorption rate and extent will be decreased.

Penicillin G potassium and sodium salts are rapidly absorbed after IM injections and yield high peak levels usually within 20 minutes of administration. In horses, equivalent doses given either IV or IM demonstrated that IM dosing would provide serum levels above 0.5 micrograms/mL for about twice as long as IV administration (approx. 3–4 hours (IV) vs. 6–7 hours (IM)).
Penicillin G is slowly hydrolyzed to penicillin G after IM injection.峰水平比用静脉注射青霉素G钠或钾盐的峰水平低，但血清水平比用静脉注射青霉素G钠或钾盐的血清水平更持久。

Benzathine penicillin G is also very slowly absorbed after IM injections after being hydrolyzed to the parent compound. Serum levels can be very prolonged, but levels attained generally only exceed MIC's for the most susceptible streptococci, and the use of benzathine penicillin G should be limited to these infections when other penicillin therapy is impractical.

After absorption, penicillin G is widely distributed throughout the body with the exception of the GI tract, joints, and milk. In lactating dairy cattle, the milk to plasma ratio is about 0.2. CSF levels are generally only 10% or less of those found in the serum when meningitis are not inflamed. Levels in the CSF may be greater in patients with inflamed meninges or if probenecid is given concurrently. Binding to plasma proteins is approximately 50% in most species.

Penicillin G is principally excreted unchanged into the urine through renal mechanisms via both glomerular filtration and tubular secretion. Elimination half-lives are very rapid and are usually one hour or less in most species (if normal renal function exists).

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, carbamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished; parenteral (preferably IV) routes should be used for these cases.

High doses of penicillin G sodium or potassium, particularly in small animals with a preexisting electrolyte abnormality, renal disease, or congestive heart failure may cause electrolyte imbalances. Other injectable penicillins, such as ticarcillin, carbenicillin, and ampicillin, have significant quantities of sodium per gram and may cause electrolyte imbalances when used in large dosages in susceptible patients.

Certain species (snakes, birds, turtles, Guinea pigs, and chinchillas) are reported sensitive to penicillin G.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence. Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemia, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neutropenia (e.g., anemia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither has there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks.

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, carbapenems, carbapenems).

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects). In humans, very high dosages of parenteral penicillins, especially those with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving penicillin G and may be of significance in veterinary patients:

- **Aminoglycosides**: In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides or cephalosporins.
- **Bacteriostatic Antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines): Use with penicillins is generally not recommended, particularly in acute infections where the organism is proliferating rapidly as penicillins tend to perform better on actively growing bacteria.
- **Methotrexate**: Penicillins may decrease renal elimination of MTX.
- **Probenecid**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

Laboratory Considerations

As penicillins and other beta-lactams can inactivate aminoglycosides in vitro and in vivo in patients with renal failure, serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Penicillin G can cause falsely elevated serum uric acid values if the copper-chelate method is used; phosphotungstate and uricase methods are not affected.

Penicillins may cause false-positive urine glucose determinations when using cupric-sulfate solution (Benedict’s Solution, Clinistix®). Tests utilizing glucose oxidase (Tes-Tape®, Clinitest®) are not affected by penicillin.

Doses

**DOGS**

For susceptible infections:

- **Penicillin G potassium**: For bacteremia, systemic infections: 20,000–40,000 Units/kg IV q4–6h for as long as necessary. For orthopedic infections: 20,000–40,000 Units/kg IV q6h for as long as necessary.
- **Penicillin G procaine**: For orthopedic surgery: 40,000 Units/kg IV one hour prior to surgery, and if surgery lasts longer than 90 minutes a second dose is given.
- **Penicillin G benzathine**: 40,000 Units/kg IM 5 days. (Greene et al. 2000)
- **Penicillin G procaine**: For susceptible infections: For soft tissue infections: 20,000 Units/kg IM, SC q4–6h for as long as necessary. For orthopedic infections: 20,000–40,000 Units/kg IM q6h for as long as necessary.
- **Penicillin G benzathine**: 50,000 Units/kg IM q5 days. (Greene et al. 2000)

**CATS**

For susceptible infections:

- **Penicillin G potassium**: For soft tissue, systemic infections: 40,000 Units/kg PO q6–8h for as long as necessary.
- **Penicillin G procaine**: For soft tissue infections: 20,000 Units/kg IM, SC q4–6h for as long as necessary.
- **Penicillin G benzathine**: 40,000 Units/kg IM q5 days. (Greene et al. 2000)
G benzathine is equivalent to 1090–1272 USP Units. The commercially available suspension for injection is buffered with sodium citrate and has a pH of 5–7.5. It is preserved with methylparaben and propylparaben.

Penicillin G procaine (also known as APPG, Aqueous Procaine Penicillin G, Benzylpenicillin Procaine, Procaine Penicillin G, Procaine Benzylpenicillin) is the procaine monohydrate salt of penicillin G.

Penicillin G procaine is soluble in 1 mL of alcohol. Potency of penicillin G procaine is usually expressed in terms of Units. One mg of penicillin G procaine is equivalent to 900–1050 USP Units.

Penicillin G sodium (also known as benzylpenicillin sodium, aqueous penicillin) occurs as colorless or white crystals, or white crystalline powder. It is very soluble in water and sparingly soluble in alcohol.

Penicillin G potassium (also known as benzylpenicillin potassium, aqueous penicillin) is hydrolyzed in vivo to penicillin G and acts as a depot, or reservoir form, of penicillin G. It occurs as white crystals or very fine, white crystalline powder. Approximately 25 mg are soluble in 1 mL of water.

Penicillin G potassium powder for injection has a pH of 6–8.5, and contains 1.7 mEq of potassium per 1 million Units.

Penicillin G benzathine (also known as Benzathine Benzylpenicillin, Benzathine Penicillin G, Benzylpenicillin Benzathine, Dibenzylthelyenediamine Benzylpenicillin) is the benzathine tetrathylate salt of penicillin G. It is hydrolyzed in vivo to penicillin G and acts as a long-acting form of penicillin G. It occurs as an odorless, white, crystalline powder. Solubilities are 0.2–0.3 mg/mL of water and 15 mg/mL of alcohol. One mg of penicillin G benzathine is equivalent to 1090–1272 USP Units.

Penicillin G benzathine is preserved with thimerosal and has a pH of 5–7.5. It is preserved with methylparaben and propylparaben.

Penicillin G amoxicillin (also known as Bicillin C-R®, Musti-Clear®, Permapen®, and Pfizerpen®)
Penicillins sodium and potassium should be protected from moisture to prevent hydrolysis of the compounds. Penicillin G potassium tablets and powder for oral solution should be stored at room temperature in tight containers; avoid exposure to excessive heat. After reconstitution, the oral powder for solution should be stored from 2-8°C (refrigerated) and discarded after 14 days. Penicillin G sodium and potassium powder for injection should be stored at room temperature (15-30°C). After reconstituting, the injectable solution is stable for 7 days when kept refrigerated (2-8°C) and for 24 hours at room temperature.

Penicillin G procaine should be stored at 2-8°C; avoid freezing. Benzathine penicillin G should be stored at 2-8°C.

Compatibility/Compounding Considerations
All commonly used IV fluids (some Dextran products are physically incompatible) and the following drugs are reportedly physically compatible with penicillin G potassium: ascorbic acid injection, calcium chloride/glucoluate, cephalin, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, colistimethate sodium, corticotropin, dimenhydrinate, diphenhydramine HCl, ephedrine sulfate, erythromycin gluceptate/lactobionate, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, mexitilin HCl, methicillin sodium, methyprednisolone sodium succinate, metronidazole with sodium bicarbonate, nitrofurantoin potassium, polymyxin B sulfate, potassium chloride, prednisolone sodium phosphate, procaine HCl, prochlorperazine edisylate, sodium iodide, sulfisoxazole disulfane, and verapamil HCl.

The following drugs/solutions are reportedly physically incompatible or confl icts regarding compatibility with penicillin G potassium injection: amikacin sulfate, aminophylline, chlorpromazine HCl, dopamine HCl, heparin sodium, hydroxyurea HCl, lincomycin HCl, metoclopromide HCl, oxytetracycline HCl, pentobarbital sodium, prochlorperazine mesylate, promazine HCl, promethazine HCl, sodium bicarbonate, tetracycline HCl, and vitamin B-complex with C.

The following drugs/solutions are either physically incompatible or confl icts regarding compatibility with penicillin G sodium injection: amphotericin B, bleomycin sulfate, chlorpromazine HCl, heparin sodium, hydroxyurea HCl, lincomycin HCl, methylprednisolone sodium succinate, oxytetracycline HCl, potassium chloride, prochlorperazine mesylate, promethazine HCl and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

**Note:** Withdrawal times are for labeled dosages only.

- Penicillin G Procaine Injection 300,000 Units/mL in 100 mL and 250 mL vials: Variety of trade names available. Depending on product, FDA-approved for use in: cattle, sheep, horses, and swine. Not intended for use in horses used for food. Do not exceed 7 days of treatment in non-lactating dairy cattle. Treatment should not exceed 4 consecutive days.
- Withdrawal times vary depending on the product are for the labeled dosage of 6,600 Units/kg once daily (rarely used clinically today). Actual withdrawal times may be longer. Milk withdrawal times (at labeled doses) = 48 hours. Slaughter withdrawal: Calves (non-eumening) = 7 days; cattle = 4–10 days; sheep = 8–9 days; swine = 6–8 days; refer to label for more information.
- Penicillin G Procaine Mastitis Syringes 100,000 Units/mL in 10 mL units: Go-Dry® (G.C. Hanford) (OTC) Milk withdrawal (at labeled doses) = 72 hours. Slaughter withdrawal (at labeled doses) = 14 days. For use in dairy cows only. Musti-Clear® (G.C. Hanford) Milk withdrawal (at labeled dose) = 60 hours. Slaughter withdrawal (at labeled dose) = 3 days. Administer no more than 3 consecutive doses or withdrawal times must lengthen.

There are also mastitis syringes in combination with novobiocin (Albadry Plus®) or dihydrostreptomycin (Quartermaster®)

**Penicillin G Benzathine 150,000 Units/mL, with Penicillin G Procaine Injection 150,000 Units/mL for injection in 100 mL and 250 mL vials: Variety of trade names available. FDA-approved (most products) in horses and beef cattle. Not FDA-approved for horses intended for food use. Slaughter withdrawal: cattle = 30 days (at labeled doses). Actual species approvals and withdrawal times may vary with the product; refer to the label of the product you are using.

**HUMAN-LABELLED PRODUCTS:**

- Penicillin G (Aqueous) Sodium Powder for Injection: 5,000,000 Units & 20,000,000 Units in vials; Pfizerpen® (Pfizer); generic (Sandoz); (Rx)
- Penicillin G (Aqueous) Potassium Injection (Premixed, frozen): 1,000,000 Units, 2,000,000 Units & 3,000,000 Units in 50 mL Galaxy containers; generic (Baxter); (Rx)
- Penicillin G Procaine Injection: 600,000 Units/vial in 1 mL; Tubex® 1,200,000 Units/vial in 2 mL; Tubex; generic; (Monarch); (Rx)
- Penicillin G Benzathine Injection: 600,000 Units/dose in 1 mL; Tubex; 1,200,000 Units/dose in 2 mL; Tubex and 2 mL; Isogex; 2,400,000 Units/dose in 4 mL pre-filled syringes; Bicillin L-A®; (Monarch); Permapen® (Roering); (Rx)
- Penicillin G benzathine/procaine IM Injection: 600,000 Units/dose (300,000 Units each penicillin G benzathine & penicillin G procaine) in 1 mL; Tubex; 1,200,000 Units/dose (600,000 Units each penicillin G benzathine & penicillin G procaine) in 2 mL; Tubex; 2,400,000 Units/dose (900,000 Units penicillin G benzathine & 300,000 Units penicillin G procaine) in 2 mL; Tubex; Bicillin C-R® and Bicillin C-R 900/300®; (Monarch); (Rx)

**References**

**Use/Indications**

Penicillins have been used for a wide range of infections in various species. See the dosage section for more information.

**Pharmacology/Actions**

The natural penicillins (G and K) have similar spectrums of activity, but penicillin G is slightly more active in vitro on a per weight basis against many organisms. This class of penicillin has in vitro activity against most streptococci, staphylococci, some coliforms, some enterococci, and gonococci. They are also inactive against anaerobes, most oral bacteria, and the pneumococci. Some bacteria such as meningococci and diptheroids are inhibited by penicillin G. Other species such as Clostridium tetani is susceptible, whereas other members of this genus are not. Penicillin G is inactive against most enterobacteria, anaerobic bacteria, and mycobacteria. It is generally considered to be active against most gram-positive cocci, but some strains of Staphylococcus aureus may be resistant. Penicillin G is partially active against H. influenzae, N. gonorrhoeae, and N. meningitidis.

Penicillin G is rapidly absorbed when given intramuscularly, but has a short half-life due to its rapid excretion. However, it has a long duration of action when given subcutaneously. The peak serum concentration is achieved 1-2 hours after IM injection. The duration of action varies with the species and the dosage. In dogs, it has a half-life of 30 minutes and the duration of action is only 1-2 hours. In horses, it has a half-life of 1-3 hours and the duration of action is 2-3 hours. Penicillin G is primarily excreted in urine and feces. It is not metabolized in the body.

Penicillin G is primarily used for the treatment of infections caused by susceptible bacteria. It is commonly used for the treatment of skin infections, respiratory tract infections, and urinary tract infections. It is also used for the prophylaxis of endocarditis in patients with prosthetic heart valves. It is often used in combination with other antibiotics to treat infections caused by penicillin-resistant bacteria.

Penicillin G is generally well tolerated, but it can cause side effects such as skin reactions, nausea, vomiting, and diarrhea. It can also cause allergic reactions in some people. It is important to consult with a healthcare provider before using penicillin G, as it may not be suitable for everyone.
Drug Interactions
The pharmacokinetics of penicillin V are very similar to penicillin G with the exception of oral bioavailability and the percent of the drug that is bound to plasma proteins. Penicillin V is significantly more resistant to acid catalyzed inactivation in the gut and bioavailability after oral administration in humans is approximately 60-73%. In veterinary species, bioavailability in calves is only 30%, but studies performed in horses and dogs demonstrated that therapeutic serum levels can be achieved after oral administration. In dogs, food will decrease the rate and extent of absorption.

Distribution of penicillin V follows that of penicillin G but, at least in humans, the drug is bound to a larger extent to plasma proteins (approximately 80% with penicillin V vs. 50% with penicillin G).

Laboratory Considerations
Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Doses
**DOGS:**
- For susceptible infections:
  a) 5.5–11 mg/kg PO q6–8h (Aronson & Aucoin 1989)
  b) For soft tissue infections: 10 mg/kg PO q6–8h for 7 days. (Greene et al. 2006)

**CATS:**
- For susceptible infections:
  a) 5.5–11 mg/kg PO q6–8h (Aronson & Aucoin 1989)
  b) For soft tissue infections: 10 mg/kg PO q6–8h for 7 days. (Greene et al. 2006)

**HORSES:**
- For susceptible infections:
  a) 110,000 U/kg (68.75 mg/kg) PO q8h (may yield supra-optimal levels against uncomplicated infections by sensitive organisms) (Schwark et al. 1983)
  b) 110,000 U/kg PO q6–12h (Brumbaugh 1987)

Monitoring
Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.
Chemistry/Synonyms
A natural-penicillin, penicillin V is produced from *Penicillium chrysogenum* and is usually commercially available as the potassium salt. Penicillin V potassium occurs as an odorless, white, crystalline powder that is very soluble in water and slightly soluble in alcohol. Potency of penicillin V potassium is usually expressed in terms of weight (in mg) of penicillin V, but penicillin V units may also be used. One mg of penicillin V potassium is equivalent to 1380–1610 USP Units of penicillin V. Manufacturers however generally state that 125 mg of penicillin V potassium is approximately equivalent to 200,000 USP units of penicillin V.

Penicillin V may also be known as: phenoxymethylpenicillin, fenoximetilpenicilina, penicillin, phenoxymethyl, phenomycilline, phenoxymethyl penicillin, phenoxymethylpenicillium, and Veetids®.

Storage/Stability
Penicillin V potassium tablets and powder for oral solution should be stored in tight containers at room temperature (15–30°C). After reconstitution, the oral solution should be stored at 2–8°C (refrigerated) and any unused portion discarded after 14 days.

Dosage/Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**
- Penicillin V Potassium Tablets: 250 mg & 500 mg; Veetids® (Geneva); generic; (Rx)
- Penicillin V Potassium Powder for Oral Solution: 25 mg/mL & 50 mg/mL, in 100 mL & 200 mL; Veetids® (Geneva); generic; (Rx)

**References**

**PENTAZOCINE LACTATE**

**PENTAZOCINE HCL**

(phen-oh-seen) Talwin®

**PARTIAL OPIATE AGONIST**

**Prescriber Highlights**

- Partial opiate agonist analgesic used in a variety of species; usage and availability are decreasing
- Contraindications: Known hypersensitivity
- Caution: Head trauma, increased CSF pressure or other CNS dysfunction, hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), & geriatric or severely debilitated patients
- Not a replacement for surgery or medical treatment for horses with colic
- Adverse Effects: *Horses:* Transient ataxia, CNS excitement, increased pulse, & respiratory rate. *Dogs:* Salivation most prevalent; ataxia, fine tremors, seizures, emesis, & swallowing at injection site possible
- Cats: Use is controversial; may cause dysphoric reactions
- C-IV controlled substance

**Uses/Indications**

Pentazocine is labeled for the symptomatic relief of pain of colic in horses and for the amelioration of pain accompanying postoperative recovery from fractures, trauma, and spinal disorders in dogs. It has also been used as an analgesic in cats (see Adverse Effects below) and swine.

**Pharmacology/Actions**

While considered a partial opiate agonist, pentazocine exhibits many of the same characteristics as the true opiate agonists. It is reported to have an analgesic potency of approximately one-half that of morphine and five times that of meperidine. It is a very weak antagonist at the opioid receptor when compared to naloxone. It will not antagonize the respiratory depression caused by drugs like morphine, but may induce symptoms of withdrawal in human patients physically dependent on narcotic agents. Pentazocine’s mixed agonist/antagonist properties limit its maximal analgesic efficacy (ceiling effect).

Besides its analgesic properties, pentazocine can cause respiratory depression, decreased GI motility, sedation, and it possesses antitussive effects. Pentazocine tends to have less sedative qualities in animals than other opiates and is usually not used as a pre-operative medication.

In dogs, pentazocine can cause a transient decrease in blood pressure; in humans, increases in cardiac output, heart rate, and blood pressure can be seen.

**Pharmacokinetics**

Pentazocine is well absorbed following oral, IM, or SC administration. Because of a high first-pass effect, only about 20% of an oral dose will enter the systemic circulation in patients with normal hepatic function. After absorption, the drug is distributed widely into tissues. In the equine, it has been shown to be 80% bound to plasma proteins. Pentazocine will cross the placenta and neonatal serum levels have been measured at 60–65% of maternal levels at delivery. It is not clearly known if or how much pentazocine crosses into milk.

The drug is primarily metabolized in the liver with resultant excretion by the kidneys of the metabolites. In the horse, approximately 30% of a given dose is excreted as the glucuronide. Pentazocine and its metabolites have been detected in equine urine for up to 5 days following an injection. Apparently, less than 15% of the drug is excreted by the kidneys in an unchanged form.

Plasma half-lives have been reported for various species: Humans = 2–3 hrs; Ponies = 97 min.; Dogs = 22 min.; Cats = 84 min.; Swine = 49 min. Volumes of distribution range from a high of 5.09 L/kg in ponies to 2.78 L/kg in cats. In horses, the onset of action has been reported to be 2–3 minutes following IV dosing with a peak effect at 5–10 minutes.

**Contraindications/Precautions/Warnings**

The drug is contraindicated in patients having known hypersensitivity to it. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients.

Like other opiates, pentazocine must be used with extreme caution in patients with head trauma, increased CNS dysfunction (e.g., coma). Pentazocine should not be used in place of appropriate therapy (medical &/or surgical) for equine colic, but only as adjunctive treatment for pain.

**Adverse Effects**

In dogs, the most predominant adverse reaction following parenteral administration is salivation. Other potential side effects at usual doses include fine tremors, emesis, and swelling at the injection site. At very high doses (6 mg/kg) dogs have been noted to develop ataxia, fine tremors, convulsions, and swelling at the injection site. Horses may develop transient ataxia and clinical signs of CNS excitement. Pulse and respiratory rates may be mildly elevated.

Plasma half-lives have been reported for various species: Humans = 2–3 hrs; Ponies = 97 min.; Dogs = 22 min.; Cats = 84 min.; Swine = 49 min. Volumes of distribution range from a high of 5.09 L/kg in ponies to 2.78 L/kg in cats. In horses, the onset of action has been reported to be 2–3 minutes following IV dosing with a peak effect at 5–10 minutes.

**Contraindications/Precautions/Warnings**

The drug is contraindicated in patients having known hypersensitivity to it. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients.

Like other opiates, pentazocine must be used with extreme caution in patients with head trauma, increased CNS dysfunction (e.g., coma). Pentazocine should not be used in place of appropriate therapy (medical &/or surgical) for equine colic, but only as adjunctive treatment for pain.

**Adverse Effects**

The drug is contraindicated in patients having known hypersensitivity to it. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison’s), and geriatric or severely debilitated patients.

Like other opiates, pentazocine must be used with extreme caution in patients with head trauma, increased CNS dysfunction (e.g., coma). Pentazocine should not be used in place of appropriate therapy (medical &/or surgical) for equine colic, but only as adjunctive treatment for pain.

**Adverse Effects**

In dogs, the most predominant adverse reaction following parenteral administration is salivation. Other potential side effects at usual doses include fine tremors, emesis, and swelling at the injection site. At very high doses (6 mg/kg) dogs have been noted to develop ataxia, fine tremors, convulsions, and swelling at the injection site. Horses may develop transient ataxia and clinical signs of CNS excitement. Pulse and respiratory rates may be mildly elevated.
Reproductive/Nursing Safety
Because reproductive studies have not been done in dogs, the manufacturer does not recommend its use in pregnant bitches or bitches intended for breeding. Studies performed in laboratory animals have not demonstrated any indications of teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Safety for use during lactation has not been established.

Overdosage/Acute Toxicity
There is little information regarding acute overdose situations with pentazocine. For oral ingestions, the gut should be emptied if indicated and safe to do so. Clinical signs should be managed by supportive treatment (O2, pressor agents, IV fluids, mechanical ventilation) and respiratory depression can be treated with naloxone. Repeated doses of naloxone may be necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pentazocine and may be of significance in veterinary patients:

**CNS DEPRESSANTS, OTHER (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.):** May cause increased CNS or respiratory depression; dosage may need to be decreased

**FLUOXETINE (and OTHER SSRI'S):** May be at increased risk for serotonin syndrome

Laboratory Considerations
Pentazocine may cause decreases for urinary 17-hydroxycorticosteroid determinations

Doses

**DOGS:**
For analgesia:
- a) Initially 1.65 mg/kg; up to 3.3 mg/kg IM. Duration of effect generally lasts 3 hours. If dose is repeated, use different injection site. (Package Insert; Talwin®-V——Winthrop)
- b) 1–6 mg/kg IM or SC q1–3h (Hendrix & Hansen 2000)
- c) 1–4 mg/kg IM, IV q2–4h (Otero 2006)

**CATS:**
- Note: Pentazocine can cause dysphoria in cats; alternative analgesics are recommended.

**FERRETS:**
- a) 5–10 mg/kg SC or IM q4h (Williams 2000)

**RABBITS, RODENTS, SMALL MAMMALS:**
- a) Rabbits: Post-operative analgesia: 5–20 mg/kg SC, IV, or IM q4h (Ivey & Morrisey 2000)

**HORSES:**
Studies have demonstrated that pentazocine is not as an effective analgesic as either butorphanol or flunixin in horses. Many clinicians no longer recommend its use. (Note: ARCl UCGFS Class 3 Drug)

For analgesia:
- a) 0.33 mg/kg slowly in jugular vein. In cases of severe pain, a second dose (0.33 mg/kg) be given IM 15 minutes later (Package Insert; Talwin®-V——Winthrop)
- b) 0.4–0.9 mg/kg IV. Duration of analgesia may last only 10–30 minutes following an IV dose. (Thurmon & Benson 1987)
- c) For standing chemical restraint for castrations: Administer acepromazine at 0.088 mg/kg (or 40 mg/450 kg) IV after about 10 minutes when patient is obviously tranquilized, give pentazocine at 0.5 mg/kg (225 mg/450 kg) IV and then administer local anesthetic to each cord and the incision sites on ventral surface of the scrotum. (Abrahamsen 2007)

Monitoring
- Analgesic efficacy
- Respiratory rate/depth
- Appetite/bowel function
- CNS effects

Client Information
- Clients should report any significant changes in behavior, appetite, bowel, or urinary function in their animals.

Chemistry/Synonyms
A synthetic partial opiate agonist, pentazocine is commercially available as two separate salts. The hydrochloride salt, which is found in oral dosage forms, occurs as a white, crystalline powder. It is soluble in water and freely soluble in alcohol. The commercial injection is prepared from pentazocine base with the assistance of lactic acid. This allows the drug to be soluble in water. The pH of this product is adjusted to a range of 4–5.

Pentazocine is a weak base with an approximate pKa of 9.0.

Pentazocine may also be known as: NIH-7958, NSC-107430, pentazocinum, Win-20228,

Storage/Stability
The tablet preparations should be stored at room temperature and in tight, light-resistant containers. The injectable product should be kept at room temperature; avoid freezing.

Compatibility/Compounding Considerations
The following agents have been reported to be physically compatible when mixed with pentazocine lactate: atruepine sulfate, benquanimide HCI, butorphanol tartrate, chlorpromazine HCl, dimenhydrinate, diphenhydramine HCl, diropidol, fentanyl citrate, hydromorphone, hydroxizine HCl, meperidine HCl, metoclopramide, morphine sulfate, perphenazine, prochlorperazine edisylate, promazine HCl, promethazine HCl, and scopolamine HBr.

The following agents have been reported to be physically incompatible when mixed with pentazocine lactate: aminophylline, amobarbital sodium, flunixin meglumine, glycopyrrolate, pentobarbital sodium, phenobarbital sodium, secobarbital sodium, and sodium bicarbonate.

Dosage Forms/Regulatory Status

**VETERINARY-Labeled PRODUCTS:** None

The ARCl (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-Labeled PRODUCTS:** Pentazocine Lactate Injection: 30 mg (as lactate)/ml in 10 mL vials, Uni-Amp®; 1 mL Uni-Amp®, 1 mL & 2 mL Carpuject; Talwin® (Abbott Hospital Products); (Rx, C-IV) Pentazocine HCl and Naloxone HCl Tablets (Scored): 50 mg (as hydrochloride) & 0.5 mg naloxone; generic; (Royce); (Rx, C-IV) Pentazocine HCl and Acetaminophen Tablets: 25 mg (as hydrochloride)/650 mg acetaminophen; Talacen® (Sanofi Winthrop); generic; (Rx, C-IV)

References
**PENTOBARBITAL SODIUM**

*Note: Pentobarbital and combinations with pentobarbital (e.g., phenytoin) for euthanasia have a separate monograph listed under Euthanasia Agents*

**Prescriber Highlights**

- **Barbiturate used therapeutically as a sedative/anesthetic, & treating intractable seizures; also used for euthanasia**

**Contraindications:** Known hypersensitivity, severe liver disease, nephritis, or severe respiratory depression (large doses). Caution: Hypovolemia, anemia, borderline hypoalbuminemia, or cardiac or respiratory disease. Use with caution in cats (sensitive to respiratory depression).

**Adverse Effects:** Respiratory depression (if using for anesthesia have ventilatory support available), hypothermia, or excitement post-anesthesia (dogs)

When giving IV, administer SLOWLY (unless for euthanasia); very irritating if given SC or perivascularly; do not give IA

Numerous drug interactions

Uses/Indications

Once pentobarbital was the principal agent used for general anesthesia in small animals, but this has been largely supplanted by the use of inhalant anesthetic agents. It is still commonly used as an anesthetic in laboratory situations, for rodents and occasionally as a sedative agent in dogs and cats.

Pentobarbital can be used for treating intractable seizures, secondary to convulsant agents (e.g., strychnine) or secondary to CNS toxins (e.g., tetanus). It should not be used to treat seizures caused by lidocaine intoxication. For refractory status epilepticus not controlled with diazepam and phenobarbital, pentobarbital can be used, but propofol is preferred by most today as it causes less cardiovascular depression and recoveries can be smoother.

Pentobarbital has been used as a sedative and anesthetic agent in horses, cattle, swine, sheep, and goats. Often the drug is given after a preanesthetic agent in order to reduce pentobarbital dosages and resultant side effects.

Pentobarbital is a major active ingredient in several euthanasia solutions. This indication is discussed in the monograph for Euthanasia Agents.

Pharmacology/Actions

While barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. While the exact mechanisms for the CNS effects caused by barbiturates are unknown, they have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. The barbiturates also have effects on GABA and pentobarbital has been shown to be GABA-mimetic. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced is dependent on the dosage, route of administration, pharmacokinetics of the drug, and species treated. Additionally, effects may be altered by patient age, physical condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. In humans, it has been shown that barbiturates reduce the rapid-eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates cause a dose-dependent respiratory depression, but, in some species, they can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses four times lower than those which will cause cardiac arrest. These drugs must be used very cautiously in cats; they are particularly sensitive to the respiratory depressant effects of barbiturates.

Besides the cardiac arresting effects of the barbiturates at euthanatizing dosages, the barbiturates have other cardiovascular effects. In the dog, pentobarbital has been demonstrated to cause tachycardia, decreased myocardial contractility and stroke volume, and decreased mean arterial pressure and total peripheral resistance.

The barbiturates cause reduced tone and motility of the intestinal musculature, probably secondary to its central depressant action. The thiobarbiturates (thiampyl, thiopental) may, after initial depression, cause an increase in both tone and motility of the intestinal musculature; however, these effects do not appear to have much clinical significance. Administration of barbiturates reduces the sensitivity of the motor end-plate to acetylcholine, thereby slightly relaxing skeletal muscle. Because the musculature is not completely relaxed, other skeletal muscle relaxants may be necessary for surgical procedures.

There is no direct effect on the kidney by the barbiturates, but severe renal impairment may occur secondary to hypotensive effects in overdose situations. Liver function is not directly affected when used acutely, but hepatic microsomal enzyme induction is well documented with extended barbiturate (especially phenobarbital) administration. Although barbiturates reduce oxygen consumption of all tissues, no change in metabolic rate is measurable when given at sedative dosages. Basal metabolic rates may be reduced with resultant decreases in body temperature when barbiturates are given at anesthetic doses.

Pharmacokinetics

Pentobarbital is absorbed quite rapidly from the gut after oral or rectal administration with peak plasma concentrations occurring between 30–60 minutes after oral dosing in humans. The onset of action usually occurs within 15–60 minutes after oral dosing and within 1 minute after IV administration.

Pentobarbital, like all barbiturates, distributes rapidly to all body tissues with highest concentrations found in the liver and brain. It is 35–45% bound to plasma proteins in humans. Although less lipophilic than the ultra-short acting barbiturates (e.g., thiopental), pentobarbital is highly lipid soluble and patient fat content may alter the distribution qualities of the drug. All barbiturates cross the placenta and enter milk (at concentrations far below those of plasma). In neonates, pentobarbital may cross into the CNS at levels up to 6 times those in adult animals.

Pentobarbital is metabolized in the liver primarily by oxidation. Excretion of the drug is not appreciably enhanced by increased urine flow or alkalizing the urine. Ruminants (especially sheep and goats) metabolize pentobarbital at a very rapid rate. The elimination half-life in the goat has been reported to be approximately 0.9 hrs. Conversely, the half-life in dogs is approximately 8 hours; in man, it ranges from 15–50 hours.

Contraindications/Precautions/Warnings

Use cautiously in patients who are hypovolemic, anemic, have borderline hypoalbuminemia, or cardiac or respiratory disease. Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction.

Barbiturates are contraindicated in patients with severe liver disease or who have demonstrated previous hypersensitivity reactions to them. Use with caution in neonates, as pentobarbital levels in the CNS may be substantially higher than in adults.

When administering IV, give SLOWLY. Use for cesarean section is not recommended because of fetal respiratory depression. Cats tend to particularly sensitive to the respiratory depressant effects of barbiturates; use with caution in this species. Female cats appear to be more susceptible to the effects of pentobarbital than male cats.

Adverse Effects

Because of the respiratory depressant effects of pentobarbital, respiratory activity must be closely monitored and respiratory assistance must be readily available when using anesthetic dosages. Pentobarbital may cause excitement in dogs during recovery from anesthetic doses. Hypothermia may develop in animals receiving pentobarbital if exposed to temperatures below 27°C (80.6°F). The barbiturates can be very irritating when administered SC or perivascularly; avoid these types of injections. Do not administer intra-arterially.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category D for use during pregnancy *(There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)* In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

Exercise caution when administering to the nursing mother, since small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported.

Overdosage/Acute Toxicity

In dogs, the reported oral LD50 is 85 mg/kg and IV LD50 is 40–60 mg/kg. Fatalities from ingestion of meat from animals euthanized by pentobarbital have been reported in dogs. Treatment of pentobarbital overdose consists of removal of ingested product from the gut if appropriate and offering respiratory and cardiovascular support. Forced alkaline diuresis is of little benefit for this drug. Peritoneal or hemodialysis may be of benefit in severe intoxications.

Drug Interactions

- Pentobarbital interactions should be considered in animals with concurrent use of drugs that have significant interactions with barbiturates, including: anticonvulsants, alpha-adrenergic agents, decongestants, ephedrine, ergot derivatives, histamine 
- H2 antagonists, phenothiazines, phenyl butazone, salicylates, and sympathetic agents.
Laboratory Considerations

Barbiturates may cause increased retention of bromosulphophthalein (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests.

Doses

note: In order to avoid possible confusion, doses used for euthanasia are listed separately under the monograph for euthanasia solutions.

**Dogs:**

As a sedative:
- a) 2–4 mg/kg IV (Kirk 1986)
- b) 2–4 mg/kg PO q6h (Davis 1985b)

For anesthesia:
- a) 30 mg/kg IV to effect (Kirk 1986)
- b) 10–30 mg/kg IV to effect (Morgan 1988)
- c) 24–33 mg/kg IV (Booth 1988)

For chemical restraint for ventilatory support:
- a) Pentobarbital should be given to effect not as a specific dose (3–15 mg/kg body weight IV) as there is tremendous individual variation in response when used at standard safe doses. Pentobarbital is a general anesthetic with negligible anticonvulsant properties. Patients treated with “barbiturate coma” commonly require an extended period of mechanical ventilation in an intensive care setting. In general, the side effects of barbiturate coma include depression of myocardial metabolism, vasodilatation with a decrease in venous return, and decreased cardiac perfusion. These effects can be minimized by the use of saline infusion and small doses of dopamine. Patients can develop poikilothermia and decreased urinary output during myocardial depression and hypotension. Neurologic evaluation is difficult because spontaneous respiratory responses and spontaneous movements cease. (Platt 2009)
- b) 2–15 mg/kg IV can effectively terminate the physical manifestations of seizure activity within several minutes, but it is not generally considered to be an effective anticonvulsant and is unlikely to stop seizure activity in the brain. (Fletcher 2009)

**Cats:**

For chemical restraint for ventilatory support:
- a) For ventilator maintenance, pentobarbital is preferred and may be administered as a CRI from 1–3 mg/kg/hour IV; it is associated with relative cardiovascular stability, but may cause seizure-like movements during recovery from anesthesia. The author prefers to switch over to a shorter acting drug like propofol about 12 hours prior to weaning from the ventilator; this will allow the pentobarbital levels to decrease and will help attenuate any seizure-like activity. Adjunctive drugs include: Fentanyl 0.5–1 micrograms/kg/minute; Propofol 50–300 micrograms/kg/minute OR Midazolam 0.5 mg/kg/hour (Brainard 2008)

**Euthanasia:**

For ventilator maintenance, pentobarbital is preferred and may be administered as a CRI from 1–3 mg/kg/hour IV; it is associated with relative cardiovascular stability, but may cause seizure-like movements during recovery from anesthesia. The author prefers to switch over to a shorter acting drug like propofol about 12 hours prior to weaning from the ventilator; this will allow the pentobarbital levels to decrease and will help attenuate any seizure-like activity. Adjunctive drugs include: Midazolam 0.3–0.5 mg/kg/hour; Medetomidine 0.3–1 micrograms/kg/hour (caution with the use of medetomidine) (Brainard 2008)

As a sedative:
- a) 2–4 mg/kg IV (Kirk 1986)
- b) 2–4 mg/kg PO q6h (Davis 1985a)

For status epilepticus:
- a) Pentobarbital should be given to effect not as a specific dose (3–15 mg/kg body weight IV) as there is tremendous individual variation in response when used at standard safe doses. Pentobarbital is a general anesthetic with negligible anticonvulsant properties. Patients treated with “barbiturate coma” commonly require an extended period of mechanical ventilation in an intensive care setting. In general, the side effects of barbiturate coma include depression of myocardial metabolism, vasodilatation with a decrease in venous return, and decreased cardiac perfusion. These effects can be minimized by the use of saline infusion and small doses of dopamine. Patients can develop poikilothermia and decreased urinary output during myocardial depression and hypotension. Neurologic evaluation is difficult because spontaneous respiratory responses and spontaneous movements cease. (Platt 2009)
- b) 2–15 mg/kg IV can effectively terminate the physical manifestations of seizure activity within several minutes, but it is not generally considered to be an effective anticonvulsant and is unlikely to stop seizure activity in the brain. (Fletcher 2009)
Pentobarbital Sodium Injection: 50 mg/mL in 2 mL

HUMAN-LABELED PRODUCTS:
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status

pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

oxytetracycline HCl, penicillin G potassium, pentazocine lactate, phenytoin sodium, prochlorperazine edisylate, promazine HCl, promethazine HCl, and streptomycin sulfate. Compatibility is dependent upon factors such as chloramphenicol sodium succinate, hyaluronidase, hydromorphone HCl, lidocaine HCl, neostigmine methylsulfate, scopolamine HBr, sodium bicarbonate, sodium iodide, thiopental sodium, and verapamil HCl.

The following solutions and drugs have been reported to be physically incompatible with pentobarbital sodium: benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, cimetidine HCl, chlorpromazine maleate, codeine phosphate, diphenhydramine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydrocortisone sodium succinate, hydroxyzine HCl, insulin (regular), meperidine HCl, nalfurafine HCl, norepinephrine bitartrate, oxytetracycline HCl, penicillin G potassium, pentoxifylline lactate, phenytoin sodium, prochlorperazine edisylate, promazine HCl, promethazine HCl, and streptomycin sulfate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

References

PENTOSAN POLYSULFATE SODIUM
(pro-ten-san) PPS, Cartrophen-Vet®, Elmiplus®
ANTINFAMMATORY, OSTEOARTHRITIS DISEASE-MODIFIER

Prescriber Highlights

♦ May be useful in treating osteoarthritis in dogs, cats & horses; may be used as adjunctive treatment of feline interstitial cystitis (feline idiopathic lower urinary tract disease—FLUTD)
  Efficacy for FLUTD not well-documented
♦ Adverse effects uncommon, but can cause bleeding, GI effects
♦ Use with caution prior to surgery or with other drugs affecting coagulation
♦ In the USA, only human oral product available; may be expensive

Uses/Indications
Pentosan may be useful in treating osteoarthritis in dogs, cats, and horses. It has been used as an adjunctive treatment of feline interstitial cystitis (feline idiopathic lower urinary tract disease—FLUTD). Studies using pentosan for FLUTD have demonstrated that it is not effective for short-term, acute lower urinary tract disease.

Pharmacology/Actions
Pentosan has a mild analgesic effect when used for interstitial cystitis. The mechanism for its action in treating interstitial cystitis is not known, but it is postulated that it may adhere to bladder wall mucosal membranes and act as a “buffer” to prevent irritating compounds in urine from reaching bladder cells.

Pentosan has disease-modifying effects on osteoarthritic joints similar to polysulfated glycosaminoglycans. It apparently modulates cytokine action, preserves proteoglycan content and stimulates hyaluronic acid synthesis. Pentosan has antiinflammatory, hypolipidemic, anticoagulant (considerably weaker than heparin—1/15th), and fibrinolytic properties. These effects potentially could increase synovial blood flow and reduce joint inflammation.

Pharmacokinetics
In rats, 10–20% of the calcium derivative (pentosan polysulfate calcium) is absorbed after oral dosing. In humans, only about 3% of an oral dose of pentosan polysulfate sodium is absorbed. It distributes primarily to the uroepithelium of the genitourinary tract with smaller concentrations found in the liver, spleen, lung skin, bone marrow, and periosteum. About two-thirds of absorbed drug is desulfated in the liver and spleen within one hour; about 3.5% of the absorbed drug is excreted into the urine.

Contraindications/Precautions/Warnings
Pentosan is contraindicated in patients hypersensitive to it. Use this drug with caution in animals also receiving other medications that can affect coagulation, or having surgery in the near future.

Adverse Effects
Pentosan is usually well tolerated. Adverse effects of pentosan in veterinary species appear to be mild and transitory in nature. In dogs, vomiting, anorexia, lethargy, or mild depression are possible. When used orally in cats, pentosan seems to be tolerated well, but oral dosing twice daily can be stressful for both cat and owner. Because pentosan has some anticoagulant effects, bleeding is possible in any species and may be more likely in animals receiving other drugs that affect coagulation (e.g., aspirin), or undergoing stressful exercise. In horses, pentosan causes dose-dependent increases in partial thromboplastin time (PTT) up to 24 hours post-dose. In a small percentage of humans (<2%) taking the medication, transient increases in liver enzymes have been reported.

Reproductive/Nursing Safety
In humans, pentosan is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Pentosan is likely safe to use during nursing.

Overdosage/Acute Toxicity
Information regarding overdoses is not readily available. Potentially, overdoses could cause bleeding, thrombocytopenia, GI distress, and liver function abnormalities. At the present time, treatment recommendations are basically supportive in nature. If an oral overdose occurs, consider protocols for gut removal from the gut.

Drug Interactions
No specific drug interactions were located; use this drug cautiously with other drugs that can affect coagulation (e.g., NSAIDs, aspirin, heparin, etc.).

Laboratory Considerations
No laboratory interactions or considerations were noted

Doses

**DOGS:**
As a chondroprotective for osteoarthritis (OA):

- a) High loading dose: 20 mg/kg PO twice weekly for 5 weeks (for treatment of OA signs of pain, lameness and stiffness); Medium Loading dose: 10 mg/kg PO once weekly for 12 weeks (for management of OA after joint surgery); Maintenance dose: 10 mg/kg once weekly for 4 weeks as needed. Always give on an empty stomach. (Label information; Cartrophen-Vet® Capsules—Arthropharm)
- b) 3 mg/kg IM or SC on four occasions with an interval of 5–7 days between injections (Label information; Pentosan 1000® Injection —Nature Vet)

**CATS:**
For treatment of persistent or recurrent FLUTD (Note: Recent studies have not shown any statistical benefit):

- a) 2–16 mg/kg PO q12h (Bartges 2002)
- b) 8 mg/kg PO q12h (Lane 2002)

**HORSES:**
For treating osteoarthritis:

- a) Intramuscular administration: 3 mg/kg IM on four occasions with an interval of 7 days between injections.

Intra-articular injection: Prepare site as for surgery. Avoid iodine based skin preps; use a neutral soapless skin cleanser. A 20 gauge non-cutting needle is preferred. Introduce into joint space with steady, even pressure. Allow approximately 1 mL of synovial fluid to escape. Attach syringe with pentosan into the syringe and withdraw more synovial fluid to enter syringe, if possible. Inject mixture back into joint; draw up approximately 2 mL of mixture and inject.
Monitoring
- When used for veterinary indications clinical efficacy is the primary monitoring parameter.
- When administered into joints, animals should be assessed for intra-articular bleeding.

Client Information
- In cats, pentosan (human product) is usually dosed at ½ capsule (50 mg) twice daily. One half the contents of a commercially available capsule may be emptied into an empty gelatin capsule and administered.
- Give oral medication on an empty stomach

Chemistry/Synonyms
A heparin-like compound, pentosan polysulfate sodium is a mixture of linear polymers of beta-1->4-linked xylose that are usually sulfated at the 2- and 3- positions. Average molecular weight is between 4000 and 6000. It is not derived from animal sources, but from Beechwood hemicellulose.

Pentosan may also be known as: pentosan polysulfate sodium; PZ-68; sodium pentosan polysulphate; sodium xylanpolysulphate; SP-54, Cartrophen-Ver®; Fibrase®, Fibrecyal®, Fibrecid®, Fibrocide®, Hemoclar®, Lelong Contusions®, Elmiron®, Pentosan®, Polyanion®, Tavan®-SP-54, and Thrombocid®.

Storage/Stability
Unless otherwise labeled, store oral pentosan products at controlled room temperature (15–30°C; 59–86°F) and injectable pentosan products under refrigeration and protected from light.

Dosage Forms/Regulatory Status

Veterinary-Labeled Products:
No products currently available in USA.
In several other countries, Cartrophen-Ver® is available as oral 100 mg capsules (pentosan polysulfate calcium) labeled for use in dogs. Injectable pentosan polysulfate sodium 100 mg/mL (Pentosan 1000® Injection, and Cartrophen-Ver® Injection) labeled for use in dogs and pentosan polysulfate sodium 250 mg/mL (Pentosan Equine® Injection) for horses are available in several countries.

HUMAN-LABELED PRODUCTS:
Pentosan Polysulfate Sodium Oral Capsules: 100 mg: Elmiron® (Ortho McNeil); (Rx)

References

Pentoxifylline
[pen-tok-si-filen (pen-tox-fi-leen) PTX, Trental®]
HEMORRHEOLOGIC, IMMUNOMODULATORY AGENT

Prescriber Highlights
- Compound that increases erythrocyte flexibility & may decrease negative effects of endotoxemia
- Contraindications: Retinal or cerebral hemorrhage, intolerant or hypersensitive to it or other xanthines (i.e., theophylline)
- Caution: Severe hepatic or renal impairment, or at risk for hemorrhage
- Adverse Effects: GI tract (vomiting/inappetence) most common. Potentially: Dizziness, other GI, CNS, or cardiovascular effects

Uses/Indications
In horses, pentoxifylline has been used as adjunctive therapy for cutaneous, vasculitis, endotoxemia and for the treatment of navicular disease.

Pentoxifylline has been used in dogs to treat immune-mediated dermatologic conditions, enhance healing, and reduce inflammation caused by ulcerative dermatitis in Shelties and Collies and for other conditions where improved microcirculation may be of benefit. There is some evidence for efficacy for pentoxifylline and misoprostol as antiinflammatory medications in dogs, but with their modest benefit, relatively high costs and adverse effects, these medications should probably not be used as first line medications to treat dogs with atopic dermatitis (Olivry et al. 2010). Pentoxifylline is being investigated for adjunctive therapy for dilated cardiomyopathy in Doberman pinchers and it has been tried in conjunction with prednisolone to decrease vasculitis associated with FIP in cats.

Pentoxifylline’s major indications for humans include symptomatic treatment of peripheral vascular disease (e.g., intermittent claudication, sickle cell disease, Raynaud’s, etc.) and cerebrovascular diseases where blood flow may be impaired in the microvasculature.

Pharmacology/Actions
The mechanisms for pentoxifylline’s actions are not fully understood. The drug increases erythrocyte flexibility probably by inhibiting erythrocyte phosphodiesterase and decreases blood viscosity by reducing plasma fibrinogen and increasing fibrinolytic activity. In horses, pentoxifylline appears to be a potent inhibitor of matrix metalloproteinase-9 and a modest inhibitor of matrix metalloproteinase-2 (Fugler et al. 2009).

Pentoxifylline is postulated to reduce negative endotoxic effects of cytokine mediators via its phosphodiesterase inhibition.

Pharmacokinetics
In horses, after PO administration of crushed, sustained-release tablets, pentoxifylline is rapidly absorbed with a wide interpatient variation of bioavailability that averages around 68%. Bioavailability may decrease with continued administration over several days. The authors concluded that 10 mg/kg q12h PO yields serum levels equivalent to those observed after administration of therapeutic doses to horses and humans.

In dogs, pentoxifylline reportedly has a bioavailability of approximately 50% with peak levels occurring about 1–3 hours after dosing. Serum half-life is approximately 6–7 hours for the parent compound, 36 hours for active metabolite 1, and 8 hours for active metabolite 5.

In humans, pentoxifylline absorption from the gastrointestinal tract is rapid and almost complete, but a significant first-pass effect occurs. Food affects the rate, but not the extent, of absorption. While the distributive characteristics have not been fully described, it is known that the drug enters maternal milk. Pentoxifylline is metabolized both in the liver and erythrocytes; all identified metabolites appear to be active.

Contraindications/Precautions/Warnings
Pentoxifylline should be considered contraindicated in patients who have been intolerant to the drug or xanthines (e.g., theophylline, caffeine, theobromine) in the past and those with cerebral hemorrhage or retinal hemorrhage. It should be used cautiously in patients with severe hepatic or renal impairment and those at risk for hemorrhage.

Adverse Effects
Most commonly reported adverse effects involve the GI tract (vomiting, inappetence, loose stools) or CNS (excitement, nervousness). Erythema multiforme may occur rarely, secondary to pentoxifylline therapy in dogs.

In horses, IV administration may be associated with transient leukocytosis, muscle fasciculations, sweating on shoulders and flanks, and mild increases in heart rate. Oral dosing at 10 mg/kg or less appears to be well tolerated.

There are reports of dizziness and headache occurring in a small percentage of humans receiving the drug. Other adverse effects, primarily GI, CNS, and cardiovascular related, have been reported in people, but are considered to occur rarely. Veterinary experience is limited with pentoxifylline and animal adverse effects may differ.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pentoxifylline and may be of significance in veterinary patients:

ANTIHYPERTENSIVE DRUGS: With pentoxifylline may increase hypotensive effect

NSAIDS: Use of non-steroidal antiinflammatory agents with pentoxifylline in horses is controversial. Some sources state that when used for endotoxicemia in horses, pentoxifylline’s beneficial effects are negated by NSAIDs, but one study showed superior efficacy when flunixin and pentoxifylline were used together, compared with either used alone.

PLATELET-AGGREGATION INHIBITORS (e.g., aspirin, clopidogrel): Increased risk for bleeding

THEOPHYLLINE: Serum levels may be increased when used concurrently with pentoxifylline

WARFARIN: When pentoxifylline is used with warfarin or other anticoagulants, increased risk of bleeding may result; use together with enhanced monitoring and caution

Doses

DOGS:

a) For dermatologic conditions (e.g., dermatomyositis, ear margin seborrhea/necrosis, ulcerative dermatitis of collies/shelties, contact dermatitis, atopy and any disease with underlying vasculitis): 10 mg/kg PO q8h, if the disease does not respond, 15 mg/kg PO q8h may be effective (Merchant 2000)
b) For atopic dermatitis: 10–25 mg/kg PO with food two to three times a day. Response may be improved by using with an antihistamine or a glucocorticoid. (Yu 2008)
c) For dermatologic disorders including dermatomyositis, vasculitis, erythema multiforme, cutaneous and renal vasculitis of Greyhounds (Alabama rot), and allergic contact dermatitis: 10–30 mg/kg PO q 12 hours (Campbell 1999)
d) For familial canine dermatomyositis: 25 mg/kg PO q12h appears to be an effective beginning dose (Rees & Boothe 2003)
e) For atopic dermatitis: 10–15 mg/kg PO q6–8h. A 6–8 week course of therapy may be required to assess efficacy, (White 2003)
f) For vasculitis, dermatomyositis: 10 mg/kg PO q8h (Boord 2007)
g) For vasculitis: 15 mg/kg PO q8h (Hillier 2006)
h) In chronic pyoderma to help reverse chronic pathologic changes (scarring, fibrosis) and to aid in antibiotic tissue penetration: 20–30 mg/kg PO q12h. (Rosenkrantz 2009)

HORSES: (Note: ARCI UCGFS Class 4 Drug)
a) 10 mg/kg q12h PO yields serum levels equivalent to those observed after administration of therapeutic doses to humans and horses. OK to crush the sustained-release tablets and mix with molasses. If efficacy wanes with time, consider increasing the dose to 15 mg/kg PO twice daily or 10 mg/kg PO three times a day. In the experience of the authors, 10 mg/kg PO twice daily for 30 days results in clinical response in horses with cutaneous vasculitis. (Lisa et al. 2006)
b) For adjunctive treatment to prevent GI thrombosis: 7.5 mg/kg IV q12 hours (can be easily filtered in a 0.5 micron filter for IV use); can make red blood cells more deformable, decrease blood viscosity, and inhibit some inflammatory cytokines. (Divers 2003)

The following regimen is based on the work of McKenzie (2009)

To reduce cytokine effects in endotoxicemia:

a) 7.5 mg/kg PO q12h, efficacy may be improved if used with flunixin (Smith 2003)
b) 8 mg/kg PO q8h (Barton 2003)
c) For adjunctive treatment (experimental) of sepsis in foals: 7.5 mg/kg IV bolus, followed by a CRI of 1.5 mg/kg/hour. Has been shown to increase regional blood flow and suppress coagulation. (McKenzie 2009)

For adjunctive treatment of equine partial dermatis:

a) If clinical signs do not resolve after 14 days of topical and other immunomodulating therapy, add pentoxifylline at 4–8 mg/kg PO q12h (Yu 2003)

For adjunctive treatment of equine partial dermatis:

To increase oxygenation of placenta in placentitis:

a) 7.5 mg/kg PO q12h (Troedsson 2003)

To increase the circulation to the podotrochlea:

a) 4.5–7 mg/kg PO three times daily (Turner 1999)

Monitoring
Efficacy

Adverse effects

Client Information
Give with food to reduce the GI effects of pentoxifylline

Clients should understand that veterinary experience with this medication is limited and that the risk versus benefit profile is not well-defined

Chemistry/Synonyms
A synthetic xanthine derivative structurally related to caffeine and theophylline, pentoxifylline occurs as a white, odorless, bitter-tasting, crystalline powder. At room temperature, approximately 77 mg are soluble in one mL of water and 63 mg in one mL of alcohol. Pentoxifylline may also be known as: BL-191, oxpentifylline, or pentoxifyllium and Trental®.

Storage/Stability
The commercially available tablets should be stored in well-closed containers, protected from light at 15–30°C.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Pentoxifylline Controlled/Extended Release Tablets: 400 mg; Trental® (Hoechst Marion Roussel); generic; (Rx)

PERGOLIDE MESYLATE  
(DOPAMINE AGONIST)

Prescriber Highlights

- Dopamine agonist that can help control signs associated with pituitary pars intermedia dysfunction (PPID, equine Cushing’s disease)
- Apparently, very well tolerated in horses; anorexia occurs in up to 10% of patients
- May be significant expense involved, since treatment is life-long
- Need to obtain via compounding pharmacies

Uses/Indications

The primary use for pergolide in veterinary medicine is in treatment of horses for pituitary pars intermedia dysfunction (PPID), commonly called equine Cushing’s disease.

Pharmacology/Actions

Pergolide is a potent agonist at dopamine receptors D1 and D2 and is 10–1000 times more potent than bromocriptine. It is thought that pituitary pars intermedia dysfunction (PPID) in horses is a dopaminergic degenerative disease and pergolide (or dopamine) can reduce expression of proopiomelanocortin (POMC) peptides from the pars intermedia. These peptides are implicated in causing the signs associated with PPID.

Pharmacokinetics

In horses (6 in the study), pergolide was rapidly absorbed following oral administration (0.01 mg/kg), with plasma concentrations reaching maximum levels within 1 hour of dosing. Maximum plasma levels ranged from 1.07–3.38 nanograms/mL. Pergolide appears to be rapidly and widely distributed. Elimination half-life averaged 27 hours, but there was high interpatient variation (Gehring et al. 2010).

In humans, the drug is orally absorbed (estimated 60% bioavailable) and is 90% bound to plasma proteins. At least 10 different metabolites have been identified, some of which are active. The principle route of elimination is via the kidneys.

Contraindications/Precautions

Pergolide is contraindicated in patients hypersensitive to it or other ergot derivatives.

Adverse Effects

Pergolide appears to be very well tolerated in horses. Decreased appetite is seen during the first week of therapy in about 10% of horses treated; temporary dose reduction is often beneficial in alleviating this effect. Colic and diarrhea have been reported to occur more rarely.

Adverse effects reported in humans include: nervous system complaints (dyskinesia, hallucinations, somnolence and insomnia), gastrointestinal complaints (nausea, vomiting, diarrhea, constipation), transient hypotension, and rinitis.

Reproductive/Nursing Safety

Safety of pergolide in pregnant horses has not been established. In humans, pergolide is designated by the FDA as a category B drug (Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known if pergolide enters maternal milk; however, like other ergot-derivative dopamine agonists, it may interfere with lactation.

Overdosage/Acute Toxicity

There is limited information available on pergolide overdoses. Potential effects include GI disturbances, CNS effects, seizures, and hypotension.

There were 9 exposures to pergolide mesylate reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 8 were dogs with all 8 showing clinical signs, and the remaining 1 case was a horse showing no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, hypertension, and piosis.

Treatment is supportive. Phenothiazines may decrease CNS stimulation effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pergolide and may be of significance in veterinary patients:

- **DOPAMINE ANTAGONISTS** (i.e., phenothiazines): May decrease the effects of pergolide
- **METOCLOPRAMIDE**: May decrease the effects of pergolide

Laboratory Considerations

- No specific laboratory interactions or considerations were noted for this drug.

Doses

**HORSES**:

- **Note:** The following doses each uses a different way of dosing (total dose, micrograms/kg, and mg/kg), do not be confused by them.

  For treatment of Equine “Cushing’s-like” Disease [pituitary pars intermedia dysfunction (PPID)]:

  a) Initial dose of 1 mg (total dose) per day for horses and ponies with PPID. If the horse owner is willing to administer half the dose twice daily, this may be preferable on the basis of recent pharmacokinetic data. If anorexia or temporary dullness develop, treatment should be halted for 2 days or until appetite improves, and then restarted at 0.25 mg per day for 2 days, 0.5 mg per day for 2 days, and 0.75 mg per day for 2 days. (Frank 2010)

  b) 1.7–5.5 micrograms/kg; dose varies considerably. The higher doses are used in the more advanced cases or those refractory to treatment at a lower dose. (Messer 2009)

  c) Author’s current opinion that initial medical treatment for equids with PPID should be pergolide at a dose of 0.002 mg/kg PO q24h. If no improvement is noted within 8–12 weeks (depending on season as hair coat changes will vary with the time of year that treatment is initiated), the daily dose can be increased by 0.002 mg/kg monthly up to a total dose of 0.006 mg/kg (3 mg/day for a 500 kg horse). If only a limited response is observed with 0.006 mg/kg dose and endocrinologic test results remain abnormal, the author typically recommends addition of ciprofloxacin (0.5 mg/kg PO q12h) to pergolide therapy. It is important to recognize that the rate of clinical improvement is higher than that for normalization of hyperglycemia and endocrinologic test results. Usually, only transient anorexia is recognized during the initial week of treatment and can be overcome in time or by cutting the dose in half for 2-4 days. (Schott II 2009)
Dexamethasone suppression test (baseline and at 4–8 weeks post pergolide therapy initiation, repeat in 4–8 weeks if dosage is adjusted)

- Blood glucose (baseline, and if abnormal and repeat as per dexamethasone suppression test)
- Clinical signs (hair coat, weight, PU/PD, etc.)
- Periodic CBC and clinical chemistry panel

**Client Information**

- Clients should understand that pergolide does not cure the disease and it may take several weeks to months to see efficacy.
- Treatment is required for the life of the horse and the drug can be expensive.
- Proper nutrition and weight control can be very important to the successful treatment of this disease.

**Chemistry/Synonyms**

An ergot derivative, dopamine receptor agonist, pergolide occurs as white to off-white powder that is slightly soluble in water, dehydrated alcohol, or chloroform. It is very slightly soluble in acetone; practically insoluble in ether and sparingly soluble in methyl alcohol.

Pergolide mesylate may also be known as: LY-127809, pergolide mesilate, celar tone®, nepar®i, parkoi®t, parle®i, or phark®en.

**Storage/Stability**

Store pergolide tablets in tight containers at room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F).

**Compatibility/Compounding Considerations**

As pergolide is no longer commercially available, compounding pharmacists must utilize the bulk powder pergolide mesylate to compound preparations of pergolide for horses. The compounding pharmacist should account for the molecular weight of the mesylate salt by using a conversion factor of 1.3 when calculating the amount of pergolide mesylate to obtain an equivalent amount of pergolide base. Pergolide aqueous suspensions are unstable after compounding. Compounded pergolide formulations in aqueous vehicles should be stored in dark containers, protected from light, and refrigerated. Do not use more than 30 days after compounding. Formulations that have undergone a color change should be considered unstable and discarded (Davis et al. 2009).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

Due to an increased potential for heart valve damage associated with pergolide use in humans, all dosage forms were withdrawn from the US market in the spring of 2007. Pergolide may be available from compounding pharmacies for veterinary use.

**References**

**PHENOBRIBTAL SODIUM**

**PHENOBRIBT**

(iso-3,5,6,8-tetrahydrobenzilidene)-2,4-dinitrophenylhydrazine

**BARBITURATE**

**Prescriber Highlights**

- Barbirurate used primarily as an antiseizure medication; also used as a sedative agent
- Contraindications: Known hypersensitivity, severe liver disease, nephritis, or severe respiratory depression (large doses)
- Caution: Hypovolemia, anemia, borderline hypoadrenal function, or cardiac or respiratory disease; use with caution in cats (sensitive to respiratory depression)
- Adverse Effects: *Dogs*: Anxiety/agitation or lethargy (when initiating treatment); profound depression, (even at low doses) is possible. Sedation, ataxia, polydipsia, polyuria, polyphagia can be seen at moderate to high serum levels. Increase in liver enzymes possible, but overt hepatotoxicity relatively uncommon. Rare: Anemia, thrombocytopenia or neutropenia.
- Adverse Effects: *Cats*: Ataxia, lethargy, polyphagia/weight gain & polydipsia/polyuria. Rare: Immune-mediated reactions & bone marrow hypoplasia
- When administering IV, give SLOWLY; do not give SC or perivascularly (very irritating)
- Drug Interactions; drug-lab interactions
- C-IV controlled substance

**Uses/Indications**

Although some believe that bromide salts are now the treatment of first choice for treating epilepsy in dogs (especially young dogs and those with liver disease), many still choose phenobarbital for dogs because of its favorable pharmacokinetic profile, relative safety, efficacy, low cost, and ability to treat epilepsy at sub-hypnotic doses. Phenobarbital is still widely considered the drug of first choice for treating epilepsy in cats. It is also occasionally used as an oral sedative agent in both species. Because it has a slightly longer onset of action, it is used principally in the treatment of status epilepticus in dogs, cats, and horses to prevent the recurrence of seizures after they have been halted with either a benzodiazepine or short-acting barbiturate. Phenobarbital may also be useful in controlling excessive feline vocalization while riding in automobiles. In cattle, the microsomal enzyme stimulating properties of phenobarbital has been suggested for its use in speeding the detoxification of organochlorine (chlorinated hydrocarbon) insecticide poisoning. Additionally, phenobarbital has been used in the treatment and prevention of neonatal hyperbilirubinemia in human infants. It is unknown if hyperbilirubinemia is effectively treated in veterinary patients with phenobarbital.

**Pharmacology/Actions**

While barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. While the exact mechanisms for the CNS effects caused by barbiturates are unknown, they have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. The barbiturates also have effects on GABA and pentobarbital has been shown to be GABA-mimetic. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced is dependent on the dosage, route of administration, pharmacokinetics of the drug, and species treated. Additionally, effects may be altered by patient age, physical condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. In humans, it has been shown that barbiturates reduce the rapid-eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates cause a dose-dependent respiratory depression, but, in some species, they can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses four times lower than that which will cause cardiac arrest. These drugs must be used very cautiously in cats; they are particularly sensitive to the respiratory depressant effects of barbiturates.
Phenobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:

- DOXORUBICIN
- CYCLOSPORINE
- CORTICOSTEROIDS
- CLONAZEPAM
- CARPROFEN
- CHLORAMPHENICOL
- OPIATES
- RIFAMPIN

The following drugs may increase the effects of phenobarbital:

- RIFAMPIN: May induce enzymes that increase the metabolism of phenobarbital

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenobarbital and may be of significance in veterinary patients:

- diuresis can also be of substantial benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal dialysis or hemodialysis may be helpful in severe intoxications or in anuric patients.

- Considerable benefit in enhancing the clearance of phenobarbital, even when the drug was administered parenterally. Charcoal acts as a “sink” for the drug to diffuse from the vasculature back into the gut.

- Forced alkaline diuresis can also be of substantial benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal dialysis or hemodialysis may be helpful in severe intoxications or in anuric patients.

Adverse Effects

- Dogs may exhibit increased clinical signs of anxiety/agitation or lethargy when initiating therapy. These effects are generally transitory in nature. Occasionally dogs will exhibit profound depression at lower dosage ranges (and plasma levels). Polyuria, polydipsia, polyphagia and polyphagia are also quite common at moderate to high serum levels and may falsely infer a diagnosis of Cushing’s disease; limiting intake of both food and water usually controls these signs. Sedation and/or ataxia often become significant concerns as serum levels reach the higher ends of the therapeutic range. Rarely, anemia, thrombocytopenia or neutropenia may occur which are reversible if detected early. Increases in liver enzymes are well described for phenobarbital in dogs and are not necessarily indicative of liver dysfunction, but if serum ALP or ALT are greater than 4–5 times the upper limit of normal, or if any elevation of AST and GGT are noted, it should raise concern. Phenobarbital should generally be discontinued if any increases in serum bilirubin, total serum bile acids or hypoalbuminemia are seen.

- Frank hepatic failure is uncommon and is usually associated with higher serum levels (>30–40 micrograms/mL). Phenobarbital may rarely cause superficial necrotic dermatitis (SND) in dogs associated with changes in hepatocytes (severe parenchymal collapse with glycogen-laden hepatocytes and moderate fibrosis) demarcated by nodules of normal hepatic parenchyma) distinct from that seen with phenobarbital hepatotoxicity.

- Cats may develop ataxia, persistent sedation and lethargy, polyphagia/weight gain, and polydipsia/polyuria. Rarely, immune-mediated reactions and bone marrow hypoplasia (thrombocytopenia, neutropenia) may be seen.

- Cats, unlike dogs, apparently do not have the issues of increased liver enzymes. Very high dosages (10–40 mg/kg/day) have caused coagulopathies in cats.

- As phenobarbital can potentially increase the metabolism of cortisol, it has been implicated in contributing to relative adrenal insufficiency.

- There is much less information regarding its use in horses (and foals in particular), it would generally be expected that adverse effects would mirror those seen in other species.

Reproductive/Nursing Safety

Phenobarbital has been associated with rare congenital defects and bleeding problems in newborns, but may be safer than other anticonvulsants. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.).

- Exercise caution when administering to a nursing mother since small amounts are excreted in maternal milk. Drowsiness in nursing offspring has been reported.

Overdosage/Acute Toxicity

There were 253 exposures to phenobarbital reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 228 were dogs with 99 showing clinical signs, 23 were cats with 10 showing clinical signs and the remaining 2 reported cases were a bird and a non-human primate. The bird showed clinical signs while the non-human primate showed no clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, lethargy, sedation, recumbency, depression, hypothermia and coma. Common findings in cats recorded in decreasing frequency included ataxia, sedation, and recumbency.

- Treatment of a phenobarbital overdose consists of removal of ingested product from the gut, if appropriate, and giving respiratory and cardiovascular support. Activated charcoal acts as a “sink” for the drug to diffuse from the vasculature back into the gut. Forced alkaline diuresis can also be of substantial benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal dialysis or hemodialysis may be helpful in severe intoxications or in anuric patients.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenobarbital and may be of significance in veterinary patients:

- ACETAMINOPHEN: Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are given
- CARPROFEN: There may be an increased risk for hepatotoxicity secondary to carprofen metabolites. One source states: Patients should not receive phenobarbital or other hepatic drug metabolizing enzyme inducers when receiving this drug (Boothe 2005).
- MONAMINE OXIDASE (MAO) INHIBITORS (e.g., amitraz, possibly selegiline): May prolong phenobarbital effects
- PHENOTHIAZINES: May induce enzymes that increase the metabolism of barbiturates.

The following drugs may increase the effects of phenobarbital:

- ANTIHISTAMINES
- CHLORAMPHENICOL
- ELBAMATE
- OPIATES
- PHENOTHIAZINES
- VALPROIC ACID

Phenobarbital (particularly after chronic therapy) may decrease the effect of the following drugs/class of drugs by lowering their serum concentrations:

- ANTICOAGULANTS, ORAL (WARFARIN)
- BETA-BLOCKERS
- CHLORAMPHENICOL
- CLONAZEPAM
- CORTICOSTEROIDS
- CYCLOSPORINE
- DOXORURICIN
Laboratory Considerations

Barbiturates may cause increased retention of bromosulfophthalein (BSP; sulfobromophthalein) and give falsely elevated results. It is recommended that barbiturates not be administered within the 24 hours before BSP retention tests; or, if they must, (e.g., for seizure control) the results be interpreted accordingly.

Phenobarbital may alter thyroid testing. Decreased total and free T4, normal T3, and either normal or increased TSH have been reported. It has been suggested to wait at least 4 weeks after discontinuing phenobarbital to perform thyroid testing.

In some dogs, phenobarbital may cause a false positive low dose dexamethasone suppression test, by increasing the clearance of dexamethasone. Phenobarbital apparently has no effect either on ACTH stimulation tests or on the hormonal equilibrium of the adrenal axis. As phenobarbital can potentially increase the metabolism of cortisol, it has been implicated in contributing to relative adrenal insufficiency.

Doses

**DOGS:**

For treatment of idiopathic epilepsy:
- **a)** Initial oral dose is 2–2.5 mg/kg PO q12h. Serum phenobarbital concentrations should be monitored 2–3 weeks after initiating therapy and after any dosage adjustment. Therapeutic serum concentrations of 20–35 micrograms/mL are recommended in dogs, with the decrease in the high end of the range reflecting suggested changes to minimize the potential for hepatotoxicity. (Munana 2010)
- **b)** Initial maintenance dose: 2.5–3 mg/kg PO q12h. A CBC, serum biochemical evaluation and urinalysis should be performed before starting maintenance anticonvulsant therapy, both as part of the diagnostic evaluation and as a baseline before starting therapy. (Mariani 2010)
- **c)** Initial oral dose: 2.5 mg/kg PO twice daily; to reach therapeutic levels faster may give an IV loading dose of 20 mg/kg. Adjust dosage based upon therapeutic levels, efficacy, and adverse effects. (Podell 2000)
- **d)** Loading dose of 16–20 mg/kg once IV; maintenance dose of 2–5 mg/kg PO q12h. (Knipe 2006; Knipe 2009)
- **e)** Begin at 3.5 mg/kg PO twice daily. Monitor at 2 to 4 weeks and 3 months later to detect induction. If response is insufficient, increase dose sufficiently to increase trough level by 3 to 5 micrograms/mL increments, rechecking at 2 to 4 weeks after each dose increase. Monitor at 3 to 12 month intervals once steady–state is achieved. As concentrations approach 30 micrograms/mL, begin monitoring hepatic function test (bile acids, albumin, BUN, chole). As concentrations approach 35 micrograms/mL, consider adding an additional drug. Avoid any other drug metabolized by the liver. Consider hepatoprotectant drugs if liver dysfunction is of concern. (Axlund 2004)

For treatment of status epilepticus:
- **a)** If seizures persist after diazepam therapy (2 or more seizures recur; or gross motor activity persists) give phenobarbital bolus of 2–5 mg/kg (can be repeated at 20 minute intervals, up to two times). Add phenobarb to diazepam infusion at a rate of 2–10 mg/hour. If seizures are sustained or high frequency seizures recur, consider pentobarbital coma.
- **b)** After using benzodiazepines (diazepam, midazolam), phenobarbital at 5–8 mg/kg IV; continue to administer every 4–6 hours until seizures are under control regardless of additional therapy. (Knipe 2009)

For sialadenosis:
- **a)** From a case report of sialadenosis after removal of an esophageal body: 1 mg/kg PO q12h. After 3 months, dog was slowly weaned off phenobarbital. (Gilor et al. 2010)

For sedation:
- **a)** 2.2–6.6 mg/kg PO twice daily (Walton 1986)
- **b)** Treatment of irritable bowel syndrome: 2.2 mg/kg PO twice daily (Morgan 1988)
- **c)** For adjunctive treatment of compulsive behaviors: 2–20 mg/kg q12–24h (Line 2000)

**CATS:**

Treatment of idiopathic epilepsy:
- **a)** Initial oral dose is 2–2.5 mg/kg PO q12h. Serum phenobarbital concentrations should be monitored 2–3 weeks after initiating therapy and after any dosage adjustment. Optimum therapeutic levels of 23-30 micrograms/mL have been recommended in cats, in an attempt to maximize seizure control with the lowest potential for side effects. (Munana 2010)
- **b)** For status epilepticus: If seizures persist after diazepam therapy (2 or more seizures recur; or gross motor activity persists) give phenobarbital bolus of 2–5 mg/kg (can be repeated at 20 minute intervals, up to two times). Add phenobarb to diazepam infusion at a rate of 2–10 mg/hour. If seizures are sustained or high frequency seizures recur, consider pentobarbital coma.

For oral maintenance therapy: 1–2 mg/kg PO every 12 hours; adjust dosages based upon serum levels (Shell 2000)
- **c)** Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–5 mg/kg PO q12h. (Knipe 2006), (Knipe 2009)
- **d)** Starting dose is 1–2 mg/kg (usually 3.25–15 mg/cat) PO q12h. Measure trough serum levels 2–3 weeks after initiating therapy and after each dosage change. In the cat, therapeutic levels are likely 50–100 mmol/L (lower than those in dogs). If seizure control is good, but levels are subtherapeutic, dose does not need to be increased. Measure phenobarbital levels, CBC and serum chemistries every 6 months. (Cochrane 2007)
- **e)** Initial maintenance dose: 2.5–3 mg/kg PO q12h. A CBC, serum biochemical evaluation and urinalysis should be performed before starting maintenance anticonvulsant therapy, both as part of the diagnostic evaluation and as a baseline before starting therapy. (Mariani 2010)
- **f)** Emergency seizure control involves intravenous diazepam (0.5 mg/kg up to three doses), along with phenobarbital 3 mg/kg IV. Phenobarbital may be repeated every 20 minutes up to 24 mg/kg in a 24-hour period, or it can be given as a “loading” of 10 mg/kg IV bolus. (Abramson 2009)
Sedation; for controlling excessive feline vocalization for situational distress (e.g., riding in automobiles):

a) 2–3 mg/kg PO as needed (Overall 2000)

**FERrets:**

a) 1–2 mg/kg PO 2–3 times daily (Williams 2000)

b) Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–2 mg/kg PO q8–12h. (Knipe 2006), (Knipe 2009)

**CATTLE:**

For enzyme induction in organochlorine toxicity:

a) 5 grams PO for 3–4 weeks, off 3–4 weeks, then repeat for 3–4 more weeks (Smith 1986)

**HORSES:**

- **Note:** ARCI UCGFS Class 2 Drug
  
a) Loading dose of 12 mg/kg IV over 20 minutes, then 6.65 mg/kg IV over 20 minutes every 12 hours (Duran et al. 1987)
  
b) Adult horses: Loading dose of 16–20 mg/kg once IV; maintenance dose of 1–5 mg/kg PO twice daily.

**Foals:**

- Loading dose of 16–20 mg/kg once IV; maintenance dose of 100–500 mg (total dose) PO twice daily. (Knipe 2006), (Knipe 2009)
  
c) Foals for seizures: 20 mg/kg diluted with normal saline to a volume of 30–35 mL infused over 25–30 minutes IV, then 9 mg/kg diluted and infused as above q8h. Recommend monitoring serum levels if possible. (Spearh et al. 1984)

**Monitoring**

- Anticonvulsant (or sedative) efficacy
  
- Adverse effects (CNS related, PU/PD, weight gain)

**Phenobarbital**

- Serum phenobarbital levels if lack of efficacy or adverse reactions noted. Recommend that all dogs have their phenobarbital level monitored once or twice a year and cats monitored every 6 months. Although there is some disagreement among clinicians, therapeutic serum levels in dogs (15–45 micrograms/mL; 65–194 mcg/mL/L) are thought to be similar to those in humans. Optimum therapeutic levels of 23–30 micrograms/mL has been recommended in cats, in an attempt to maximize seizure control with the lowest potential for side effects. Similarly, serum levels of 20–35 micrograms/mL are recommended in the dog, with the decrease in the high end of the range reflecting suggested changes to minimize the potential for hepatotoxicity (Munana 2010). Animals on bromides and phenobarbital may require lower serum levels for seizure control. If phenobarbital was not “loaded”, wait at least 5–6 half-lives (approximately 12–14 days in dogs and 9–10 days in cats) before measuring serum concentrations; time of sampling does not appear to be significant.

- If used chronically, routine CBC’s, liver enzymes (especially ALT and AST), and bilirubin at least every 6 months.

**Client Information**

- Keep medications out of reach of children and stored in child-resistant packaging.

- If used chronically, routine CBC’s, liver enzymes (especially ALT and AST), and bilirubin at least every 6 months.

**Chemistry/Synonyms**

Phenobarbital, a barbiturate, occurs as white, glistening, odorless, small crystals or a white, crystalline powder with a melting point of 174°–178°C and a pKa of 7.41. One gram is soluble in approximately 1000 mL of water; 10 mL of alcohol. Compared to other barbiturates it has a low-lipid solubility.

Phenobarbital sodium occurs as bitter-tasting, white, odorless, flaky crystals or crystalline granules or powder. It is very soluble in water, soluble in alcohol, and freely soluble in propylene glycol. The injectable product has a pH of 8.5–8.8.

SI units (mcg/mL) are multiplied by 0.232 to convert phenobarbital levels to conventional units (micrograms/mL).

Phenobarbital may also be known as fenobarbital, phenobarbitalum, phenobarboline, phenylethybarbituric acid, or phenylethylmalonylurea, Laminal Sodium® and Solfoton®.

**Storage/Stability**

Phenobarbital tablets should be stored in tight, light-resistant containers at room temperature (15–30°C); protect from moisture.

Phenobarbital elixir should be stored in tight containers at 20–20°C.

Phenobarbital sodium injection should be stored at room temperature (15–30°C).

Aqueous solutions of phenobarbital are not very stable. Propylene glycol is often used in injectable products to help stabilize the solution. Solutions of phenobarbital sodium should not be added to acidic solutions nor used if they contain a precipitate or are grossly discolored.

**Compatibility/Compounding Considerations**

The following solutions and drugs have been reported to be physically compatible with phenobarbital sodium: Dextrose IV solutions, Ringer’s injection, lactated Ringer’s injection, Saline IV solutions, dextrose-saline combinations, dextrose-Ringer’s combinations, dextrose-Ringer’s lactate combinations, amikacin sulfate, aminophylline, atropine sulfate (stable for at least 15 minutes, but not 24 hours), calcium chloride and gluconate, dimenhydrinate, polymyxin B sulfate, sodium bicarbonate, thiopental sodium, and verapamil HCl.

**Adverse effects (CNS related, PU/PD, weight gain)**

- Anticonvulsant (or sedative) efficacy

- **HORSES:**
  
  **Loading dose of 16–20 mg/kg once IV; maintenance dose of 100–500 mg (total dose) PO twice daily.** (Knipe 2006), (Knipe 2009)

  **Foals:**

  - Loading dose of 16–20 mg/kg once IV; maintenance dose of 100–500 mg (total dose) PO twice daily. (Knipe 2006), (Knipe 2009)
  
  - **For seizures:** 20 mg/kg diluted with normal saline to a volume of 30–35 mL infused over 25–30 minutes IV, then 9 mg/kg diluted and infused as above q8h. **Recommend monitoring serum levels if possible.** (Spearh et al. 1984)

**References**

**Prescriber Highlights**

- Alpha-adrenergic blocker used in small animals: detrusor areflexia, pheochromocytoma (hypertension); horses: laminitis or diarrhea

- Contraindications: When hypotension would be deleterious; possibly glaucoma or diabetes mellitus, horses with clinical signs of colic. Caution: CHF or other heart disease, renal damage, or cerebral/coronary arteriosclerosis

- Adverse Effects: Hypotension, hypertension (rebound), miosis, increased intraocular pressure, tachycardia, inhibition of ejaculation, nasal congestion, weakness/dizziness, and GI effects (e.g., nausea, vomiting). Constipation may occur in horses.

- May need to be obtained from compounding pharmacy

---

**Uses/Indications**

Phenoxybenzamine is used in small animals primarily for its effect in reducing internal urethral sphincter tone in dogs and cats when urethral sphincter hypertonus is present. It can also be used to treat the hypertension associated with pheochromocytoma prior to surgery or as an adjunctive therapy in endotoxicosis.

In horses, phenoxybenzamine has been used for preventing or treating laminitis in its early stages and to treat secretory diarrheas.

**Pharmacology/Actions**

Alpha-adrenergic response to circulating epinephrine or norepinephrine is noncompetitively blocked by phenoxybenzamine. The effect of phenoxybenzamine has been described as a "chemical sympathectomy." No effects on beta-adrenergic receptors or on the parasympathetic nervous system occur.

Phenoxybenzamine causes cutaneous blood flow to increase, but little effects are noted on skeletal or cerebral blood flow. Phenoxybenzamine can also block pupillary dilation, lid retraction, and nictitating membrane contraction. Both standing and supine blood pressures are decreased in humans.

**Pharmacokinetics**

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, phenoxybenzamine is variably absorbed from the GI, with a bioavailability of 20–30%. Onset of action of the drug is slow (several hours) and increases over several days after regular dosing. Effects persist for 3–4 days after discontinuation of the drug.

Phenoxybenzamine is highly lipid soluble and may accumulate in body fat. It is unknown if it crosses the placenta or is excreted into milk. The serum half-life is approximately 24 hours in humans. It is metabolized (dealkylated) and excreted in both the urine and bile.

**Contraindications/Precautions/Warnings**

Phenoxybenzamine is contraindicated in horses with clinical signs of colic and in patients when hypotension would be undesirable (e.g., shock, unless fluid replacement is adequate). One author (Labato 1988) lists glaucoma and diabetes mellitus as contraindications for the use of phenoxybenzamine in dogs.

Phenoxybenzamine should be used with caution in patients with CHF or other heart disease as drug-induced tachycardia can occur. It should be used cautiously in patients with renal damage or cerebral/coronary arteriosclerosis.

**Adverse Effects**

Adverse effects associated with alpha-adrenergic blockade include: hypotension, hypertension, miosis, increased intraocular pressure, tachycardia, sodium retention, inhibition of ejaculation, and nasal congestion. Additionally, it can cause weakness/dizziness and GI effects (e.g., nausea, vomiting). Constipation may occur in horses.

**Reproductive/Nursing Safety**

Phenoxybenzamine has been shown to cause abnormalities in the closure of the patent ductus in guinea pigs. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown if phenoxybenzamine is excreted into milk.

**Overdosage/Acute Toxicity**

Overdosage of phenoxybenzamine may yield signs of postural hypotension (dizziness, syncope), tachycardia, vomiting, lethargy, or shock.

Treatment should consist of emptying the gut if the ingestion was recent and there are no contraindications to those procedures. Hypotension can be treated with fluid support. Epinephrine is contraindicated (see Drug Interactions) and most vasopressor drugs are ineffective in reversing the effects of alpha-blockade. Intravenous norepinephrine (levarterenol) may be beneficial, however, if clinical signs are severe.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenoxybenzamine and may be of significance in veterinary patients:

- **EPINEPHRINE:** If used with drugs that have both alpha- and beta-adrenergic effects increased hypotension, vasodilatation or tachycardia may result
- **PHENYLEPHRINE:** Phenoxybenzamine will antagonize the effects of alpha-adrenergic sympathomimetic agents
- **RESERPINE:** Phenoxybenzamine can antagonize the hypothermic effects of reserpine

**Doses**

**DOGS:**

To treat functional urethral obstruction by decreasing sympathetic-mediated urethral tone:

- a) 0.25 mg/kg PO q12–24h or 2.5–20 mg (total dose) PO q12–24h (Lane 2000)
- b) 0.25 mg/kg PO q12h (Lulich 2004)
- c) 0.25–0.5 mg/kg PO once or twice daily (Coates 2004)
- d) 5–15 mg (total dose) PO q12h (Bartges 2003)

Treatment of hypertension associated with pheochromocytoma:

- a) To minimize perioperative complications prior to surgical removal of tumor: Initially 0.5 mg/kg PO twice daily and gradually increase dosage every few days until clinical signs of hypotension (e.g., lethargy, weakness, syncope), adverse drug reactions (e.g., vomiting) or a maximum dosage of 2.5 mg/kg PO twice daily is attained. Surgery is recommended 1-2 weeks later. Continue phenoxybenzamine until the time of surgery. Close monitoring of the dog during the perioperative period is critical for a successful outcome. (Nelson 2008)
- b) Initial dose is 0.25 mg/kg PO twice daily, dose is then gradually increased every few days until signs of hypotension or adverse drug reaction occur or a maximum dosage of 2.5 mg/kg twice a day is attained. In cases in where adrenalectomy is not an option, phenoxybenzamine should be used long-term to control blood pressure. Additional beta-blockers may be necessary in patients with severe tachycardia, but should not be given without prior alpha-blockade to avoid severe hypotension. (Reusch, C. 2006), (Reusch, C.E. et al. 2010)

For adjunctive treatment of endotoxicosis with appropriate antimicrobial agents, steroids (if indicated), and other supportive care:

- a) 0.25–0.5 mg/kg PO q6h (Coppock & Mostrom 1986)
To treat functional urethral obstruction by decreasing sympathetic-mediated urethral tone:  

- For short-term treatment of hypertension:  
  - a) 0.5 mg/kg q12h (Sparkes 2003)  
  - b) 2.5 mg (total dose) q12h increasing by 2.5 mg up to a maximum of 10 mg (total dose) q12h PO (Brovold 2002)  
  - c) 2.5–7.5 mg per cat q8–12h (Waddell 2005)

**HORSES:** (Note: ARCI UCFS Class 3 Drug)  

- a) To decrease urethral sphincter tone in horses with bladder paresis: 0.7 mg/kg PO 4 times a day (in combination with bethanechol at 0.25–0.75 mg/kg PO 2–4 times a day) (Schott II & Carr 2003)  
- b) For adjunctive treatment of laminitis (developmental phase): 1 mg/kg IV q12h for 2 doses (Brumbaugh et al. 1999)  
- c) For treatment of profuse, watery diarrhea: 200–600 mg q12h (Clark 1988)

**Monitoring**  
- Clinical efficacy (adequate urination, etc.)  
- Efficacy for urinary problems may take a week or longer and the drug should be given for several weeks before determining it is not effective  
- Blood pressure, if necessary/possible

**Client Information**  
- Contact veterinarian if animal has continuing problems with weakness, appears dizzy, collapses after standing, or has persistent vomiting. GI upset may be reduced if the drug is given with meals.

**Chemistry/Synonyms**  
An alpha-adrenergic blocking agent, phenoxybenzamine HCl occurs as an odorless, white crystalline powder with a melting range of 136°–141° and a pKa of 4.4. Approximately 40 mg are soluble in 1 mL of water and 167 mg are soluble in 1 mL of alcohol.  
Phenoxybenzamine may also be known as: SKF-688A, Dibenzyline®, Dibenzyran®, or Fenoxene®.

**Storage/Stability**  
Phenoxybenzamine capsules should be stored at room temperature in well-closed containers.

**Dosage Forms/Regulatory Status**  
**VETERINARY-LABELED PRODUCTS:** None  
**HUMAN-LABELED PRODUCTS:**  
Phenoxybenzamine HCl Capsules: 10 mg; Dibenzyline® (Wellspring); (Rx)

**References**

**PHENYLButAZONE**  
(fen-il-byoo-za-ton) Butazolidin®, “Buta”  
NON-STEROIDAL ANTIINFLAMMATORY AGENT

**Prescriber Highlights**

- NSAID used primarily in horses; little reason to use in dogs today

**Contraindications:** Known hypersensitivity, history or preexisting hemolytic or bone marrow abnormalities, preexisting GI ulcers, food producing animals  
Caution: Foals or ponies, preexisting renal disease, CHF, other drug allergies  
Adverse Effects: *Horses:* Oral & GI erosions & ulcers, hypoalbuminemia, diarrhea, anorexia, & renal effects. *Dog:* GI ulceration, sodium & water retention, diminished renal blood flow, blood dyscrasias,  
Do not give IM or SC; 1A injections may cause seizures,  
Drug Interactions; lab interactions

**Uses/Indications**  
One manufacturer lists the following as the indications for phenylbutazone: “For the relief of inflammatory conditions associated with the musculoskeletal system in dogs and horses.” (Package Insert; Butazolidin®—Cooper's)  
It has been used primarily for the treatment of lameness in horses and, occasionally, as an analgesic/antiinflammatory, antipyretic in dogs, cattle, and swine.

**Pharmacology/Actions**  
Phenylbutazone has analgesic, antiinflammatory, antipyretic, and mild uricosuric properties. The proposed mechanism of action is by the inhibition of cyclooxygenase, thereby reducing prostaglandin synthesis. Other pharmacologic actions phenylbutazone may induce include reduced renal blood flow and decreased glomerular filtration rate, decreased platelet aggregation, and gastric mucosal damage.

**Pharmacokinetics**  
Following oral administration, phenylbutazone is absorbed from both the stomach and small intestine. The drug is distributed throughout the body with highest levels attained in the liver, heart, lungs, kidneys, and blood.  
Protein binding in horses exceeds 99%. Both phenoxybenzamine and oxphenbutazone cross the placenta and are excreted into milk.

The serum half-life in the horse ranges from 3.5–6 hours, and like aspirin is dose-dependent. Therapeutic efficacy, however, may last for more than 24 hours, probably due to the irreversible binding of phenylbutazone to cyclooxygenase. In horses and other species, phenylbutazone is nearly completely metabolized, primarily to oxphenbutazone (active) and gamma-hydroxyphenylbutazone. Oxphenbutazone has been detected in horse urine.
Phenylbutazone is contraindicated in patients demonstrating previous hypersensitivity reactions to it, and should be used very cautiously in patients with a history of allergies to other drugs.

Phenylbutazone is contraindicated in patients with a history of or preexisting hematologic or bone marrow abnormalities, preexisting GI ulcers, and in food producing animals or lactating dairy cattle. Cautious use in both foals and ponies is recommended because of increased incidences of hypoprothrombinemia and GI ulceration. Foals with a heavy parasite burden or that are undernourished may be more susceptible to developing adverse effects.

In horses with known or suspected EUGS, use should be avoided; single doses of phenylbutazone will probably not result in catastrophic consequences, but repeated doses can exacerbate gastric ulcers (Videla & Andrews 2009).

Phenylbutazone may decrease renal blood flow and sodium and water retention, and should be used cautiously in animals with preexisting renal disease or CHF.

Because phenylbutazone may mask clinical signs of lameness in horses for several days following therapy, unethical individuals may use it to disguise lameness for "soundness" exams. States have different standards regarding the use of phenylbutazone in track animals. Complete elimination of phenylbutazone in horses may take 2 months and it can be detected in the urine for at least 7 days following administration.

Phenylbutazone is contraindicated in patients demonstrating previous hypersensitivity reactions to it, and should be used very cautiously in patients with a history of allergies to other drugs.

Do not administer injectable preparation IM or SC as it is very irritating (swelling, to necrosis and sloughing). Intracarotid injections may cause CNS stimulation and seizures.

Adverse Effects

While phenylbutazone is apparently a safer drug to use in horses and dogs than in people, serious adverse reactions can still occur. Toxic effects that have been reported in horses include oral and GI erosions and ulcers, hypoaesthetic injury, diarrhea, anorexia, and renal effects (azotemia, renal papillary necrosis). Unlike humans, it does not appear that phenylbutazone causes much sodium and water retention in horses at usual doses, but edema has been reported. In dogs, however, phenylbutazone may cause sodium and water retention, and diminished renal blood flow. Phenylbutazone-induced blood dyscrasias and hepatotoxicity have also been reported in dogs. Although gastric ulceration is frequently observed in adult horses and foals, evidence of an association between this disease and administration of NSAIDs such as phenylbutazone or flunixin at recommended dosages is lacking. On the basis of current evidence, prophylactic anti-ulcer medications for horses receiving therapeutic doses of NSAIDs is probably unnecessary in patients that are otherwise at low risk for gastric ulceration (Fennell & Franklin 2009).

The primary concerns with phenylbutazone therapy in humans include its bone marrow effects (agranulocytosis, aplastic anemia), renal and cardiovascular effects (fluid retention to acute renal failure), and GI effects (dyspepsia to perforated ulcers). Other serious concerns with phenylbutazone include hypersensitivity reactions, neurologic, dermatologic, and hepatic toxicities. IM or SC injection can cause swelling, necrosis and sloughing. Intracarotid injections may cause CNS stimulation and seizures. Therapy should be halted at first signs of any toxic reactions (e.g., anorexia, oral lesions, depression, reduced plasma proteins, increased serum creatinine or BUN, leukopenia, or anemias). The use of sucralfate or the H2 blockers (cimetidine, ranitidine) can be suggested for use in treating the GI effects. Misoprostrol, a prostaglandin E analog, may also be useful in reducing the gastrointestinal effects of phenylbutazone.

Reproductive/Nursing Safety

Although phenylbutazone has shown no direct teratogenic effects, rodent studies have demonstrated reduced litter sizes, increased neonatal mortality, and increased stillbirth rates. Phenylbutazone should, therefore, be used in pregnancy only when the potential benefits of therapy outweigh the risks associated with it.

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

The safety of phenylbutazone during nursing has not been determined; use is not recommended in nursing animals.

Overdose/Acute Toxicity

Manifestations (human) of acute overdosage with phenylbutazone include a prompt respiratory or metabolic acidosis with compensatory hyperventilation, seizures, coma, and acute hypotensive crisis. In an acute overdose, clinical signs of renal failure (oliguria, with proteinuria and hematuria), liver injury (hepatomegaly and jaundice), bone marrow depression, and ulceration (and perforation) of the GI tract may develop. Other symptoms reported in humans include: nausea, vomiting, abdominal pain, diaphoresis, neurologic and psychiatric symptoms, edema, hypertension, and respiratory depression, and cyanosis.

There were 27 exposures to phenylbutazone reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 24 were dogs with 10 showing clinical signs, and 2 were equines with 1 showing clinical signs. The remaining reported case consisted of 1 cat that did not show any clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, seizures, tachycardia, trembling, and tremors.

Most common clinical signs in dogs (per unpublished APCC data) are tremors, seizures, ataxia, vomiting, and tachypnea. Oral LD50 in dogs is 332mg/kg (per RTECS 1988). Most common clinical signs in horses (per unpublished APCC data) are colic, anorexia, and ataxia.

Standard overdose procedures should be followed (empty gut following oral ingestion, etc.). Supportive treatment should be instituted as necessary and intravenous diazepam used to help control seizures. Monitor fluid therapy carefully, as phenylbutazone may cause fluid retention.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylbutazone and may be of significance in veterinary patients:

- **FUROSEMIDE**: Phenylbutazone may antagonize the increased renal blood flow effects caused by furosemide
- **HEPATOTOXIC DRUGS**: Phenylbutazone administered concurrently with hepatotoxic drugs may increase the chances of hepatotoxicity developing
- **NSAIDs**: Concurrent use with other NSAIDs may increase the potential for adverse reactions, however, some clinicians routinely use phenylbutazone concomitantly with flunixin in horses. One study did not show synergistic actions with flunixin, but did however, when phenylbutazone and ketoprofen were "stacked".
- **PENICILLAMINE**: May increase the risk of hematologic and/or renal adverse reactions
- **PENICILLIN G**: Phenylbutazone may increase plasma half-life of penicillin G
- **SULFONAMIDES**: Phenylbutazone could potentially displace sulfonamides from plasma proteins; increasing the risk for adverse effects
- **WARFARIN**: Phenylbutazone could potentially displace warfarin from plasma proteins; increasing the risk for bleeding

Laboratory Considerations

- Phenylbutazone and oxyphenbutazone may interfere with thyroid function tests by competing with thyroxine at protein binding sites or by inhibiting thyroid iodine uptake. Interpretation of thyroid function tests may be complicated.

Doses

**DOGS:**

Note: With the release of safer and FDA-approved NSAIDs, it is this author’s (Plumb) opinion that there is little reason to use this agent today in dogs.

a) 14 mg/kg PO three times daily initially (maximum of 800 mg/day regardless of weight), titrate dose to lowest effective dose (Package Insert; Butazolidin®—Coopers)

b) 15–22 mg/kg PO q12h (Posner & Papich 2009)

c) For analgesia: 1–5 mg/kg PO q8h (Taylor 2003)

**CATTLE:**

Note: The Food and Drug Administration (FDA) has issued an order prohibiting the extralabel use of phenylbutazone animal and human drugs in female dairy cattle 20 months of age or older. In addition, many believe that phenylbutazone use in any food animal should be banned.

a) 4–8 mg/kg PO or 2–5 mg/kg IV (Howard 1986)

b) 10–20 mg/kg PO, then 2.5–5 mg/kg q24h or 10 mg/kg every 48 hours PO (Jenkins 1987)

**HORSES:**

a) To reduced pain or pyrexia associated with pleuropneumonia: 2.2–4.4 mg/kg PO or IV q12h. NSAIDs are commonly used for the first week of treatment or longer. (Sprayberry 2009)

b) 1–2 grams IV per 454 kg (1000 lb.) horse. Injection should be made slowly and with care. Limit IV administration to no more than 5 successive days of therapy. Follow with oral forms if necessary; or 2–4 grams PO per 454 kg (1000 lb.) horse. Do not exceed 4 grams/day. Use high end of dosage range initially, then titrate to lowest effective dose. (Package Insert; Butazolidin®—Coopers)

c) For conjunctive treatment of colic (to reduce endotoxic effects): 2.2 mg/kg twice daily (Moore 1999)
Phenylephrine is an alpha-adrenergic agonist and is primarily used to increase blood pressure. It is also used to treat hypotension and shock in human medicine.

**Uses/Indications**

- To treat hypotension and shock in humans.
- To increase blood pressure in cases of hypotension.
- Used in the treatment of paroxysmal supraventricular tachycardia.
Phenylephrine is a sympathomimetic amine, occurring as white to nearly white crystals with a melting point of 145–146°C. It is freely soluble in water and alcohol. The pH of the commercially available injection is 3–6.5. It is not a replacement for adequate volume therapy in patients with shock.

### Overdosage/Acute Toxicity
There were 195 exposures to phenylephrine reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 189 were dogs with 51 showing clinical signs, 5 were cats with 1 showing clinical signs, and 1 was a bird that did not show any clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, depression, hyperactivity, and tachycardia.

Overdosage of phenylephrine can cause hypertension, seizures, vomiting, paresthesias, ventricular extrasystoles, and cerebral hemorrhage, but the margin of safety with phenylephrine overdose is fairly wide, especially after oral administration. Overdoses may cause hypertension, seizures, vomiting, paresthesias, ventricular extrasystoles, and cerebral hemorrhage, but the margin of safety with phenylephrine overdose is fairly wide, especially after oral administration. Vomiting is commonly seen with overdoses. CNS stimulation (agitation, hyperactivity, and muscle tremors) or cardiovascular changes, most commonly tachycardia and hypertension, are also seen. Cardiovascular changes often respond well to fluids. Beta-blockers or nitroprusside may be indicated when signs are refractory to fluids.

### Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving phenylephrine (systemically) and may be of significance in veterinary patients:

- **PDE-ADRENERGIC BLOCKERS (phenotolamine, phentolamines, phenoxybenzamine):** Higher dosages of phenylephrine may be required to attain a pressor effect if these agents have been used prior to therapy.

- **OXYTOCIN:** When used concurrently with oxytocic agents, the pressor effects may be enhanced.

- **SYMPATHOMIMETIC AGENTS (epinephrine):** Tachycardia and serious arrhythmias are possible.

### Doses

**DOGS:**
- a) As a CRI: Low dose is 1 microgram/kg/min, high dose is 3 micrograms/kg/min. Increases peripheral vascular resistance and mean arterial blood pressure. May decrease reflex bradycardia and vasoconstriction. May increase systolic blood pressure. May elicit a reflex bradycardia (blocked by atropine) and partial heart block or with other heart disease. Phenylephrine is not a replacement for adequate volume therapy in patients with shock.
- b) As a constant rate infusion: 2–10 micrograms/kg/minute. Can be useful when the patient suffers profound vasodilation due to septic shock. (Ko 2009)
- c) As a vasopressor in catastrophic stages of hypovolemic shock: 1–3 micrograms/kg/min (Rudloff 2002)

**CATS:**
- a) When it is advantageous to increase blood pressure by vasoconstriction, phenylephrine may be useful in patients with pronounced systemic vasodilatation (e.g., visceral inflammation) or to increase blood pressure when myocardial contractility may be disadvantageous (e.g., hypotrophic cardiomyopathy): 1–2 micrograms/kg/minute as a CRI. In this study, infusions of 1 microgram/kg/min significantly increased mean arterial pressure without a change in cardiac output. At 2 micrograms/kg/min, cardiac index also was increased with an increase in stroke volume index. (Pascoe et al. 2006)
- b) As a constant rate infusion: 2–10 micrograms/kg/minute. Can be useful when the patient suffers profound vasodilatation due to septic shock. (Ko 2009)
- c) As a vasopressor in catastrophic stages of hypovolemic shock: 1–3 micrograms/kg/min (Rudloff 2002)
- d) As a CRI: Low dose is 1 microgram/kg/min, high dose is 3 micrograms/kg/min. Increases peripheral vascular resistance and mean arterial blood pressure. May increase reflex bradycardia, and vasoconstriction can lead to excessive decreases in blood flow to liver, GI tract, and kidneys, although coronary blood flow is increased. (Quandt 2009)

**HORSES:**
- Note: ARCI UCGFS Class 3 Drug
  - a) 5 mg IV (Enos & Keiser 1985)

### Monitoring
- **Cardiac rate/rhythm**
- **Blood pressure, and blood gases if possible**

### Client Information
- **Parenteral phenylephrine should only be used by professionals in a setting where adequate monitoring is possible.**

### Chemistry/Synonyms
An alpha-adrenergic sympathomimetic amine. It is an alkaloid occurring as bitter-tasting, odorless, white to nearly white crystals with a melting point of 145–146°C. It is freely soluble in water and alcohol. The pH of the commercially available injection is 3–6.5.

Phenylephrine may also be known as: fenilefrina, phenylephrinum, or m-synephrine, AH-chew D®, Little Colds Decongestant for Infants & Children®, Lusonal®, Nasop®, Neo-Synephrine®, Sudgest® PE®, and Sudafed® PE®.

### Storage/Stability
The injectable product should be stored protected from light. Do not use solutions if the container is brown or contain a precipitate. Oxidation of the drug can occur without a color change. To protect against oxidation, the air in commercially available ampules for injection is replaced with nitrogen and a sulfite added.
Phenylephrine is reported to be physically compatible with all commonly used IV solutions and the following drugs: cefuroxime, cefoxitin sodium, cefazolin, tetracycline, ampicillin, amikacin, and sodium bicarbonate. While stated to be physically incompatible with ferric salts, oxidizing agents, and metals.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:**

There are oral combination products marketed as “cough” syrups for veterinary use that contain phenylephrine, pyrilamine (antihistamine), guaifenesin, sodium citrate, and sometimes ammonium chloride. The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**

Phenylephrine HCl Oral Tablets: 10 mg (regular & chewable); AH-chew DB® (WE Pharm); Sadafed PE® (McNeil); Sadogest PE® (Major) (OTC or Rx)

Phenylephrine HCl Oral Solution/Liquid: 2.5 mg/mL (concentrate), 2.5 mg/5mL & 7.5 mg/5 mL; in 30 mL, 115 mL & 473 mL; Little Colds Decongestant for Infants & Children® (Vetco); Lasonol® (WraSet); Pedial Care Children’s Decongestant® (Pfizer Cons Health); (OTC or Rx)

Phenylephrine HCl Oral Strips: 2.5 mg; Tramician Thin Strips Cold® (Novartis Consumer Health); (OTC)

Phenylephrine HCl Injection: 1% (10 mg/mL) in 1 mL & 5 mL vials and 1 mL Uni-Nest amps; Neo-Synephrine® HCl (Hospira); generic; (Rx)

Phenylephrine is also available in ophthalmic and intranasal dosage forms and in combination with antihistamines, analesgesics, decongestants, etc., for oral administration in humans.

- Enos, L.R. & K. Keiser (1985). Formulary: Veterinary Medical Teaching Hospital; University of California at Davis. Davis.

### PHENYLPROPA-NOLAMINE HCL (fen-il-proe-pa-nol-a-men) PPA

#### SYMPTOMATIC

**Prescriber Highlights**

- Sympathomimetic used primarily for urethral sphincter hypotonus
- Caution: Glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension
- Adverse Effects: Restlessness, irritability, hypertension, & anorexia

### Uses/Indications

Phenylpropanolamine is used chiefly for the treatment of urethral sphincter hypotonus and resulting incon tinence in dogs and cats. It has also been used in an attempt to treat nasal congestion in small animals.

### Pharmacology/Actions

While the exact mechanisms of phenylpropanolamine’s actions are undetermined, it is believed that it indirectly stimulates both alpha- and beta-adrenergic receptors by causing the release of norepinephrine. Prolonged use or excessive dosing frequency can deplete norepinephrine from its storage sites, and tachyphylaxis (decreased response) may ensue. Tachyphylaxis has not been documented in dogs or cats when used for urethral sphincter hypotonus, however.

Pharmacologic effects of phenylpropanolamine include increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased nasal congestion and appetite. Phenylpropanolamine can also increase urethral sphincter tone and produce closure of the bladder neck; its principle veterinary indications are because of these effects.

### Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, phenylpropanolamine is readily absorbed after oral administration and has an onset of action (nasal decongestion) of about 15–30 minutes with duration of effect lasting approximately 3 hours (regular capsules or tablets).

Phenylpropanolamine is reportedly distributed into various tissues and fluids, including the CNS. It is unknown if it crosses the placenta or enters milk. The drug is partially metabolized to an active metabolite, but 80–90% is excreted unchanged in the urine within 24 hours of dosing. The serum half-life is approximately 3–4 hours.

### Contraindications/Precautions/Warnings

Phenylpropanolamine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension.

### Adverse Effects

Most likely side effects include restlessness, anxiety, irritability, urine retention, tachycardia, and hypertension. Anorexia may be a problem in some animals. Rare reports of “stroke” have occurred in dogs given therapeutic dosages of phenylpropanolamine.

### Reproductive/Nursing Safety

Phenylpropanolamine may cause decreased ovum implantation; uncontrolled clinical experience, however, has not demonstrated any untoward effects during pregnancy.

### Overdose/Acute Toxicity

Clinical signs of overdosage may consist of an exacerbation of the adverse effects listed above or, if a very large over-dose, severe cardiovascular (hypertension to rebound hypotension, bradycardias to tachycardias, and cardiovascular collapse) or CNS effects (stimulation to coma) can be seen.

A dog ingesting 48 mg/kg of PPA has been reported (Crandell and Ware 2005). Ventricular tachycardia and regions of myocardial necrosis were noted. All abnormalities resolved within 6 months. There were 146 exposures to phenylpropanolamine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 144 were dogs with 97 showing clinical signs. The remaining 2 monamines (e.g., amitraz, possibly selegiline): Phenylpropanolamine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors

### NSAIDS:

An increased chance of hypertension if given concomitantly with NSAIDs, including aspirin

### Reserpine:

An increased chance of hypertension if given concomitantly

### Sympathomimetic Agents, Other:

Phenylpropanolamine should not be administered with other sympathomimetic agents (e.g., ephedrine) as increased toxicity may result

### Tricyclic Antidepressants (clomipramine, amitriptyline, etc.):

An increased chance of hypertension if given concomitantly
**Doses**

**DOGS:**
For urethral sphincter hypotonus:
- a) 12.5–50 mg (total dose) or 1–2 mg/kg PO q8h (Bartges 2009)
- b) Using the time-release 75 mg capsules: Dogs weighing less than 40 lbs: ½ capsule PO daily. Dogs 40–100 lbs: 1 capsule PO daily. Dogs weighing >100 lbs: 1.5 capsules PO per day. (Label information; Cystodin®—VPL)
- c) 1–1.5 mg/kg PO two to three times a day controls 74–92% of dogs with primary sphincter mechanism incontinence. Over half of dogs not responding to regular PPA will respond to sustained-release PPA. Incontinence control becomes less over time in some dogs. (Chew 2007)
- d) 5–50 mg per dog PO q8h or 1.5 mg/kg PO q8h–12h (Vernau 2006)
For retrograde ejaculation:
- a) 3–4 mg/kg PO twice daily may be tried. (Fontbonne 2007)

**CATS:**
For urethral sphincter hypotonus:
- a) 12.5 mg PO q8h (Labato 1988)(Polzin & Osborne 1985)
- b) 1–1.5 mg/kg PO q8h (Bartges 2009)
- c) 1.1–2.2 mg/kg PO two to three times daily (Lane 2003)

**Monitoring**
- Clinical effectiveness
- Adverse effects (see above)
- Blood pressure

**Client Information**
In order for this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.
Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

**Chemistry/Synonyms**
A sympathomimetic amine, phenylpropanolamine HCl occurs as a white crystalline powder with a slightly aromatic odor, a melting range between 191°–194°C, and a pKa of 9.4. One gram is soluble in approximately 1.1 mL of water or 7 mL of alcohol.

Phenylpropanolamine may also be known as: (+/-)-norephedrine, dl-norephedrine or PPA, Cystodin®, Propalin®, Uricon®, and Uriflex-PT®.

**Storage/Stability**
Store phenylpropanolamine products at room temperature in light-resistant, tight containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
Note: There are no phenylpropanolamine products at the time of writing—February 2011 approved by the FDA for use in animals.

Phenylpropanolamine Chewable Tablets: 25 mg, 50 mg, & 75 mg; Proin® (PRN Pharmacal), Propalin® (Vetoquinol), Uriflex-PT® (Butler), Uricon® (Neogen); (Rx). Labeled for use in dogs.

Phenylpropanolamine Timed-Release Capsules: 75 mg; Cystodin® (VPL); (Rx). Labeled for use in dogs.

Phenylpropanolamine oral solution: 25 mg/mL in 60 mL bottles; Proin® Drops (PRN Pharmacal) (Rx); 50 mg/mL in 30 mL and 100 mL bottles; (Rx). Labeled for use in dogs.

The ARCI (Racing Commissioners International) has designated as a class 3 substance. See the appendix for more information.

In the USA, phenylpropanolamine is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

**HUMAN-LABELED PRODUCTS:**
Note: Because of potential adverse effects in humans, phenylpropanolamine has been removed from the US market for human use.

**References**

---

**PHENYTOIN SODIUM**
(phen-toe-in) Dilantin®
ANTICONVULSANT, ANTIDYSSRHYTHMIC

**Prescriber Highlights**
- Rarely used (in USA) for seizures in small animals; sustained release formulations may be useful (not available in USA)
- Potentially useful as a treatment for ventricular dysrhythmias in horses or digoxin-induced arrhythmias in dogs or horses; may be useful in cats with myokemia and neuromyotonia
- Contraindications: Hypersensitivity; IV use contraindicated for 2nd or 3rd degree heart block, sinoatrial block, Adams-Stokes syndrome, or sinus bradycardia.
- Adverse Effects: Dogs: Anorexia & vomiting, ataxia, sedation, gingival hyperplasia, hepatotoxicity. Cats: Ataxia, sedation, anorexia, dermal atrophy syndrome, thrombocytopenia
- Potentially teratogenic; many drug interactions possible

---

**Uses/Indications**
Because of its undesirable pharmacokinetic profiles in dogs and cats, the use of phenytoin as an anticonvulsant for long-term treatment of epilepsy has diminished over the years and few use it today for this purpose. It remains, however, of interest due to its efficacy in humans, and the potential for sustained-release products to be marketed for dogs. Until then, prerequisites for successful therapy in dogs include: a motivated client who will be compliant with multiple daily dosing and willing to assume the financial burden of high dose phenytoin therapy and therapeutic drug monitoring expenses.

Although not commonly used, phenytoin has been employed as an oral or IV antiarrhythmic agent in both dogs and cats. It has been described as the drug of choice for digitalis-induced ventricular arrhythmias in dogs.
Phenytoin may have been studied as a treatment for ventricular dysrhythmias in horses and preliminary reports demonstrate efficacy (Wijnberg & Ververs 2004). It has been suggested that phenytoin be used as adjunctive treatment of hypoglycemia secondary to hyperinsulinism, but apparently, little clinical benefit has resulted from this therapy.

**Pharmacology/Actions**

The anticonvulsant actions of phenytoin are thought to be caused by the promotion of sodium efflux from neurons, thereby inhibiting the spread of seizure activity in the motor cortex. It is believed that excessive stimulation or environmental changes can alter the sodium gradient, which may lower the threshold for seizure spread. Hydantoins tend to stabilize this threshold and limit seizure propagation from epileptogenic foci.

The cardiac electrophysiologic effects of phenytoin are similar (not identical) to that of lidocaine (Group 1B). It depresses phase 0 slightly and can shorten the action potential. Its principle cardiac use is in the treatment of digitalis-induced ventricular arrhythmias.

Phenytoin can inhibit insulin and vasopressin (ADH) secretion.

**Pharmacokinetics**

After oral administration, phenytoin is nearly completely absorbed in humans, but in dogs, bioavailabilities may only be about 40%. Phenytoin is well distributed throughout the body and about 78% bound to plasma proteins in dogs (vs. 95% in humans). Protein binding may be reduced in uremic patients. Small amounts of phenytoin may be excreted into the milk and it readily crosses the placenta.

The drug is metabolized in the liver with much of the drug conjugated to a glucuronide form and then excreted by the kidneys. Phenytoin will induce hepatic microsomal enzymes, which may enhance the metabolism of itself and other drugs. The serum half-life (elimination) differences between various species are striking. Phenytoin has reported half-lives of 2–8 hours in dogs, 8 hours in horses, 15–24 hours in humans, and 42–108 hours in cats. Because of the pronounced induction of hepatic enzymes in dogs, phenytoin metabolism is increased with shorter half-lives within 7–9 days after starting treatment. Puppies possess smaller volumes of distribution and shorter elimination half-lives (1.6 hours) than adult dogs.

**Contraindications/Precautions/Warnings**

Some data suggest that additive hepatotoxicity may result if phenytoin is used with either primidone or phenobarbital. Weigh the potential risks versus the benefits before adding phenytoin to either of these drugs in dogs.

Phenytoin is contraindicated in patients known to be hypersensitive to it or other hydantoins. Intravenous use of the drug is contraindicated in patients with 2nd or 3rd degree heart block, sinoatrial block, Adams-Stokes syndrome, or sinus bradycardia.

**Adverse Effects**

Adverse effects in dogs associated with high serum levels include anorexia and vomiting, ataxia, and sedation. Liver function tests should be monitored in patients on chronic therapy as hepatotoxicity (elevated serum ALT, decreased serum albumin, hepatocellular hypertrophy and necrosis, hepatic lipidosis, and extrahepatic hematoipoiesis) have been reported. Gingival hyperplasia has been reported in dogs receiving chronic therapy. Oral absorption may be enhanced and GI upset decreased if given with food. Cats exhibit ataxia, sedation, and anorexia secondary to accumulation of phenytoin and high serum levels. Cats have also been reported to develop thrombocytopenia and a dermat atrophy syndrome secondary to phenytoin.

High plasma concentrations of phenytoin in horses can cause excitement and recumbency.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefits of therapy clearly outweighs the risks.)

Phenytoin is excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, consider whether to accept the risks, discontinue nursing or to discontinue the drug.

**Overdosage/Acute Toxicity**

Clinical signs of overdosage may include sedation, anorexia, and ataxia at lower levels, and coma, hypotension, and respiratory depression at higher levels. Treatment of overdoses in dogs is dependent on the severity of the clinical signs demonstrated, since dogs rapidly clear the drug. Severe intoxications should be handled supportively.

**Drug Interactions**

- **CHLORAMPHENICOL**: A case report of chloramphenicol increasing the serum half-life of phenytoin from 3 to 15 hours in a dog has been reported.

  - **LITHIUM**: The toxicity of lithium may be enhanced.

  - **MEPERIDINE**: Phenytoin may decrease the analgesic properties meperidine, but enhance its toxic effects.

  - **PHENOBARBITAL/PRIMIDONE**: The pharmacologic effects of primidone may be altered. Some data suggest that additive hepatotoxicity may result if phenytoin is used with either primidone or phenobarbital. Weigh the potential risks versus the benefits before adding phenytoin to either of these drugs in dogs.

  The following agents may increase the effects of phenytoin:

  - **ALLOPURINOL**
  - **CHLORAMPHENICOL**
  - **CHLORPHENIRAMINE**
  - **CIMETIDINE**
  - **DIAZEPAM**
  - **ETHANOL**
  - **ISONIAZID**

  - **PHENYL BUTAZONE**
  - **SALICYLATES**
  - **SULFONAMIDES**
  - **TRIMETHOPRIM**
  - **VALPROIC ACID**

  The following agents may decrease the pharmacologic activity of phenytoin:

  - **ANTACIDS**
  - **ANTINEOPLASTICS**
  - **BARBITURATES**
  - **CALCICUM (DIETARY AND GLUCONATE)**
  - **DIAZOXIDE**
  - **ENTERAL FEEDINGS**
  - **FOLIC ACID**
  - **NITROFURANTOIN**
  - **PYRIDOXINE**

Phenytoin may decrease the pharmacologic activity of the following agents:
Doses

**DOGS:**

For treatment of seizures:

- a) 15–40 mg/kg PO three times daily (Morgan 1988)
- b) 20–35 mg/kg three times daily (Bunch 1986)
- c) Initially, 8.8–17.6 mg/kg PO in divided doses, then gradually increase or decrease dose to maintain control. May take several days for seizure control to be attained. (Package insert; Dilantin® Veterinary—Parke-Davis)

(Plumb’s Note): Because of the extremely fast half-life of phenytoin in dogs, it is unlikely that this dosage regimen (“c”) will attain serum levels of 10–20 micrograms/mL which are thought to be necessary for adequate seizure control.

For treatment of ventricular arrhythmias:

- a) Up to 10 mg/kg IV in increments of 2–4 mg/kg or 20–35 mg/kg PO three times daily (Moses 1988)
- b) 10 mg/kg slowly IV; 30–50 mg/kg PO q4h (Ware 2003)

For treatment (or prophylaxis) of digitalis intoxication:

- a) 50 mg/kg PO q8h; long-term use may cause increases in serum alkaline phosphatase and increased hepatic cell size. (Kittleson 2006)

For treatment of hypoglycemia secondary to tumor:

- a) 6 mg/kg PO two to three times daily (Morgan 1988)

**CATS:**

- a) For treatment of ventricular arrhythmias: 2–3 mg/kg PO q24h (Wilcke 1985)
- b) For treatment of seizures: 2–3 mg/kg daily PO; 20 mg/kg per week (Bunch 1986)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)

- a) For seizures: 2.83–16.43 mg/kg PO q8h to obtain serum levels from 5–10 micrograms/mL. Suggest monitoring serum levels to adjust dosage. (Kowalczyk & Beech 1983)
- b) For digoxin induced arrhythmias: 10–22 mg/kg PO q12h. Adverse effects are muscle fasciculations and sedation. (Mogg 1999)
- c) For treatment of ventricular dysrhythmias: For persistent ventricular extra systoles or ventricular tachycardia where conventional treatment has failed: 20 mg/kg PO q12h initially for the first 3–4 doses, followed by a maintenance dose of 10–15 mg/kg PO q12h. Suggest monitoring plasma concentrations. (Wijnberg & Ververs 2004)

Monitoring

- Level of seizure control; sedation/ataxia
- Body weight (anorexia)
- Liver enzymes (if chronic therapy) and serum albumin
- Serum drug levels if signs of toxicity or lack of seizure control

Client Information

- Notify veterinarian if patient becomes anorectic, lethargic, ataxic, or seizures are not adequately controlled.
- The importance of regular dosing is imperative for successful therapy.

Chemistry/Synonyms

A hydantoin-derivative, phenytoin sodium occurs as a white, hygroscopic powder which is freely soluble in water and warm propylene glycol, and soluble in alcohol.

Because phenytoin sodium slowly undergoes partial hydrolysis in aqueous solutions to phenytoin (base) with the resultant solution becoming turbid, the commercial injection contains 40% propylene glycol and 10% alcohol. The pH of the injectable solution is approximately 12.

Phenytoin sodium is used in the commercially available capsules (both extended and prompt) and the injectable preparations. Phenytoin (base) is used in the oral tablets and suspensions. Each 100 mg of phenytoin sodium contains 92 mg of the base.

Phenytoin may also be known as: diphenylhydantoin, DPH, fenitoina, phenantoinum, or phenytoinum, **Dilantin®, and Phenytek®**.

Storage/Stability

Store capsules at room temperature (below 86°F) and protect from light and moisture. Store phenytoin sodium injection at room temperature and protect from freezing. If injection is frozen or refrigerated, a precipitate may form which should resolubolize when warmed. A slight yellowish color will not affect either potency or efficacy, but do not use precipitated solutions. Injectable solutions at less than a pH of 11.5 will precipitate.

Compatibility/Compounding Considerations

Phenytoin sodium injection is generally physically incompatible with most IV solutions (upon standing) and drugs. It has been successfully mixed with sodium bicarbonate and verapamil HCl.

Because an infusion of phenytoin sodium is sometimes desirable, several studies have been performed to determine whether such a procedure can be safely done. The general conclusions and recommendations of these studies are: 1) use either normal saline or lactated Ringer’s; 2) a concentration of 1 mg/mL phenytoin be used; 3) start infusion immediately and complete in a relatively short time; 4) use a 0.22 µm in-line IV filter; 5) watch the admixture carefully.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

- Phenytoin Sodium Extended-Release Capsules: 30 mg, 100 mg, 200 mg & 300 mg; **Dilantin Kapseals® (Pfizer); Phenytek® (Bertek); generic (Rx)**
- Phenytoin Oral Suspension: 25 mg/mL in 240 mL; **Dilantin-125® (Pfizer); generic; (Rx)**
- Phenytoin Tablets: 50 mg (chewable); **Dilantin® Info-Tabs (Pfizer); (Rx)**
- Phenytoin Sodium Injection: 50 mg/mL, (46 mg/mL phenytoin) in 2 mL & 10 mL; generic; (Rx)

References

PHEROMONES

| (for-mones) | Feliway®, D.A.P.® |

PHEROMONE BEHAVIOR MODIFIER

Prescriber Highlights

- Commercially available pheromones may be useful in Cats for urinating or spraying, vertical scratching, avoidance of social contact, loss of appetite, stressful situations, or inter-cat aggression.
- Dogs: Behaviors associated with fear or stress or for calming in new environments or situations; Horses: Alleviating stressful situations
- May need adjunctive therapy (behavior modification, drug therapy) for negative behaviors
- Dog/Cat products are administered via the environment; Equine product administered intranasally
- Appears to be safe

Uses/Indications

Pheromones may be useful adjuncts to reduce anxiety and stress. In cats, FFP may be useful in treating urinating or spraying, vertical scratching, avoidance of social contact, loss of appetite, stressful situations, or inter-cat aggression. Behavioral modification and/or concomitant drug therapy may be required.

In dogs, DAP may be useful in treating behaviors associated with fear or stress (e.g., separation anxiety, destruction, excessive barking, house soiling, licking, phobias) or calming animals in new environments or situations.

In horses, EAP may be useful in alleviating stressful situations (e.g., transport, shoeing, clipping, new environments, training).

Pharmacology/Actions

Appeasing pheromones produced during nursing are thought to exist with all mammals. They are detected by the Jacobson’s organ or vomero-nasal organ (VNO). The VNO is more sensitive in young animals, but is believed to continue to function in older animals as well. It is not well understood what neurotransmitters or neurochemical processes are involved for pheromones to exhibit their effects. In most animals, pheromones have a general calming effect. In cats, the F3 facial pheromone is thought to inhibit urine marking, encourage feeding, and enhance exploratory behaviors in unfamiliar situations. The F4 pheromone is a so-called allomarking pheromone that calms and familiarizes the cat with its surroundings.

Pharmacokinetics

No information located.

Contraindications/Precautions/Reproductive Safety

No information located.

Adverse Effects

No significant adverse effects were located for these products and are unlikely to occur.

Overdosage/Acute Toxicity

No specific animal toxicity data was located. Although the ingredients in these products are not thought toxic, the manufacturer recommends that humans accidentally exposed resulting in an adverse reaction should report to a physician or poison control center.

Drug Interactions

- None were located. Effects may be reduced or negated by concurrent use of drugs that cause CNS stimulation.

Laboratory Considerations

- No information was located.

Doses

**CATS:**
- a) Diffusers: Diffuser vial lasts approximately 4 weeks and covers 500-650 sq. ft. Plug diffuser into electric outlet in the room most often used by the animal. Do not cover diffuser or place behind or under furniture. When plugged in, do not touch diffuser with wet hands or metal objects. Do not touch diffuser with uncovered hands during, or immediately after use. May require up to 72 hours to saturate area, so effects may not be immediate. (Label Information; Feliway® Diffuser—VPL)
- b) Spray: Do not spray directly on cats. Pump spray approximately 4 inches from site, 8 inches from the floor. One spray per application site. Clean urine marks with clear water only. Urine marks and prominent objects (furniture, window or doorframes) should be sprayed 1–2 times daily for 30 days. If cat is observed rubbing its own facial pheromones onto a spot, treatment is no longer necessary at that location. Maintenance sprays every 2–3 days may be required. Inter-cat aggression problems may require behavior modification and concomitant drug therapy. (Label Information; Feliway® Spray—VPL)

**DOGS:**
- a) Diffusers: Diffuser vial lasts approximately 4 weeks and covers 500-650 sq. ft. Plug diffuser into electric outlet in the room most often used by the animal. Do not cover diffuser or place behind or under furniture. When plugged in, do not touch diffuser with wet hands or metal objects. Do not touch diffuser with uncovered hands during, or immediately after use. May require up to 72 hours to saturate area, so effects may not be immediate. (Label Information; D.A.P.® Diffuser—VPL)
- b) Spray: Do not spray directly on dogs. May spray in car, kennels, crates, carriers, or on neck bandanas. Spray approximately 20 minutes prior to travel, etc. When entering unfamiliar places/rooms, spray twice daily in the area. (Label Information; D.A.P.® Spray—VPL)

**HORSES:**
- a) Administer 2 sprays into each nostril ½ hour before anticipated stress or event. After administration, keep horse in a non-stressful environment for ½ hour to achieve best results. (Label Information; Modipher EQU® Spray—VPL)

Monitoring

- Clinical efficacy

Chemistry

- Administer two sprays of Feliway® (Felvawy) onto the dog's neck, using the D.A.P.® (Dog Appeasing Pheromone) product, or the EQU® (Equine Pheromone) product, as directed by the manufacturer.
Both sodium and potassium phosphate injections must be diluted before intravenous administration.

Doses

The following drug interactions have either been reported or are theoretical in humans or animals receiving phosphates and may be of significance in veterinary patients:

- Serum potassium should be monitored and treated if required.
- Patients developing hyperphosphatemia secondary to intravenous therapy with potassium phosphate should have the infusion stopped and be given appropriate parenteral calcium therapy to restore serum calcium levels.

Overdosage/Acute Toxicity

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in maternal milk. It is unlikely to be of concern.

For hypophosphatemia:

Contraindications:

- Hyperphosphatemia, hypocalcemia, oliguric renal failure, or if tissue necrosis is present; Potassium phosphate contraindicated if hyperkalemia present; sodium phosphate if hypernatremia present
- Caution: Cardiac (esp. if receiving digoxin) or renal disease
- Adverse Effects: Hyperphosphatemia, resulting in hypocalcemia, hypotension, renal failure or soft tissue mineralization; hyperkalemia or hypernatremia are possible
- Dilute before giving IV

Uses/Indications

Phosphate is useful in large volume parenteral fluids to correct or prevent hypophosphatemia when adequate oral phosphorous intake is not possible. Hypophosphatemia may cause hemolytic anemia, thrombocytopenia, neuromuscular and CNS disorders, bone and joint pain, and decompensation in patients with cirrhotic liver disease. There is some controversy whether “a low phos” indicates that treatment is necessary.

Pharmacology/Actions

Potassium salts (potassium phosphate) must be used very cautiously in patients on digitalis therapy and should not be used in digitalized patients with heart block.

Contraindications/Precautions/Warnings

Both potassium and sodium phosphate are contraindicated in patients with hyperphosphatemia, hypocalcemia, oliguric renal failure, or if tissue necrosis is present. Potassium phosphate is contraindicated in patients with hyperkalemia. It should be used with caution in patients with cardiac or renal disease. Particular caution should be used in using this drug in patients receiving digitalis therapy.

Adverse Effects

Overuse of parenteral phosphate can result in hyperphosphatemia, resulting in hypocalcemia (refer to the Overdose section for more information). Phosphate therapy can also result in hypotension, renal failure or soft tissue mineralization. Either hyperkalemia or hypernatremia may result in susceptible patients.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in maternal milk. It is unlikely to be of concern.

Overdosage/Acute Toxicity

Patients developing hyperphosphatemia secondary to intravenous therapy with potassium phosphate should have the infusion stopped and be given appropriate parenteral calcium therapy to restore serum calcium levels. Serum potassium should be monitored and treated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phosphates and may be of significance in veterinary patients:

-鋁製酸化物 (oral) and SEVELAMER: May reduce phosphorus levels
- ANGIOTENSIN CONVERTING ENZYME INHIBITORS (ACE Inhibitors): May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.
- DIGOXIN: Potassium salts (potassium phosphate) must be used very cautiously in patients on digitalis therapy and should not be used in digitalized patients with heart block
- POTASSIUM SPARING DIURETICS (e.g., spironolactone): May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.

Doses

Both sodium and potassium phosphate injections must be diluted before intravenous administration.

DOGS/CATS:

For hypophosphatemia:

- Dilute before giving IV
- May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.

Uses/Indications

Potassium salts (potassium phosphate) must be used very cautiously in patients on digitalis therapy and should not be used in digitalized patients with heart block.

Contraindications/Precautions/Warnings

Both potassium and sodium phosphate are contraindicated in patients with hyperphosphatemia, hypocalcemia, oliguric renal failure, or if tissue necrosis is present. Potassium phosphate is contraindicated in patients with hyperkalemia. It should be used with caution in patients with cardiac or renal disease. Particular caution should be used in using this drug in patients receiving digitalis therapy.

Adverse Effects

Overuse of parenteral phosphate can result in hyperphosphatemia, resulting in hypocalcemia (refer to the Overdose section for more information). Phosphate therapy can also result in hypotension, renal failure or soft tissue mineralization. Either hyperkalemia or hypernatremia may result in susceptible patients.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in maternal milk. It is unlikely to be of concern.

Overdosage/Acute Toxicity

Patients developing hyperphosphatemia secondary to intravenous therapy with potassium phosphate should have the infusion stopped and be given appropriate parenteral calcium therapy to restore serum calcium levels. Serum potassium should be monitored and treated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phosphates and may be of significance in veterinary patients:

-鋁製酸化物 (oral) and SEVELAMER: May reduce phosphorus levels
- ANGIOTENSIN CONVERTING ENZYME INHIBITORS (ACE Inhibitors): May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.
- DIGOXIN: Potassium salts (potassium phosphate) must be used very cautiously in patients on digitalis therapy and should not be used in digitalized patients with heart block
- POTASSIUM SPARING DIURETICS (e.g., spironolactone): May cause potassium retention. When used with potassium products such as potassium phosphate, hyperkalemia can result.

Doses

Both sodium and potassium phosphate injections must be diluted before intravenous administration.

DOGS/CATS:

For hypophosphatemia:
a) The treatment of hypophosphatemia is to maintain serum levels above 2 mg/dL. For mild to moderate hypophosphatemia, oral supplementation in the form of sodium phosphate or potassium phosphate can be administered. Treatment with intravenous supplementation should begin when levels are less than 1.5 mg/dL or if clinical symptoms are present. Intravenous administration of potassium phosphate is recommended at 0.01–0.06 mmol/kg/hr IV mixed in saline or dextrose. Serum phosphate levels should be monitored every 4–6 hours. Once levels exceed 2–2.5 mg/dL, the patient may be maintained on oral phosphorus supplementation. (Schrupp & Kovacic 2007)

b) For hypophosphatemia associated with diabetic ketoacidosis: Phosphorus can be added to IV fluids in the form of potassium phosphate. Dosing ranges from 0.03–0.12 mmol/kg/hour are added to the IV fluids. Alternatively, ½–⅓ of the calculated dose of potassium supplementation can be added as potassium phosphate, with KCl used for the remainder. (O’Brien 2010)
c) Correct underlying cause if possible. If serum phosphorus concentration is >1.5 mg/dL and unlikely to decrease further, no treatment is usually necessary. If <1.5 mg/dL, clinical signs or hemolysis present, treat. Also, consider treating during the first 24 hours of therapy for DKA. Goal of therapy is to maintain serum phosphorus >2 mg/dL without causing hyperphosphatemia. Oral phosphate supplementation is preferred; either a buffered phosphate laxative (e.g., Phospho-Soda), balanced commercial diet or milk. Severe hypophosphatemia is treated with intravenous therapy: Using either potassium phosphate (3 mEq phosphate/mL and 4.4 mEq potassium/mL) or sodium phosphate (if potassium supplementation is contraindicated, 2 mEq phosphate/mL and 4 mEq sodium/mL), give 0.01–0.03 mmol/kg/hr preferably by CRI. Avoid hyperphosphatemia. Monitor serum phosphorus every 6–8 hours and adjust dose. (Nelson & Elliott 2003)
d) In treating diabetic ketoacidosis, the IV potassium should be administered as potassium phosphate, particularly in small dogs and cats who are most susceptible to hemolysis caused by hypophosphatemia. Use caution as over supplementation of phosphorus can result in metastatic calcification and hypercalcemia. (Greco 2007)
e) Cats with DKA and a serum phosphorus of <2 mg/dL: CRI of potassium phosphate at 0.03–0.06 mmol/kg/hr; severe cases of hypophosphatemia (<1 mg/dL) may require doses as high as 0.12–0.2 mmol/kg/hr. Recheck phosphorus after 6–12 hours. Alternatively may provide half the potassium requirements as KCl and half as K Phos. (Wakill 2007)

**MUSCULANTS:**

For hypophosphatemia:

a) Oral phosphate is the preferred method of administration in ruminants with rumen motility. Recommended dose is: 200 grams of feed grade monosodium phosphate (contains 50 grams of phosphate) administered in gelatin boluses, drench, or by ororeuminal intubation. Almost all commercially available intravenous solutions use phosphate or phosphate salts as the source of phosphorus because these salts are very soluble, even in the presence of calcium and magnesium, but the phosphorus in phosphate and hypophosphate is unavailable to ruminants, meaning that the vast majority of “phosphate” containing solutions have no efficacy in treating hypophosphatemia. Instead, the monobasic monophosphate form of sodium phosphate (NaH₂PO₄) should be administered. The pH of the solution should be mildly acidic (pH=5.8) to maintain phosphate solubility in cold weather, but is not needed in warm ambient temperatures. A recommended treatment to adult cattle with severe hypophosphatemia is 300 mL of 10% NaH₂PO₄ (monohydrate) solution by slow IV injection, this provides 7 grams of phosphate and increases plasma phosphate concentrations for at least 6 hours (the calculated phosphorus deficit in adult cattle is approximately 5 grams phosphate). A major drawback with IV administration of phosphate solutions is that they should not be administered within 2 hours of intravenous calcium administration because of concerns that calcium-phosphate precipitates may be formed in the plasma of cattle with treatment-induced hypercalcemia and hyperphosphatemia. (Constable 2008)

**Monitoring**

- Serum inorganic phosphate (phosphorus)
- Other electrolytes, including calcium

**Chemistry**

Potassium phosphate injection is a combination of 224 mg monobasic potassium phosphate and 236 mg dibasic potassium phosphate. The pH of the injection is 6.5 and has an osmolality of 7357 mOsm/L. Sodium phosphate injection is a combination of 276 mg monobasic sodium phosphate and 142 mg dibasic sodium phosphate. The pH of the injection is 5.7 and has an osmolality of about 7000 mOsm/L.

Because commercial preparations are a combination of monobasic and dibasic forms, prescribe and dispense in terms of mMoles of phosphate.

**Storage/Stability**

Unless otherwise instructed by the manufacturer, store potassium or sodium phosphate injection at room temperature; protect from freezing.

**Compatibility/Compounding Considerations**

Phosphates may be physically incompatible with metals such as calcium and magnesium.

Potassium phosphate injection is reportedly physically compatible with the following intravenous solutions and drugs: amino acids 4%/dextrose 25%, D10LRS, D10Ringer’s, Dextrose 2.5%–10% injection, sodium chloride 0.45%–0.9%, magnesium sulfate, metoclopramide HCl, and verapamil HCl.

Potassium phosphate injection is reportedly physically incompatible with the following solutions or drugs: D2.5 in half normal Ringer’s or LRS, D5 in Ringer’s, D10/sodium chloride 0.9%, Ringer’s injection, LRS, and dobutamine HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Potassium Phosphate Injection; each mL provides 3 mM of phosphate (93 mg/dL of phosphorous) and 4 mEq of sodium per mL in 10, 15, 30, and 50 mL vials; generic; (Rx)

Potassium Phosphate Injection; each mL provides 3 mM of phosphate (99.1 mg/dL of phosphorous) and 4.4 mEq of potassium per mL in 5, 10, 15, 30, and 50 mL vials; generic; (Rx)

HUMAN-LABELED PRODUCTS:

- Sodium Phosphate Injection; each mL provides 3 mM of phosphate (93 mg/dL of phosphorous) and 4 mEq of sodium per mL in 10, 15, 30, and 50 mL vials; generic; (Rx)

**REFERENCES**

[Schropp & Kovacic 2007]

**USP**

**PHYSOSTIGMINE SALICYLATE**

- **Stabilizer:** 0.1% benzyl alcohol
- **Solution:** 1:200,000

**CHOLINESTERASE INHIBITOR**

**Prescriber Highlights**

- Cholinesterase inhibitor that may be used for the adjunctive treatment of ivetmercin toxicity in dogs, as a provocative agent for the diagnosis of narcolepsy in dogs & horses, or as a treatment for anticholinergic toxicity
- Crosses into the CNS, so it is effective for treating central anticholinergic toxicity, but also increases the risks for central physostigmine toxic effects (e.g., seizures)
- Must be administered with direct patient supervision; toxic effects from this drug can be serious

**USES/INDICATIONS**

Physothigmine has been used for the adjunctive treatment of ivetmercin toxicity in dogs, as a provocative agent for the diagnosis of narcolepsy in dogs and horses, and as a treatment for anticholinergic toxicity. Because of
Physostigmine reversibly inhibits the destruction of acetylcholine by acetylcholinesterase, thereby increasing acetylcholine at receptor sites. Because physostigmine is a tertiary amine, unlike the quaternary amine neostigmine and pyridostigmine, it crosses the blood-brain barrier and inhibits acetylcholinesterase both centrally and peripherally. Pharmacologic effects include miosis, bronchial constriction, hypersalivation, muscle weakness, and sweating (in species with sweat glands). At higher dosages, cholinergic crisis can occur; seizures, bradycardia, tachycardia, asystole, nausea, vomiting, diarrhea, depolarizing neuromuscular block, pulmonary edema, and respiratory paralysis are possible.

Overdosage/Acute Toxicity
Overdoses or acute toxicity can be life-threatening (see Adverse Reactions), however, because of the short duration of effect, supportive care may be all that is required. Treatment of serious acute toxicity includes mechanical ventilation, repeated bronchial aspiration, and administration of IV atropine. Refer to the Atropine monograph for dosages for cholinergic toxicity. Readministration of atropine may be required. Pralidoxime (2-PAM) may be useful in reversing the ganglionic and skeletal muscle effects of physostigmine. Refer to the Pralidoxime monograph for more information. An animal poison control center may be helpful in assisting with monitoring.

Little information is available, but it would be expected that physostigmine would cross the placenta. Teratogenic effects (behavioral, biochemical and metabolic) have reportedly been observed in mice studies. Weigh the potential risks of using physostigmine during pregnancy versus its potential benefits. In humans, the FDA categorizes alendronate as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is not known if physostigmine enters milk, but it would unlikely pose much risk to nursing offspring.

PHARMACOLOGY/ACCTIONS
Physostigmine salicylate is made from an extract of Physostigma venenosum (Calabar Bean) seeds. It occurs as white, shining, odorless, crystals or crystalline powder. Upon exposure to heat, light, air, or exposure to traces of metals for a long period, it develops a red tint. One gram is soluble in 75 mL of water and 16 mL of alcohol. The injection has a pH of 3.5–5.

Physostigmine salicylate may also be known as eserine salicylate, physostigmine monosalicylate and Anticholin®.

Storage/Stability
This medication must be administered in a setting where direct veterinary supervision is available.

Chemistry/Synonyms
Physostigmine salicylate is made from an extract of Physostigma venenosum (Calabar Bean) seeds. It occurs as white, shining, odorless, crystals or crystalline powder. Upon exposure to heat, light, air, or exposure to traces of metals for a long period, it develops a red tint. One gram is soluble in 75 mL of water and 16 mL of alcohol. The injection has a pH of 3.5–5.

Physostigmine salicylate may also be known as eserine salicylate, physostigmine monosalicylate and Anticholin®.
Compatibility/Compounding Considerations

Phytonadione is labeled for human use to be administered IV undiluted. It may be given via a Y-site or stopcock port on IV set, but it should not be added to IV solutions. IM dosing (although not FDA-approved) is not uncommon in humans.

Dosage Forms/Regulatory Status

THE ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

References

Mayo Clinic 92: 227–228.

Equine Internal Medicine, 2nd Ed

Sreed, L. (2003). "Narcolepsy/Cataplexy." Equine Internal Medicine, 2nd Ed

Physostigmine is absorbed from the GI tract in monogastric animals via the intestinal lymphatics, but only in the presence of bile salts. Oral absorption of phytonadione may be significantly enhanced by administration with fatty foods. The relative bioavailability of the drug is increased 4–5 times in dogs given canned dog food with the dose. After oral administration, increasing in clotting factors may not occur until 6–12 hours later. In humans, oral administration may be more rapidly absorbed than with SC administration.

Phytonadione may concentrate in the liver for a short period of time, but is not appreciably stored in the liver or other tissues. Only small amounts are distributed across the placenta in pregnant animals. Exogenously administered phytonadione enters milk. The elimination of Vitamin K1 is not well understood.

Contraindications/Precautions/Warnings

Many veterinary clinicians state that the intravenous use of phytonadione is contraindicated because of increased risk of anaphylaxis development, and while intravenous phytonadione is used in human medicine and several intravenous dosage regimens are outlined below in the Dosage section, the FDA-CVM has warned to avoid administering the drug IV. However, in human medicine, intravenous phytonadione is recommended (with caution) for severe bleeding associated with very high INR. Phytonadione is contraindicated in patients hypersensitive to it or any component of its formulation.

Vitamin K does not correct hypoprothrombinemia due to hepatocellular damage.

Adverse Effects

Anaphylactoid reactions have been reported following IV administration of Vitamin K1; use with extreme caution (See Contraindications above). Intramuscular administration may result in acute bleeding from the site of injection during the early stages of treatment. Small gauge needles are recommended for use when injecting SC or IM. Subcutaneous injections or oral dosages may be slowly or poorly absorbed in hypovolemic animals.

Because 6–12 hours may be required for new clotting factors to be synthesized after phytonadione administration, emergency needs for clotting factors must be provided by giving blood products.

Reproductive/Nursing Safety

Phytonadione crosses the placenta only in small amounts, but its safety has not been documented in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Vitamin K is excreted in maternal milk, but is unlikely to have negative effects in nursing offspring.

Overdosage/Acute Toxicity

Phytonadione is relatively non-toxic, and it would be unlikely that toxic clinical signs would result after a single overdose. However, refer to the Adverse Effects section for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving phytonadione and may be of significance in veterinary patients:

- **ANTIBIOTICS, ORAL:** Although chronic antibiotic therapy should have no significant effect on the absorption of phytonadione, these drugs may decrease the numbers of vitamin K producing bacteria in the gut

- **MINERAL OIL:** Concomitant administration of oral mineral oil may reduce the absorption of oral vitamin K.

- **WARFARIN:** As would be expected, phytonadione antagonizes the anticoagulant effects of coumarin (and indandione agents. There are many drugs that may prolong or enhance the effects of anticoagulants and
Because most veterinarians clinically state that phytonadione is contraindicated for intravenous use; consult specialized references or a hospital pharmacist for more specific information on compatibility of phytonadione with other products. Well-closed, light-resistant containers should be used. Phytonadione should be protected from light at all times, as it is quite sensitive to light. If used as an intravenous infusion, the container should be wrapped with an opaque material. Tablets and capsules should be stored in well-closed, light-resistant containers.

**Chemistry/Synonyms**

A naphthoquinone derivative identical to naturally occurring vitamin K1, phytonadione occurs as a clear, yellow to amber, viscous liquid. It is insoluble in water, slightly soluble in alcohol and soluble in lipids.

**Doses**

**DOGS/CATS:**

For anticoagulant rodenticide toxicity:

- a) Initially 0.5–2.5 mg/kg IV in D5W at a rate of 10 mg/minute. Subsequent doses may be given IM or SC. Second generation agents may require 3–4 weeks of treatment. (Bailey 1986)

- b) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D5W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

- c) For acute hypoprothrombinemia with hemorrhage: 0.5–2.5 mg/kg IV, not to exceed 10 mg/minute in mature animals and 5 mg/minute in newborn and very young animals.

For anticoagulant rodenticide or if the anticoagulant is unknown, treatment should be instituted for at least 30 days. Absorption is enhanced when a fatty meal is fed at the same time the dose is given. In all patients, check the PT or PIVKA 48 hours after stopping phytonadione therapy, and if the test result is prolonged, continue treatment for another week. Again, a patient must be tested for adequate clotting 48 hours after phytonadione has been discontinued. (Merola 2002)

**RABBITS, RODENTS, SMALL MAMMALS:**

- a) Stabilize the animal if clinical signs are evident. Decontaminations with whole blood or plasma may be necessary to replace clotting factors. Decontamination is only effective early; do not attempt to induce emesis in rodents, rabbits, or birds. 3% hydrogen peroxide is an effective emetic for ferrets. Following its use, the mouth could be gently rinsed with water to dilute the remaining peroxide. (An option would be amophosphate 5 mg/kg SC; however, adverse effects include sedation or hyperexcitability.) Activated charcoal (1–3 grams/kg body weight) effectively adsorbs anticoagulants and can facilitate excretion via the feces. Injectable forms of phytonadione can be given PO at 5 mg/kg/day divided q8-12h. Give with a fatty meal, such as peanut butter, to enhance absorption. Phytonadione should not be given IV; SC administration can cause anaphylaxis. (Richardson & Gwaltney-Brant 2002)

- b) In symptomatic patients, give a loading dose of 2.5–5 mg/kg PO. In cases of large ingestions, begin phytonadione therapy at 3–5 mg/kg PO divided twice daily. Treat pocket pets at the high end of this dosage range. SC dosing may be required in vomiting or anorectic patients or pocket pets, but PO is preferred. For first-generation anticoagulants, treatment with phytonadione for 14 days is usually sufficient. For a second-generation anticoagulant or if the anticoagulant is unknown, treatment should be instituted for at least 30 days. Absorption is enhanced when a fatty meal is fed at the same time the dose is given. In all patients, check the PT or PIVKA 48 hours after stopping phytonadione therapy, and if the test result is prolonged, continue treatment for another week. Again, a patient must be tested for adequate clotting 48 hours after phytonadione has been discontinued. (Merola 2002)

**CATTLE:**

For anticoagulant rodenticide toxicity:

- a) For the exposed but non-bleeding patient, inducing emesis along with repeated doses of activated charcoal and cathartic will help reduce further absorption of the rodenticide. If the exposure dose is high enough, phytonadione at 1.25–2.5 mg/kg PO twice daily with a fatty meal for 2–4 weeks. Only give SC with starting dose if patient is vomiting or activated charcoal was administered. In the bleeding patient, decontamination procedures are generally not worthwhile due to time delay between ingestion and onset of bleeding. When clotting times are prolonged, plasma transfusions are a necessity. Blood transfusions may be necessary if the patient is severely anemic. Phytonadione at 2.5 mg/kg PO twice daily with a fatty meal should be administered for a minimum of 4 weeks. Other supportive measures may include broad-spectrum antibiotics, oxygen therapy and exercise restriction. Removing free blood from the thoracic cavity should only be performed when respiratory function is severely compromised. It is recommended that clotting times be re-examined 2–3 days following cessation of phytonadione therapy. (Talcott 2008)

- b) In symptomatic patients, give a loading dose of 2.5–5 mg/kg PO. In cases of large ingestions, begin phytonadione therapy at 3–5 mg/kg PO divided twice daily. Treat pocket pets at the high end of this dosage range. SC dosing may be required in vomiting or anorectic patients or pocket pets, but PO is preferred. For first-generation anticoagulants, treatment with phytonadione for 14 days is usually sufficient. For a second-generation anticoagulant or if the anticoagulant is unknown, treatment should be instituted for at least 30 days. Absorption is enhanced when a fatty meal is fed at the same time the dose is given. In all patients, check the PT or PIVKA 48 hours after stopping phytonadione therapy, and if the test result is prolonged, continue treatment for another week. Again, a patient must be tested for adequate clotting 48 hours after phytonadione has been discontinued. (Merola 2002)

**HORSES:**

For warfarin (or related compounds) toxicity:

- a) 500 mg SC q4–6h until one-stage prothrombin time (OSPT) returns to normal control values. Whole blood or fresh plasma may also be necessary early in the course of treatment. (Byars 1987)

- b) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D5W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

**SWINE:**

For warfarin (or related compounds) toxicity:

- a) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D5W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

**SHEEP & GOATS:**

For warfarin (or related compounds) toxicity:

- a) 0.5–2.5 mg/kg IM, if IV use is necessary (avoid if possible), dilute in saline or D5W/saline and give very slowly (not to exceed 5 mg/minute). (Upson 1988)

**BIRDS:**

For hemorrhagic disorders:

- a) 0.25–0.5 mL/kg IM of the 10 mg/mL injectable product. Commonly used before surgery where hemorrhage is anticipated. (McDonald 1989)

- b) 0.2–2.5 mg/kg IM as needed; usually only 1–2 injections are required. May also be used prophylactically when amprolium and sulfas are administered. (Clubb 1986)

**Monitoring**

- Clinical efficacy (lack of hemorrhage)

- One-stage prothrombin time (OSPT); INR

**Client Information**

- Because it may take several weeks to eliminate some of the anticoagulant rodenticides from the body, clients must be counseled on the importance of continuing to administer the drug (phytonadione) for as long as instructed or renewed bleeding may occur.

- Unless otherwise instructed, oral phytonadione should be administered with food, preferably foods high in fat content.

- During therapy, animals should be kept quiet whether at home or hospitalized.

**Chemistry/Synonyms**

Phytonadione is a yellow to amber, viscous liquid. It is insoluble in water, slightly soluble in alcohol and soluble in lipids. Phytonadione may also be known as: methylphytylnaphthoquinone, phyloquinone, phytonemadione, phytonemalide, vitamin K1, AntiThe®, GlaSyl®, Aqua-Mephyton®, K1®, K-Chapt®, K-Chew®, K-Jec®, K-P®, Kanakion®, Kanavit®, Kaytwo® sp., Melilotus® spp.) or lespedeza (Lespedeza sp.) toxicity:

- a) 1–1.5 mg/kg SC for several days, remove from source, avoid stress/injury. (Oehme 2009)

- b) Stabilize the animal if clinical signs are evident. Decontaminations with whole blood or plasma may be necessary to replace clotting factors. Decontamination is only effective early; do not attempt to induce emesis in rodents, rabbits, or birds. 3% hydrogen peroxide is an effective emetic for ferrets. Following its use, the mouth could be gently rinsed with water to dilute the remaining peroxide. (An option would be amophosphate 5 mg/kg SC; however, adverse effects include sedation or hyperexcitability.) Activated charcoal (1–3 grams/kg body weight) effectively adsorbs anticoagulants and can facilitate excretion via the feces. Injectable forms of phytonadione can be given PO at 5 mg/kg/day divided q8-12h. Give with a fatty meal, such as peanut butter, to enhance absorption. Phytonadione should not be given IV; SC administration can cause anaphylaxis. (Richardson & Gwaltney-Brant 2002)

**Storage/ Stability**

Phytonadione should be protected from light at all times, as it is quite sensitive to light. If used as an intravenous infusion, the container should be wrapped with an opaque material. Tablets and capsules should be stored in well-closed, light-resistant containers.

**Compatibility/Compounding Considerations**

Because most veterinarians clinically state that phytonadione is contraindicated for intravenous use; consult specialized references or a hospital pharmacist for more specific information on compatibilities of phytonadione with other products.
Phytonadione (Vitamin K1) is used to treat dogs with congestive heart failure (CHF) secondary to dilated cardiomyopathy (DCM) or chronic mitral valve insufficiency (CMVI), myxomatous/degenerative mitral valve disease (MMVD, DMVD). Two recent studies (Haggström et al. 2008; Lombard, C.W. et al. 2006) have shown that in dogs with MMVD and heart failure pimobendan can improve survival times and quality of life when compared with standard treatment consisting of an ACE inhibitor and furosemide. A study done in Doberman Pinschers concluded that pimobendan should be used as first-line therapy in Doberman Pinschers for the treatment of CHF caused by DCM (O’Grady, M. et al. 2008). Pimobendan has been shown that it may be viable as a first-line or adjunctive treatment option for dogs with PHT secondary to mitral valve disease (Atkinson et al. 2009). In the 2009 ACVIM Consensus Statement: Guidelines for the Diagnosis and Treatment of Canine Chronic Valvular Heart Disease (Atkins et al. 2009) the panel recommended to incorporate pimobendan (0.25–0.3 mg/kg PO q12h) in the acute and chronic treatment of stage C heart failure (Patients have a structural abnormality and current or previous clinical signs of heart failure caused by CVD). Ongoing studies may help determine if pimobendan should be used in the occult or preclinical stage of heart failure, or if additional significant benefit occurs when used concurrently with an ACE inhibitor.

While pimobendan is not FDA-approved for use in cats, there is anecdotal evidence for use in restricted and dilated cardiomyopathy. One small (11 cats) case series has been reported. However, since cats with heart failure commonly have hypertrophic cardiomyopathy and positive inotropic therapy is generally contraindicated, it probably has a limited role in cats (Cote 2008).

Pharmacology/Actions 
Pimobendan is a so-called inodilator; it has both inotropic and vasodilator effects. Pimobendan usually decreases heart rate (negative chronotrope) in animals with CHF. Its isotropic effects occur via inhibition of phosphodiesterase III (PDE-III) and by increasing intracellular calcium sensitivity in the cardiac contractility apparatus. Cardiac contractility is enhanced without an increase in myocardial oxygen consumption, as pimobendan does not increase intracellular calcium levels. Commercially available pimobendan is a 50:50 mixture of l- and d-isomers. In dogs, the d-isomer of pimobendan has about 1.5X greater isotropic activity than the d-isomer. Pimobendan’s vasodilator effects are via vascular PDE-III inhibition and both arterial and venous dilation occur. Pimobendan also possesses antithrombotic activity.

Pharmacokinetics 
In dogs, following a single oral administration of 0.25 mg/kg pimobendan peak levels of the parent compound and the active metabolite were observed 1–4 hours post-dose (mean: 2 and 3 hours, respectively). Food decreased the bioavailability of an aqueous solution of pimobendan, but the effect of food on the absorption of pimobendan from chewable tablets is unknown. The steady-state volume of distribution of pimobendan is 2.6 L/kg. Protein binding of pimobendan and the active metabolite in dog plasma is >90%. Pimobendan is oxidatively demethylated to a pharmaco logically active metabolite that is then conjugated with sulfate or glucuronic acid and excreted mainly via feces. Clearance of pimobendan is approximately 90 mL/min/kg, and the terminal elimination half-lives of pimobendan and the active metabolite are approximately 0.5 hours and 2 hours, respectively. Plasma levels of pimobendan and the active metabolite were below quantifiable levels by 4 and 8 hours respectively after oral administration.

In humans with heart failure, pimobendan is rapidly absorbed with peak levels occurring in less than one hour after dosing. The volume of distribution was about 3.2 L/kg; clearance about 25 mL/min/kg. Terminal half-life is slightly less than 3 hours.

Contraindications/Precautions/Warnings 
Pimobendan is contraindicated in animals hypersensitive to it, with hypertrophic cardiomyopathy, aortic stenosis, or any other condition where an augmentation of cardiac output is inappropriate for functional or anatomic reasons. It should be used with caution in patients with uncontrolled cardiac arrhythmias.

The label states the drug has not been evaluated in dogs younger than 6 months of age, dogs with congenital heart defects, diabetes mellitus or other serious metabolic diseases, dogs used for breeding, or pregnant or lactating bitches.

Adverse Effects 
The primary adverse effects that have been noted in dogs are gastrointestinal effects. There is some evidence that pimobendan may increase the development of arrhythmias. Atrial fibrillation or increased ventricular ectopic beats have been reported in dogs on pimobendan, but it is not known this cause arrhythmia, a causative effect has not been fully established. A trial of pimobendan in humans with heart failure demonstrated an increased mortality rate while on the drug, but this result has not been duplicated in canine studies. In studies field trial (56 day) done in dogs, the adverse effect incidence (at least one occurrence reported per dog) was poorly tolerated (38%), lethargy (33%), diarrhea (30%), dyspnea (29%), anorexia (14%), weakness and ataxia (13%), pleural effusion (10%), syncope (9%), cough (7%), sudden death (6%), ascites (6%), and heart murmur (3%). As experience with the drug continues, a more detailed adverse effect profile will be developed.

In a study comparing canine adverse effects of pimobendan with benzamipril (Chetboul et al. 2007), dogs with mitral valve regurgitation had increases in systolic function but also developed worsening mitral valve disease and specific mitral valve lesions (acute hemorrhages, endocardial papillary hyperplasia on the dorsal surfaces of the leaflets, and infiltration of chordae tendineae by glycosaminoglycans) not seen in the beagel group. The authors recommend that patients with mitral valve disease that are treated chronically with pimobendan be regularly and cautiously examined for any worsening of mitral valve lesions and regurgitation.

Reproductive/Nursing Safety 
The label states the drug has not been evaluated in dogs used for breeding, or pregnant or lactating bitches. When pimobendan was given in high dosages (300 mg/kg) to pregnant laboratory animals, increased resorptions occurred. Rabbits given 100 mg/kg showed no adverse fetal effects.

No information on the safety of pimobendan during nursing was located.
HUMAN-LABELED PRODUCTS:

Pimobendan Chewable Tablets: 1.25 mg, 2.5 mg and 5 mg:

- Unless otherwise labeled, pimobendan chewable tablets or capsules should be stored at room temperature below 25°C (77°F) in a dry place.

Storage/Stability

Pimobendan's chemical name is: 4,5-Dihydro-6-[(2-(p-methoxyphenyl)-5-benzimidazolyl)-5-methyl-3(2H)pyridazinone. It has a molecular weight of 334.4.

Client Information

- Give medication approximately one hour before feeding.
- Dosage may depend on the concentration in the product being used. Give 0.2–0.6 mg/kg PO divided q12h (U.K. Label directions; Vetmedin®; Bl; 2003)
- As an adjunctive drug for the emergency treatment of CHF (if the case is not overtly critical and a strong positive oral inotrope is needed): 0.1–0.3 mg/kg PO q12h. (Erling & Mazzaferro 2008)
- For adjunctive treatment of severe and chronic stage D heart failure (patients have clinical signs of failure refractory to standard treatment for Stage C heart failure from CVHD (chronic valvular heart disease)): No consensus was reached by the panel regarding the following, but some panelists increase the pimobendan dose to 0.3 mg/kg PO to three times daily. Because this dosage recommendation is outside of the FDA-approved labeling for pimobendan, the use of the drug should be explained to, and approved by the client. (Atkins et al. 2009)

CATS:

- For management of myocardial failure (DCM), especially if the DCM is not associated with taurine deficiency: However, because this is a relatively rare condition in cats, there is little information about clinical efficacy. Additionally, the manufacturers have not conducted any trials in cats to determine efficacy or safety, but there do not appear to be any obvious safety concerns. The dose of pimobendan in cats is 1.25–1.5 mg/cat PO q12hrs. (Rishniw 2005)

Monitoring

- Cardiovascular parameters used to monitor heart function, including ECG (rate/rhythm), blood pressure, echo studies, clinical signs, etc.

Chemistry/Synonyms

A benzimidazole-derivative phosphodiesterase inhibitor, pimobendan occurs as a white or slightly yellowish, hygroscopic powder. It is practically insoluble in water and slightly soluble in aceton or methyl alcohol.

Pimobendan’s chemical name is: 4,5-Dihydro-6-[2-(p-methoxyphenyl)-5-benzimidazolyl]-5-methyl-3(2H)pyridazine. It has a molecular weight of 334.4.

Pimobendan may also be known as: UDCG-115, Acarbo®, and Vetmedin®.

Storage/Stability

Unless otherwise labeled, pimobendan chewable tablets or capsules should be stored at room temperature below 25°C (77°F) in a dry place.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Pimobendan Chewable Tablets: 1.25 mg, 2.5 mg and 5 mg: Vetmedin® (B-I); (Rx). FDA-approved for use in dogs.

HUMAN-LABELED PRODUCTS: None

Piperacillin SODIUM

Also available with a beta-lactamase inhibitor (tazobactam); see the next monograph

PIPERACILLIN SODIUM

(Piperacillin/tazobactam) Pipercillin®

EXTENDED SPECTRUM PENICILLIN

Prescriber Highlights

- Extended-action penicillin, with good gram-negative spectrum, including many strains of Pseudomonas
- Limited experience in veterinary medicine, but appears quite safe
- Also available with a beta-lactamase inhibitor (tazobactam); see the next monograph
Labs

Laboratory Considerations

A. glucose determinations (using cupric sulfate solution): Piperacillin will give false-positive results, but these tests utilizing glucose oxidase (Fehling’s, Clinistix®) are not affected by piperacillin.

Aminoacylase assay: A high percentage of penicillins can inactivate aminoacylase (in vivo and in vitro) in patients in renal failure or when penicillins are used in massive dosages, serum concentrations of aminoacylase may be falsely decreased if the patient is also receiving beta-lactam antibiotics. The serum is stored prior to analysis. This potential “beneficial” interaction requires further investigation before dosing recommendations can be made for veterinary patients.

B. Proteinuria: may be affected by high levels of penicillins in the urine.

Uses/Indications

Although veterinary experience is limited with piperacillin or piperacillin/tazobactam, these drugs have expanded coverage against many bacteria and may be suitable for empiric use until culture and susceptibility data are available, or for surgical prophylaxis when gram-negative or mixed aerobic/anaerobic infections are concerns.

Pharmacology/Actions

Piperacillin is a bactericidal, extended-action acylaminopenicillin that inhibits septum formation and cell wall synthesis in susceptible bacteria. It has a wide spectrum of activity against many aerobic and anaerobic gram-positive (including many enterococci) and gram-negative bacteria. It has a similar spectrum of activity as the aminopenicillins, but with additional activity against several gram-negative organisms of the Enterobacteriaceae, including many strains of Pseudomonas aeruginosa. Like the aminopenicillins, it is susceptible to inactivation by beta-lactamases. The addition of a beta-lactamase inhibitor (tazobactam) in the product Zosyn® (see next monograph), increases piperacillin’s spectrum of activity against many beta lactamase producing strains of bacteria.

Pharmacokinetics

Limited information is available for veterinary species. In mares, piperacillin has an elimination half-life of about 7 hours. IM bioavailability is 86% and protein binding about 19%.

In humans, piperacillin is not appreciably absorbed from the gut so it must be administered parenterally. After IM administration peak levels occur in about 30 minutes. The drug exhibits low protein binding and has a volume of distribution of 0.1L/kg. It is widely distributed into many tissues and fluids including lung, gallbladder, intestinal mucosa, uterus, bile, and interstitial fluid. With inflamed meninges, piperacillin levels in the CSF are approximately 30% those in serum. If meninges are normal, CSF concentrations are only about 6% of serum levels. Piperacillin crosses the placenta and is distributed into milk in low concentrations. Piperacillin is metabolized somewhat in the liver to a desethyl metabolite that has only minimal antibacterial activity. Piperacillin is primarily (68%) eliminated unchanged in the urine via active tubular secretion and glomerular filtration; it is also excreted in the bile. Elimination half-life in humans is approximately one hour.

Contraindications/Precautions/Warnings

Piperacillin should not be used in patients with documented hypersensitive reactions to a beta-lactam.

Because of sodium content, high dosages of piperacillin may adversely affect patients with cardiac failure or hypernatremic conditions.

Dosage adjustment may be required in patients with significantly decreased renal function (CrCl <40 mL/min).

Because of sodium content, high dosages of piperacillin may adversely affect patients with cardiac failure or hypernatremic conditions.

Adverse Effects

Piperacillin is generally well tolerated. Hypersensitivity reactions are possible. Local effects (thrombophlebitis, etc.) associated with intravenous injection or pain after IM injection may occur. Alterations in gut flora may lead to antibiotic-associated diarrhea.

In humans, piperacillin has caused coagulation abnormalities on occasion, particularly in patients with renal failure. Very high doses may cause neurotoxicity (seizures); again, these are more likely in patients with diminished renal function. Superinfections with Clostridium difficile have been reported rarely.

Overdosage/Acute Toxicity

Single overdoses are unlikely to pose much risk although very large overdoses may cause vomiting, diarrhea, or neurotoxicity. Dogs receiving up to 800 mg/kg/day of piperacillin/tazobactam for 6 months demonstrated no serious toxic effects. Doses at 400 mg/kg/day or greater caused some transient toxic effects to the liver (glycogen granules in the cytoplasm and increases in smooth endoplasmic reticulum in hepatocytes) that were mostly reversed after one month.

Treatment for overdoses, if required, is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperacillin and may be of significance in veterinary patients:

AMINOGLYCOSIDES (amikacin, gentamicin, tobramycin): In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. Beta-lactam antibiotics, however, can inactivate aminoacylase in vivo and in vivo in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.

ANTICOAGULANTS: Because piperacillin may rarely affect platelets, increased monitoring of coagulation parameters is suggested for patients on heparin or warfarin.

METHOTREXATE: Piperacillin may increase MTX serum levels.

PROBENECID: Can reduce the renal tubular secretion of piperacillin thereby maintaining higher systemic levels for longer periods; this potential “beneficial” interaction requires further investigation before dosing recommendations can be made for veterinary patients.

VECURONIUM: Piperacillin may prolong neuromuscular blockade.

Dosage

DOGS/CATS:

a) For bacteremia with or without endocarditis: 30 mg/kg IV q6h for 7–14 days. (Calvert & Wall 2006)

b) For respiratory infections: 25–50 mg/kg IV q6h. (Greene & Reimer 2006)

c) Dogs: For systemic treatment of otitis media or proliferative otitis externa complicated by gram-negative (especially Pseudomonas) bacteria: 20 mg/kg SC three times daily. (Bloom 2006)

BIRDS:

a) For Bordetella avium infections: 150 mg/kg IM q6–12h; minimum treatment period is two weeks. (Flammer, K 2006)

b) For susceptible infections: 100 mg/kg IM two to three times daily. (Antinoff 2004)

c) For empirical treatment in Psittacines of gram-negative bacterial infections: 100 mg/kg IM 3–4 times a day if immunocompetent; 4 times a day if immunocompromised. (Flammer, K 2006)

HORSES:

a) For susceptible infections: 15–50 mg/kg IV or IM q6–12h. (Bertone & Horspool 2004)

REPTILES:

a) For susceptible infections: 100 mg/kg route not specified q48h. (Antinoff 2004)
Piperacillin/tazobactam is thought relatively safe to use during pregnancy. No teratogenic effects have been attributed to either drug in either humans or laboratory animals. In humans, the FDA categorizes piperacillin/tazobactam as Category B for use during pregnancy.

Adverse Effects
Piperacillin/tazobactam is generally well tolerated. Hypersensitivity reactions are possible. Local effects (thrombophlebitis, etc.) associated with intravenous injection may occur. Alterations in gut flora may lead to antibiotic-associate diarrhea.

Contraindications/Precautions/Warnings
Piperacillin/tazobactam should not be used in patients with documented hypersensitive reactions to a beta-lactam or beta-lactamase inhibitor. Because of sodium content, high dosages of piperacillin/tazobactam may adversely affect patients with cardiac failure or hypernatremic conditions.

References

PIPERACILLIN SODIUM + TAZOBACTAM
虔 erad-ah-sill-in; tay-zoh-bak-tam) Zosyn®
EXTENDED SPECTRUM PENICILLIN + BETA-LACTAMASE INHIBITOR

Prescriber Highlights

- Limited action parenteral penicillin with a beta lactamase inhibitor; has increased spectrum of activity when compared with piperacillin alone, but is more expensive
- Limited experience or research in veterinary medicine, but appears quite safe

Uses/Indications
Although veterinary experience is limited with piperacillin or piperacillin/tazobactam, these drugs have expanded coverage against many bacteria and may be suitable for empiric use until culture and susceptibility data are available, or for surgical prophylaxis when gram-negative or mixed aerobic/anaerobic infections are concerns.

Pharmacology/Actions
For information on piperacillin, refer to the preceding monograph. Tazobactam irreversibly binds to beta-lactamases thereby “protecting” the beta-lactam ring of piperacillin from hydrolysis. When tazobactam is combined with piperacillin, it extends piperacillin’s spectrum of activity to those bacteria that produce beta-lactamases of Richmond-Sykes types II-V that would otherwise render it ineffective. It has slightly more activity than either clavulanate or sulbactam against some Type I beta-lactamases.

Tazobactam has minimal antibacterial activity when used alone, but in combination with piperacillin, synergistic effects may result. It is more potent than sulbactam and, unlike clavulanic acid, does not induce chromosomal beta-lactamases at serum concentrations achieved.

Pharmacokinetics
For information on the pharmacokinetics of piperacillin, refer to the previous monograph; tazobactam’s pharmacokinetics generally mirrors that of piperacillin. In dogs, piperacillin reduced the renal clearance of tazobactam, presumably due to competition for tubular secretion.

Contraindications/Precautions/Warnings
Piperacillin/tazobactam should not be used in patients with documented hypersensitive reactions to a beta-lactam or beta-lactamase inhibitor. Because of sodium content, high dosages of piperacillin/tazobactam may adversely affect patients with cardiac failure or hypernatremic conditions.

Dosage adjustment may be required in patients with significantly decreased renal function (GFR < 40 mL/min).

Adverse Effects
Piperacillin/tazobactam is generally well tolerated. Hypersensitivity reactions are possible. Local effects (thrombophlebitis, etc.) associated with intravenous injection may occur. Alterations in gut flora may lead to antibiotic-associated diarrhea.

In humans, piperacillin has caused coagulation abnormalities on occasion, particularly in patients with renal failure. Very high doses may cause neurotoxicity (seizures); again, this is more likely in patients with diminished renal function. Superinfections with Clostridium difficile have been rarely reported.
Piperacillin is distributed in milk in low concentrations. It is not known if tazobactam enters milk. This drug combination is likely safe to use during nursing.

Overdosage/Acute Toxicity

Single overdoses are unlikely to pose much risk although very large overdoses may cause vomiting, diarrhea, or neurotoxicity. Dogs receiving up to 800 mg/kg/day of piperacillin/tazobactam for 6 months demonstrated no serious toxic effects. Doses at 400 mg/kg/day or greater caused some transient effects to the liver (glycogen granules in the cytoplasm and increases in smooth endoplasmic reticulum in hepatocytes) that were mostly reversed after one month.

Treatment for overdoses, if required, is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving piperacillin/tazobactam and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES (amikacin, gentamicin, tobramycin):** In vitro studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. Beta-lactam antibiotics however, can inactivate aminoglycosides in vitro and in vivo in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.

- **ANTICOAGULANTS:** Because piperacillin may rarely affect platelets, increased monitoring of coagulation parameters is suggested for patients on heparin or warfarin.

- **METHOTREXATE:** Piperacillin may increase MTX serum levels.

- **PROBENECID:** Can reduce the renal tubular secretion of both piperacillin and tazobactam, thereby maintaining higher systemic levels for a longer period of time; this potential “beneficial” interaction requires further investigation before dosing recommendations can be made for veterinary patients.

- **VECURONIUM:** Piperacillin may prolong neuromuscular blockade

Laboratory Considerations

- **Urine glucose determinations** when using cupric sulfate solution (Benedict’s Solution, Clinistix®): Piperacillin may cause false-positive results. Tests utilizing glucose oxidase (Tes-Tape®, Clinistix®) are not affected by piperacillin.

- **Aminoglycoside serum quantitative analysis:** As penicillins and other beta-lactams can inactivate aminoglycosides in vitro and in vivo in patients in renal failure or when penicillins are used in massive dosages, serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

- **Direct antiglobulin (Coombs’ tests):** False-positive results may occur

- **Urine protein:** Piperacillin may produce false-positive urine protein results with the sulfosalicylic acid and boiling test, nitric acid test, or the acetic acid test. Strips using bromophenol blue reagent (e.g., Multi-Stix®) do not appear to be affected by high levels of penicillins in the urine.

Doses

- **DOGS/CATS:**
  a) For single-agent therapy of intra-abdominal sepsis: 50 mg/kg IV or IM q4–6h for 5–7 days; dose extrapolated from human dosage with limited studies in dogs or cats. (Greene 2006)
  b) For bacterial sepsis in dogs: 3.375 grams (total dose per dog) IV q8h or 4.5 grams (total dose per dog) IV q8h for 7 days. (Greene et al. 2006)

- **HIBRDS:**
  a) For susceptible infections: Reconstitute to 200 mg/mL and administer at 100 mg/kg IM q8–12h; for severe polymicrobial bacteremia give 100 mg/kg IV q6h; for preoperative orthopedic or coelomic surgery: 100 mg/kg IM q12h. (Nemetz & Lennox 2006)

Monitoring

- **Efficacy for the infection treated (CBC, clinical signs, etc.)**

Client Information

- **Limited experience in veterinary medicine**
- **Best suited for inpatient use**

Chemistry/Synonyms

Piperacillin sodium/tazobactam sodium occurs as a white or almost white, cryodesiccated powder. Tazobactam is structurally related to sulbactam and a penicillanic acid sulfone derivative. The commercially available piperacillin/tazobactam injection contains 2.79 mEq of sodium and 0.25 mg of EDTA per gram of piperacillin. Tazobactam may also be known as: CL 298741, or YTR 830H. Piperacillin may also be known as piperacillinum, BL-P 1908, Cl 867, CL 227193, T 12220, and TA 058. International trade names for piperacillin/tazobactam include: Tazocin®, Zosyn®, Zosyn® and others.

Storage/Stability

Piperacillin/tazobactam injection vials and ADD-Vantage® vials should be stored at controlled room temperature (20–25°C).

Conventional vials should be reconstituted with 5 mL of diluent per gram of piperacillin. Suitable diluents include 0.9% sodium chloride, sterile water for injection, and bacteriostatic saline or water for injection. Once reconstituted, further dilute for intravenous infusion with 50–150 mL of 0.9% sodium chloride, LRS (reconstituted product only—see below) or D5W. IV infusion should be over at least 30 minutes.

Once reconstituted, vials should be used immediately. It is recommended to discard after 24 hours if kept at room temperature or 48 hours if stored in the refrigerator. The manufacturer recommends not freezing reconstituted vials. IV bags (50–150 mL) containing further diluted product are stable for up to 24 hours at room temperature and one week if refrigerated. As no preservatives are used, sterility is not assured in stored reconstituted products.

Compatibility/Compounding Considerations

Zosyn® (piperacillin/tazobactam) injection underwent a formulation change in 2006. Sodium citrate (buffer) and EDTA (metal chelator) were added that made it compatible with lactated Ringer’s injection and via simultaneous Y-site administration at specific concentrations of gentamicin and amikacin (but not tobramycin). This reformulated product has a yellow background behind the Zosyn® name on the label. Refer to the package insert for specific information on diluent and concentration compatibility.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- **Piperacillin Sodium & Tazobactam Injection (powder for solution): Zosyn® (Wyeth); (Rx)
  2.25 grams, concentrate (piperacillin 2 grams/tazobactam 0.25 g), preservative free, in vials and ADD-Vantage® vials
  3.375 grams (piperacillin 3 grams/tazobactam 0.375 g), preservative free, in vials and ADD-Vantage® vials
  4.5 grams (piperacillin 4 grams/tazobactam 0.5 grams) preservative free, in vials and ADD-Vantage® vials
  40.5 grams (piperacillin 36 grams/tazobactam 4.5 grams) preservative free, in bulk vials

Also available in 3.375 grams/50 mL (piperacillin 3 grams/tazobactam 0.375 grams) and 4.5 grams/100 mL (piperacillin 4 grams/tazobactam 0.5 grams) premixed, frozen Galaxy containers.

PIPERAZINE
(p-i-per-az-een) Pipa-Tabs®
ANTIPARASITIC (ASCARIDS)

Prescriber Highlights

- Anthelmintic for ascarids in a variety of species
- Contraindications: Chronic liver, kidney disease, & gastrointestinal hypomotility.
- Caution: Seizure disorders, horses with heavy infestations of P. equorum
- Adverse Effects: Unlikely, but diarrhea, emesis, or ataxia possible

Uses/Indications
Piperazine is used for the treatment of ascarids in dogs, cats, horses, swine and poultry. Piperazine is considered safe to use in animals with concurrent gastroenteritis and during pregnancy.

Pharmacology/Actions
Piperazine is thought to exert "curare-like" effects on susceptible nematodes, thereby paralyzing or narcotizing the worm and allowing it to be passed out with the feces. The neuromuscular blocking effect is believed to be caused by blocking acetylcholine at the myoneural junction. In ascarids, succinic acid production is also inhibited.

Pharmacokinetics
Piperazine and its salts are reportedly readily absorbed from the proximal sections of the GI tract and the drug is metabolized and excreted by the kidneys. Absorptive, distribution, and elimination kinetics on individual species were not located.

Contraindications/Precautions/Warnings
Piperazine should be considered contraindicated in patients with chronic liver or kidney disease, and those with gastrointestinal hypomotility. There is some evidence in humans that high-dose piperazine may provoke seizures in patients with a history of seizures, or with renal disease.

If used in horses with heavy infestations of P. equorum, rupture or blockage of intestines is possible due to the rapid death and detachment of the worm.

Adverse Effects
Adverse effects are uncommon at recommended doses, but diarrhea, emesis, and ataxia may be noted in dogs or cats. Horses and foals generally tolerate the drug quite well, even at high dosage rates, but a transient softening of the feces may be seen. Other adverse effects have been seen at toxic dosages; refer to the Overdosage section below for more information.

Reproductive/Nursing Safety
In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

No information was located on use during nursing, but it probably is safe to use.

Overdosage/Acute Toxicity
Acute massive overdosage can lead to paralysis and death, but the drug is generally considered to have a wide margin of safety. The oral LD50 of piperazine adipate in mice is 11.4 grams/kg.

In cats, adverse effects occur within 24 hours after a toxic dose is ingested. Emesis, weakness, dyspnea, muscular fasciculations of ears, whiskers, tail and eyes, rear limb ataxia, hypersalivation, depression, dehydration, head pressing, positional nystagmus and slowed pupillary responses have all been described after toxic ingestions. Many of these effects may also be seen in dogs after toxic piperazine ingestions.

Treatment is symptomatic and supportive. If ingestion was recent, use of activated charcoal and a cathartic has been suggested. Intravenous fluid therapy and keeping the animal in a quiet, dark place is recommended. Recovery generally takes place within 3–4 days.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving piperazine and may be of significance in veterinary patients:

- **CHLORPROMAZINE**: Although data conflicts, piperazine and chlorpromazine may precipitate seizures if used concomitantly
- **LAXATIVES**: The use of purgatives (laxatives) with piperazine is not recommended as the drug may be eliminated before its full efficacy is established
- **PYRANTEL/MORANTEL**: Piperazine and pyrantel/morantel have antagonistic modes of action and should generally not be used together

Laboratory Considerations
Piperazine can have an effect on uric acid blood levels, but references conflict with regard to the effect. Both falsely high and low values have been reported; interpret results cautiously.

Doses
Caution: Piperazine is available in several salts that contain varying amounts of piperazine base (see Chemistry below). Many of the doses listed below do not specify what salt (if any) is used in the dosage calculations. If the dose is in question, refer to the actual product information for the product you are using.

- **DOGS**:
  
  For treatment of ascarids (Note: Because larval stages in the host’s tissues may not be affected by the drug, many clinicians recommend retreating about 2–3 weeks after the first dose):
  
  a) 45–65 mg of base/kg PO; for pups less than 2.5 kg: 150 mg maximum. (Cornelius & Roberson 1986)
  b) 110 mg/kg PO (Chiapella 1989)
  c) 100 mg/kg PO; repeat in 3 weeks (Morgan 1988)
  d) 20–30 mg/kg PO once (Davis 1985)
  e) 110 mg/kg PO; repeat in 21 days (Kirk 1989)
  f) 45–65 mg/kg (as base) PO (Roberson 1988)

- **CATS**:
  
  For treatment of ascarids (Note: Because larval stages in the host’s tissues may not be affected by the drug, many clinicians recommend retreating about 2–3 weeks after the first dose):
  
  a) 45–65 mg of base/kg PO; 150 mg maximum (Cornelius & Roberson 1986)
  b) 110 mg/kg PO (Chiapella 1989)
  c) 100 mg/kg PO; repeat in 3 weeks (Morgan 1988)
  d) 20–30 mg/kg PO once (Davis 1985)
  e) 110 mg/kg PO; repeat in 21 days (Kirk 1989)
  f) 45–65 mg/kg (as base) PO (Roberson 1988)

- **RABBITS, RODENTS, SMALL MAMMALS**:
Pirlimycin mastitis tubes are indicated for the treatment of clinical and subclinical mastitis caused by susceptible organisms in lactating dairy cattle.

WormEze™ Canine Anthelmintic, WormEze™ Feline Anthelmintic Paste, WormEze™ Canine and Advanced Care™ Once-a-Month for Horses, D-Worm™ Liquid Wormer for Cats and Dogs, Wazine Additional OTC products and combination products may be available for a variety of species. Products and/or trade names include:

- Piperazine Dihydrochloride tablets equivalent to 50 mg or 250 mg base.

**VETERINARY-LABELED PRODUCTS:**

**Dosage Forms/Regulatory Status**

Unless otherwise specified by the manufacturer, piperazine products should be stored at room temperature (15–30°C).

Piperazine occurs as a white, crystalline powder that may have a slight odor. It is soluble in water and alcohol. Piperazine is available commercially in a variety of salts, including citrate, adipate, phosphate, hexahydrate, and dihydrochloride. Each salt contains a variable amount of piperazine (base): adipate (37%), chloride (48%), citrate (35%), dihydrochloride (50–53%), hexahydrate (44%), phosphate (42%), and sulfate (46%).

Piperazine may also be known as diethylenediamin, dispermin, hexahydropyrazin, piperazineum, and Pipa-Tabs®.

**Storage/Stability**

Unless otherwise specified by the manufacturer, piperazine products should be stored at room temperature (15–30°C).

**DOSAGE FORMS/REGULATORY STATUS**

**VETERINARY-LABELED PRODUCTS:**

Piperazine Dihydrochloride tablets equivalent to 50 mg or 250 mg base. Pipa-Tabs® (Vet-A-Mix); (Rx). FDA-approved for use in dogs and cats.

**Prescriber Highlights**

- Lincosamide antibiotic for intramammary use in dairy cattle
- Milk withdrawal (at labeled doses) = 36 hours after last treatment; Meat withdrawal (at labeled doses) = 9 days

**Uses/Indications**

Pirlimycin lincosamide antibiotic is indicated for the treatment of clinical and subclinical mastitis caused by susceptible organisms in lactating dairy cattle.
Pirlimycin mastitis tubes are indicated for the treatment of clinical and subclinical mastitis caused by susceptible organisms in lactating dairy cattle.

**Pharmacology/Actions**

Like other lincosamides, pirlimycin acts by binding to the 50S ribosomal subunit of susceptible bacterial RNA, thus interfering with bacterial protein synthesis. It is primarily active against gram-positive bacteria, including a variety of species of staphylococcus (S. aureus, S. epidermidis, S. chromogenes, S. hyicus, S. xylosus), streptococcus (S. agalactiae, S. dysgalactiae, S. uberis, S. bovis) and Enterococcus faecalis.

Organisms with a MIC of ≤2 micrograms/mL are considered susceptible, and organisms with a MIC value of 4 micrograms/mL are considered resistant. If using a 2 microgram disk for Kirby-Bauer plate testing, a zone diameter of ≤12mm indicates resistance and a diameter of ≥13mm indicates susceptibility.

**Pharmacokinetics**

Little information is available; the manufacturer states that the drug penetrates the udder well and is absorbed systemically from the udder and then secreted into the milk of all four quarters. Tissue levels in treated quarters of pirlimycin are approximately 2–3 times those found in the extracellular fluid.

**Contraindications/Precautions/Warnings**

No information was noted.

**Adverse Effects**

No adverse affects, including udder irritation have been reported thus far.

Milk from untreated quarters must be disposed of during withdrawal time as residues may be detected from untreated quarters.

**Reproductive/Nursing Safety**

No information was noted.

**Overdosage/Acute Toxicity**

No data was located.

**Drug Interactions**

Because erythromycin and clindamycin have shown antagonism in vitro, this could also occur with pirlimycin.

**Laboratory Considerations**

The established tolerance of pirlimycin in milk is 0.4 ppm.

**Doses**

**CATTLE:**

a) Lactating Dairy Cattle: Infuse contents of one syringe into each affected quarter. Use proper teat end preparation, sanitation and intramammary infusion technique. Repeat treatment after 24 hours. Daily treatment may be repeated at 24-hour intervals for up to 8 consecutive days. (Package Insert; Pirsue® — Pfizer)

**Monitoring**

- Efficacy
- Withdrawal periods

**Client Information**

- Be sure clients understand dosage recommendations and withdrawal periods.
- Milk from untreated quarters must be disposed of during withdrawal time as residues may be detected from untreated quarters.

**Chemistry/Synonyms**

Pirlimycin HCl is a lincosamide antibiotic. It has a molecular weight of 465.4.

Pirlimycin HCl may also be known as U-57930E and Pirsue®.

**Storage/Stability**

Store syringes at or below 25°C (77°F); protect from freezing.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Pirlimycin HCl Sterile Solution 50 mg (equiv. to free base) in a 10 mL disposable teat syringe; Pirsue® Aqueous Gel (Pfizer); (Rx). FDA-approved for use in lactating dairy cattle. Milk withdrawal (at labeled doses) = 36 hours after last treatment; Meat withdrawal if two infusions 24 hours apart are used = 9 days; following any extended duration of therapy (more than two infusions at a 24-hour interval, up to 8 consecutive days), animals must not be slaughtered for 21 days.

**HUMAN-LABELED PRODUCTS:**

None
Uses/Indications
In dogs, piroxicam may be beneficial in reducing the pain and inflammation associated with degenerative joint disease, but there are safer alternatives available. Its primary use is in dogs as adjunctive treatment of bladder transitional cell carcinoma. It may also be of benefit in squamous cell carcinomas, mammary adenocarcinoma, and transmissible venereal tumor (TVT). There is some use of it in cats for its anti-tumor effects, but there presently are no studies published documenting its safety or efficacy in cats and it should be used with caution in this species.

Pharmacology/Actions
Like other non-steroidal anti-inflammatory agents, piroxicam has anti-inflammatory, analgesic, and antipyretic activity. The drug’s anti-inflammatory activity is thought to be primarily due to its inhibition of prostaglandin synthesis, but additional mechanisms (e.g., superoxide formation inhibition) may be important. As with other NSAIDs, piroxicam can affect renal function, cause GI mucosal damage, and inhibit platelet aggregation.

Piroxicam’s antitumor effects are believed to be due to its action on the immune system and not because of direct effects on tumor cells.

Pharmacokinetics
After oral administration, piroxicam is well absorbed from the gut. While the presence of food will decrease the rate of absorption, it will not decrease the amount absorbed. It is not believed that antibiotics significantly affect absorption.

In dogs, piroxicam has high oral bioavailability (100%) with peak plasma levels reached around 3 hours after dosing. Volume of distribution is about 0.3 L/kg; total body clearance is 0.066 L/hour and elimination half-life is about 40 hours (Galbraith & McKellar 1991).

After single oral doses in cats, piroxicam is well absorbed with an oral bioavailability of about 80%. Peak levels occur in approximately 3 hours. Elimination half-life after intravenous or oral dosing is about 12-13 hours. Piroxicam is highly bound to plasma proteins. In humans, synovial levels are about 40% of those found in plasma. Maternal milk concentrations are only about 1% of plasma levels.

In humans, piroxicam has a very long plasma half-life (about 50 hours). The drug is principally excreted as metabolites in the urine after hepatic biotransformation.

Contraindications/Precautions/Warnings
Piroxicam is contraindicated in patients hypersensitive to it or who are severely allergic to aspirin or other NSAIDs. It should be used only when its potential benefits outweigh the risks in patients with active or history of GI ulcer disease or bleeding disorders. Because peripheral edema has been noted in some human patients, it should be used with caution in patients with severely compromised cardiac function.

Piroxicam has not been evaluated for use in cats. It must be used with extreme caution, if at all, in this species.

Adverse Effects
Like other NSAIDs used in dogs, piroxicam has the potential for causing significant GI ulceration and bleeding. The therapeutic window for the drug is very narrow in dogs, as doses as low as 1 mg/kg given daily have caused significant GI ulceration, renal papillary necrosis, and peritonitis. Other adverse effects reported in humans and potentially possible in dogs include: CNS effects (headache, dizziness, etc.), otic effects (tinnitus), elevations in hepatic function tests, pruritus and rash, and peripheral edema. Renal papillary necrosis has been seen in dogs at post-mortem but, apparently, clinical effects have not been noted with these occurrences.

In cats, GI effects (vomiting, anorexia, diarrhea) may be seen, particularly early in therapy. There are anecdotal reports of piroxicam decreasing hematocrits in cats when dosed daily for 7-14 days. Renal toxicity is possible if used for prolonged periods.

Reproductive/Nursing Safety
Animal studies have not demonstrated any teratogenic effects associated with piroxicam. The drug is excreted into milk in very low concentrations (about 1% found in maternal plasma). In humans, the FDA categorizes this as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) If using in the third trimester or near delivery in humans, the FDA categorizes all NSAIDs as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Most NSAIDs are excreted in maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity
There is limited information available, but dogs may be more sensitive to the drugs ulcerative effects than are humans.

There were 63 exposures to piroxicam reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 58 were dogs with 12 showing clinical signs and 5 were cats with 1 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, and bloody vomitus.

As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis is should be considered. Patients ingesting significant overdoses should be monitored carefully and treated supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving piroxicam and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc.): Increased risk for nephrotoxicity
- **ANTICOAGULANTS** (heparin, LMWH, warfarin): Increased risk for bleeding possible
- **ASPIRIN**: When aspirin is used concurrently with piroxicam, plasma levels of piroxicam could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with piroxicam cannot be recommended.
- **BISPHOSPHONATES** (alendronate, etc.): May increase risk for GI ulceration
- **CISPLATIN**: Piroxicam may potentiate the renal toxicity of cisplatin when used in combination
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **FUROSEMIDE**: Piroxicam may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (e.g., phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, and the sulfonilurea antidiabetic agent(s): Because piroxicam is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.
- **MEHTOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution

Laboratory Considerations
- Piroxicam may cause falsely elevated blood glucose values when using the glucose oxidase and peroxidase method using ABTS as a chromogen.

Dosage

**DOGS:**

As an adjunctive therapy of transitional cell carcinomas, squamous cell carcinomas, and palliative therapy for other neoplastic diseases:

a) 0.3 mg/kg PO once a day (Frimberger & London 2003)

b) 0.3 mg/kg PO once a day. Give with food. Consider adding misoprostol at 3 micrograms/kg, PO q8h for dogs who tolerate NSAIDs poorly. Discontinue if severe irritation or ulceration occurs. Treat ulcers and if signs abate, may resume piroxicam with misoprostol. (Frimberger 2000)

c) For adjuvant therapy for splenic hemangiosarcoma (stage II): Etoposide 50 mg/m² PO once daily for 3 weeks, alternating 3 week cycles with cyclophosphamide at 12.5-25 mg/m² PO once daily. Piroxicam is given at 0.3 mg/kg PO every day. Continue until disease recurrence and progression is noted. (Lana et al. 2007)

d) For transitional cell carcinoma after laser ablation of the primary tumor: Mitoxantrone at IV 5 mg/m² every 3 weeks for 4 treatments. Piroxicam was given at a dosage of 0.3 mg/kg PO once daily for the remaining life of the dog. (Upton et al. 2006)

e) To inhibit local recurrence in dogs with incompletely resected soft tissue sarcomas: piroxicam at 0.3 mg/kg PO once daily with cyclophosphamide at 10 mg/m² (NOT mg/kg) PO once daily. If dog develops unacceptable adverse effects dosing interval increased to every other day. (Elmslie et al. 2008)

As an antiinflammatory/analgesic:
PSGAG administered either IM or IA is indicated for the treatment of non-infectious and/or traumatic joint dysfunction and associated lameness of the carpal joints in horses. Some studies have indicated that PSGAG is

**CATS:**

As an antiinflammatory/analgesic:

a) For adjunctive therapy of transitional cell carcinomas: 0.3 mg/kg PO q24–72h. Gastric protectants (misoprostol, H₂ blockers sucralfate, omeprazole) may be useful to prevent/treat GU ulceration. Use with caution in patients with pre-existing renal disease and avoid use with other nephrotoxic drugs. Fluid supplementation may be warranted. (Smith 2003)

b) For an adjunctive therapy of transitional cell carcinomas, but may be of limited utility in squamous cell carcinoma: Doses of 0.3 mg/kg PO every 24–48 hours have been used for neoplastic diseases; it is unknown if this dose provides anti-inflammatory or analgesic effects. (Lascelles et al. 2007)

As an antiinflammatory/analgesic:

a) For cancer pain: 0.3 mg/kg PO q24–48h or 1 mg (total dose) per cat PO q24h for a maximum of 7 days. (Gaynor 2008)

b) 1 mg per cat (total dose) PO once daily for a maximum of 7 days. (Note: After compounding, drug is stable for 10 days). (Rochette 2007)

c) Idiopathic chronic rhinosinusitis: Some cats’ clinical signs can be reduced with piroxicam at 0.3 mg/kg PO once daily or every other day. (Kuehn 2007a)

**HORSES:**

- For neoplastic diseases:
  
a) From a case report treating mucocutaneous squamous cell carcinoma: 80 mg (total dose) PO once daily; lip lesion resolved completely over 3 months, but patient developed colic signs twice. Dose was eventually reduced to every other day or every third day. (Moore et al. 2003)

b) From a case report treating a squamous cell carcinoma of the third eyelid after surgical excision: 80 mg (total dose) PO once daily. (Iwabe et al. 2009)

**RABBITS, RODENTS, SMALL MAMMALS:**

For fracture associated limb swelling:

a) Rabbits: 0.1–0.2 mg/kg PO q8h for 3 weeks (Ivey & Morrisey 2000)

**Monitoring**

- Adverse Effects (particularly GI bleeding)

- Liver function and renal function tests should be monitored occasionally with chronic use

**Client Information**

- Have clients monitor for GI ulceration/bleeding (anorexia, tarry stools, etc.).

- Do not exceed dosage recommendations without veterinarian’s approval. It has been suggested to give the drug with food to reduce GI upset potential.

**Chemistry/Synonyms**

An oxicam derivative non-steroidal antiinflammatory agent, piroxicam occurs as a white, crystalline solid. It is sparingly soluble in water. Piroxicam is structurally not related to other non-steroidal antiinflammatory agents.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Piroxicam Oral Capsules: 10 mg & 20 mg;

Piroxicam Oral Capsules: 10 mg & 20 mg; Feldene® (Pfizer); generic; (Rx)

POLYSULFATED GLYCOSAMINOLIGYAN (PSGAG)

Uses/indications

PSGAG administered either IM or IA is indicated for the treatment of non-infectious and/or traumatic joint dysfunction and associated lameness of the carpal joints in horses & non-infectious degenerative &/or traumatic arthritis in dogs

- Protostatic enzyme inhibitor used IM or intra-articularly for non-infectious &/or traumatic joint dysfunction & associated lameness of the carpal joints in horses & non-infectious degenerative &/or traumatic arthritis in dogs

- Contraindications: Intra-articular injection if patient hypersensitive to PSGAG. Should not be used in place of other treatments when infection suspected or present, or when surgery or joint immobilization required

Polysulfated Glycosaminoglycan (PSGAG) for Intra-Articular Injection: 250 mg/mL in 1 mL single-use vials; boxes of 6.

**VETERINARY-LABELED PRODUCTS:**

Commercial products should be stored in a cool place 8–15°C (46–59°F). The manufacturer recommends discarding any unused portion from the vial or ampule and does not recommend mixing with any other drug or chemical.

### Chemistry/Synonyms

Polysulfated glycosaminoglycan (PSGAG) is chemically similar to natural mucopolysaccharides found in cartilaginous tissues. PSGAG is reportedly an analog of heparin.

### Client Information

The following drug interactions have either been reported or are theoretical in humans or animals receiving PSGAG and may be of significance in veterinary patients:

- Specific drug interactions have not been detailed to date, using this product in conjunction with either steroids or non-steroidal anti-inflammatory agents could mask the signs and clinical signs associated with septic arthritis.
- While specific drug interactions have not been detailed to date, using this product in conjunction with either steroids or non-steroidal anti-inflammatory agents could mask the signs and clinical signs associated with septic arthritis.
- There is some concern that since PSGAG is a heparin analog that it should not be used in conjunction with other NSAIDs or other anticoagulants. Clinical significance remains unclear, but use together with caution.

### Contraindications/Precautions/Warnings

- PSGAG is contraindicated for intra-articular administration in patients hypersensitive to it. While the manufacturer states there are no contraindications for IM use of the drug, the drug should not be used in place of other therapies in cases where infection is present or suspected, or in place of surgery or joint immobilization where indicated.
- Some clinicians feel that PSGAG should not be used within one week of arthrotomy in dogs, because it may cause increased bleeding. This effect apparently has not been confirmed in the literature, however.

### Adverse Effects

- Adverse effects are unlikely when using the IM route. Intra-articular administration may cause a post-injection inflammation (joint pain, effusion, swelling, and associated lameness) secondary to sensitivity reactions, traumatic injection technique, overdosage, or the number or frequency of the injections. Treatment consisting of anti-inflammatory drugs, cold hydrotherapy, and rest is recommended. Although uncommon, joint sepsis secondary to intrarticular injection is possible; strict aseptic technique should be employed to minimize this occurrence. Several sources recommend adding 125 mg of amikacin if PSGAG is to be injected in joints of horses.
- In dogs, a dose-related inhibition of coagulation/hemostasis has been described.

### Reproductive/Nursing Safety

Reproductive studies have apparently not been performed; use with caution during pregnancy or in breeding animals (the manufacturer does not recommend use in breeding animals).

- In humans, the FDA categorizes glycosaminoglycans as category B for use during pregnancy. *Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*
- It is not known whether glycosaminoglycans are excreted in maternal milk, but is unlikely to be of significant concern.

### Overdosage/Acute Toxicity

- Doses five times those recommended (2.5 grams) given IM to horses twice weekly for 6 weeks revealed no untoward effects. Approximately 2% of horses receiving overdoses (up to 1250 mg) IA showed transient clinical signs associated with joint inflammation.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving PSGAG and may be of significance in veterinary patients:

- Specific drug interactions have not been detailed to date, using this product in conjunction with either steroids or non-steroidal anti-inflammatory agents could mask the signs and clinical signs associated with septic arthritis.
- There is some concern that since PSGAG is a heparin analog that it should not be used in conjunction with other NSAIDs or other anticoagulants. Clinical significance remains unclear, but use together with caution.

### Doses

#### HORSES:

- For IM administration: 500 mg IM (of IM product) every 4 days for 28 days. Thoroughly cleanse injection site before injecting. Do not mix with other drugs or chemicals. (Package Insert; Adequan® I.M.)
- For intra-articular administration: 250 mg (of IA product) IA once a week for 5 weeks. Joint area should be shaved, and cleansed as if a surgical procedure, prior to injecting. Do not mix with other drugs or chemicals. (Package Insert; Adequan® I.A.)
- For IM injection: 500 mg IM every 3–4 days for a minimum of 4 and preferably, 7 treatments.
- For intra-articular injection: As above; author recommends adding 125 mg of amikacin for injection into the IA injection to reduce potential for infection. (Nixon 1992)

#### DOGS:

- For the treatment of non-infectious degenerative and/or traumatic arthritis:
  - 4.4 mg/kg IM twice weekly for up to 4 weeks. (Label information; Adequan® Canine—Luitpold)
  - 1.1–4.8 mg/kg IM every 4 days for six doses and then as needed (Kelly 1995)
  - 5 mg/kg IM twice a week (McLaughlin 2000)
  - 5 mg/kg IM once weekly (Hardie & Grauer 2007)

- For osteoarthritis: 5 mg/kg IM twice a week (McLaughlin 2000)

#### CATS:

- As a chondroprotective drug:
  - 1.1–4.8 mg/kg IM every 4 days for six doses and then as needed (Kelly 1995)
  - 2 mg/kg IM every 3–5 days for 4 treatments; only anecdotal experience in cats. (Kerwin 2007)

#### RABBITS, RODENTS, SMALL MAMMALS:

- For arthritis: 2.2 mg/kg SC or IM every 3 days for 21–28 days, then once every 2 weeks (Ivey & Morrisey 2000)

### Monitoring

- Efficacy
- Joint inflammation/infection if administered IA.

### Client Information

- The IA product must be administered by veterinary professionals; the IM product could, with proper instruction, be administered by the owner.

### Chemistry/Synonyms

- Polysulfated glycosaminoglycan (PSGAG) is chemically similar to natural mucopolysaccharides found in cartilaginous tissues. PSGAG is reportedly an analog of heparin.
- Polysulfated glycosaminoglycan is also known as PSGAG, Adequan® and Chondroprotect®.

### Storage/Stability

Commercial products should be stored in a cool place 8–15°C (46–59°F). The manufacturer recommends discarding any unused portion from the vial or ampule and, also does not recommend mixing with any other drug or chemical.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

- Adequan® (Polysulfated Glycosaminoglycan) 250 mg/mL in 1 mL single-use vials, boxes of 6. (Manufactured by Luitpold Pharmaceuticals, Inc., Allendale, New Jersey; © 2008 Luitpold Pharmaceuticals, Inc.)

- It is also FDA-approved for the control of signs associated with non-infectious degenerative and/or traumatic arthritis in dogs.
PONAZURIL
(pon-az-yor-ill) Marquis®
ANTIPROTOZOAL
Prescriber Highlights

- Equine FDA-approved triazine for treating EPM
- Adverse Effect profile not well established; in field trials: rashes, hives, blisters, or GI signs noted
- Treatment is relatively expensive

Uses/Indications
Ponazuril is indicated for the treatment of equine protozoal myeloencephalitis (EPM) caused by Sarcocystis neurona.

Field trials showed some animals developing blisters on nose and mouth or a rash/hives. Single animals developed diarrhea, mild colic or seizures.

Pharmacology/Actions
The triazine class of antiprotzoal drugs is believed to target the “plastid” body, an organelle found in the members of the Apicomplexa phylum, including Sarcocystis neurona. In vitro levels required to kill Sarcocystis neurona range from 0.1–1 micrograms/mL.

Pharmacokinetics
When administered orally to horses in water, ponazuril has an approximate bioavailability of 30% and elimination half-life of 80 hours. After daily (5 mg/kg) oral administration to horses, ponazuril reaches its peak serum levels in about 18 days and peak CSF levels in about 15 days. Peak CSF levels are about \( \frac{V_c}{V_{ss}} \) th (0.21 micrograms/mL) those found in the serum. Elimination half-life from serum averages about 4.5 days. If ponazuril is given orally (2.2 mg/kg) dissolved in DMSO, bioavailability is significantly enhanced (Dirikolu, Karpiesiuk et al. 2009).

In cattle, 5 mg/kg oral doses of ponazuril are relatively well absorbed and have an approximate elimination half-life of 58 hours (Dirikolu, Yohn et al. 2009).

Contraindications/Precautions/Warnings
None were noted. Before treating, other conditions that can cause ataxia should be ruled out.

Adverse Effects
Field trials showed some animals developing blisters on nose and mouth or a rash/hives. Single animals developed diarrhea, mild colic or seizures.

Successful treatment may not negate all the clinical signs associated with EPM.

Keratoconjunctivitis sicca (KCS) has been reported in some dogs, especially those breeds with a predilection towards developing KCS or when the drug was given in overdose quantities.

Reproductive/Nursing Safety
Safety during pregnancy or in lactating mares has not been evaluated.

Overdosage/Acute Toxicity
Daily doses of up to 30 mg/kg (6X) primarily caused loose feces. Moderate edema of the uterine epithelium was noted on histopathology for female horses receiving the 6X dose.

Drug Interactions/Laboratory Considerations
None noted

Doses

- **DOGS/CATS:**
  a) For Neosporosis or Toxoplasmosis: 7.5–15 mg/kg PO once daily for 28 days. Dose extrapolated between doses for horses and mice. (Greene et al. 2006)
  b) For coccidiosis: Aneadotally, 15–30 mg/kg PO once or repeated after 7–10 days. (Hurley 2007)
  c) For coccidiosis: 20 mg/kg PO daily for 3 days; must be compounded for administration in kittens or cats. Has been well tolerated and been associated with rapid resolution of diarrhea and eradication of coccidia in infected kittens. (Marks, S. 2007), (Marks, S.L. 2009)

- **SMALL MAMMALS:**
  a) For Eimeria: 20 mg/kg PO q24h for 7 days. (Kelleher 2008)

- **HORSES:**
  a) For EPM: 5 mg/kg, PO once daily for 28 days. See the package insert for specific dosing instructions. (Package insert; Marquis®—Bayer)

- **CAMELIDS (NW):**
  a) For Eimeria macausanienesis in Crías: 20 mg/kg, PO once daily for 3 days. Because E. mac can cause clinical disease or even death before oocysts are present in feces, prophylactic treatment should be considered in calves that have unexplained weight loss with concurrent hypoproteinemia and without severe anemia. The commercially available paste (Marquis®) is too concentrated to be given to camelids and should be diluted before being administered. Recommend diluting the paste to 100 mg/mL by taking 40 grams of paste, q.s. with distilled water to 60 grams total and mixing well. It is very water-soluble and can be easily syringed into the animal. (Walker 2009)

- **BIRDS:**
  a) For Cryptosporidium respiratory disease: Case report of two patients: 20 mg/kg PO (as a compounded suspension) once daily for 7 days. (Van Sant & Stewart 2009)

- **REPTILES:**

References

Potassium is the principal intracellular cation in the body. It is essential in maintaining cellular turgor; nerve impulse transmission; smooth, skeletal and cardiac muscle contraction; and maintenance of normal renal function. Potassium is also used in carbohydrate utilization and protein synthesis. Potassium requirements in mature dogs are approximately 3.7 mEq/kg/day, and in mature cats approximately 1.5 mEq/kg/day. Puppies and kittens require higher dietary potassium than do mature animals.

**Pharmacology/Actions**

Potassium is the principal intracellular cation in the body. It is essential in maintaining cellular turgor; nerve impulse transmission; smooth, skeletal and cardiac muscle contraction; and maintenance of normal renal function.

Potassium is also used in carbohydrate utilization and protein synthesis. Potassium requirements in mature dogs are approximately 3.7 mEq/kg/day, and in mature cats approximately 1.5 mEq/kg/day. Puppies and kittens require higher dietary potassium than do mature animals.

**Uses/Indications**

Potassium supplementation is used to prevent or treat potassium deficits. When feasible and appropriate, because it is generally safer, oral or nutritional therapy is generally preferred over parenteral potassium administration.

**Pharmacokinetics**

Approximately 98% of total body potassium is found in the intracellular fluid space while only 2% is in the extracellular fluid space. Plasma pH can alter distribution. Acidosis can shift potassium out of the intracellular space and conversely, alkalosis shifts potassium into the intracellular space. Potassium is primarily (80-90%) excreted via the kidneys with the majority of the remainder excreted in the feces. Very small amounts may be excreted in perspiration (animals with sweat glands).

**Contraindications/Precautions/Warnings**

Potassium salts are contraindicated in patients with hyperkalemia, renal failure or severe renal impairment, severe hemolytic reactions, untreated Addison’s disease, and acute dehydration. Solid oral dosage forms should not be used in patients where GI motility is impaired. Use cautiously in digitalized patients (see Drug Interactions).

Because potassium is primarily an intracellular electrolyte, serum levels may not adequately reflect the total body stores of potassium. Acid-base balance may also mask the actual potassium picture. Patients with systemic acidosis conditions may appear to have hyperkalemia when, in fact, they may be significantly low in total body potassium. Conversely, alkalosis may cause a falsely low serum potassium value. Assess renal and cardiac function prior to therapy and closely monitor serum potassium levels. Supplementation should generally occur over 3–5 days to allow equilibration to occur between extracellular and intracellular fluids. Some clinicians feel that if acidosis is present or a concern, use potassium acetate, citrate or bicarbonate; if alkalosis is present, use potassium chloride.

**Drug Interactions**

Acid/base, hydration status important

**Adverse Effects:** Hyperkalemia. Oral therapy: GI distress; IV therapy may be irritating to veins

**Caution:** Patients on digoxin

**Adverse Effects:** Hyperkalemia. Oral therapy: GI distress; IV therapy may be irritating to veins

**Intravenous potassium salts must be diluted before administering & drug must be given slowly**

**Acid/base, hydration status important**

**Drug Interactions**

**References**

Compatibility/Compounding Considerations

Potassium chloride occurs as either white, granular powder or as colorless, elongated, prismatic, or cubical crystals. It is odorless and has a saline taste. One gram is soluble in about 3 mL of water and is insoluble in alcohol.

Chemistry/Synonyms

This section above. Treatment of hyperkalemia is dependent upon the cause and/or severity of the condition and can consist of: discontinuation of the drug with ECG, acid/base and electrolyte monitoring, glucose/insulin infusions, sodium bicarbonate, calcium therapy, and polystyrene sulfonate resin. It is suggested to refer to other references appropriate for the species being treated for specific protocols for the treatment of hyperkalemia.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving potassium and may be of significance in veterinary patients:

ACE INHIBITORS (e.g., enalapril): Potassium retention may occur; increased risk for hyperkalemia

DIGOXIN: In patients with severe or complete heart block who are receiving digitalis therapy, it is often recommended not to use potassium salts

NSAIDs: Oral potassium given with non-steroidal antiinflammatory agents may increase the risk of gastrointestinal adverse effects

POTASSIUM-SPARING DIURETICS (e.g., spironolactone): Potassium retention may occur; increased risk for hyperkalemia

Doses

DOGS/CATS:

For hypokalemia:

a) Treatment of chronic mild hypokalemia (3.0-3.5 mEq/L) can be accomplished with dietary measures or commercially available oral potassium supplement tablets and elixirs (diluted in water) at 0.5–1 mEq/kg mixed 2–4 times daily depending on body size; adjust as necessary. 

For moderate to severe (<3.0 mEq/L) or acute hypokalemia with or without metabolic alkalosis requiring the administration of IV potassium; no accurate formulas available for calculating the exact amount of KCl needed to restore normokalemia. The rate of administration of intravenous KCl is more critical than the total amount administered. Under most circumstances the rate should not exceed 0.5 mEq/kg/hour. But, under the most dire circumstances (serum potassium < 2.0 mEq/L), rate can be increased to 1.5 mEq/kg/hour along with close EKG monitoring. Amounts exceeding more than 10 mEq/hour to a small animal (<10 kg body weight) can be potentially life-threatening because of the effects of a more concentrated solution on the wall of the right ventricle, if the solution is given through a central intravenous line.

KCl supplementated fluids can also be safely given in patients weighing less than 10 kg. Isotonic fluids such as lactated Ringers or 0.9% saline containing 30–35 mEq/L KCl per Liter and administered at a dose of 150 mL SC every 12 hours. (Schaer 2009)

b) Oral using Tumil-K® (Virbac): ¼ teaspoonful (2 mEq) per 4.5 kg body weight PO in food twice daily. Adjust dose as necessary. (Package insert; Tumil-K®—Virbac).

c) Intravenous replacement: potassium chloride IV at a rate not to exceed 0.5 mEq/hour. Concentration of replacement fluid should exceed 60 mEq/L. Begin oral supplementation as soon as possible using potassium gluconate for dogs at a dose of 2–44 mEq/day depending on body size; cats get 2–4 mEq/day. (Peres 2000)

d) Potassium administration should be considered on the basis of how much potassium to administer to the patient, not how much to add to a bag of fluid. Dosages usually range from maintenance (0.05–0.1 mEq/kg/hour) to 0.5 mEq/kg/hour. (Hansen 2007)

e) There are no exact formulas for calculating the total body potassium depletion, or the rate of replacement fluid required from the information presented. Guidelines should always be modified based on patient response. Patients with hypokalemia and an osmotic diuresis will have a much higher requirement for potassium than ones with normal urine output. Guidelines are: Serum K+ <2 mEq/L = 60 mEq/1000 mL IV fluid; Serum K+ 2-2.5 mEq/L = 40 mEq/1000 mL IV fluid; Serum K+ 2.5-3 mEq/L = 30 mEq/1000 mL IV fluid; Serum K+ 3–3.5 mEq/L = 20 mEq/1000 mL IV fluid. Infusion rates should generally not exceed 0.6 mEq/kg/hour; however, higher rates may be required in some patients. Rates as high as 1.5 mEq/kg/hour can be used as long as the patient’s heart rate and electrocardiogram are monitored continuously. Hypomagnesemia should be ruled out in patients with refractory hypokalemia. (Devey 2009)

HORSES:

For hypokalemia:

a) To counteract potassium depletion in a completely anorectic horse, IV fluids should be supplemented with KCL (at least 50 mEq/hour). Hypertonic oral KCL pastes can be administered to horses with diarrhea. (Schaer II 2009)

Ruminants:

For hypokalemia:

a) In “downer” cows: 80 grams sodium chloride and 20 grams potassium chloride in 1 liters of water PO via stomach tube. Provide a bucket containing similar solution for cow to drink and another containing fresh water. (Caple 1986)

b) 50 grams PO daily; 1 mEq/kg/hour IV drip(Howard 1986)

c) For severe hypokalemia (<2.5 mEq/L) with severe muscle weakness or recumbency: Isotonic potassium chloride (11.5 grams of potassium chloride per 1 liter of sterile water) at a rate of 4 mL/kg/hour. Combined with large doses of oral potassium salts (i.e., 200 grams of KCl per day). (Smith 2006)

Monitoring

Level and frequency of monitoring associated with potassium therapy is dependent upon the cause and/or severity of hypokalemia, acid/base abnormalities, renal function, concomitant drugs administered, or disease states and can include:

- Serum potassium
- Other electrolytes
- Acid/base status
- Glucose
- ECG
- CBC
- Urinalyses

Chemistry/Synonyms

Potassium chloride occurs as either white, granular powder or as colorless, elongated, prismatic, or cubical crystals. It is odorless and has a saline taste. One gram is soluble in about 3 mL of water and is insoluble in alcohol.

The pH of the injection ranges from 4–8. One gram of potassium contains 13.4 mEq of potassium. A 2 mLmEq/mL solution has osmolality of 4000 mOsm/L. Potassium chloride may also be known as KCl.

Potassium gluconate occurs as white to yellowish white, crystalline powder or granules. It is odorless, has a slightly bitter taste, and is freely soluble in water. One gram of potassium gluconate contains 4.3 mEq of potassium.

Potassium Chloride may also be known as: KCl, cloreto de potassio, E508, kalii chloridum, or kalium chloratum.

Potassium gluconate occurs as white to yellowish white, crystalline powder or granules. It is odorless, has a slightly bitter taste, and is freely soluble in water. One gram of potassium gluconate contains 4.3 mEq of potassium.

Potassium chloride may also be known as: KCl, cloreto de potassio, E508, kalii chloridum, or kalium chloratum.

Potassium retention may occur; increased risk for hyperkalemia

Storage/Stability

Potassium chloride oral products should be stored in tight, light resistant containers at room temperature (15–30°C), unless otherwise instructed by the manufacturer.

Unless otherwise directed by the manufacturer, potassium chloride products should be stored in tight, light resistant containers at room temperature (15–30°C); protect from freezing.

Serum [K+] E577, E508, E508,
Pralidoxime chloride for injection is reportedly physically compatible with the following intravenous solutions and drugs (as an additive); all commonly used intravenous replacement fluids (not 10% fat emulsion), aminophylline, amidronate HCI, bentonite, calcium gluconate, chloramphenicol sodium succinate, cimetidine HCI, clindamycin phosphate, corticosteroids (ACTH), cytarabine, dexamethasone, dopamine, ephedrine, epinephrine, esmolol, etoposide, furosemide, gemcitabine, gentamicin, glycopyrrolate, heparin sodium, hydrocortisone sodium succinate, isoproterenol, lidocaine, metaraminol bitartrate, methicillin, methylprednisolone, meperidine, methotrexate, meropenem, metronidazole, miconazole, mexiletine, midazolam, mitomycin, mitoxantrone, morphine, nafamostat, neostigmine, nevirapine, norepinephrine, oxacillin sodium, oxytetracycline HCl, penicillin G potassium, phenylephrine HCl, piperacillin sodium, sodium bicarbonate, tetracycline HCI, tioconazole, vancomycin HCl, verapamil HCl, and vitamin B-complex with C.

Pralidoxime chloride for injection compatibility information conflicts or is dependent on diluent or concentration factors with the following drugs or solutions: fat emulsion 10%, amikacin sulfate, dobutamine HCl, methylprednisolone sodium succinate (at Y-site), penicillin G sodium, and promethazine HCl (at Y-site). Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Pralidoxime chloride for injection is reportedly physically incompatible with the following solutions or drugs: amphotericin B, diazepam (at Y-site), and phenytoin sodium (at Y-site).

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
There are several products for parenteral use that contain potassium; refer to the tables in the appendix or individual proprietary veterinary products for additional information.

Potassium Chloride IV Solution: 2 mEq (149 mg) in 10 mL vials; Potassium Chloride Gel 4 mEq (298 mg) in 10 mL vials.

Parenteral Products:
Potassium Chloride Injection Concentrate: 20 mEq in 25 mL, bulk vials; 40 mEq in 50 mL, bulk vials; 80 mEq in 100 mL, bulk vials; undiluted; (OTC and Rx)

HUMAN-LABELED PRODUCTS: Not a complete list.

Potassium chloride for injection and potassium phosphate for injection (see Phosphate monograph) are also available. There are a multitude of human-labeled potassium salts for oral use available in several dosage forms; refer to human drug references for more information on these products. Tablets, controlled/sustained release tablets and capsules, effervescent tablets, liquids, and powder in varying strengths available; (OTC and Rx)

References

Compatibility/Compounding Considerations
Pralidoxime must generally be given within 24 hours of exposure to be effective, but some benefits may occur, particularly in large exposures, if given within 36–48 hours.

Adverse Effects: Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, or laryngospasm

Most-effective if given within 24 hours of exposure

Cholinesterase reactivator used for adjunctive treatment of organophosphate poisoning

Contraindications: Hypersensitivity; generally not recommended for carbamate poisoning

Caution: Renal impairment, patients receiving anticholinesterase agents for the treatment of myasthenia gravis

Adverse Effects: Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, or laryngospasm

Most-effective if given within 24 hours of exposure

Uses/Indications
Pralidoxime is used in the treatment of organophosphate poisoning, often in conjunction with atropine and supportive therapy.

Pharmacology/Actions
Pralidoxime reactivates cholinesterase that has been inactivated by phosphorylation secondary to certain organophosphates. Via nucleophilic attack, the drug removes and binds the offending phosphoryl group attached to the enzyme, which is then excreted.

Pharmacokinetics
Pralidoxime is only marginally absorbed after oral dosing; oral dosage forms are no longer available in the United States. It is distributed primarily throughout the extracellular water. Because of its quaternary ammonium structure, it is not believed to enter the CNS in significant quantities, but recent studies and clinical responses have led some to question this belief.

Pralidoxime is only marginally absorbed after oral dosing; oral dosage forms are no longer available in the United States. It is distributed primarily throughout the extracellular water. Because of its quaternary ammonium structure, it is not believed to enter the CNS in significant quantities, but recent studies and clinical responses have led some to question this belief.

Contraindications/Precautions/Warnings
Pralidoxime is contraindicated in patients hypersensitive to it. Pralidoxime is generally not recommended for use in instances of carbamate poisoning because inhibition is rapidly reversible, but there is some controversy regarding this issue.

Pralidoxime should be used with caution in patients receiving anticholinesterase agents for the treatment of myasthenia gravis as it may precipitate a myasthenic crisis. It should also be used cautiously and at a reduced dosage rate in patients with renal impairment.

Adverse Effects
At usual doses, pralidoxime generally is safe and free of significant adverse effects. Rapid IV injection may cause tachycardia, muscle rigidity, transient neuromuscular blockade, and laryngospasm.

Pralidoxime must generally be given within 24 hours of exposure to be effective, but some benefits may occur, particularly in large exposures, if given within 36–48 hours.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in maternal milk; exercise caution.

Overdosage/Acute Toxicity
The acute LD50 of pralidoxime in dogs is 190 mg/kg and, at high dosages, causes signs associated with its own anticholinesterase activity. Clinical signs of toxicity in dogs may be exhibited as muscle weakness, ataxia, vomiting, hyperpnea, seizures, respiratory arrest, and death.
Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pralidoxime and may be of significance in veterinary patients:

**Barbiturates:** Anticholinesterases can potentiate the action of barbiturates; use with caution.

**Cimetidine, Succinylcholine, Theophylline, Reserpine, and Respiratory Depressant Drugs (e.g., narcotics, phenothiazines):** Use should be avoided in patients with organophosphate toxicity.

### Doses

**Note:** Often used in conjunction with atropine; refer to that monograph and/or the references below for more information.

**Dogs/Cats:**

For organophosphate poisoning:

a) Pralidoxime works best when combined with atropine. Pralidoxime at 20 mg/kg, 2-3 times a day. Initial dose may be given either IM or slow IV. Subsequent doses may be given IM or SC. (Refer to reference for more specific guidelines regarding adjunctive therapy) (Fikes 1990)

b) 10-15 mg/kg IM or SC q8-12h; 36 hour minimum (Firth 2000)

c) Give atropine first at 0.1 mg/kg IV, followed by an additional 0.3 mg/kg IM. Then pralidoxime at 50 mg/kg diluted in 10% glucose and administered via slow IV. If a severe poisoning and muscle weakness has not been relieved, may give another dose in one hour. For small dogs or cats, pralidoxime may be administered IM or IP. Reduce dose in presence of renal failure. Recovery should occur gradually over 48 hours. (El Bab 2002)

d) Dogs: 50 mg/kg; Cats 20 mg/kg. Give IV slowly or with fluids over a 30-minute period. Repeat in one hour if clinical signs persist and then q8h for 24–48 hours. Author recommends using pralidoxime in animals that are severely depressed, weak, and anorectic one or more days after exposure if not previously treated with pralidoxime. In animals that have clinical signs intensified (e.g., respiratory depression), reduce dose and give as repeated one-hour infusions every 4–8 hours in combination with atropine (0.04–0.4 mg/kg) once or as needed (Mount 1989)

e) Cats: 20 mg/kg IM or IV within first 24 hours of exposure. May repeat q6-8h and combine with atropine or give separately. Do not use in carbamate toxicity. (Reid & Oehme 1989)

**Horses:**

For organophosphate poisoning:

a) 20 mg/kg (may require up to 35 mg/kg) IV and repeat q4-6h (Oehme 1987)

**Birds:**

For organophosphate poisoning:

a) 10–20 mg/kg q8–12h (route not specified) with atropine (0.2–0.5 mg/kg IM q3–4h). (Jones 2007)

b) 10–100 mg/kg IM q24–48h or repeat once in 6 hours. (Johnson-Delaney & Reavill 2009)

### Monitoring

**Pralidoxime therapy is monitored via the clinical signs associated with organophosphate poisoning. For more information, refer to one of the references outlined in the dosage section.**

### Client Information

This agent should only be used with close professional supervision.

### Chemistry/Synonyms

A quaternary ammonium oxime cholinesterase reactivator, pralidoxime chloride occurs as a white to pale yellow, crystalline powder with a pKa of 7.8–8. It is freely soluble in water. The commercially available injection has a pH of 3.5–4.5 after reconstitution.

Pralidoxime Chloride may also be known as: 2-Formyl-1-methylpyridinium chloride oxime, 2-PAM, 2-PAM chloride, 2-PAMCl, 2-pyridine aldoxime methochloride and Protopam®.

### Storage/Stability

Unless otherwise instructed by the manufacturer, pralidoxime chloride powder for injection should be stored at room temperature. After reconstituting with sterile water for injection, the solution should be used within a few hours. Do not use sterile water with preservatives added.

### Dosage Forms/Regulatory Status

**Veterinary-Labeled Products:** None

**Human-Labeled Products:**

Pralidoxime Chloride Powder for Injection: 1 gram in 20 mL, single-use vials; Protopam® Chloride (Wyeth-Ayerst); (Rx)

### References

Praziquantel is indicated for (FDA-approved labeling) for the treatment of *Dipylidium caninum*, *Taenia pisiformis*, and *Echinococcus granulosus* in dogs, and *Dipylidium caninum* and *Taenia taeniaeformis* in cats. Fasting is not required nor recommended before dosing. A single dose is usually effective, but measures should be taken to prevent reinfection, particularly against *D. caninum*. Praziquantel can also be used for treating *Alaria* spp. in dogs and cats and *Spirometra mansonoides* infections in cats.

Praziquantel has been used in birds and other animals, but it is usually not economically feasible to use in large animals. In humans, praziquantel is used for schistosomiasis, other trematodes (lung, liver, intestinal flukes) and tapeworms. It is not routinely effective in treating *F. hepatica* infections in humans.

Combination products can give a wide spectrum of internal parasite control in a variety of species.

**Uses/Indications**

**Pharmacology/Actions**

Praziquantel’s exact mechanism of action against cestodes has not been determined, but it may be the result of interacting with phospholipids in the integument causing ion fluxes of sodium, potassium and calcium. At low concentrations in vitro, the drug appears to impair the function of their suckers and stimulates the worm’s motility. At higher concentrations in vitro, praziquantel increases the contracture (irreversibly at very high concentrations) of the worm’s strobilla (chain of proglottids). In addition, praziquantel causes irreversible focal vacuolization with subsequent cestodal disintegration at specific sites of the cestodal integument. In schistosomes and trematodes, praziquantel directly kills the parasite, possibly by increasing calcium ion flux into the worm. Focal vacuolization of the integument follows and the parasite is phagocytized.

**Pharmacokinetics**

Praziquantel is rapidly and nearly completely absorbed after oral administration, but there is a significant first-pass effect. Peak serum levels are achieved between 30–120 minutes in dogs. Praziquantel is distributed throughout the body. It crosses the intestinal wall and across the blood-brain barrier into the CNS. Praziquantel is metabolized in the liver via CYP3A enzymes to metabolites of unknown activity. It is excreted primarily in the urine; elimination half-life is approximately 3 hours in the dog. In dogs, orally administered grapefruit juice can increase the area under the curve by 150–200%.

**Contraindications/Precautions/Warnings**

The manufacturer recommends not using praziquantel in puppies less than 4 weeks old or in kittens less than 6 weeks old. However, a combination product containing praziquantel and febantel from the same manufacturer is FDA-approved for use in puppies and kittens of all ages. No other contraindications are listed for this compound from the manufacturer. In humans, praziquantel is contraindicated in patients hypersensitive to the drug.

**Adverse Effects**

When used orally, praziquantel can cause anorexia, vomiting, lethargy, or diarrhea in dogs, but the incidence of these effects is less than 5%. In cats, adverse effects were quite rare (<2%) in field trials using oral praziquantel, with salivation and diarrhea being reported.

A greater incidence of adverse effects has been reported after using the injectable product. In dogs, pain at the injection site, vomiting, drowsiness, and/or a staggering gait were reported from field trials with the drug. Some cats (9.4%) showed clinical signs of diarrhea, weakness, vomiting, salivation, sleepiness, transient anorexia, and/or pain at the injection site.

**Reproductive/Nursing Safety**

Praziquantel is considered safe to use in pregnant dogs or cats. In humans, the FDA categorizes this drug as category *B* for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Praziquantel appears in maternal milk at a concentration of approximately 25% of that in maternal serum, but is unlikely to pose harm to nursing offspring.

**Dosage**

**DOGS:**

a) For susceptible cestodes:

IM or SC using the 56.8 mg/mL injectable product:

<table>
<thead>
<tr>
<th>Body weight</th>

b) For *Taenia, Echinococcus, Dipylidium caninum, Mesocystoides* (adult): 5 mg/kg PO or SC.

For *Diphyllobothrium*: 7.5 mg/kg PO either once or for 2 days.

For *Sparganum proliferum* (adult): 7.5 mg/kg or 25 mg/kg PO or SC daily for 2 days. (Conboy 2009)

c) For *Echinococcus granulosus*: 10 mg/kg (Sherding 1989)

d) For *Spirometra mansonioides* or *Diphyllobothrium erinacei*: 7.5 mg/kg, PO once daily for 2 days (Roberson 1988)

e) For treatment of *Paragonimiasis (Paragonimus kellicotti)*: 23–25 mg/kg PO q8h for 3 days (Reinemeyer 1995), (Hawkins 2000)

f) For treatment of liver flukes (*Platynosum* or *Opisthorchiidae families*): 20–40 mg/kg PO once daily for 3–10 days (Taboada 1999)

g) For *Alaria* spp.: 20 mg/kg PO (Ballweber 2004)

h) For giardia using *Drontal Plus®*: Use label dose once daily PO for 3 days. (Lappin 2006)
i) For adjunctive treatment of the flukes (Nanophyetus salmincola) associated with Salmon poisoning: Single dose of 10–30 mg/kg PO or SC. (Headley et al.)

CATS:

a) For susceptible cestodes:

- IM or SC using the 56.8 mg/mL injectable product:
  - Body weight: Dose
    - <5 lbs: 11.4 mg (0.2 mL)
    - 5–10 lbs: 22.7 mg (0.4 mL)
    - >10 lbs: 34.1 mg (0.6 mL, maximum)
  - Oral: Using the 23 mg feline tab
  - Body weight: Dose
    - <4 lbs: 11.5 mg (½ tab)
    - 5–11 lbs: 23 mg (1 tab)
    - >11 lbs: 34.5 mg (1.5 tabs)

(Package insert; Droncit® Injectable and Tablets—Bayer)

b) For susceptible parasites using combination product with pyrantel pamoate (Drontal®): Administer a minimum dose of 2.27 mg praziquantel and 9.2 mg pyrantel pamoate per pound of body weight according to the dosing tables on labeling. May be given directly by mouth or in a small amount of food. Do not withhold food prior to or after treatment. If reinfection occurs, treatment may be repeated. (Package insert; Drontal®—Bayer)

c) For treatment of Paragonimiasis (Paragonimus kellicotti): 23–25 mg/kg PO q8h for 3 days (Reinemeyer 1995)(Hawkins 2000)

d) For treatment of Giardia infections: Give two small dog tablets of Drontal Plus® (febantel 113.4 mg; pyrantel 22.7 mg; praziquantel 22.7 mg) once daily PO for 5 days. (Scorza et al. 2004)

e) For Alaria spp.: 20 mg/kg PO (Ballerweyer 2004)

f) For Spirometra mansonioides: 30–35 mg/kg PO. (Bowman 2006)

g) For Taenia, Echinococcus, Dipylidium caninum, Mesocostoides (adult): 5 mg/kg PO or SC.
   - For Diphyllolobothrium (adults): 35 mg/kg PO once has been recommended.
   - For Sparganum proliferum (adult): 7.5 mg/kg or 25 mg/kg PO or SC daily for 2 days. (Comboy 2009)

RABBITS, RODENTS, SMALL MAMMALS:

a) Chinchillas: 6–10 mg/kg (Hayes 2000)

b) Mice, Rats, Hamsters and Gerbils: For tapeworms: 30 mg/kg, PO once (note the high dosage required) (Burke 1999)

c) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: For tapeworms: 6–10 mg/kg PO (Adamcak & Otten 2000)

d) Rabbits: For cestodes and trematodes: 5–10 mg/kg PO once. (Bryan 2009)

SHEEP & GOATS:

a) For all species of Moniezia, Stilesia, or Avitellina: 10–15 mg/kg (Roberson 1988)

HORSES:

For labeled parasites using the oral gel combination of moxidectin/praziquantel:

- Dial in the weight of the animal on the syringe. Administer gel by inserting the syringe applicator into the animal’s mouth through the interdental space and depositing the gel in the back of the mouth near the base of the tongue. Once the syringe is removed, the animal’s head should be raised to insure proper swallowing of the gel. Horses weighing more than 1250 lb require additional gel from a second syringe. (Label Directions; Quest® Plus—Fort Dodge)

LAMAS:

For susceptible parasites:

- 5 mg/kg, PO (Fowler 1989)

BIRDS:

For susceptible parasites (tapeworms):

- ¼ of one 23 mg tablet/kg PO; repeat in 10–14 days. Add to feed or give by gavage. Injectable form is toxic to finches. (Clubb 1986)

- For common tapeworms in chickens: 10 mg/kg (Roberson 1988)

- For cestodes and some trematodes: Direct dose: 5–10 mg/kg PO or IM as a single dose -or- 12 mg of crushed tablets baked into a 9”x9”x2” cake. Finches should have their regular food withheld and be pre-exposed to a non-medicated cake. (Marshall 1993)

PELZTILES/AMPHIBIANS

a) Reptiles: For cestodes and trematodes in most species: 7.5 mg/kg PO once; repeat in 2 weeks PO (Gauvin 1993)

- For removal of common tapeworms in snakes: 3.5–7 mg/kg (Roberson 1988)

- For cestodes and trematodes in reptiles and amphibians: 7–8 mg/kg PO, IM, SC. (del la Navarre 2003)

Monitoring

- Clinical efficacy

Client Information

- Fasting is neither required nor recommended before dosing. A single dose is usually effective, but measures should be taken to prevent re-infection, particularly against D. caninum.

- Tablets may be crushed or mixed with food.

- Because tapeworms are often digested, worm fragments may not be seen in the feces after using.

Chemistry/Synonyms

A prazinoisoquinoline derivative anthelmintic, praziquantel occurs as a white to practically white, hygroscopic, bitter tasting, crystalline powder, either odorless or having a faint odor. It is very slightly soluble in water and freely soluble in alcohol.

Praziquantel may also be known as: EMBAY-8440, praziquantelum, Biltricide®, Bio-Cest®, Cercon®, Cesto®, Cestor®, Cisticid®, ComboCare®, Cysticid®, Drontic®, Drontal®, Ehliten®, Equimax®, Extiser Q®, Mycristec®, Opticide®, Quest® Plus, Prasiquante®, Prasikon®, Prazitel®, Froctel®, Sincerc®, Teniker®, Virbantel®, Waycide®, or Zipharte® and Zimecterin Gold Paste®.

Storage/Stability

Unless otherwise instructed by the manufacturer, praziquantel tablets should be stored in tight containers at room temperature. Protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Praziquantel Tablets: 23 mg (feline); 34 mg (canine); Drontal® Tablets (Bayer); generic; (Rx; OTC). FDA-approved for use in cats and dogs.
There were 12 exposures to prazosin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 6 were dogs with none showing clinical signs and 6 were cats with 1 showing clinical reproduction studies and no adequate studies in humans.

### Reproductive/Nursing Safety

Prazosin should be used with caution in patients with chronic renal failure or preexisting hypotensive conditions.

### Contraindications/Precautions/Warnings

- Prazosin should be used with caution in patients with chronic renal failure or preexisting hypotensive conditions.
- Prazosin should be used with caution in dogs tested positive for this mutation until more information becomes available; if this is not possible, consider reducing the dosage and increasing monitoring (particularly blood pressure).

### Pharmacokinetics

- Prazosin's effects are a result of its selective, competitive inhibition of alpha1-adrenergic receptors. It reduces blood pressure and peripheral vascular resistance and, unlike hydralazine, has dilatory effects on both the arterial and venous systems.
- Prazosin is less well studied in dogs than hydralazine, and its capsule dosage form makes it less convenient for dosing. Prazosin, however, appears to have fewer problems with causing tachycardia, and its venous dilation may be an advantage over hydralazine when preload reduction is desired. It could be considered for therapy for the adjunctive treatment of CHF, particularly when secondary to mitral or aortic valve insufficiency.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving prazosin and may be of significance in veterinary patients:

- **BETA-BLOCKING AGENTS** (e.g., propranolol): May enhance the postural hypotensive effects seen after the first dose of prazosin
- **CLONIDINE**: May decrease prazosin antihypertensive effects
- **SILDENAFIL** (and other PDE INHIBITORS): May increase risk for hypotension
- **VERAPAMIL** or **NIFEDIPINE**: May cause synergistic hypotensive effects when used concomitantly with prazosin

**Doses**

**DOGS:**

a) For adjunctive treatment of heart failure: 1 mg PO three times daily for dogs weighing less than 15 kg; 2 mg three times daily PO for dogs weighing more than 15 kg (Atkins 2007; Kittleson 1985)

b) For hypertension: 1–4 mg (total dose) PO q12–24 hours (Brown & Henik 2000)

c) For hypertension in a large dog: 1 mg (total dose) PO q8–12h (Ware 2003)

d) To decrease urethral resistance: 1 mg per 15 kg of body weight PO q12–24h (Lane 2000)

e) For functional urethral obstruction: 1 mg/kg body weight PO q8–24h (Latich 2004)

f) To decrease urethral resistance: 1 mg per 15 kg of body weight PO q12–24h (Bartges 2006; Vernau 2006)

g) To reduce urethral tone: 1 mg/kg body weight PO two to three times a day. (Dickinson 2010)

**CATS:**

To decrease urethral resistance:

a) 0.5 mg (total dose) PO q8h or 0.03 mg/kg IV (Lane 2000)

b) 0.03 mg/kg IV (Osborne et al. 2000)

c) For functional urethral obstruction: 0.25–0.5 mg/cat (total dose) PO q12–24h (Coates 2004; Latich 2004), (Vernau 2006)

d) For urethral spasm: 0.25–1 mg/cat (total dose) PO q8–12h; initially give for 5–7 days then wean off if possible. (Gunn-Moore & Casey 2009)

e) To reduce urethral tone: 0.5 mg/cat (total dose) PO once to two times a day. (Dickinson 2010)

**Monitoring**

- Baseline thoracic radiographs
- Mucous membrane color; CRT
- If possible, arterial blood pressure and venous PO2

**Client Information**

- Compliance with directions is necessary to maximize the benefits from this drug. If possible, give medication with food.
- Notify veterinarian if patient’s condition deteriorates or if the animal becomes lethargic or depressed.

**Chemistry/Synonyms**

A quinazoline-derivative postsynaptic α1-adrenergic blocker, prazosin HCl occurs as a white to tan powder. It is slightly soluble in water and very slightly soluble in alcohol.

Prazosin may also be known as: CP-12299-1, furazosin hydrochloride, prazosini hydrochloridum; many trade names are available.

**Storage/Stability**

Prazosin capsules should be stored in well-closed containers at room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS**: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS**: Prazosin Capsules: 1 mg, 2 mg & 5 mg (as base); Minipress® (Pfizer); generic; (Rx)

**References**

Minipress® (Pfizer); generic; (Rx)

**PREDNISOLONE**

**PREDNISOLONE SODIUM SUCINICATE**

**PREDNISOLONE ACETATE**

**PREDNISONE** (prednisone)

For more information refer to the monograph: Glucocorticoids, General Information or to the manufacturer’s product information for veterinary labeled products.

Note: Although separate entities, prednisone and prednisolone are often considered bioequivalent; most species rapidly convert prednisone to prednisolone in the liver. Horses, cats and patients in frank hepatic failure do not appear to either absorb or convert prednisone to prednisolone efficiently. Use either prednisolone or an alternative glucocorticoid in these patients when possible.

**Prescriber Highlights**

- Classic glucocorticoids used for many conditions in many species. Antiinflammatory activity is 4X more potent than hydrocortisone; has some mineralocorticoid activity

- Contraindications (relative): Systemic fungal infections
Drug Interactions

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but for prednisolone/prednisone, there are four primary uses and dose ranges: 1) replacement or supplementation (e., relative adrenal insufficiency associated with septic shock) of glucocorticoid effects secondary to hyponadocorticism, 2) as an antiinflammatory, 3) as an immunosuppressive, and, 4) as an antineoplastic agent. Current evidence does not support high dose use for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma, or sepsis. In general, in using glucocorticoids, the following principles should be followed:

1. Glucocorticoids can mask disease! Try not to use them until you have a diagnosis.
2. Make a specific diagnosis!
3. Determine course from outset.
4. Determine endpoint before you starting treating.
5. Use the least potent form for the minimal time.
6. Know where glucocorticoids inappropriate. (Behrend 2007)

Pharmacology/Actions

Prednisolone and prednisone are intermediate acting corticosteroids with a biologic “half-life” of 12–36 hours. Glucocorticoids have effects on virtually every cell type and system in mammals. For more information, refer to the Glucocorticoid Agents, General Information monograph.

Pharmacokinetics

In cats, prednisolone is much better absorbed when administered orally than prednisone. Reported bioavailabilities (of active prednisolone) are 100% and 21%, respectively.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipemias, activation or worsening of diabetes mellitus, muscle wasting, and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Glucocorticoids appear to have a greater hyperglycemic effect in cats than other species. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects, however.

Reproductive/Nursing Safety

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Use with caution in nursing dams. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit growth, interfere with endogenous corticosteroid production or cause other unwanted effects in nursing offspring. In humans, however, several studies suggest that amounts excreted in breast milk are negligible when prednisone or prednisolone doses in the mother are less than or equal to 20 mg/day or methylprednisolone doses are less than or equal to 8 mg/day. Larger doses for short periods may not harm the infant.

Overdosage/Acute Toxicity

Overdoses of glucocorticoids used alone are unlikely to cause harmful effects, but gastrointestinal signs can be seen in dogs. Should clinical signs occur, use supportive treatment if required. Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

There were 175 exposures to prednisone reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 164 were dogs with 16 showing clinical signs, and 10 were cats with 2 showing clinical signs. The remaining 1 case was a bird that showed no clinical signs. Common findings in dogs included polydipsia and polyuria.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral prednisolone/prednisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels. In dogs, prednisone with ultra low-dose (0.5 mg/kg) aspirin does not increase the severity of GI lesions when compared with prednisone alone, but may increase incidence of diarrhea (Graham & Leib 2009).
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
- **DIOXIN:** Secondary to hypokalemia, increased risk for arrhythmias
- **DURETICS, POTASSIUM-DEPLETING (furomide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May increase metabolism of glucocorticoids
- **ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE:** May decrease metabolism of glucocorticoids
- **NITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitoxantrone-induced adrenal insufficiency

Caution: Active bacterial infections, corneal ulcer, Cushingoid syndrome, diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency

Goal of therapy is to use as much as is required & as little as possible for as short an amount of time as possible

Prednisone poorly absorbed after oral use in horses; prednisone may not be readily converted to prednisolone in cats. Prednisolone is preferred in these two species.

Primary adverse effects are “Cushingoid” in nature with sustained use

Many potential drug & lab interactions
The use of glucocorticoids in therapy is guided by many factors, including patient-specific factors, the nature of the disease process, and the potential adverse effects of glucocorticoids. It is important to have a thorough understanding of the effects of glucocorticoids and to carefully consider the dose and duration of therapy, as well as to monitor for and manage potential adverse effects.

### Laboratory Considerations

- **Glucocorticoids may increase serum cholesterol and urine glucose levels.**
- **Glucocorticoids may decrease serum potassium.**
- **Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce T3 & T4 values.** Thyroid gland atrophy has been reported after chronic glucocorticoid administration.
- **There are reactions to skin tests may be suppressed by glucocorticoids.**
- **False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.**

### Doses

There are a plethora of doses and protocols associated with many specific indications for systemic administration of glucocorticoids, but there are four primary uses and dose ranges:

1. Replacement or supplementation (e.g., relative adrenal insufficiency associated with septic shock) of glucocorticoid effects secondary to hypoadrenocorticism.
2. As an antiinflammatory.
3. As an immunosuppressive, and,
4. As an antineoplastic agent.

Current evidence does not support high dose use for hemorrhagic or hypovolemic shock, head trauma, spinal cord trauma, or sepsis.

#### As an antiinflammatory agent:

- **Dogs:** 0.5–1 mg/kg PO per day. See above note for additional information. (Maddison 2009)
- **B) Dogs or Cats:** 0.55–1.1 mg/kg PO per day, either once per day or divided twice per day. (Lowe et al. 2008)

#### As an immunosuppressive:

- **Dogs:** Doses up to 2.2 mg/kg PO per day. Doses above 2.2 mg/kg/day do not give more immunosuppression, but do cause more adverse effects. If further immunosuppression is required, an additional immunosuppressive drug is needed. Many internists believe that prednisone doses should not exceed 80 mg per day, regardless of dog’s weight. A sample prednisone immunosuppressive protocol for dogs follows but doses and dosage schedule must be tailored to the ongoing requirements of the individual patient: 2.2 mg/kg/day (not to exceed 80 mg total dose per day) for 3 weeks, then 1 mg/kg/day for 3 weeks, then 0.5 mg/kg/day for 3 weeks, then 0.5 mg/kg every other day.
- **Cats:** Often require up to 4.4 mg/kg/day PO for immunosuppression. If further immunosuppression is required, an additional immunosuppressive drug is needed. A sample prednisolone immunosuppressive protocol for cats follows but doses and dosage schedule must be tailored to the ongoing requirements of the individual patient: 4.4 mg/kg/day for 3 weeks, then 2.2 mg/kg/day for 3 weeks, then 1 mg/kg/day every other day. (Wilson 2010; Wilson 2011)
- **Dogs:** >1.5 mg/kg, up to 4 mg/kg PO per day; no clinical advantage in using a higher dose and risk of side effects increase. See above note for additional information. (Maddison 2009)
- **Cats (prednisolone):** 2.2–8.8 mg/kg per day. Some authors believe that dividing the daily dose is indicated to decrease GI irritation. (Lowe et al. 2008)

#### As an antineoplastic/cytotoxic:

When prednisolone is used as an antineoplastic agent, whether alone or in a multi-drug chemotherapy protocol, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references (e.g., Henry & Higginbotham 2009; Argyle et al. 2008; Withrow & Vail 2007; Villalobos 2007; Ogilvie & Moore 2006; Ogilvie & Moore 2001) is strongly recommended.

- **Dogs:** 2 mg/kg per day. Cats are relatively steroid resistant and require higher doses than dogs. Doses can usually be safely doubled compared to dogs. See above note for additional information. (Maddison 2009)
  - **Note:** When used with other cytotoxic agents in chemo protocols, prednisolone doses may be reduced.
- **When prednisolone is used as a single agent, the dose must be kept fairly high.** When using it as part of a multi-drug protocol, the dose will be tapered. (Wilson 2010; Wilson 2011)

#### As adjunctive treatment for hypoadrenocorticism:

- **Acute treatment:** After second blood draw for cortisol measurement (ACTH stimulation test), prednisolone sodium succinate 2–20 mg/kg IV. If animal is in shock, give steroids at shock doses instead of trying to get an immediate diagnosis, then give desamethasone (0.05–0.1 mg/kg IV q12h) in IV fluids until able to switch to PO steroids.

  For oral glucocorticoid replacement (ongoing, with a mineralocorticoid): Prednisone initially at 0.1–0.22 mg/kg, then taper to lowest dose to control clinical signs. (Scott-Moncrieff et al. 2008, 2011)

  For glucocorticoid activity:
  - **a) Prednisolone (assuming sodium succinate salt) 100–200 mg IM or IV; continue therapy for 2–3 days** (Berg 1986)
  - **b) For physiologic replacement, it is common for dogs to require no more than 0.1 mg/kg once per day of prednisone, and often less will be sufficient to prevent recurrence of signs of glucocorticoid insufficiency.**

  **As an antiinflammatory, and,**

  - **For glucocorticoid activity:**
    - **c) Acute treatment:** After second blood draw for cortisol measurement (ACTH stimulation test), prednisolone sodium succinate 2–20 mg/kg IV. If animal is in shock, give steroids at shock doses instead of trying to get an immediate diagnosis, then give desamethasone (0.05–0.1 mg/kg IV q12h) in IV fluids until able to switch to PO steroids.

  - **b) For physiologic replacement, it is common for dogs to require no more than 0.1 mg/kg once per day of prednisone, and often less will be sufficient to prevent recurrence of signs of glucocorticoid insufficiency.**

#### As an antineoplastic/cytotoxic:

When prednisolone is used as an antineoplastic agent, whether alone or in a multi-drug chemotherapy protocol, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references (e.g., Henry & Higginbotham 2009; Argyle et al. 2008; Withrow & Vail 2007; Villalobos 2007; Ogilvie & Moore 2006; Ogilvie & Moore 2001) is strongly recommended.

- **Dogs:** 2 mg/kg per day. Cats are relatively steroid resistant and require higher doses than dogs. Doses can usually be safely doubled compared to dogs. See above note for additional information. (Maddison 2009)
  - **Note:** When used with other cytotoxic agents in chemo protocols, prednisolone doses may be reduced.
- **When prednisolone is used as a single agent, the dose must be kept fairly high.** When using it as part of a multi-drug protocol, the dose will be tapered. (Wilson 2010; Wilson 2011)

#### As adjunctive treatment for hypoadrenocorticism:

- **Acute treatment:** After second blood draw for cortisol measurement (ACTH stimulation test), prednisolone sodium succinate 2–20 mg/kg IV. If animal is in shock, give steroids at shock doses instead of trying to get an immediate diagnosis, then give desamethasone (0.05–0.1 mg/kg IV q12h) in IV fluids until able to switch to PO steroids.

  For oral glucocorticoid replacement (ongoing, with a mineralocorticoid): Prednisone initially at 0.1–0.22 mg/kg, then taper to lowest dose to control clinical signs. (Scott-Moncrieff et al. 2008, 2011)

  For glucocorticoid activity:

  - **Note:** When used with other cytotoxic agents in chemo protocols, prednisolone doses may be reduced.
- **When prednisolone is used as a single agent, the dose must be kept fairly high.** When using it as part of a multi-drug protocol, the dose will be tapered. (Wilson 2010; Wilson 2011)

#### As a corticosteroid replacement or supplementation:

- **a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM.** (Howard 1986)

#### For aseptic laminitis:

- **a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM.** (Howard 1986)

#### For dogs or cats:

- **a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM.** (Dill 1986)

#### For dogs or cats:

- **a) Prednisolone sodium succinate: 0.2–1 mg/kg IV or IM.** (Howard 1986)
Ophthalmic solutions/suspensions are available.

Prednisone Oral Solution/Syrup: 1 mg/mL; generic; (Rx)

Prednisolone Syrup/Oral Liquid or Solution: 1 mg/mL, 2 mg/mL, 3 mg/mL, 4 mg/mL; Prednisolone Oral Tablets: 5 mg; generic; (Rx)

HUMAN-LABELED PRODUCTS:
Prednisolone & Trimeprazine Tartrate Tablets: each tablet contains trimeprazine 5 mg and prednisolone 2 mg.

for use in dogs, cats, and horses.

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status

Prednisolone sodium succinate should be stored at room temperature and protected from light (store in carton). After reconstitution, the product is recommended for immediate use and not to be stored for later use.

Compatibility/Compounding Considerations

Little data appears to be available regarding the compatibility of prednisolone sodium succinate injection (Solo-Delta Cortef®—Pfizer) with other products. A related compound, prednisolone sodium phosphate is reportedly physically compatible with the following drugs/solutions: ascorbic acid injection, cytarabine, erythromycin lactobionate, fluorouracil, heparin sodium, methicillin sodium, penicillin G potassium/sodium, tetracycline HCl, and vitamin B-Complex with C. It is reportedly physically incompatible with: calcium gluconate/gluceptate, dimenhydrinate, metaraminol bitartrate, methotrexate sodium, prochlorperazaine edisylate, polymyxin B sulfate, promazine HCl, and promethazine. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

Veterinary-Labeled Products

A zero tolerance of residues in milk for these compounds has been established for dairy cattle. All these agents require a prescription (Rx). Known FDA-approved-veterinary products for systemic use are indicated below. The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

Prednisolone Sodium Succinate for Injection act-o-vial® System 100 mg (equivalent to 10 mg prednisolone) & 500 mg (equivalent to 50 mg prednisolone) per 10 mL vial; Solo-Delta-Cortef® (Pfizer); (Rx). FDA-approved for use in dogs, cats, and horses.

Prednisolone Tablets: 5 mg, 20 mg: Prednis-Tail® (various); generic; (Rx). FDA-approved for use in dogs.

Prednisolone, Tetracycline, Novobiocin Tablets: each tablet contains 60 mg tetracycline, 60 mg novobiocin, 1.5 mg prednisolone. Delta Aluplex®; each tablet contains 180 mg tetracycline, 180 mg novobiocin, and 4.5 mg prednisolone Delta Aluplex®-3X (Pfizer); (Rx). FDA-approved for use in dogs.

Prednisolone & Trimethazine Tartrate Tablets: each tablet contains trimethazine 5 mg and prednisolone 2 mg. Temaril-P® (Pfizer Animal Health); (Rx). FDA-approved for use in dogs.

Human-Labeled Products:

Prednisolone Oral Tablets: 5 mg; generic; (Rx)

Prednisolone Sodium Phosphate Orally Disintegrating Tablets: 10 mg, 15 mg & 30 mg (as base); Orapred OD® (Sciele); (Rx)

Prednisolone Syrup/Oral Liquid or Solution: 1 mg/mL, 2 mg/mL, 3 mg/mL, 4 mg/mL; Pediapred® (Celltech Pharmaceuticals); Millipred® (Laszer); Orapred® (Sciele); Veripred® 20 (Hawthorn); Flo-Pred® (Taro); generic; (Rx)

Prednisone Tablets: 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg & 50 mg; generic; (Rx)

Prednisone Oral Solution/Syrup: 1 mg/mL; Prednisone and Prednisone Intensol Concentrate (Roxane); (Rx)

Ophthalmic solutions/suspensions are available.

References
PREGABALIN
(pregabalin/Lyrica®)
ANTICONVULSANT; NEUROPATHIC PAIN AGENT

Prescriber Highlights

- Similar to gabapentin; may be useful as an anticonvulsant or to treat neuropathic pain
- Little information available on safety and efficacy in dogs or cats
- Most common adverse effects are sedation and ataxia
- Currently very expensive

Uses/Indications

Like gabapentin, pregabalin may be useful as adjunctive therapy for refractory or complex partial seizures and in treating chronic pain, particularly neuropathic pain in small animals.

In an open label, non-comparative study in dogs that were not controlled with phenobarbital and/or bromides, in 79 dogs pregabalin reduced seizures by about 60%. Two dogs were considered non-responders to pregabalin (Dewey et al. 2009).

Pharmacology/Actions

Pregabalin has antiepileptic, analgesic, and anxiolytic activity. Like gabapentin, pregabalin is a structural analog of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA). The mechanism of action of pregabalin, for either its anticonvulsant or analgesic actions is not fully understood, but it appears to bind to CaVa2-d (alpha2-delta subunit of the voltage-gated calcium channels). By decreasing calcium influx, release of excitatory neurotransmitters (e.g., substance P, glutamate, noradrenaline) is inhibited. It is 3-10 times as potent as gabapentin.

Pharmacokinetics

After single oral doses in six dogs, pregabalin median parameters were: T max = 1.5 hours; Cmax = 7.15 micrograms/mL; elimination half-life = 6.9 hours (Salazar a). In humans, oral bioavailability is about 90%. Presence of food can delay the rate, but not the amount absorbed and it can be administered regardless of feeding status. Pregabalin is not bound to plasma proteins and it has an apparent volume of distribution of about 500 mL/kg. Hepatic metabolism is negligible and it does not appear to affect hepatic enzymes. The drug is almost exclusively cleared unchanged by renal routes with a renal clearance of 67-81 mL/min in young, healthy subjects. Elimination half-life is approximately 6 hours. Dosage adjustment may be required in patients with diminished renal function.

Contraindications/Precautions/Warnings

Pregabalin is contraindicated in patients hypersensitive to it. Use with caution in patients with renal insufficiency; if required, dosage adjustment should be considered. In humans, pregabalin doses are adjusted based on creatinine clearance. Pregabalin is used with caution in human patients with heart failure.

In humans, abrupt discontinuation may lead to increased seizure frequency, diarrhea, headache, insomnia, or nausea.

Adverse Effects

Most common adverse effects reported include sedation and ataxia. Because use to date is limited in animals, adverse effect profile may evolve with additional clinical experience.

In humans, the most common adverse effects reported are: somnolence, dizziness, ataxia, difficulty with concentration/attention/memory, blurred vision, dry mouth, peripheral edema, constipation and weight gain.

Pregabalin may have an anticonvulsant effect on the fetus, but there are no adequate studies in humans; or there are no animal reproducibility studies and no adequate studies in humans.) Very high dosages of pregabalin have caused skeletal malformations in offspring when given to pregnant rats and rabbits. Pregabalin is excreted into milk, and safety has not been established. Weigh the potential risks of treating versus the benefits when using this drug in pregnant or nursing animals.

Overdosage/Acute Toxicity

There is limited experience with overdoses of pregabalin. One human ingested 8 grams without significant effect. There is no specific antidote for overdose with pregabalin. Standard decontamination protocols can be employed if indicated. Contact an animal poison center for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pregabalin and may be of significance in veterinary patients:

ACE INHIBITORS (e.g., benazepril,enalapril): In humans, co-administration with pregabalin may increase risks edema and hives

CNS DEPRESSANTS: Pregabalin may cause additive CNS depression

NSAIDS: In humans, ketorolac and naproxen have been cited as possibly reducing anticonvulsant effectiveness. Substantive evidence is weak, however.

Laboratory Considerations

None noted.

Doses

In a small single-dose pharmacokinetic study, the authors concluded that 4 mg/kg PO twice daily would produce plasma levels within the extrapolated (from humans) therapeutic range; further studies evaluating its
Reproductive/Nursing Safety

Margin is particularly narrow with this drug in cats (see Overdoses).

Vomiting is the most common adverse effect in cats associated with primaquine; dosing with food may help alleviate this problem. Other concerns include myelosuppression, methemoglobinemia and hemolysis. Safety precautions are similar to those for other antimalarial drugs. The CDC states the drug is contraindicated in individuals with G-6-PD deficiency, and during pregnancy or lactation (unless nursing infant determined not to be G-6-PD deficient).

Primaquine is contraindicated in patients with known hypersensitivity to it. In humans, it is contraindicated in patients receiving other bone marrow suppressant medications or patients susceptible to granulocytopenia (e.g., Pneumocystis pneumonia).

Uses/Indications

Primaquine is considered the drug of choice for treating Babesia felis in cats. Primaquine does not apparently “cure” the infection; repeated courses of therapy may be necessary.

May also be useful in treating Hepa tagon canis in dogs or Plasmodium spp. in birds.

Most common adverse effect in cats is nausea; giving with food may help.

Very narrow therapeutic index (safety margin); must be careful in determining dosages.

Monitoring

Efficacy/Adverse effects

At present, primaquine plasma levels are not routinely monitored in human medicine.

Client Information

Most common adverse effects seen in animals are sleepiness and sometimes difficulty walking; if these are severe or persist contact veterinarian.

Advise clients that there is little clinical experience with this medication at present, and to report any adverse effects (other than those noted above) that are seen. If allergic effects are noted (rash, hives, wheezing, or collapse) they should contact veterinarian immediately.

Do not stop this medication abruptly without veterinarian’s approval. Stopping the medication abruptly may cause increased adverse effects and increase seizures in patients with epilepsy.

Chemistry/Synonyms

Pregabalin is (S)-3-(Aminomethyl)-5-methylhexanoic acid. It is freely soluble in water and in both basic and acidic aqueous solutions.

Pregabalin may also be known as CI-1008, PD-144723, pregabalina, prégabaline or pregabalinum. A common trade name is Lyrica®.

Storage/Stability

Store capsules and oral solution at room temperature, 25°C (77°F); excursions permitted between 15-30°C (59-86°F).

Use the oral solution within the first 45 days after opening the bottle.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pregabalin Oral Capsules: 25 mg, 50 mg, 75 mg, 100 mg, 150 mg, 200 mg, 225 mg, & 300 mg; Lyrica® (Pfizer); (Rx; C-V controlled substance)

Pregabalin Oral Solution: 20 mg/mL; Lyrica® (Pfizer); (Rx; C-V controlled substance)

References

The CDC recommends using chloroquine or mefloquine for humans during pregnancy and to defer using primaquine until after delivery primarily because primaquine can cause hemolytic anemia in G-6-PD deficient fetuses. It is also contraindicated during lactation in nursing infants unless they are determined not to be G-6-PD deficient. While significance for veterinary patients is not clear, primaquine should be avoided during pregnancy and lactation.

**Overdosage/Acute Toxicity**

In cats, it has been reported that dosages greater than 1 mg/kg can be lethal. Overdoses should initially be handled aggressively using standardized protocols for removal of drug from the gut and to prevent absorption. Because of the potential seriousness of overdoses, it is recommended to contact an animal poison control center for guidance.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving primaquine and may be of significance in veterinary patients:

- **QUINACRINE:** May potentiate the toxicity of one another; use of primaquine within 3 months of quinacrine is not recommended
- **BONE MARROW DEPRESSANT DRUGS** (e.g., amphotericin B, azathioprine, chloramphenicol, many antineoplastic drugs) or HEMOLYTIC DRUGS (e.g., acetohydroxamic acid, sulfonylureas, quinidine, sulfonamides); Use with primaquine may cause increased risk for toxicity

**Laboratory Considerations**

- **No specific concerns noted**

**Doses**

- **CATS:**
  - **Note:** Dosing for humans for primaquine is usually described in terms of primaquine base, but dosages for cats may not directly specify whether primaquine is being dosed as the phosphate or as the base. Because primaquine has an extremely narrow therapeutic index in cats, this is problematic as a 26.3 mg primaquine phosphate tablet contains only 15 mg of primaquine base. Additionally, commercially available tablets are usually too concentrated to be accurately dosed in domestic cats; a specialized compounding pharmacy should be employed to prepare a suitable dosage form. Be clear as to the amount of primaquine base or phosphate wanted per dose.
  - a) For *Babesia felis:* 0.5 mg (as base)/kg PO once daily for 1–3 days. (Greene et al. 2006)
  - b) For *Babesia felis:* 1 mg (total dose per cat) primaquine phosphate PO every 36 hours for 4 treatments, then 1 mg (total dose) per cat every 7 days for 4 treatments. The drug does not sterilize the infection. (Lobetti 2005)
  - c) For *Babesia felis:* Primaquine phosphate 1 mg/kg IM one time. (Birkenheuer 2005) **Note:** IM dosage form must be compounded.

**Monitoring**

- CBC; weekly while treating
- Improved clinical signs (increased appetite and body weight, improvement in anemia)

**Client Information**

- **Note:**
  - This drug has a very low safety margin when used in cats; exact adherence with the prescribed dosage is very important; do not double-up the next dose if a dose was previously missed
  - Give dose with food to reduce chance for GI problems (vomiting)

**Chemistry/Synonyms**

Primaquine phosphate is an 8-amino-quinoline compound that occurs as an orange-red, odorless, bitter-tasting, crystalline powder. It is soluble (1 gram in 15 mL) in water and practically insoluble in alcohol. 1 mg of primaquine phosphate contains 0.57 mg of primaquine base.

Primaquine may also be known as primachina, primachinum, primaquina or SN 13272.

**Storage/Stability**

Primaquine phosphate tablets should be stored in a tight, light resistant container below 40°C, preferably between 15–30°C.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Primaquine Phosphate Oral Tablets: 26.3 mg (equiv. to 15 mg primaquine base); generic (Sanofi Winthrop); (Rx)

**PRIMIDONE**

(prī-mi-dōn) My絡sine®, Neurontin®

**ANTICONVULSANT**

**Prescriber highlights**

- Phenobarbital precursor that may be useful for treating seizures in dogs; most recommend using phenobarbital instead
- Contraindications: Severe liver disease or patients with demonstrated previous hypersensitivity. Large Doses Contraindicated: Nephritis or severe respiratory dysfunction
- Extreme Caution: Cats
- Caution: Hypovolemic, anemic, have borderline hypoadrenal function, or cardiac or respiratory disease
- Adverse Effects: *Dogs:* anxiety & agitation when initiating therapy, increases in liver enzymes, hepatic lipodisosis, hepatocellular hypertrophy/necrosis, extramedullary hematopoiesis, depression, polydipsia, polyuria, & polyphagia, anorexia, tachycardia, dermatitis, episodic hyperventilation, urolith formation; rarely megaloblastic anemia
- Possibly more hepatotoxic than phenobarbital to dogs
- Most of the anticonvulsant activity comes from the phenobarbital metabolite of primidone
- Drug Interactions, lab interactions
Uses/Indications
Primidone is indicated for seizure control (idiopathic epilepsy, epileptiform convulsions) in the dog. Because it is rapidly converted into phenobarbital in this species (see Pharmacokinetics below), and has a greater incidence of hepatotoxicity and behavioral effects, most neurologists do not recommend its use. However, some clinicians feel that some animals not responding to phenobarbital do benefit from primidone therapy, perhaps as a result that PEMA has been demonstrated to potentiate the anticonvulsant activity of phenobarbital in animals. When compared with phenobarbital, increased incidence of hepatotoxicity associated with primidone is considered the major limitation to long-term therapy with this agent. Primidone is considered more toxic in rabbits and cats than in humans or dogs.

Pharmacology/Actions
Primidone and its active metabolites, phenylethamalonamide (PEMA) and phenobarbital have similar anticonvulsant actions. While the exact mechanism for this activity is unknown, these agents raise seizure thresholds or alter seizure patterns.

Pharmacokinetics
Primidone is slowly absorbed after oral administration in the dog, with peak levels occurring 2–4 hours after dosing. The bioavailability of primidone in humans has been reported as 60–80%. Primidone is rapidly converted to PEMA and phenobarbital in the dog. Serum half-lives of primidone, PEMA, and phenobarbital have been reported to be 1.85 hrs, 7.1 hrs, and 41 hours, respectively (Yeary 1980). In dogs, the conversion rate of primidone to phenobarbital is approximately 4 to 1; a 250 mg dose of primidone is approximately equivalent to 60 mg of phenobarbital (Platt 2005).

Primidone, like phenobarbital (possibly due to the phenobarbital?), can induce hepatic microsomal enzymes that can increase the rate of metabolism of itself and other drugs. For more information on the pharmacokinetics of phenobarbital, refer to its monograph.

Contraindications/Precautions/Warnings
Many clinicians and the veterinary manufacturers of primidone feel that primidone is contraindicated in cats, other clinicians dispute this, but it is recommended that primidone be used in cats only with extreme caution. Use cautiously in patients who are hypovolemic, anemic, have borderline hypoadrenal or respiratory disease. Large doses are contraindicated in patients with nephritis or severe respiratory dysfunction.

Primidone is contraindicated in patients with severe liver disease or have had hypersensitivity reactions.

When converting dogs from primidone to phenobarbital, it has been suggested to do this slowly (½ of the dose each month) (Platt 2005).

Adverse Effects
Adverse effects in dogs are similar for both primidone and phenobarbital. Dogs may exhibit increased clinical signs of anxiety and agitation when initiating therapy. These effects may be transitory in nature and often will resolve with small dosage increases. Occasionally, dogs will exhibit profound depression at lower dosage ranges (and plasma levels). Polydipsia, polyuria, and polyphagia are quite commonly displayed at moderate to high serum levels; these are best controlled by limiting intake of both food and water. Sedation and/or ataxia often become significant concerns as serum levels reach the higher ends of the therapeutic range.

Increases in liver enzymes (ALT, ALP, glutamate dehydrogenase) and decreased serum albumin with chronic therapy are common (up to 70% of dogs treated), and more prevalent than with phenobarbital. Hepatic lipidosis, hepatocellular hypertrophy and necrosis, and extramedullary hematopoesis can be seen after 6 months of therapy. Serious hepatic injury probably occurs in approximately 6–14% of dogs treated.

In dogs, anorexia, tachycardia, dermatitis, episodic hyperventilation, urolith formation and, rarely, megaloblastic anemia have also been reported with primidone therapy.

A urinalysis consisting of primidone has been reported in one cat (Osborne et al. 1999).

Reproductive/Nursing Safety
The effects of primidone in pregnancy are unknown. In pregnant humans, primidone is designated by the FDA as a category D drug (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Primidone appears in maternal milk in substantial quantities. It is suggested that if somnolence occurs in nursing newborns to consider discontinue nursing.

Overdosage/Acute Toxicity
Because primidone is rapidly metabolized to phenobarbital in dogs, similar clinical signs (sedation to coma, anorexia, vomiting, nystagmus) are seen and correspond procedures should be used for the treatment of acute primidone overdose. This includes the removal of ingested product from the gut if appropriate, and offering respiratory and cardiovascular support. Activated charcoal has been demonstrated to be of considerable benefit in enhancing the clearance of phenobarbital, even when the drug was administered parenterally. Charcoal acts as a “sink” for the drug to diffuse from the vasculature back into the gut. Forced alkaline diuresis can be of considerable benefit in augmenting the elimination of phenobarbital in patients with normal renal function. Peritoneal or hemodialysis may also be helpful in severe intoxications or in anuric patients.

Drug Interactions
The following drug interactions have either been reported or are theoretic in humans or animals receiving primidone or phenobarbital (primidone’s active metabolite) and may be of significance in veterinary patients:

- ACETAMINOPHEN: Increased risk for hepatotoxicity, particularly when large or chronic doses of barbiturates are given
- CARBONIC ANHYDRAZE INHIBITORS (e.g., acetazolamide): Oral administration may decrease the GI absorption of primidone.
- MONAMINE OXIDASE (MAO) INHIBITORS (e.g., amitraz, possibly selegline): May prolong phenobarbital effects
- PHENOTINO: Barbiturates may affect the metabolism of phenytoin, and phenytoin may alter barbiturate levels; monitoring of blood levels may be indicated
- RIFAMPIN: May induce enzymes that increase the metabolism of barbiturates
- THEOPHYLLINE
- PHENOTHIAZINES
- OPIATES
- BETA-BLOCKERS
- CLONAZEPAM
- CYCLOSPORINE
- DOXORUBICIN
- DOXYCYCLINE (may persist for weeks after barbiturate discontinued)
- GRISEOFULVIN
- METHADONE
- METRONIDAZOLE
- QUINIDINE
- PAROXETINE
- PHENOTHIAZINES
- PROGESTINS
- PHENOBARBITAL (particularly after chronic therapy) may decrease the effect of the following drugs/drug classes by lowering their serum concentrations:
- ANTIMYCOTICS
- ANTI-INFECTIVE
- ANTIBIOTICS
- ANTIACIDS
- ANTIHISTAMINES
- ANTICOAGULANTS, ORAL (WARFARIN)
- ANTIDIABETIC
**THEOPHYLLINE**

**TRICYCLIC ANTIDEPRESSANTS**

**VERAPAMIL**

**Probenecid**

**Pharmacology/Actions**

Probenecid reduces serum uric acid concentrations by enhancing uric acid excretion into the urine by competitively inhibiting urate reabsorption at the proximal renal tubules. It may make it particularly useful in this species; however, at present there is little research supporting this use of probenecid in veterinary patients.

**Uses/Indications**

Although there has been very limited clinical use or research on probenecid in veterinary medicine, it can be useful in treating gout (hyperuricemia), particularly in reptiles. Probenecid’s effect in inhibiting renal tubular secretion of certain beta-lactam antibiotics and other weak organic acids is of interest for increasing serum concentrations, or reducing doses and dosing frequency of these drugs. This may allow greater efficacy (but also toxic effects) and reduce the cost or dosing frequency of expensive human drugs. Probenecid has a significantly long elimination half-life in dogs (about 18 hours), which may make it particularly useful in this species; however, at present there is little research supporting this use of probenecid in veterinary patients.

**Dosages**

**DOGS:**

a) Initially, 10–30 mg/kg per day divided into 2–3 doses (LeCouteur 1999)
b) 10 mg/kg PO q8h; not recommended as first choice (Taylor 2003)

**CATS:**

a) 20 mg/kg, PO q12h (Neff-Davis 1985)

**Monitoring**

- Anticonvulsant efficacy
- Adverse effects (CNS related, PL/PD, weight gain)
- Serum phenobarbital levels if lack of efficacy or adverse reactions noted. Although there is some disagreement, therapeutic serum levels in dogs are thought to mirror those in people at 15–40 micrograms/mL. See the phenobarbital monograph for more information.
- If used chronically, routine CBCs and liver enzymes at least every 6 months

**Chemistry/Synonyms**

An analog of phenobarbital, primidone occurs as a white, odorless, slightly bitter-tasting, crystalline powder with a melting point of 279°–284°C. One gram is soluble in approximately 2000 mL of water or 200 mL of alcohol.

Primidone may also be known as: hexamidinum, primaclone, primidonum, Cyrol®, Epidon®, Liskamin®, Mylespinum®, Mysoline®, Neurosyn®, Primidone®, Primitil®, or Sertan®.

**Storage/Stability**

Tablets should be stored in well-closed containers preferably at room temperature. The oral suspension should be stored in tight, light-resistant containers preferably at room temperature; avoid freezing. Commercially available suspension and tablets generally have expiration dates of 5 years after manufacture.

**Disease Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Primidone Tablets: 50 mg and 250 mg; Neurosyn® (BI-Vetmedica); (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**

Primidone Tablets: 50 mg & 250 mg; Mysoline® (Xcel Pharm); generic; (Rx)

**References**

**Uses/Indications**

Although there has been very limited clinical use or research on probenecid in veterinary medicine, it can be useful in treating gout (hyperuricemia), particularly in reptiles.

**Pharmacology/Actions**

Probenecid reduces serum uric acid concentrations by enhancing uric acid excretion into the urine by competitively inhibiting urate reabsorption at the proximal renal tubules.
Probenecid competitively inhibits tubular secretion of weak organic acids including the penicillins, some cephalosporins (not ceftriaxone, ceftazidime, or cefoperazone), sulbactam and tazobactam (not clavulanate), oseltamivir, etc.

Pharmacokinetics

There is limited information available for veterinary species. In dogs, information on oral bioavailability was not located, but after intravenous administration the distribution half-life was 2.3 hours and apparent volume of distribution at steady state was 0.46 L/kg. Probenecid exhibits biphasic concentration dependent plasma protein binding characteristics in the dog and appears to bind less to plasma proteins than in humans. Plasma clearance was 0.343 mL/min/kg and elimination half-life was 17.7 hours, which is considerably longer than in humans (6.5 hrs) or sheep (1.55 hrs) (Kakizaki et al. 2005).

After administration to mares, probenecid had an oral bioavailability of approximately 90%. The drug is highly bound (99.9%) to equine plasma proteins. Elimination half-life is approximately 90–120 minutes.

In humans, absorption after oral administration is rapid and complete. The drug is converted in the liver to glucuronidated, carboxylated, and hydroxylated compounds that have uricosuric and renal tubular secretion inhibition activity. Elimination half-life is dosage dependent and large dosages (above 500 mg) have longer half-lives.

Contraindications/Precautions/Warnings

Probenecid should not be used in patients with, or susceptible to, uric acid renal or bladder calculus formation or urate nephropathy (e.g., cancer chemotherapy with rapidly cytolytic agents). Probenecid requires sufficient renal function to be effective; efficacy decreases with increasing renal function impairment. The drug has no efficacy in human patients with a creatine clearance of less than 30 mL/min.

Probenecid is not usually recommended for treating gout in birds as it can exacerbate the condition.

Adverse Effects

An accurate adverse effect profile for probenecid has not been determined for animal patients. In humans, probenecid occasionally causes headache, gastrointestinal effects (inappetence, nausea, mild vomiting), or rash. When used for gout, it can initially cause an increased rate of gouty attacks unless prophylaxis with colchicine is used concurrently. Rarely, hypersensitivity, bone marrow suppression, hepatotoxicity, or nephrotic syndrome have been reported in humans.

Reproductive/Nursing Safety

Probenecid apparently crosses the placenta, but adverse effects to fetuses have not been reported. In humans, the FDA categorizes probenecid as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) It is unknown if probenecid enters milk, but it is unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity

Limited information is available. One massive (>45 g) overdose in a human patient caused CNS stimulation, seizures, protracted vomiting and respiratory failure. Consider contacting an animal poison control center for guidance with large overdoses. Generally, probenecid overdoses should initially be handled using standardized protocols for removal of drug from the gut and preventing absorption. Treat supportively, but use caution co-administrating drugs that may compete with probenecid for tubular secretion.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving probenecid and may be of significance in veterinary patients:

- ACYCLOVIR: Increased acyclovir serum concentrations; probenecid can decrease renal excretion
- ANTINEOPLASTICS (rapidly cytolytic): Increased chance of uric acid nephropathy
- ASPIRIN (and other salicylates): Salicylates antagonize the uricosuric effects of probenecid
- BENZODIAZEPINES (lorazepam, oxazepam): Probenecid may prolong action or reduce time for onset of action
- BETA-LACTAM ANTIBIOTICS (including penicillins and some cephalosporins): Probenecid may increase serum concentrations by reducing renal excretion
- BETA-LACTAMASE INHIBITORS (including sulbactam and tazobactam, but not clavulanic acid): Probenecid may increase serum concentrations by reducing renal excretion
- CHLORPROPAMIDE (and potentially other sulfonylureas): Probenecid decreases elimination; hypoglycemia is possible
- CIPROFLOXACIN/ENROFLOXACIN: Probenecid reduces renal tubular secretion of ciprofloxacin by about 50%. In goats, probenecid significantly reduced renal excretion of enrofloxacin (Narayan et al. 2009).
- DAPSONE: Possible accumulation of dapsone or its active metabolites
- FUROSEMIDE: Increased serum furomide levels
- Heparin: Probenecid may increase and prolong heparin’s effects
- METHOTREXATE: Probenecid may increase levels; increased risks for toxicity
- NSAIDS (including carprofen, ketoprofen & potentially others): Probenecid may increase plasma levels and increase risks for toxicity
- NITROFURANTOIN: Reduced urine levels; increased chance for systemic toxicity
- OSELTAMIVIR: Probenecid may increase serum concentrations by reducing renal excretion
- RIFAMPIN: Probenecid may reduce hepatic uptake of rifampin and serum levels can be increased; use together is not recommended as effect is inconsistent and can lead to toxicity
- SULFONAMIDES: Probenecid decreases renal elimination of sulfonamides, but as free serum concentrations of sulfonamides are not increased this interaction is not therapeutically beneficial and may increase risks for sulfonamide toxicity
- THIOPENTAL: Anesthesia may be extended or dose required for anesthesia decreased

Laboratory Considerations

The following laboratory alterations have been reported in humans with probenecid and may be of significance in veterinary patients:

- urine glucose determinations: When using cupric sulfate solution (Benedict’s Solution, Clinitest®); Probenecid may cause false-positive results. Tests utilizing glucose oxidase (Tes-Tape®, Clinitest®) are not affected.
- Theophylline levels: Serum theophylline levels may be falsely elevated (Schack and Waxler technique)
- 17-ketosteroid concentrations in urine: May be decreased
- Phosphorus: Probenecid may increase phosphorus reabsorption in hypoparathyroid patients
- Aminohippuric acid (PAH) or Phenolsulphonphthalein (PSP) clearance studies: Probenecid decreases renal clearance
- Renal function studies using iodohippurate sodium I 123 or I 131, or technetium TC 99: Decreased kidney uptake
- Homovanillic acid (HVA) or 5-Hydroxyindoleacetic acid (5-HIAA): Probenecid inhibits transport from CSF into blood

Doses

- REPTILES:
  - For gout:
    - a) 250 mg PO q12h; can be increased as needed. Suggested dosage based upon human data as dose is not established for reptiles. (Johnson-Delaney 2005)
    - b) 40 mg/kg PO q12h (Coke 2004)
    - c) 250 mg (total dose) PO twice daily; may increase as needed. (de la Navarre et al. 2009)

Monitoring

- Depending on purpose for use: serum and urine uric acid, if concomitant urine alkalinization is used, consider monitoring acid-base balance
In small animals, there is little scientific data supporting using probenecid for increasing blood levels of drugs that compete with probenecid for renal excretion; probenecid’s adverse effects are not well known in these patients.

**Chemistry/Synonyms**
Probenecid is a sulfonamide derivative that occurs as a white, to practically white, practically odorless, fine, crystalline powder. It is practically insoluble in water and soluble in alcohol.

**Probenecid may also be known as:** probenecidas, probenecidam, Benemid® and Benuryl®.

**Storage/Stability**
Probenecid tablets should be stored at room temperature in well-closed containers. Expiration dates are generally 3–5 years after manufacture.

**Dosage Forms/Regulatory Status**

### VETERINARY-LABELLED PRODUCTS: None

### HUMAN-LABELLED PRODUCTS:

**Probenecid Tablets:** 500 mg; generic; (Rx)

Also available as fixed-dose tablets containing probenecid 500 mg and colchicine 0.5 mg, but this dosage form is unlikely to be useful in veterinary patients.

**References**

**Uses/Indications**
Probenecid potentially may be useful for the treatment of ventricular premature complexes (VPC’s), ventricular tachycardia, or supraventricular tachycardias associated with wide QRS complexes. When a tachycardia with a wide QRS is seen that cannot be definitively identified as supraventricular or ventricular in origin, probenecid is an ideal first-line IV therapeutic agent because of its broad spectrum of activity for atrial and ventricular arrhythmias (Saunders et al. 2009).

**Pharmacology/Actions**
A class 1A antiarrhythmic agent, procainamide exhibits cardiac action similar to that of quinidine. It is considered both a supraventricular and ventricular antidysrhythmic. Procainamide prolongs the refractory times in both the atria and ventricles, decreases myocardial excitability, and depresses automaticity and conduction velocity. It has anticholinergic properties that may contribute to its effects. Procainamide’s effects on heart rate are unpredictable, but it usually causes only slight increases or no change. It may exhibit negative inotropic actions on the heart, although cardiac outputs are generally not affected. On ECG, QRS widening, and prolonged PR and QT intervals can be seen. The QRS complex and T wave may occasionally show some slight decreases in voltage.

**Pharmacokinetics**

After IM or IV administration, the onset of action is practically immediate. After oral administration in humans, approximately 75–95% of a dose is absorbed in the intestine, but some patients absorb less than 50% of a dose. Food, delayed gastric emptying, or decreased stomach pH may delay oral absorption. In dogs, it has been reported that the oral bioavailability is approximately 85% and the absorption half-life is 0.5 hours; however, there is an apparent large degree of variability in both bioavailability and half-life of absorption. Distribution of probenecid is highest into the CSF, liver, spleen, kidneys, lungs, heart and muscles. The volume of distribution in dogs is approximately 1.4–3 L/kg. It is only approximately 20% protein bound in humans and 15% in dogs. Probenecid can cross the placenta and is excreted into milk.

The elimination half-life in dogs has been reported to be variable; most studies report values between 2–3 hours. In humans, probenecid is metabolized to N-acetyl-probenecid (NAPA), an active metabolite. It appears, however, that dogs do not form appreciable amounts of NAPA from procainamide as they are unable to appreciably acetylate aromatic and hydrazine amino groups. In the dog, approximately 90% (50–70% unchanged) of an intravenous dose is excreted in the urine as procainamide and metabolites within 24 hours after dosing.

**Contraindications/Precautions/Warnings**

**Procainamide may be contraindicated in patients with myasthenia gravis (see Drug Interactions).** Procainamide is contraindicated in patients hypersensitive to it, procaine or other chemically related drugs. In humans, procainamide is contraindicated in patients with systemic lupus erythematosus (SLE), but it is unknown if it adversely affects dogs with this condition. Procainamide should not be used in patients with torsade de pointes, or with 2nd or 3rd degree heart block (unless artificially paced). Procainamide should be used with extreme caution, if at all, in patients with cardiac glycoside intoxication. It should be used with caution in patients with significant hepatic or renal disease or with congestive heart failure.

It has been recommended to not use procainamide in Doberman pinschers and boxers with dilated cardiomyopathy or dogs with subaortic stenosis; the drug may be proarrhythmic in certain patients susceptible to tachyarrhythmia-induced sudden death. (Kittleson 2006)

**Adverse Effects**
Adverse effects are generally dosage (blood level) related in the dog. Gastrointestinal effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension, negative inotropicism, widened QRS complex and QT intervals, AV block, multiform ventricular tachycardias. Fevers and leukopenias are a possibility. Profound hypotension can occur if injected too rapidly IV. In humans an SLE syndrome can occur, but its incidence has not been established in the dog.

Dosages should usually be reduced in patients with renal failure, congestive heart failure, or those who are critically ill.
The solution may be used if the color is no darker than a light amber. Refrigeration may retard the development of oxidation, but the solution may be stored at room temperature.

Structurally related to procaine, procainamide is used as an antiarrhythmic agent. Procainamide HCl differs from procaine by the substitution of an amide group for the ester group found on procaine. It occurs as an odorless,

In horses, therapeutic levels have been suggested as 4–10 micrograms/mL for procainamide and 10–30 micrograms/dL as procainamide and NAPA together. (Kimberly & McGurrin 2006)

need not be automatically run for canine patients.

therapeutics, but not to hesitate increasing doses to attain the higher values if efficacy is not achieved and toxicity is not a problem. Digitalis-induced ventricular arrhythmias may require substantially higher blood levels for

Because of the variability in pharmacokinetics reported in the dog, it is recommended to monitor therapy using serum drug levels. Because dogs apparently do not form the active metabolite NAPA in appreciable quantities,

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving procainamide and may be of significance in veterinary patients:

Use with caution with other antidyssrhythmic agents, as additive cardiotoxic or other toxic effects may result.

- **AMIODARONE:** May increase procainamide levels, procainamide dose may need to be reduced
- **ANTICHOLINESTERASE AGENTS** (e.g., pyridostigmine, neostigmine): Procainamide may antagonize effects in patients with myasthenia gravis
- **CIMETIDINE:** May increase procainamide levels
- **HYPOTENSIVE DRUGS:** Procainamide may enhance effect
- **LIDOCAINE:** Toxic effects may be additive, and cardiac effects unpredictable
- **NEUROMUSCULAR BLOCKING AGENTS:** Procainamide may potentiate or prolong the neuromuscular blocking activity
- **QUINIDINE:** Toxic effects may be additive, and cardiac effects unpredictable
- **PHENOTYOIN:** Toxic effects may be additive, and cardiac effects unpredictable
- **PROPRANOLOL:** Toxic effects may be additive, and cardiac effects unpredictable
- **RANITIDINE:** May increase procainamide levels
- **TRIMETHIOPRIM:** May increase procainamide levels

**Doses**

- **DOGS:**
  a) For ventricular tachyarrhythmias: When used IV: intermittent boluses of 2–4 mg/kg IV slowly (over two minutes) up to a total dose of 12–20 mg/kg until arrhythmia controlled and then a CRI may be started at 10–40 micrograms/kg/minute. PO use at 20–30 mg/kg PO q6–8h (could be too low—previous recommendations of 8–20 mg/kg PO q6–8h are almost certainly too low). (Kittelson 2006)
  b) For acute management of SVT’s: After drugs have been used to slow AV nodal conduction (i.e., dilatuzem), procainamide at 6–8 mg/kg IV over 3 minutes or 6–20 mg/kg IM may terminate atrial tachyarrhythmias.
  c) For ventricular tachycardia: For acute treatment of VT: 10–15 mg/kg IV bolus over 1–2 minutes; if continued parenteral administration required may use a constant rate IV infusion at 25–50 micrograms/kg/minute. For chronic treatment: 10–20 mg/kg PO q4h (Moise 2000)
  d) For ventricular tachycardia: 6.6–8.8 mg/kg slowly IV over 5 minutes, then give as a CRI at 40–100 micrograms/kg/minute. (Fine 2006)
  e) For chronic treatment of ventricular arrhythmias: 20–23 mg/kg PO q8h (Meurs 2002)
  f) Using sustained-release tablets: 20 mg/kg PO q8h; For intravenous therapy: 6–8 mg/kg IV bolus, 20–40 micrograms/kg/min CRI (Hogan 2004)
  g) For acute treatment of atrial fibrillation: 5–15 mg/kg IV slowly to effect. (Saunders et al. 2009)
  h) If lidocaine ineffective for ventricular tachycardia: 20–50 micrograms/kg/min IV or 6–15 mg/kg IM q4–6h. (Rush 2006)
- **CATS:**
  a) For chronic management of SVT’s: 3–8 mg/kg PO q6–8h. (Wright 2000)
  b) 1–2 mg/kg slowly IV; 10–20 micrograms/kg/minute constant rate IV infusion. Oral dose: 7.5–20 mg/kg q 6–8h (Ware 2000)
- **HORSES:** (Note: ARCI UCGFS Class 4 Drug)
  a) For atrial fibrillation (not as effective as quinidine); also has been used for ventricular tachycardia: IV at 1 mg/kg/min, not too exceed 20 mg/kg (20 minutes) total dose. Alternatively administer 25–35 mg/kg PO q8h. (Kimberly & McGurrin 2006)
  b) For V-Tach: 1 mg/kg/minute IV up to a total dose of 20 mg/kg; or 25–35 mg/kg PO q8h (Mogg 1999)

**Monitoring**

- ECG; continuously with IV dosing
- Blood pressure, during IV administration
- Clinical signs of toxicity (see Adverse Effects/Overdosage)
- Serum levels

Because of the variability in pharmacokinetics reported in the dog, it is recommended to monitor therapy using serum drug levels. Because dogs apparently do not form the active metabolite NAPA in appreciable quantities, the therapeutic range for procainamide is controversial. Therapeutic ranges from 3–8 micrograms/ml to 8–20 micrograms/ml have been suggested. This author would suggest using the lower range as a guideline to initiate and maintain therapy. Because NAPA is routinely monitored with procainamide in human medicine, it may be necessary to request to the laboratory that NAPA levels not be automatically run for canine patients.

In horses, therapeutic levels have been suggested as 4–10 micrograms/ml for procainamide and 10–30 micrograms/dL as procainamide and NAPA together. (Kimberly & McGurrin 2006)

**Client Information**

- Oral products should be administered at evenly spaced intervals throughout the day/night. Unless otherwise directed, give the medication at least 1 hour before feeding to animal with an empty stomach.
- Notify veterinarian if animal’s condition deteriorates or clinical signs of toxicity (see Adverse Effects/Overdosage) occur.

**Chemistry/Synonyms**

Structurally related to procaine, procainamide is used as an antidyssrhythmic agent. Procainamide HCl differs from procaine by the substitution of an amide group for the ester group found on procaine. It occurs as an odorless, white to tan, hygroscopic, crystalline powder with a pKa of 9.23 and a melting range from 165–169°C. It is very soluble in water and insoluble in alcohol. The pH of the injectable product ranges from 4–6.

Procainamide may also be known as: novocainamidum, procainamidi chloridum, procainamidi hydrochloridum, Biosor®®, Procan®, Procanbid®, or Pronestyl®.

**Storage/Stability**

The solution may be used if the color is no darker than a light amber. Refrigeration may retard the development of oxidation, but the solution may be stored at room temperature.

The injectable product is reportedly physically compatible with sodium chloride 0.9% injection, and water for injection. Procainamide is also physically compatible with dobutamine HCl, lidocaine HCl, and verapamil.
The following drug interactions have either been reported or are theoretical in humans or animals receiving procarbazine and may be of significance in veterinary patients:

**Drug Interactions**

be extensions of the drug’s adverse effect profile (GI, bone marrow suppression, CNS effects). Monitor and support as necessary. Contact an animal poison control center for further guidance.

**Overdosage/Acute Toxicity**

The LD50 for laboratory animals range from 150 mg/kg (rabbits) to 1.3 grams/kg (mice). Treat overdoses aggressively to remove drug from the gut if overdose was within an hour or two. Anticipated adverse effects would

**Procarbazine is potential teratogen.** In pregnant humans, procarbazine is designated by the FDA as a category D drug (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

It is unknown if procarbazine enters milk. It is recommended to use milk replacer if the dam requires procarbazine.

The following drug interactions have either been reported or are theoretical in humans or animals receiving procarbazine and may be of significance in veterinary patients:
**PROCHLORPERAZINE**
(proe-klor-per-a-zeen) Compazine®, Compes®

**PHENOTHIAZINE ANTIEMETIC**

**Prescriber Highlights**

- Phenothiazine used alone as an antiemetic; formerly in combination with an anticholinergic for other GI effects (e.g., diarrhea)
- Relative Contraindications: Hypovolemia/dehydration or shock & in patients with tetanus or strychnine intoxication
- Caution: Hepatic dysfunction, cardiac disease, general debilitation, or very young animals
- Adverse Effects: Sedation or hypotension

**Uses/Indications**

Prochlorperazine as a single agent is used in dogs and cats as an antiemetic. The only FDA-approved products for animals were combination products containing prochlorperazine, isopropamide, with or without neomycin (Darbazaine®, Neo-Darbazine®—SKB Labs). These products are no longer marketed in the USA. The FDA-approved indications for these products were: vomiting, non-specific gastroenteritis, drug induced diarrhea, infectious diarrhea, spastic colitis, and motion sickness in dogs and cats (injectable product only).

**Pharmacology/Actions**

The basic pharmacology of prochlorperazine is similar to that of the other phenothiazines (refer to the acepromazine monograph for more information). Prochlorperazine has weak anticholinergic effects, strong antiemetic effects, and little sedative effects. It is used mainly to control vomiting in animals. Prochlorperazine is not recommended for use in pregnant or lactating animals.

**DOGS:**

For vomiting, prochlorperazine is used, it is as part of a protocol in combination with other antineoplastic agents and usually given for the first 14 days of the treatment cycle. Usual doses for dogs are: 50 mg/m² PO.

- For treatment of granulomatous meningoencephalitis (GME):
  a) 25–50 mg/m² PO once daily, initially with prednisone treatment. After the first month of therapy, we attempt to reduce prochlorperazine dose to every other day. Monitor CBC weekly for first month, and then monthly thereafter. Wear gloves when handling. To prepare a 10 mg/mL oil-based solution: Five 50 mg capsules, oil-based flavor (chicken, liver, fish) drops, 0.25 teaspoonful of silica gel (to keep in suspension), and gradually add sesame oil to a total of 25 mL. Assigned expiration date of 30 days. (Cuddon & Coates 2002)

- **CATS:**

  For MOPP lymphoma rescue: When prochlorperazine is used, it is as part of a protocol in combination with other antineoplastic agents and usually given for the first 14 days of the treatment cycle. Usual doses for cats are: 50 mg/m² PO or 10 mg (total dose per cat).

**Monitoring**

- **Baseline:** CBC, hepatic and renal function, urinalysis
- **Repeat CBC at least once weekly for the first month of treatment and then monthly**
- **In humans, it is recommended to repeat urinalysis, transaminases/alkaline phosphatase, and BUN at least weekly**

**Client Information**

- Avoid skin contact with the medication. Wear gloves or wash hands thoroughly after dosing. Avoid contact with patient’s saliva or urine.
- Contact veterinarian immediately if any signs associated with toxicity occur. These could include vomiting, lack of appetite, diarrhea, bleeding, depression or agitation, bleeding, sores in mouth, lameness, etc.

**Chemistry/Synonyms**

A derivative of hydrazine, procarbazine HCl occurs as a white to pale yellow crystalline powder having a slight odor. It is soluble, but unstable in water or aqueous solutions.

Procarbazine may also be known as: Ibenzemethyzin, NSC-77213, Ro-4-6467/1, MIH, N-Methylhydrazine, Matulane® (Sigma-Tau); (Rx) Natulan® (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)]) is strongly recommended.

**Storage/Stability**

Procarbazine capsules should be stored in air-tight containers, protected from light at temperatures less than 40°C (preferably between 15–30°C, (59–86°F). An expiration date of 4 years is assigned after the date of manufacture.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

None

**HUMAN-LABELLED PRODUCTS:**

Procarbazine HCl Capsules: 50 mg; (Sigma-Tau); (Rx)

**References**

**PROCHLORPERAZINE**
(proe-klor-per-a-zeen) Compazine®, Compes®

**PHENOTHIAZINE ANTIEMETIC**

Prescriber Highlights

- Phenothiazine used alone as an antiemetic; formerly in combination with an anticholinergic for other GI effects (e.g., diarrhea)
- Relative Contraindications: Hypovolemia/dehydration or shock & in patients with tetanus or strychnine intoxication
- Caution: Hepatic dysfunction, cardiac disease, general debilitation, or very young animals
- Adverse Effects: Sedation or hypotension

**Uses/Indications**

Prochlorperazine as a single agent is used in dogs and cats as an antiemetic. The only FDA-approved products for animals were combination products containing prochlorperazine, isopropamide, with or without neomycin (Darbazaine®, Neo-Darbazine®—SKB Labs). These products are no longer marketed in the USA. The FDA-approved indications for these products were: vomiting, non-specific gastroenteritis, drug induced diarrhea, infectious diarrhea, spastic colitis, and motion sickness in dogs and cats (injectable product only).
The basic pharmacology of prochlorperazine is similar to that of the other phenothiazines (refer to the acepromazine monograph for more information). Prochlorperazine has weak anticholinergic effects, strong extrapyramidal effects, and moderate sedative effects. Antiemetic activity of prochlorperazine is due to its effects primarily in the brain’s emetic center and chemoreceptor trigger zone, but it also has some peripheral activity. Alpha-adrenergic, dopaminergic, histaminergic, and cholinergic receptor antagonism all contribute to its antiemetic action.

**Pharmacokinetics**
Little information is available regarding the pharmacokinetics of prochlorperazine in animals, although it probably follows the general patterns of other phenothiazines in absorption, distribution, and elimination.

**Contraindications/Precautions/Warnings**
Animals may require lower dosages of general anesthetics following phenothiazines. Cautious use and smaller doses of phenothiazines should be given to animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of their hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia/dehydration or shock. Phenothiazines may exacerbate depression in patients with CNS depression. It should not be used for tetanus or strychnine intoxication due to effects on the extrapyramidal system. Use cautiously in very young or debilitated animals.

**Adverse Effects**
Alone, prochlorperazine is most likely to cause sedation or hypotension. Muscle fasciculations/tremors, and prolactin release have been reported in small animals

**Reproductive/Nursing Safety**
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

**Overdosage/Acute Toxicity**
Refer to the information listed in the acepromazine monograph. Acute extrapyramidal clinical signs (torticollis, tremor, salivation) have been successfully treated with injectable diphenhydramine in humans.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving prochlorperazine or other phenothiazines and may be of significance in veterinary patients:

- **ANTACIDS**: May cause reduced GI absorption of oral phenothiazines
- **ANTIDIARRHEAL MIXTURES** *(e.g., Kaolin/pectin, bismuth subsalicylate mixtures)*: May cause reduced GI absorption of oral phenothiazines
- **CNS DEPRESSANT AGENTS** *(barbiturates, narcotics, anesthetics, etc.)*: May cause additive CNS depression if used with phenothiazines
- **DOPAMINE**: Phenothiazines may decrease pressor effects
- **EPINEPHRINE**: Phenothiazines block alpha-adrenergic receptors and concomitant epinephrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- **METOCLOPRAMIDE**: Phenothiazines may potentiate the extrapyramidal effects of metoclopramide
- **OPIATES**: May enhance the hypotensive effects of the phenothiazines; dosages of prochlorperazine may need to be reduced when used with an opiate
- **ORGANOPHOSPHATE AGENTS**: Phenothiazines should not be given within one month of worming with these agents as their effects may be potentiated
- **PARAQUAT**: Toxicity of the herbicide paraquat may be increased by prochlorperazine
- **PHENYTOIN**: Metabolism may be decreased if given concurrently with phenothiazines
- **PHYSOSTIGMINE**: Toxicity may be enhanced by prochlorperazine
- **PROCAINE**: Activity may be enhanced by phenothiazines
- **PROPANOLOL**: Increased blood levels of both drugs may result if administered with phenothiazines
- **WARFARIN**: Prochlorperazine may decrease anticoagulant effect

**Doses**

**DOGS:**
As an antiemetic:
- a) 0.5 mg/kg IM or SC q8h; ensure adequate hydration (Washabau and Elie 1995; Marks 2006; Simpson 2003)
- b) 0.1 mg/kg IM q6–8h; use with extreme caution in dehydrated or hypotensive animals. (Silverstein 2003)
- c) 0.1–0.5 mg/kg IM or SC q6–8h (Otto 2005)

**CATS:**
As an antiemetic:
- a) 0.5 mg/kg SC or IM three times a day; ensure adequate hydration (Simpson 2003)
- b) 0.5 mg/kg SC or IM q8h (Washabau and Elie 1995);(Marks 2006)
- c) 0.1–0.5 mg/kg IM or SC q6–8h (Otto 2005)

**Monitoring**
- Cardiac rate/rhythm/blood pressure if indicated and possible to measure
- Anti-emetic/anti-spasmodic efficacy; hydration and electrolyte status
- Body temperature (especially if ambient temperature is very hot or cold)

**Client Information**
- Observe animal for at least one hour following dosing. Dry mouth may be relieved by applying small amounts of water to animal’s tongue for 10–15 minutes.
- May discolor the urine to a pink or red-brown color; this is not abnormal.
- Protracted vomiting and diarrhea can be serious; contact veterinarian if clinical signs are not alleviated. Contact veterinarian if animal exhibits abnormal behavior, becomes rigid or displays other abnormal body movements.

**Chemistry/Synonyms**
Prochlorperazine, a piperazine phenothiazine derivative, is available commercially as the base in rectal formulations, the edisylate salt in injectable and oral solutions, and as the maleate salt in oral tablets and capsules. Each 8 mg of the maleate salt and 7.5 mg of the edisylate salt are approximately equivalent to 5 mg of prochlorperazine base.

The base occurs as a clear, pale yellow, viscous liquid that is very slightly soluble in water and freely soluble in alcohol. The edisylate salt occurs as white to very light yellow, odorless, crystalline powder. 500 mg are soluble in 1 mL of water and 750 mL of alcohol. The maleate salt occurs as a white or pale yellow, practically odorless, crystalline powder. It is practically insoluble in water or alcohol.

The commercial injection is a solution of the edisylate salt in sterile water. It has a pH of 4.2–6.2. Prochlorperazine may also be known as: chlorpromazine, prochlorperazine, Compazine®, Compro®, Prochlor®, Prozin®, Stemetil®, or Temeni®.

**Storage/Stability**
Store in tight, light resistant containers at room temperature. Avoid temperatures above 40°C and below freezing. A slight yellowing of the oral or injectable solution has no effects on potency or efficacy, but do not use if a precipitate forms or the solution is substantially discolored.
Compatibility/Compounding Considerations

The following products have been reported to be physically compatible when mixed with prochlorperazine edisylate injection: all usual IV fluids, ascorbic acid injection, atropine sulfate, butorphanol tartrate, chlorpromazine HCl, dexmethasone sodium phosphate, droperidol, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, lidocaine HCl, meperidine HCl, metoclopramide, morphine sulfate, nafcillin sodium, nalbuphine HCl, pentazocine lactate, perphenazine, promazine HCl, promethazine, scopolamine HBr, sodium bicarbonate, and vitamin B complex with C.

The following drugs have been reported to be physically incompatible when mixed with prochlorperazine edisylate: aminophylline, amphetamine B, ampicillin sodium, calcium gluconate, chloramphenicol sodium succinate, chlorothiazide sodium, dimenhydrinate, hydrocortisone sodium succinate, methohexital sodium, penicillin G sodium, phenobarbital sodium, pentobarbital sodium, and thiopental sodium. Do not mix with other drugs/diluents having parabens as preservatives. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VERTEBRATE-LABELED PRODUCTS:

None; Darbazine® is no longer available.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Prochlorperazine for Injection: 5 mg/mL in 2 mL vials; generic; (Rx)
Prochlorperazine Tablets: 5 mg & 10 mg (as maleate); generic; (Rx)
Prochlorperazine (base) Suppositories: 25 mg; Compro® (Paddock); generic; (Rx)

References

PROMETHAZINE HCL
(pro-o-meth-a-zeen) Phenergan®

PHENOTHIAZINE

Prescriber highlights

• Phenothiazine used as an antihistamine & antiemetic in small animals
• Relatively little experience with this drug in veterinary medicine; not frequently recommended for use
• Adverse Effects: sedation or anticholinergic effects

Uses/Indications

Promethazine may be useful in dogs and cats as an antiemetic. Because of its antihistamine actions, it has been tried for treating pruritus in atopic dogs, but its efficacy has been poor.

Pharmacology/Actions

The basic pharmacology of promethazine is similar to that of the other phenothiazines (refer to the acepromazine monograph for more information). It exhibits antiemetic, antihistaminic, anticholinergic, sedative, and local anesthetic actions.

Pharmacokinetics

Little information is available regarding the pharmacokinetics of promethazine in animals, although it probably follows the general patterns of other phenothiazine agents in absorption, distribution, and elimination.

In humans, the drug is well absorbed following oral or rectal administration, and via IM injection. Sedative effects occur within minutes of IV administration and persist for several hours. The drug is metabolized in the liver and these metabolites are eliminated primarily in the urine. Elimination half-life in humans is about 10 hours.

Contraindications/Precautions/Warnings

Animals may require lower doses of general anesthetics following phenothiazines. Cautions use and smaller doses of phenothiazines should be given to animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of their hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia or shock. Do not use in patients with tetanus or strychnine intoxication due to effects on the extrapyramidal system. Use cautiously in very young or debilitated animals.

In humans, promethazine has a “black box warning” to not use the medication in children less than 2 years old; fatal respiratory depression has occurred in that patient group.

Adverse Effects

Little experience has been reported with this drug in animals, but prochlorperazine would most likely cause sedation or anticholinergic effects (dry mouth, etc.).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether promethazine is distributed into milk; a related compound, chlorpromazine has been detected in maternal milk. Although few cases are documented, a milk to plasma ratio of 0.5–0.7 or less is reported. Promethazine is unlikely to pose significant risk to nursing animals.

Overdosage/Acute Toxicity

Refer to the information listed in the acepromazine monograph. Acute extrapyramidal clinical signs (torticollis, tremor, salivation) have been successfully treated with injectable diphenhydramine in humans.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine or other phenothiazines and may be of significance in veterinary patients:

- ANTACIDS: May cause reduced GI absorption of oral phenothiazines
- ANTIDIARRHEAL MIXTURES (e.g., Kaolin/pectin, bismuth subsalicylate mixtures): May cause reduced GI absorption of oral phenothiazines
- ATROPINE & OTHER ANTICHOLINERGICS: May have additive effects when used with promethazine
- CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.): May cause additive CNS depression when used with phenothiazines
- EPINEPHRINE: Phenothiazines block alpha-adrenergic receptors and concomitant epinephrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- METOCLOPRAMIDE: Phenothiazines may potentiate the extrapyramidal effects of metoclopramide
- MONOAMINE OXIDASE INHIBITORS: May potentiate extrapyramidal effects
- OPIATES: May enhance the hypotensive effects of the phenothiazines; dose of meprobamate may need to be reduced when used with an opiate
**Laboratory Considerations**

- Promethazine can cause false positive results for salicylates in urine
- Promethazine can cause false positive or false negative results for chorionic gonadotropin in urine

**Doses**

**DOGS/CATS:**
- As an antihistamine:
  - a) 2 mg/kg PO or IM once daily (Dowling 2003)
  - As an anticholinergic:
    - a) 0.2-0.4 mg/kg PO three to four times a day. (Morgan 2003)
    - b) 1–2 mg/kg PO q12h. (Mueller 2000)

**Monitoring**

- **Efficacy**
  - Dry mouth may be relieved by applying small amounts of water to animal’s tongue for 10–15 minutes
  - May cause sedation or behavior changes; contact veterinarian if these are a concern
  - Protracted vomiting or diarrhea can be serious; contact veterinarian if clinical signs are not alleviated
  - Contact veterinarian if animal exhibits abnormal movements or becomes rigid

**Chemistry/Synonyms**

Promethazine HCl occurs as a white to faint yellow, practically odorless, crystalline powder. It slowly oxidizes and acquires a blue color on prolonged exposure to air. Promethazine HCl is freely soluble in water, in hot dehydrated alcohol, and in chloroform, but practically insoluble in acetone, ether, or ethyl acetate. The pH of a 5% solution in water is between 4–5.

Promethazine may also be known as: Lilly 01516, PM 284, RP 3277, prometazina or Phenergan®. There are many other trade names available.

**Storage/Stability**

Store tablets at room temperature (20–25°C) in tight, light resistant containers. The syrup should be stored from 15–25°C and protected from light.

The injection should be stored at room temperature 20–25°C and protected from light. Keep in covered carton until time of use. Do not use if a precipitate forms or the solution is discolored. Promethazine can be adsorbed to plastic IV bags and tubing.

Promethazine suppositories should be stored in the refrigerator (2–8°C)

**Compatibility/Compounding Considerations**

The following products have been reported to be physically compatible when promethazine injection is mixed with them: all usual IV fluids, amikacin, ascorbic acid, buprenorphine, butorphanol, cimetidine, diphenhydramine, fentanyl, fluconazole, glycopyrrolate, hydromorphone, hydroxyzine, meperidine, metoclopramide, midazolam, ondansetron, pancuronium, pentazocine, procainamide, and ranitidine.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Promethazine HCl for Injection: 25 mg/mL, in 1 mL ampules; Phenergan® (Wyeth); generic; (Rx)
- Promethazine HCl Oral syrup: 1.25 mg/mL, in 473 mL; generic; (Rx)
- Promethazine HCl Oral Tablets: 12.5 mg, 25 mg & 50 mg; Phenergan® (Wyeth); generic; (Rx)
- Promethazine HCl Rectal Suppositories: 12.5 mg, 25 mg, & 50 mg; Phenergan® (Wyeth), Phenanoc® (Paddock), Promethegyn® (G & W Labs); generic; (Rx)

**References**

---

**PROPANTHELINE BROMIDE**

(proe-pan-the-lin) Pro-Banthine®

**QUATERNARY ANTIMUSCARINIC**

**Prescriber Highlights**

- Quaternary antimuscarinic agent used for its antispasmodic/antisecretory for treatment of diarrhea, hyperreflexic detrusor or urge incontinence & anticholinergic responsive bradycardias. In horses, IV to reduce colonic peristalsis & relax rectum to allow easier examination & surgery.

- Contraindications: Hypersensitivity to anticholinergics, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive urethropy, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).

- Extreme Caution: Known or suspected GI infections, autonomic neuropathy. Caution: hepatic or renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, & geriatric or pediatric patients.

- Adverse Effects: Similar to atropine (dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation, etc.), but less effects on eye or CNS. Cats may exhibit vomiting & hypersalivation. High doses may cause ileus.
In small animal medicine propantheline bromide has been used for its antispasmodic/antisecretory effects in the treatment of diarrhea. It is also employed in the treatment of hyperreflexic detrusor or urge incontinence and as oral treatment in anticholinergic responsive bradycardias. In horses, propantheline has been used intravenously to reduce colonic peristalsis and for relaxing the rectum to allow easier rectal examination and surgery.

**Pharmacology/Actions**

An antimuscarinic with similar actions as atropine, propantheline is a quaternary ammonium compound and does not cross appreciably into the CNS. It should not exhibit the same extent of CNS adverse effects that atropine possesses. For further information, refer to the atropine monograph.

**Pharmacokinetics**

Quaternary anticholinergic agents are not completely absorbed after oral administration because they are completely ionized. In humans, peak levels occur about 2 hours after oral administration. Food apparently decreases the amount of drug absorbed. Propantheline is reportedly variably absorbed in dogs; dosages should be adjusted for each patient.

The distribution of propantheline has not been extensively studied, but like other quaternary antimuscarinics, propantheline is poorly lipid soluble and does not extensively penetrate into the CNS or eye.

Propantheline is believed to be prevalently metabolized in the GI and/or liver; less than 5% of an oral dose is excreted unchanged in the urine.

**Contraindications/Precautions/Warnings**

Use of propantheline should be considered contraindicated if the patient has a history of hypersensitivity to anticholinergic drugs, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).

Antimuscarinic agents should be used with extreme caution in patients with known or suspected GI infections. Propantheline or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Antimuscarinic agents should be used with caution in patients with hepatic disease, renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, and in geriatric or pediatric patients.

**Adverse Effects**

With the exception of fewer effects on the eye and the CNS, propantheline can be expected to have a similar adverse reaction profile as atropine (dry mouth, dry eyes, urinary hesitancy, tachycardia, constipation, etc.). Vomiting and hypersalivation have also been reported in cats. High doses may lead to the development of ileus with resultant bacterial overgrowth in susceptible animals. For more information, refer to the atropine monograph.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus; there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Although anticholinergics (especially atropine) may be excreted in milk and can cause toxicity and reduce milk production, it is unknown if propantheline enters maternal milk. Use with caution in nursing patients.

**Overdosage/Acute Toxicity**

Because of its quaternary structure, it would be expected that minimal CNS effects would occur after an overdose of propantheline when compared to atropine. See the information listed in the atropine monograph for more information on the clinical signs that may be seen following an overdose.

If a recent oral ingestion, emptying gut contents and administration of activated charcoal and saline cathartics may be warranted. Treat clinical signs supportively and symptomatically. Do not use phenothiazines as they may contribute to anticholinergic effects. Fluid therapy and standard treatments for shock may be instituted.

The use of physostigmine is controversial and should probably be reserved for cases where the patient exhibits either extreme agitation and is at risk for injuring themselves or others, or where supraventricular tachycardias and sinus tachycardias are severe or life threatening. The usual dose for physostigmine (human) is 2 mg IV slowly (for average sized adult); if no response may repeat every 20 minutes until reversal of toxic effects has occurred. Use with caution in patients with hepatic or renal disease, or in patients with increased intracranial pressure.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving propantheline and may be of significance in veterinary patients:

- **ANTIHISTAMINES**: May enhance the activity of propantheline
- **BENZODIAZEPINES**: May enhance the activity of propantheline
- **CIMETIDINE**: Propantheline may decrease the absorption of cimetidine
- **CORTICOSTEROIDS (long-term use)**: May increase intraocular pressure
- **MEPERIDINE**: May enhance the activity of propantheline
- **NITRATES**: May potentiate the adverse effects of propantheline
- **NITROFURANTOIN**: Propantheline may enhance actions
- **PHENOTHIAZINES**: May enhance the activity of propantheline
- **SYMPATHOMIMETICS**: Propantheline may enhance actions
- **RANITIDINE**: Propantheline delays the absorption, but increases the peak serum level of ranitidine; the relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine
- **THIAZIDE DIURETICS**: Propantheline may enhance actions

**Uses/Indications**

For detrusor hyperreflexia, urge incontinence:

- **DOGS**: 0.2 mg/kg PO q8–12h; increase dose if necessary to the lowest dose that will control clinical signs (Polzin & Osborne 1985)
- **DOGS**: 5–7.5 mg (total dose) PO once a day to q8h (Bartges 2003)
- **DOGS**: 7.5–30 mg PO q8–12h; occasionally dosages of 30 mg q8h are required (Lane 2000)
- **DOGS**: 0.25–0.5 mg/kg PO q8–12h (Hogan 2004)
- **DOGS**: 0.5 mg/kg PO q12h (Chiapella 1986)

For sinus bradycardia, incomplete AV block, etc.

- **DOGS**: 0.25 mg/kg PO three times a day; do not use longer than 48–72 hours (48 hours for acute colitis) (DeNovo, R.C. 1988)
- **DOGS**: 0.25 mg/kg PO twice to three times daily (Rishniw & Thomas 2000)

**CATS**

For detrusor hyperreflexia, urge incontinence:

- **CATS**: 0.25–0.5 mg/kg PO q12–24h. Empirical dosage. Further studies required to substantiate beneficial effect. (Osborne et al. 2003)
For sinus bradyardia, incomplete AV block, etc.:

- Although generally ineffective, a trial may be attempted using: 0.8–1.6 mg/kg three times daily (Harpster 1986)
- 7.5 mg PO q8–12h; usually well tolerated, but improvement is usually partial and often temporary (Rishniw & Thomas 2000)

For chronic colitis:

- 0.5 mg/kg two to three times (Chiapella 1986)
- As an antiemetic/antidiarrheal:
  - 0.25 mg/kg PO q6h (DeNovo, R.C., Jr. 1986)

- **HORSES:**

  To reduce rectal contractions:
  
  a) During acute collection: 0.04 mg/kg IV (Carnevale & Coutinho da Silva 2003)
  
  b) 30 mg IV to inhibit peristalsis for 2 hours during rectal surgery (Merkt et al. 1979)

  **Note:** There is no commercially available injectable product available in the U.S.A. Should a preparation be made from oral tablets, it should be freshly prepared and filtered through a 0.22 micron-filter before administering. Use with caution.

**Monitoring**

Dependent on reason for use:

- Clinical efficacy
- Heart rate and rhythm if indicated
- Adverse effects

**Client Information**

- Dry mouth may be relieved by applying small amounts of water to animal’s tongue for 10–15 minutes.
- Protracted vomiting and diarrhea can be serious; contact veterinarian if symptoms are not alleviated.

**Chemistry/Synonyms**

A quaternary ammonium antimuscarinic agent, propantheline bromide occurs as bitter-tasting, odorless, white or practically white crystals, with a melting range of 156–162° (with decomposition). It is very soluble in both water and alcohol.

Propantheline bromide may also be known as: bromuro de propantelina, propanthelini bromidum, Pro-Banthine®, Propantheline® (Schiapparelli Searle); generic; (Rx)

**Storage/Stability**

Propantheline bromide tablets should be stored at room temperature in tight containers.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Propantheline Bromide Tablets: 7.5 mg & 15 mg; Pro-Banthine® (Schiapparelli Searle); generic; (Rx)

**References**

- VanVleck, D.C. et al. (2003). Immunoregulin® (Immunoregulin®, Eqstim® Immunoregulin®, Eqstim®) is labeled as an immunostimulant for adjunctive therapy of primary or secondary viral or bacterial respiratory tract infections.

**PROPINIBACTERIUM ACNES INJECTION**

**Immunostimulant**

**Prescriber Highlights**

- Immunostimulant for Staph pyoderma, FeLV, feline herpes, equine respiratory infections
- Contraindications: Hypersensitivity to compound, canine lymphoma, or leukemias with CNS involvement. Caution: Cardiac dysfunction
- Adverse Effects: Lethargy, hyperthermia, chills, & anorexia. Anaphylactic reactions are possible
- Extravasation may cause local tissue inflammation

**Uses/Indications**

The manufacturer’s label notes the product (Immunoregulin®) “...indicated in the dog as adjunct to antibiotic therapy in the treatment of chronic recurring canine pyoderma to decrease the severity and extent of lesions and increase the percentage of dogs free of lesions after the appropriate therapeutic period.” The equine product (Eqstim®) is labeled as an immunostimulant for adjunctive therapy of primary or secondary viral or bacterial respiratory tract infections.

Additionally, it has been used as an immunostimulant for the adjunctive treatment of feline rhinotracheitis and feline leukemia virus-induced disease. In dogs, it may be of use in the adjunctive treatment of oral melanoma and mastocytoma. Unfortunately, controlled studies documenting efficacy were not located for these potential indications.

**Pharmacology/Actions**

A non-specific immunostimulant, Propionibacterium acnes injection may induce macrophage activation, lymphokine production, increase natural killer cell activity, and enhance cell-mediated immunity.

HUMAN-LABELED PRODUCTS:
Labeled for use in dogs. Propionibacterium acnes

VETERINARY-LABELED PRODUCTS:
Dosage Forms/Regulatory Status
Store refrigerated; do not freeze. Shake well before using.

Storage/Stability
Store refrigerated; do not freeze. Shake well before using.

Doses

**DOGS:**
For labeled indications (as adjunct to antibiotic therapy in the treatment of chronic recurring canine pyoderma):
a) Shake well. Give via intravenous route at the following dosages: For animals weighing up to 15 lbs = 0.25–0.5 mL; 15–45 lbs = 0.25–1 mL; 45–75 lbs = 1–1.5 mL; >75 lbs = 1.5–2 mL. During the first two weeks, give 4 times at 3-4 day intervals, then once weekly until symptoms abate or stabilize. Maintenance doses once per month are recommended. (Package Insert; Immunoregulin®)
b) For adjunctive therapy of chronic recurrent canine pyoderma: 0.03–0.07 mL/kg twice weekly for 10 weeks (combined with antibiotic therapy) (Barta 1992)

**CATS:**
For adjunctive therapy of feline retrovirus infections:
a) 0.5 mL IV twice weekly for 2 weeks, then one injection weekly for 20 weeks or until cat is seronegative. (McCaw 1994)
b) 0.25–0.5 mL IV twice weekly then every other week for 16 weeks (Levy 2004)
c) As an antiviral immunostimulant in cats to increase hematopoiesis in FeLV-positive cats: 5 lb cats: 0.25 mL IV, IP twice weekly for 2 weeks, then once weekly until remission and once monthly after that to maintain clinical improvement. For 10 lb cats: 0.5 mL IV, IP twice weekly for 2 weeks, then once weekly for 3 weeks and once monthly for 2 months for a total of nine injections after that to maintain clinical improvement. Some protocols suggest follow-up with injections once every 2 weeks or longer as needed. Others suggest follow-up with once weekly until clinical remission, and then once per month. (Greene et al. 2006)

**HORSES:**
As an immunostimulant for adjunctive therapy of primary or secondary viral or bacterial respiratory tract infections:
a) Using EqStim®: 1 mL per 114 kg (250 lb) body weight IV q48-72h (Flamino 2003)
b) Using EqStim®: 1 mL per 114 kg (250 lb) body weight IV. Repeat dosage on day 3 (or day 4), at day 7, and weekly as needed (Label information; Eqstim®—Neogen)
c) As an adjunctive treatment to improve fertility in mares with endometritis: Using EqStim®: 1 mL per 114 kg (250 lb) body weight IV. Given days 0, 2, and 6. Best results in mares bred 2 days before to 8 days after initial administration. (Dascanio 2009; Rohrbach et al. 2007)

Monitoring
- Efficacy
- Adverse effects (see above)

Chemistry/Synonyms
Propionibacterium acnes injection is an immunostimulant agent, containing nonviable Propionibacterium acnes suspended in 12.5% ethanol in saline.

Propionibacterium acnes may also be known as: Corynebacterium parvum; NSC-220537, Arbohekan A10, Coparvax®, Corymunun®, Eqstim®, Imanoparvum®, and Immunoregulin®.

Storage/Stability
Store refrigerated; do not freeze. Shake well before using.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Propionibacterium acnes (non-viable) IV: 0.4 mg/mL, in 5 mL, and 50 mL vials; Immunoregulin® (Neogen); (OTC-biologic; manufacturer states that use is restricted to use by, or under the supervision of a veterinarian). Labeled for use in dogs. Eqstim® (Neogen). For use in horses and restricted to use by or under to the supervision of a veterinarian.

**HUMAN-LABELED PRODUCTS:** None

---

**PROPOFOL**
(pro-fo-fol) Rapinovet®, PropoFlo®, Diprivan®
INJECTABLE ANESTHETIC

Prescriber Highlights

- Short-acting injectable hypnotic agent
- Contraindications: Hypersensitivity to it or any component of the product
- Caution: Severe stress or having undergone trauma, hypoproteinemia, hyperlipidemia, seizures, or anaphylaxis history
- Adverse Effects: Transient respiratory depression is common but usually clinically tolerable. Apnea possible, especially if given too rapidly. May cause histamine release; anaphylactoid reactions
Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving propofol and may be of significance in veterinary patients:

- **ANESTHETICS, INHALATION (halothane, isoflurane):** Propofol serum concentrations may be increased
- **ANESTHETICS, LOCAL:** Propofol dosage requirements for sedation or hypnosis reduced
- **ANTIACHOLINERGICS:** Propofol-induced bradycardia may be exacerbated in animals, particularly when opiate premedications are used
- **CHLORAMPHENICOL:** May decrease clearance of propofol and increase recovery times.
- **CLONIDINE:** When used as a premed, may reduce propofol dosage requirements
- **CNS DEPRESSANTS:** Increased sedative, anesthetic, and cardiorespiratory depression possible

**DRUGS THAT INHIBIT THE HEPATIC P-450 ENZYME SYSTEM** (e.g., chloramphenicol, cimetidine, ketoconazole, etc.): May potentially increase the recovery times associated with propofol; clinical

**Additionally:**

- **Little, if any, analgesia is provided**
- **Consider dose reduction if using other CNS depressant**
- **Sufficient monitoring & patient-support capabilities are mandatory**
- **Cats with preexisting liver disease may be susceptible to longer recovery times**
Propofol doses and rates for the above premedicants were based upon the following average dosages which may be lower than the label directions for their use as a single medication: Acepromazine 0.06 mg/kg IM, SC, IV; Oxytetrins 0.09 mg/kg IM, SC, IV; Xylazine 0.33 IM, SC. The use of these drugs as preanesthetics markedly reduces propofol requirements. As with other sedative hypnotic agents, the amount of opioid and/or alpha2 antagonist premedication will influence the response of the patient to an induction dose of propofol. In the presence of premedication, the dose of propofol may be reduced with increasing age of the animal. The dose of propofol should always be titrated against the response of the patient. During induction, additional low doses of propofol, similar to those used for maintenance with propofol, may be administered to facilitate intubation or the transition to inhalant maintenance anesthestia.

**DOGS: Maintenance Of General Anesthesia Using PropoFlo®**

A. Intermittent Propofol Injections: Anesthesia can be maintained by administering propofol in intermittent IV injections. Clinical response will be determined by the amount and the frequency of maintenance injections. The following table is provided for guidance:

<table>
<thead>
<tr>
<th>Premeathetic</th>
<th>Propofol Maintenance Dose: Dogs (mg/kg)</th>
<th>Propofol Rate of Administration</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>1.8-2.2</td>
<td>2-4 mL/min</td>
</tr>
<tr>
<td>Acepromazine</td>
<td>3.8-5.2</td>
<td>3-4 mL/min</td>
</tr>
<tr>
<td>Acepromazine + Xylazine</td>
<td>3.8-5.2</td>
<td>3-4 mL/min</td>
</tr>
</tbody>
</table>

Repeated maintenance doses of propofol do not result in increased recovery times or dosing intervals, indicating that the anesthetic effects of propofol are not cumulative.

B. Maintenance by Inhalant Anesthetics: Due to the rapid metabolism of propofol, additional low doses of propofol, similar to those used for maintenance with propofol, may be required to complete the transition to inhalant maintenance anesthestia. Clinical trials using propofol have shown that it may be necessary to use a higher initial concentration of the inhalant anesthetic halothane than is usually required following induction using barbiturate anesthetics, due to rapid recovery from propofol. (Label Information; PropoFlo®—Abbott)

**CATS: Induction of General Anesthesia Using PropoClear®**

Induction dose guidelines are 4.1–8 mg/kg for cats that do not receive a preanesthetic, and 2.7–8 mg/kg for cats that receive a preanesthetic. The induction dose is reduced by 16-24% for cats that receive a preanesthetic (dose sparing effect). Anesthesia is usually observed within 60 seconds after the end of the induction dose administration. Duration of anesthesia following the recommended induction dose is approximately 3 minutes without a preanesthetic and 3-6 minutes with a preanesthetic. Full standing recovery occurs within approximately 30 minutes in cats. Individual anesthesia times vary. Induction doses for cats given propofol alone, or when it is preceded by a preanesthetic, are indicated in the following table. The table is for guidance only. The actual induction dose should be based on patient response.

<table>
<thead>
<tr>
<th>Premeathetic</th>

**CATS: Maintenance of General Anesthesia Using PropoClear®**

Anesthesia can be maintained by administration of propofol using intermittent IV injections. For cats, the duration of anesthesia following each propofol maintenance dose is approximately 3-5 minutes. Clinical response may vary, and is determined by the dose, rate of administration and frequency of maintenance injections. Propofol maintenance dose sparing is greater in cats that receive a preanesthetic. The maintenance dose and frequency should be based on the patient’s response. The following table is provided for guidance:

<table>
<thead>
<tr>
<th>Premeathetic</th>
<th>Mean Maintenance Dose (mg/kg)</th>
<th>Maintenance Dose Range (mg/kg)</th>
</tr>
</thead>
<tbody>
<tr>

Inhalant Anesthetic Maintenance of General Anesthesia in Cats: Additional low doses of propofol, similar to a maintenance dose, may be necessary to facilitate the transition to inhalant maintenance anesthesia. (Label Information; PropoClear®—Pfizer)

**Note:** The following dosages are for propofol macroemulsion unless otherwise noted.

As an anesthetic:

a) As a single injection (25% of the calculated dose every 30 seconds until desired effect):
   - For healthy, unpremedicated animal: 6 mg/kg IV;
   - For healthy, premedicated animal: After tranquilizer (e.g., acepromazine) = 4 mg/kg IV; after sedative (e.g., xylazine, opioids) = 3 mg/kg IV.

b) As a constant infusion:
   - For sedation only: 0.1 mg/kg/minute;
   - For minor surgery: 0.6 mg/kg/min, or 1 mL (10 mg) per minute per 12-25 kg of body weight (Robinson et al. 1993)

1. **DOGS/CATS:** Doses should be based on the patient’s response. The following table is provided for guidance.

2. **Propofol Maintenance Dose:** Due to the rapid metabolism of propofol, additional low doses of propofol, similar to those used for maintenance with propofol, may be required to complete the transition to inhalant maintenance anesthestia. Clinical trials using propofol have shown that it may be necessary to use a higher initial concentration of the inhalant anesthetic halothane than is usually required following induction using barbiturate anesthetics, due to rapid recovery from propofol. (Label Information; PropoFlo®—Pfizer)

9. **Repeated Maintenance Doses:** Repeated maintenance doses of propofol do not result in increased recovery times or dosing intervals, indicating that the anesthetic effects of propofol are not cumulative.

10. **Maintenance by Inhalant Anesthetics:** Due to the rapid metabolism of propofol, additional low doses of propofol, similar to those used for maintenance with propofol, may be required to complete the transition to inhalant maintenance anesthestia. Clinical trials using propofol have shown that it may be necessary to use a higher initial concentration of the inhalant anesthetic halothane than is usually required following induction using barbiturate anesthetics, due to rapid recovery from propofol. (Label Information; PropoFlo®—Pfizer)

11. **Note:** The following dosages are for propofol macroemulsion unless otherwise noted.

12. **As an anesthetic:**

   a) As a single injection (25% of the calculated dose every 30 seconds until desired effect):
      - For healthy, unpremedicated animal: 6 mg/kg IV;
      - For healthy, premedicated animal: After tranquilizer (e.g., acepromazine) = 4 mg/kg IV; after sedative (e.g., xylazine, opioids) = 3 mg/kg IV.

   b) As a constant infusion:
      - For sedation only: 0.1 mg/kg/minute;
      - For minor surgery: 0.6 mg/kg/min, or 1 mL (10 mg) per minute per 12-25 kg of body weight (Robinson et al. 1993)
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

VETERINARY-LABELED PRODUCTS:

### Dosage Forms/Regulatory Status
- epinephrine, fentanyl, furosemide, heparin sodium, insulin, ketamine, lorazepam, magnesium sulfate, mannitol, naloxone, pentobarbital, phenobarbital, potassium chloride, propranolol, sodium bicarbonate, succinylcholine,

Unused portions 28 days after first use.

The manufacturer recommends discarding any unused portion at the end of the anesthetic procedure or after 6 hours, whichever occurs sooner.

Macroemulsion: Store propofol (macroemulsion) injection below 22°C (72°F), but not below 4°C (40°F); do not refrigerate or freeze. Protect from light. Shake well before using. Do not use if the emulsion has separated.

### Storage/Stability
- Propofol is an alkylphenol derivative (2,6-diisopropylphenol). The commercially available injections are either a milky-white macroemulsion containing 100 mg/mL of soybean oil, 22.5 mg/mL of glycerol, and 12 mg/mL of egg lecithin with a pH of 7-8.5 or a clear (at room temperature) lipid-free microemulsion that contains methylparaben and propylparaben as preservatives.

### Monitoring
- **Level of anesthesia/CNS effects**
- **Respiratory depression**
- **Cardiovascular status (cardiac rate/rhythm; blood pressure)**

### Chemistry/Synonyms
- Propofol is an alkylphenol derivative (2,6-diisopropylphenol). The commercially available injections are either a milky-white macroemulsion containing 100 mg/mL of soybean oil, 22.5 mg/mL of glycerol, and 12 mg/mL of egg lecithin with a pH of 7-8.5 or a clear (at room temperature) lipid-free microemulsion that contains methylparaben and propylparaben as preservatives.

### Propofol may also be known as: disoprofol, ICI-358686, propofolum, Ansiver®, Biopropofol®, Cryoto®, Diprifer®, Diprop®, Dipriven®, Disoprine®, Fresofol®, Isoflo®, Iloflo®, Klimofo®, Oloex-Laz®, Pofof®, Propoven®, Promect®, Propabbot®, Propocam®, PropoClear®, PropoFlo®, Propovet®, Provirol®, Rapinol®, Recofol®, or Recofol®.

### Storage/Stability
- **Macroemulsion**: Store propofol (macroemulsion) injection below 22°C (72°F), but not below 4°C (40°F); do not refrigerate or freeze. Protect from light. Shake well before using. Do not use if the emulsion has separated.

The manufacturer recommends discarding any unused portion at the end of the anesthetic procedure or after 6 hours, whichever occurs sooner.

**Microemulsion**: Store propofol (microemulsion) injection protected from light at controlled room temperature. Do not store above 30°C and do not refrigerate. Exposure for an extended period to temperatures below 22°C may result in a cloudy appearance. A clear appearance will return upon allowing the product to warm to 20–30°C. Gentle agitation will speed the process. Do not administer if opaque or precipitates are noted. Discard unused portions 28 days after first use.

### Compatibility/Compounding Considerations
- Propofol (macroemulsion) is physically compatible with the commonly used IV solutions (e.g., LRS, D5W) when injected into a running IV line. Drugs that are reported to be compatible with propofol (macroemulsion) at Y-site administration include (partial listing): ampicillin, butorphanol, calcium gluconate, cefazolin, cefotaxin, clindamycin, dexamethasone sodium phosphate, dextromethorphan, diphenhydramine, dobutamine, dopamine, epinephrine, fentanyl, furosemide, heparin sodium, insulin, ketamine, lorazepam, magnesium sulfate, mannitol, naloxone, pentobarbital, phenobarbital, potassium chloride, propranolol, sodium bicarbonate, succinylcholine, thiopental, and vecuronium. It is incompatible with atracurium and vecuronium. Refer to specialized references or a hospital pharmacist for more information.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:**
- Propofol Injectable (macroemulsion): 10 mg/mL in 5 mL and 20 mL (single use) vials; Ripanver®, Schering Plough; PropoFlo® (Abbott); (Rx). FDA-approved for use in dogs and cats.

**Propofol Injectable (microemulsion):** 10 mg/mL in 20 mL, 50 mL and 100 mL multi-dose vials; PropoClear® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELLED PRODUCTS:**
- Propofol Injectable Emulsion: 10 mg/mL in 20 mL amps & vials, 50 mL & 100 mL vials; 50 mL & 100 mL infusion vials and 50 mL prefilled single-use syringes; Dipriven® (AstraZeneca); Propofol (Baxter); Fresenius Propofol® (APP Pharmaceutical); (Rx)

### References
May be treated with atropine. If atropine fails, isoproterenol given cautiously has been recommended. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with digoxin, diuretics, oxygen and, if possible, blood pressure; treatment of the cardiovascular and CNS effects are symptomatic. Use fluids and pressor agents to treat hypotension. Bradycardia, respiratory depression, pulmonary edema, other arrhythmias (especially AV block), or asystole.

The most predominant clinical signs expected would be hypotension and bradycardia. Other possible effects could include: CNS (depressed consciousness to seizures), bronchospasm, hypoglycemia, hyperkalemia, impaired AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, decreased hepatic and renal blood flow, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia. Electrolythrophic effects on the heart increase automaticity, increased or no effect on effective refractory period, and no effect on conduction velocity.

Additional pharmacologic effects of propranolol include: increased airway resistance (especially in patients with bronchoconstrictive disease), prevention of migraine headaches, increased urine output (more so in the non-pregnant uterus), decreased platelet aggregation, inhibited glycogenolysis in cardiac and skeletal muscle, and increased numbers of circulating eosinophils.

Uses/Indications
While propranolol is used for hypertension, migraine headache prophylaxis, and angina in human patients, it is used primarily in veterinary medicine for its antiarrhythmic effects. Dysrhythmias treated with propranolol include: atrial premature complexes, ventricular premature complexes, supraventricular premature complexes and tachyarrhythmias, ventricular or atrial tachyarrhythmias secondary to digitalis, atrial tachycardia secondary to Wolff-Parkinson-White (WPW) with normal QRS complexes, and atrial fibrillation (generally in combination with digoxin). Propranolol reportedly improves cardiac performance in animals with hypertrophic cardiomyopathy. It has been used to treat systemic hypertension and clinical signs associated with thyrotoxicosis and pheochromocytoma.

Pharmacology/Actions
Propranolol blocks both beta1- and beta2-adrenergic receptors in the myocardium, bronchi, and vascular smooth muscle. Propranolol does not have any intrinsic sympathomimetic activity (ISA). Additionally, propranolol possesses membrane-stabilizing effects (quinidine-like) affecting the cardiac action potential and direct myocardial depressant effects. Cardiovascular effects secondary to propranolol include: decreased sinus heart rate, decreased AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, decreased hepatic and renal blood flow, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia. Electrophysiological effects on the heart increase automaticity, increased or no effect on the effective refractory period, and no effect on conduction velocity.

Propranolol is highly lipid soluble and readily crosses the blood-brain barrier. The apparent volume of distribution has been reported to be 3.3–11 L/kg in the dog. Propranolol crosses the placenta and enters milk (at very low levels). In humans, propranolol is approximately 90% bound to plasma proteins. Propranolol metabolism occurs primarily by the liver. An active metabolite, 4-hydroxypropranolol, has been identified after oral administration in humans. Less than 1% of a dose is excreted unchanged into the urine. The half-life in dogs has been reported to range from 0.77–2 hours, and in horses, less than 2 hours. It has been reported that thyrotoxic cats have a decreased clearance of propranolol when compared with normal cats.

Contraindications/Precautions/Warnings
Propranolol is contraindicated in patients with overt heart failure, hypersensitivity to this class of agents, greater than 1st degree heart block, or sinus bradycardia. Non-specific beta-blockers are generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blockers or with bronchospastic lung disease.

Propranolol should be used cautiously in patients with significant renal or hepatic insufficiency, or with sinus nodal dysfunction. Propranolol can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients. Propranolol can mask the clinical signs associated with thyrotoxicosis, but it has been used clinically to treat the clinical signs associated with this condition. Use propranolol cautiously with diabetics or in diabetics intoxicated patients; severe bradycardias may result.

Adverse Effects
It is reported that adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Clinically relevant adverse effects include: bradycardia, lethargy, depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, syncope, diarrhea, hypoglycemia, and bronchoconstriction. Syncpe and diarrhea have also been reported in canine patients.

Overdosage/Acute Toxicity
The most predominant clinical signs expected would be hypotension and bradycardia. Other possible effects could include: CNS (depressed consciousness to seizures), bronchospasm, hypoglycemia, hyperkalemia, respiratory depression, pulmonary edema, other arrhythmias (especially AV block), or asystole.

There were 115 exposures to propranolol reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 96 were dogs with 6 showing clinical signs, 18 were cats with 3 showing clinical signs, and 1 was a ferret that showed clinical signs. Common findings in dogs reported in decreasing frequency included bradycardia and lethargy.

If overdose is secondary to a recent oral ingestion, removing the bit and charcoal administration may be considered. Seizures are reported in people, but in a review of the APCC database, seizures were not reported in animals. Monitor patient’s ECG, blood glucose, potassium and, if possible, blood pressure; treatment of the cardiovascular and CNS effects are symptomatic. Use fluids and pressor agents to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol given cautiously has been recommended. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with digoxin, diuretics, oxygen and, if necessary, IV amphotericin. Glucagon (5–10 mg IV; human dose) may increase heart rate and blood pressure and reduce the cardio depressant effects of propranolol. Seizures generally will respond to IV diazepam.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving propranolol and may be of significance in veterinary patients:

- **ANTACIDS**: May reduce oral propranolol absorption; separate doses by at least one hour
- **ANESTHETICS, GENERAL**: Additive myocardial depression may occur with the concurrent use of propranolol and mycardial depressant anesthetic agents
- **ANTICHOLINERGICS**: May negate cardiac effects of beta-blockers
- **CALCIUM CHANNEL BLOCKERS**: Concurrent use of beta-blockers with calcium channel blockers (or other negative inotropes) should be done with caution, particularly in patients with preexisting cardiomyopathy or CHF
In addition, fixed dose combination products containing propranolol and hydrochlorothiazide are available to treat hypertension in humans:

- Propranolol for Injection: 1 mg/mL in 1 mL amps or vials;
- Propranolol HCl Extended/Sustained-Release Capsules: 60 mg, 80 mg, 120 mg & 160 mg;
- Propranolol HCl Oral Tablets: 10 mg, 20 mg, 40 mg, 60 mg & 80 mg; generic; (Rx)

**HUMAN-LABELED PRODUCTS:**

- Propranolol injection is reported to be physically compatible with D5W, 0.9% sodium chloride, or lactated Ringer’s injection. It is also physically compatible with dobutamine HCl, verapamil HCl, and benzquinamide.

**References**

**Protamine Sulfate**

**Antidote (Heparin)**

**Prescriber Highlights**

- Protein that complexes with heparin (treatment of overdoses); may also be useful for Bracken Fern poisoning
- Contraindications: Hypersensitivity to protamine
- Adverse Effects: If injected IV too rapidly: Acute hypotension, bradycardia, pulmonary hypertension, & dyspnea; hypersensitivity possible
- Monitor for heparin “rebound effect”

**Uses/Indications**

Protamine is used in all species for the treatment of heparin overdosage when significant bleeding occurs. While protamine will neutralize the anti-thrombin effects of low molecular weight heparins (e.g., dalteparin or enoxaparin), it does not completely inhibit their anti-Xa activity. Laboratory animal studies however, shows it does improve microvascular bleeding associated with LMWH overdoses. Protamine has been suggested for use for Bracken Fern toxicity in ruminants (see Doses).

**Pharmacology/Actions**

Protamine is strongly basic and heparin, strongly acidic; protamine complexes with heparin to form an inactive stable salt. Protamine has intrinsic anticoagulant activity, but its effects are weak and rarely cause problems.

**Pharmacokinetics**

After IV injection, protamine binds to heparin within 5 minutes. The exact metabolic fate of the heparin-protamine complex is not known, but there is evidence that the complex is partially metabolized and/or degraded by fibrinolysis thus freeing heparin.

**Contraindications/Precautions/Warnings**

Protamine is contraindicated in patients who have demonstrated hypersensitivity or intolerance to the drug in the past.

**Adverse Effects**

If protamine sulfate is injected IV too rapidly, acute hypotension, bradycardia, pulmonary hypertension, and dyspnea can occur. These effects are usually absent or minimized when the drug is administered slowly (over 1–3 minutes). Hypersensitivity reactions have also been reported.

A heparin “rebound” effect has been reported where anticoagulation and bleeding occur several hours after heparin has apparently been neutralized. This may be due to either a release of heparin from extracellular compartments or the release of heparin from the protamine-heparin complex.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in milk.

**Overdosage/Acute Toxicity**

Because protamine has inherent anticoagulant activity, overdoses of protamine may, theoretically, result in hemorrhage; however, in one human study, overdoses of 600–800 mg resulted only in mild, transient effects on coagulation. The LD50 of protamine in mice is 100 mg/kg.

**Drug Interactions; Laboratory Considerations**

- None were located.

**Doses**

- **Dogs/Cats** (and presumably other species):
  - For heparin overdose:
    a) Give 1–1.5 mg protamine sulfate to antagonize each mg (100 units) of heparin via slow IV injection. Reduce dose as time increases between heparin dose and start of treatment (after 30 minutes give only 0.5 mg). (Bailey 1986)
    b) Administer 1 mg protamine for each 100 Units of heparin to be inactivated. Decrease protamine dose by ½ for every 30 minutes that have lapsed since heparin was administered. (Plumb’s Note: This may be ineffective if heparin has been administered by deep SC injection). Give dose slowly IV, do not give at a rate faster than 50 mg over a 10-minute period. (Adams 1988)
  - **CATTLE**:
    - For Bracken Fern (*Pteridium* spp.) poisoning:
      a) In combination with whole blood (2.25–4.5 L), 1 injection of 10 mL of 1% protamine sulfate IV (Osweiler & Ruhr 1986)

**Monitoring**

- See the Heparin monograph

**Client Information**

- Should only be used in a setting where adequate monitoring facilities are available.

**Chemistry/Synonyms**

Simple, low molecular weight, cationic proteins, protamines occur naturally in the sperm of fish. Commercially available protamine sulfate is produced from protamine obtained from the sperm or mature testes of salmon (or related species). It occurs as a fine, white to off-white crystalline or amorphous powder that is sparingly soluble in water and very slightly soluble in alcohol. The injection is available as either a prepared solution with a pH of 6–7 or a lyophilized powder that has a pH of 6.5–7.5 after reconstituting.

Protamine Sulfate may also be known as: protamine sulphate, protamini sulfas, sulfato de protamina, Prosulf®, or Protas®.

**Storage/Stability**

- Simple, low molecular weight, cationic proteins, protamines occur naturally in the sperm of fish. Commercially available protamine sulfate is produced from protamine obtained from the sperm or mature testes of salmon (or related species). It occurs as a fine, white to off-white crystalline or amorphous powder that is sparingly soluble in water and very slightly soluble in alcohol. The injection is available as either a prepared solution with a pH of 6–7 or a lyophilized powder that has a pH of 6.5–7.5 after reconstituting.

Protamine Sulfate may also be known as: protamine sulphate, protamini sulfas, sulfato de protamina, Prosulf®, or Protas®.
The powder for injection should be stored at room temperature (15–30°C), and the injection (liquid) in the refrigerator (2–8°C); avoid freezing. The injection is stable at room temperature for at least 2 weeks, however. The powder for injection should be used immediately if reconstituted with Sterile Water for Injection and within 72 hours if reconstituted with Bacteriostatic Water for Injection. It is recommended to use either D5W or normal saline for protamine sulfate infusions. Cimetidine and verapamil are reported to be physically compatible with protamine sulfate for injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Protamine Sulfate Injection: 10 mg/mL, preservative-free in 5 mL and 25 mL vials; generic; (Rx)

References

Current Veterinary Therapy: Food Animal Practice 2

Adverse effects are dose related and adrenergic in nature with panting, decreased appetite, lethargy, and rapid heart rate the most likely to be seen at usual doses; CNS excitement/restlessness/insomnia are possible. Increases in blood pressure and arrhythmias can occur in susceptible individuals, particularly at high doses. Because pseudoephedrine may be used to manufacture methamphetamine, be alert for clients wanting to purchase very large amounts of the drug.

Pharmacology/Actions

While the exact mechanisms of pseudoephedrine’s actions are undetermined, it is believed that it indirectly stimulates both alpha- and beta- (to a lesser degree) adrenergic receptors by causing the release of norepinephrine. Pharmacologic effects of pseudoephedrine include increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased nasal congestion and appetite. Pseudoephedrine can also increase urethral sphincter tone and produce closure of the bladder neck.

Pharmacokinetics

Pseudoephedrine is rapidly and nearly completely absorbed from the GI tract. Food may delay the absorption somewhat, but not the extent. In children, the apparent volume of distribution is about 2.5 L/kg. Pseudoephedrine is only partially metabolized and the bulk is excreted unchanged in the urine. Urine pH can affect excretion rates. Alkaline urine (pH 8) can prolong half-life while acidic urine (pH 5) can decrease it.

Contraindications/Precautions/Warnings

Pseudoephedrine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders, or hypertension.

Adverse Effects

Adverse effects are dose related and adrenergic in nature with panting, decreased appetite, lethargy, and rapid heart rate the most likely to be seen at usual doses; CNS excitement/restlessness/insomnia are possible. Increases in blood pressure and arrhythmias can occur in susceptible individuals, particularly at high doses.

Reproductive/Nursing Safety

Safe use has not been established during pregnancy; use with care. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

In humans, it is not recommended to use systemic pseudoephedrine during breastfeeding as the drug enters maternal milk and infants may be very susceptible to the drug’s effects. Use with caution in veterinary patients.

Overdosage/Acute Toxicity

Overdoses of pseudoephedrine can cause hyperthermia, mydriasis, tachycardia, hypertension, vomiting, disorientation, and seizures. In small animals, adverse reactions may develop at doses of 5–6 mg/kg. Deaths have occurred at doses >10–12 mg/kg.

There were 221 exposures to pseudoephedrine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 213 were dogs with 64 showing clinical signs and 8 were cats with 3 showing clinical signs. Common findings in dogs recorded in decreasing frequency included hyperactivity, tachycardia, agitation, mydriasis, restlessness, head bobbing, and panting. Common findings in cats included tachycardia.

Large overdoses should be treated with gastric evacuation (if not contraindicated); otherwise, treat supportivey and symptomatically (e.g., propranolol for tachycardia). Phenothiazines are preferred to treat hyperactivity, agitation, and tremors as diazepam may worsen dysphoria. It is recommended to contact an animal poison control center for further guidance in the case of a large pseudoephedrine overdose.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pseudoephedrine and may be of significance in veterinary patients:

- **Monoamine Oxidase (MAO) Inhibitors (e.g., amitraz, possibly selegiline):** Pseudoephedrine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors
- **Reserpine:** An increased chance of hypertension if given concomitantly
- **Sympathomimetic Agents, Other:** Phenylephrine should not be administered with other sympathomimetic agents (e.g., ephedrine) as increased toxicity may result
- **Tricyclic Antidepressants** (clomipramine, amitriptyline, etc.): An increased chance of hypertension if given concomitantly

**Doses**

**DOGS:**

- a) For urinary incontinence, or as a decongestant: 0.2–0.4 mg/kg [or practically, 15–60 mg (total dose) per dog] PO q8–12h (Tilley & Smith 2000)
- b) To increase urethral tone: 1.5 mg/kg PO two to three times a day. (Dickinson 2010)
- c) For retrograde ejaculation: 4–5 mg/kg PO three times daily or 1 to 3 hours before semen collection or attempted breeding may be tried. (Fontbonne 2007)

**CATS:**
In the first trimester of pregnancy, and there is no evidence of risk in later trimesters. Though it is a bulk-forming laxative, psyllium is considered safe for use in pregnant animals. In humans, the FDA categorizes this drug as category B for use during pregnancy.

### Chemistry/Synonyms
Psyllium may also be known as: pseudoephedrin, pseudoephedrina, Equi-Phar Equi-Hist 1200 Granules®, Drixoral®, Equiphed®, Histgranules®, Sudafed®, and Tri-Hist®.

### Monitoring
- **Efficacy**
- **Adverse effects** (heart rate, CNS stimulation, appetite)

### Client Information
- For this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.
- Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

### Chemistry/Synonyms
A sympathomimetic, pseudoephedrine HCl is the stereoisomer of ephedrine. It occurs as a fine, white to off-white powder or crystals. Approximately 2 grams are soluble in 1 mL of water.

Psyllium may also be known as: pseudoephedrin, pseudoephedrina, Equi-Phar Equi-Hist 1200 Granules®, Drixoral®, Equiphed®, Histgranules®, Sudafed®, and Tri-Hist®.

### Storage/Stability
Oral psyllium products should be stored at room temperature in tight containers. Oral liquid preparations should be protected from light and freezing.

### Dosage Forms/Regulatory Status
In the USA, psyllium is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

### Veterinary-Labeled Products:
- Pseudoephedrine HCl 600 mg/oz and Pyrillum maleate 600 mg/oz Granules in 20 oz, 5 lb and 10 lb containers; Equiphed® (AHC), Equi-Phar Equi-Hist 1200 Granules® (Vedco); Tri-Hist® Granules (Neoeng);
- Histgranules® (Butler); (Rx), FDA-approved for use in horses not intended for food. Do not use at least 72 hours before sporting events.
- The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### Human-Labeled Products:
- Pseudoephedrine Tablets and Capsules: 30 mg & 60 mg; Extended/Controlled Release: 120 mg and 240 mg (immediate-release 60 mg, controlled-release 180 mg). A common trade name is Sudafed®, but there are many others and generically labeled pseudoephedrine is available.
- All are OTC, but sales are now restricted to "behind-the-counter" status.
- Pseudoephedrine Liquid: 3 mg/mL and 6 mg/mL, in 118 mL, 120 mL, 237 mL, 480 mL, and 3.8 L. A common trade name is Sudafed®, but there are many others, including generically labeled pseudoephedrine available. All are OTC, restricted.
- Pseudoephedrine Oral Drops: 7.5 mg/0.8 mL in 15 mL & 30 mL; Kid Kare® (Rugby); Nasal Decongestant Oral (various); (OTC, restricted)

### References

### Uses/Indications
Bulk forming laxatives are used in patients where constipation is a result of too little fiber in their diets or when straining to defecate may be deleterious. Psyllium is considered the laxative of choice in the treatment and prevention of sand colic in horses.

Psyllium has also been used to increase stool consistency in patients with chronic, watery diarrhea. The total amount of water in the stool remains unchanged.

### Pharmacology/Actions
By swelling after absorbing water, psyllium increases bulk in the intestine and is believed to induce peristalsis and decrease intestinal transit time. In the treatment of sand colic in horses, psyllium is thought to help collect sand and to help lubricate its passage through the GI tract.

### Pharmacokinetics
Psyllium is not absorbed when administered orally. Laxative action may take up to 72 hours to occur.

### Contraindications/Precautions/Warnings
Bulk-forming laxatives should not be used in cases where prompt intestinal evacuation is required, or when fecal impaction (no feces being passed) or intestinal obstruction is present. Psyllium products are not recommended for use in rabbits as they may damage intestinal mucosa and cause blockage.

### Adverse Effects
With the exception of increased flatulence, psyllium rarely produces any adverse reactions if adequate water is given or is available to the patient. If insufficient liquid is given, there is an increased possibility of esophageal or bowel obstruction occurring.

### Reproductive/Nursing Safety
Because there is no appreciable absorption of psyllium from the gut, it should be safe to use in pregnant animals. In humans, the FDA categorizes this drug as category B for use during pregnancy. (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Psyllium should be safe to administer to lactating animals.
HUMAN-LABELED PRODUCTS:
Vetasyl Fiber Tablets for Cats

VETERINARY-LABELED PRODUCTS:

Storage/Stability
Psyllium is obtained from the ripe seeds of varieties of Plantago species. The seed coating is high in content of hemicellulose mucilage that absorbs and swells in the presence of water.

Client Information

Monitoring
Be sure animal has free access to water
Stool consistency, frequency

Drug Interactions

ASPIRIN (and other SALICYLATES): Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more

DIGOXIN: Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more

NITROFURANTOIN: Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more

Doses

DOGS:

a) For a trial to treat chronic idiopathic large bowel diarrhea using Metamucil®: Median dose is 2 tablespoonsful (1.33 grams/kg/day; range: 0.32–4.9 grams/kg/day) per day added to a highly digestible diet such as Hill’s c/d® (Leib 2004; Leib 2005)
b) To increase fiber in dogs with chronic colitis: Add 1–2 tablespoonsful (15–30 mL) per 25 kg body weight to animal’s regular diet. (Jergens 2007)
c) In cases of predominantly large bowel diarrhea (colitis with typical clinical presentation) if parasiticide treatment and elimination diet fail, a therapeutic trial can be made: metronidazole 20–25 mg/kg PO twice daily for 5–10 days with the addition of fiber to the diet (e.g., psyllium at 0.5 tablespoon for toy breeds, 1 tablespoon for small dogs, 2 tablespoons for medium dogs, and 3 tablespoons for large dogs). However, sampling of mucosal biopsies prior to further treatment may be the best course of action. (Gaschen 2008)
d) In dogs prone to constipation, 2% psyllium was added as part of diet. 80% of studied dogs had easier defecation process. (Tortola et al. 2009)
e) As an adjunct (source of soluble fiber) for treatment of hepatic encephalopathy: 1–3 teaspoonsful per day as a dietary supplement. (Tweedt 2009)

CATS:

a) For chronic constipation: 1–4 teaspoonsful per meal added to canned cat food. Be sure cat is properly hydrated. (Washabau 2001)
b) For adjunctive treatment of feline megacolon: 1–4 teaspoonsful mixed with food PO q12–24h (Scherk 2003)

HORSES:

a) For sand colic: 1 gram/kg twice daily. Administration of psyllium, approximately 1 lb, in powdered form can be given via nasogastric tube once the powder has been mixed with water; mix and administer immediately via NG tube or mixture will thicken. If giving orally to foals, esophageal obstruction can occur. Give small amounts of the mixture at a time and confirm that the foal swallows after each bolus. A liquid-like versus paste-like mixtures can help also. Pelleted psyllium is also available and most horses find this form more palatable than if the powdered form is mixed with dry or moistened feed. If horse refuses the pelleted form, experimentation with different flavors andsmells produced by different suppliers of psyllium pellets may be helpful. Another option is to try mixing the psyllium pellets with the horse’s favorite treat or grain source to improve intake. (Tillotson & Traub-Dargatz 2003)
b) For sand colic: In this experimental study, 0.5 kg psyllium was mixed with 1 liter of mash and given twice daily and 2 liters of mineral oil via NG tube were administered once daily. This combination was more effective (measured ash content of feces) than giving mineral oil alone. (Hottwagner & Iben 2008)
c) For sand impactions: 8 ounces in water via NG tube q24h. (Blikslager 2006)

Overdosage/Acute Toxicity

If administered with sufficient liquid, psyllium overdose should cause only an increased amount of soft or loose stools.

Drug Interactions

If administered with sufficient liquid, psyllium overdose should cause only an increased amount of soft or loose stools.

OVERDOSAGE: Unlikely, emesis possible in small animals

Contraindications: Severely debilitated animals

Adverse Effects: Unlikely, emesis possible in small animals

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Equine Enteric Colloidal® (Techmix); Equi-Phar® Sweet Psyllium (Vedco); (not for horses intended for food); Sandclear® (Farnam), Anipryl® Powder (AHC), Purepsyll® Powder (AHC), Vino-Flex Sand Relief® (Vita-lex), Equa Aid Psyllium® (Equi-Aid); (OTC). Products may be available in 28 oz, 56 oz, 1 lb, 10 lb and 30 lb pails and are labeled for use in horses.

Salicylates): Potential exists for psyllium to bind and reduce absorption if given at the same time; if possible, separate doses by 3 hours or more

HUMAN-LABELED PRODUCTS:

There are many human-approved products containing psyllium, most products contain approximately 3.4 grams of psyllium per rounded teaspoonful. Dosages of sugar-free products may be different from those containing sugar.

References

PYRANTEL PAMOATE
(pye-ran-tel pa-mo-ate) Strongid T®, Nemex®

ANTIPARASITIC

Prescriber Highlights

- Pyrimidine anthelmintic used primarily for ascarids in a variety of species
- Contraindications: Severely debilitated animals
- Adverse Effects: Unlikely, emesis possible in small animals
All doses are for pyrantel pamoate unless otherwise noted.

**Drug Interactions**

Profuse sweating (in species with sweat glands), ataxia or other cholinergic effects.

**Pharmacokinetics**

Pyrantel pamoate is poorly absorbed from the GI tract, thus allowing it to reach the lower GI in dogs, cats and equines. Pyrantel tartrate is absorbed more readily than the pamoate salt. Pigs and dogs absorb pyrantel tartrate more so than do ruminants, with peak plasma levels occurring 2-3 hours after administration. Peak plasma levels occur at highly variable times in ruminants.

Absorbed drug is rapidly metabolized and excreted into the urine and feces.

**Contraindications/Precautions/Warnings**

Use with caution in severely debilitated animals. The manufacturers usually recommend not administering the drug to severely debilitated animals.

**Adverse Effects**

When administered at recommended doses, adverse effects are unlikely. Emetis may possibly occur in small animals receiving pyrantel pamoate.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (Probably safe. Although specific studies may not have proved he safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

Pyrantel is considered safe to use in veterinary patients.

**Overdose/Acute Toxicity**

Pyrantel has a moderate margin of safety. Dosages up to approximately 7 times recommended generally result in no toxic reactions. In horses, doses of 20X yielded no adverse effects. The LD50 in mice and rats for pyrantel tartrate is 170 mg/kg; >690 mg/kg for pyrantel pamoate in dogs.

**Pharmacology/Actions**

Pyrantel acts as a depolarizing, neuromuscular-blocking agent in susceptible parasites, which paralyzes the organism. The drug possesses nicotine-like properties and acts similarly to acetylcholine. It also inhibits cholinesterase.

**Uses/Indications**

**HORSES:**

- Ascaris edentatus,
- small strongyles. Pyrantel is active against ileocecal tapeworm (A. perfoliatus) when used at twice the recommended dose, although resistance has been reported. Resistance to antiparasitic agents is an ongoing problem. It is recommended to perform fecal egg count reduction testing (FECRT) for strongyle nematodes. A value of less than 90% in 5-10 horses is the suggested cut off for determining resistance on a given farm (Nielsen & Kaplan 2009).

**RABBITS, RODENTS, SMALL MAMMALS:**

- Ascaris suum
- Oesophagostomum spp. The drug has activity against the swine stomach worm (Hyostrongylus rubidus).

Although not FDA-approved, pyrantel has been used in pet birds and llamas. See the Dosage section for more information.

Listed dosages are often not specified as to whether using the salt or base.

For additional information using this drug in dogs in cats, see: Companion Animal Parasite Council recommendations: http://go/gl/wlbq1

**Dogs:**

For susceptible parasites:

- a) For dogs weighing <5 lb: 10 mg/kg (as base) PO; for dogs weighing >5 lbs: 5 mg/kg (as base) PO. Treat puppies at 2, 3, 4, 6, 8, and 10 weeks of age. Treat lactating bitches 2–3 weeks after whelping. Do follow-up fecal 2–4 weeks after treating to determine need for retreatment. (Label directions; Nemex® Tabs—Pfizer)
- b) For hookworms, or roundworms: 5 mg/kg PO after meals; repeat in 7–10 days (Willard 2003)
- c) Puppies: Can be treated as early as 2–3 weeks of age at 5–10 mg/kg PO; can be repeated every 2–3 weeks until at least 12 weeks of age. (Hoskins 2005)
- d) 20 mg/kg PO; be sure that liquid is well mixed before using; tablets may be broken for accurate dosing. Not FDA-approved for cats but very safe and effective. (Blagburn 2005)

**Cats:**

For susceptible parasites:

- a) For susceptible parasites using combination product with praziquantel (Drontal®): Administer a minimum dose of 2.27 mg praziquantel and 9.2 mg pyrantel pamoate per pound of body weight according to the dosing tables on labeling. May be given directly by mouth or in a small amount of food. Do not withhold food prior to or after treatment. If reinfection occurs, treatment may be repeated. (Package insert; Drontal®— Bayer)
- b) Ascariids, Hookworms, Physaloptera: 5 mg/kg, PO; repeat in 2 weeks (one time only for Physaloptera) (Dimski 1989)
- c) 10 mg/kg PO, repeat in 3 weeks (Kirk 1989)
- d) Kittens: Can be treated as early as 2–3 weeks of age at 5–10 mg/kg PO; can be repeated every 2–3 weeks until at least 12 weeks of age. (Hoskins 2005)

**Rabbits, Rodents, Small Mammals:**

- a) Rabbits: 15–10 mg/kg PO, repeat in 2–3 weeks (Ivey & Morrisey 2000)

**Horses:**

For susceptible parasites:

- a) 6.6 mg/kg PO every 6-8 weeks for ascarid control in foals and every 4 weeks for ascarid control on some farms. For tapeworm control, double the dose (13.2 mg/kg PO) and use once to twice yearly. (Taylor 2010)
- b) 6.6 mg (as base)/kg PO; 13.2 mg (as base)/kg for cestodes (Roberson 1988; Robinson 1987)

**Swine:**

For susceptible parasites:
Pyridostigmine is used in the treatment of myasthenia gravis (MG) in dogs (and rarely in cats). It is considered to be much more effective in acquired MG, than in congenital MG.

**CATTLE, SHEEP & GOATS:**
For susceptible parasites:
- Pyrantel tartrate: 25 mg/kg, PO (Roberson 1988)

**LAMAS:**
For susceptible parasites:
- 18 mg/kg, PO for one day (Cheney & Allen 1989; Fowler 1989)

**BIRDS:**
For intestinal nematodes:
- Pseudacanthoecus: In endemic areas, outdoor breeding birds and their offspring should be routinely dewormed for ascarids: 25 mg/kg PO q2 weeks. (Lightfoot 2008)
- 100 mg/kg, PO as a single dose in psittacines and passerines (Marshall 1993)

Client Information
- Shake suspensions well before administering.

**Chemistry/Synonyms**
A pyrimidine-derivative anthelmintic, pyrantel pamoate occurs as yellow to tan solid and is practically insoluble in water and alcohol. Each gram of pyrantel pamoate is approximately equivalent to 347 mg (34.7%) of the base.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
Note: Many products available; a partial listing of products follows:

- **Pyrantel Pamoate Oral Tablets:** 180 mg & 720.5 mg (chewable);
- **Pyrantel Soft-gel Oral Capsules:** 180 mg (equivalent to 62.5 mg pyrantel base);
- **HUMAN-LABELED PRODUCTS:** approved for use in dogs.

For over 2 lbs:
- **Pyrantel Tartrate 1.06% (4.8 grams/lb) Top Dress:** in 25 lb pails:
- **VETERINARY-LABELED PRODUCTS:** approved for use in horses not intended for food.

**Pyrantel Pamoate Oral Paste:** 43.9% w/w pyrantel base in 23.6 grams (20 mL) paste (180 mg pyrantel base/mL); several products are available. A commonly known trade name is **Pyrantel Pamoate Oral Suspension:** 50 mg/mL (of base); Many products are available; a commonly known trade name is **Pyrantel Pamoate Oral Suspension:** 4.54 mg/mL (as base) (for dogs only); in 60 mL, 120 mL 280 mL and 473 mL bottles. Many products are available; a commonly known trade name is **Pyrantel Pamoate Tablets:** 22.7 mg (of base), 113.5 mg (of base); (OTC). FDA-approved for use in dogs. A commonly known product is **Drontal® Tablets (Bayer);** (OTC) **Drontal® Tablets (Bayer):** some sizes may be available as generics or under various trade names (OTC). FDA-approved for use in cats and kittens that are 2 months of age or older and weigh 2 lb. or more.

Praziquantel 30 mg/pyrantel pamoate 30 mg; & Praziquantel 114 mg/pyrantel pamoate 114 mg Chewable Tablets: Viraheal Flavored Chewables® (Virbac); generic; (OTC). FDA-approved for use in dogs.

Praziquantel/pyrantel pamoate plus febantel Tablets: Small, medium and large dog sizes. **Drontal® Plus Tablets (Bayer):** (Rx); FDA-approved for dogs and puppies 3 weeks of age or older and weighing 2 lb. or greater. Ivermectin/Pyrantel Oral Chewable Tablets: 68 micrograms/57 mg, 136 micrograms/114mg, 272 micrograms/228 mg; **Heartgard® Plus Chewables** (Merial); **Tri-Heart® Plus Chewable Tablets** (Schering); (Rx). FDA-approved for use in dogs.

**HUMAN-LABELED PRODUCTS:**

**Pyrantel Pamoate Oral Suspension:** 50 mg/mL & 144 mg/mL (equiv to 50 mg/mL pyrantel base) in 30 mL; **Reese’s Pinworm (Reese); Pin-X® (Pfizer);** (OTC). Labeled for use in horses (not intended for food).

**Pyrantel Soft-gel Oral Capsules:** 180 mg (equivalent to 62.5 mg pyrantel base); **Pin-Rid® (Pen-X);** (OTC) **Pin-Rid® (Pfizer);** (OTC). FDA-approved for use in dogs.

**Pyrantel Pamoate Oral Tablets:** 180 mg & 720.5 mg (chewable); **Reese’s Pinworm® (Reese); Pin-X® (Pfizer);** (OTC)

**References**

**PYRIDOSTIGMINE BROMIDE**
(formerly known as Mestinon®)

**ANTICHOLINESTERASE AGENT**

**Prescriber Highlights**

- Anticholinesterase used for treatment of myasthenia gravis
- Contraindications: hypersensitivity to this class of compounds or bromides, patients with mechanical or physical obstructions of the urinary or GI tract
- Caution: bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases
- Adverse Effects: Usually dose related cholinergic effects GI (nausea, vomiting, diarrhea), salivation, sweating, respiratory (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic (miosis, blurred vision, lacrimation), cardiovascular (bradycardia or tachycardia, cardiopasm, hypotension, cardiac arrest), muscle cramps, & weakness

**Uses/Indications**

Pyridostigmine is used in the treatment of myasthenia gravis (MG) in dogs (and rarely in cats). It is considered to be much more effective in acquired MG, than in congenital MG.
Pharmacology/Actions
Pyridostigmine inhibits the hydrolysis of acetylcholine by directly competing with acetylcholine for attachment to acetylcholinesterase. Because the pyridostigmine-acetylcholinesterase complex is hydrolyzed at a much slower rate than the acetylcholine-acetylcholinesterase complex, acetylcholine tends to accumulate at cholinergic synapses with resultant cholinergic activity.

At usual doses, pyridostigmine does not cross into the CNS (quaternary ammonium structure), but overdoses can cause CNS effects.

Pharmacokinetics
Pyridostigmine is only marginally absorbed from the GI tract and absorption may be more erratic with the sustained-release tablets than the regular tablets. The onset of action after oral dosing is generally within one hour.

At usual doses, pyridostigmine is apparently distributed to most tissues, but not to the brain, intestinal wall, fat or thymus. The drug crosses the placenta.

Pyridostigmine is metabolized by both the liver and hydrolyzed by cholinesterases.

Contraindications/Precautions/Warnings
Pyridostigmine is contraindicated in patients hypersensitive to this class of compounds or bromides, or in those who have mechanical or physical obstructions of the urinary or GI tract.

The drug should be used with caution in patients with bronchospastic disease, epilepsy, hyperthyroidism, bradycardia or other arrhythmias, vagotonia, or GI ulcer diseases.

Adverse Effects
Adverse effects associated with pyridostigmine are generally dose related and cholinergic in nature. Although usually mild and easily treatable with dosage reduction, severe adverse effects are possible (see Overdosage below).

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Pyridostigmine is excreted in maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity
Overdosage of pyridostigmine may induce a cholinergic crisis. Clinical signs of cholinergic toxicity can include: GI effects (nausea, vomiting, diarrhea), salivation, sweating (species with sweat glands), respiratory effects (increased bronchial secretions, bronchospasm, pulmonary edema, respiratory paralysis), ophthalmic effects (miosis, blurred vision, lacrimation), cardiovascular effects (bradycardia or tachycardia, cardiopasm, hypotension, cardiac arrest), muscle cramps, and weakness.

Overdoses in myasthenic patients can be very difficult to distinguish from the effects associated with a myasthenic crisis. The time of onset of clinical signs or an edrophonium challenge may help to distinguish between the two.

Treatment of pyridostigmine overdosage consists of both respiratory and cardiac supportive therapy and atropine if necessary. Refer to the atropine monograph for more information on its use for cholinergic toxicity.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pyridostigmine and may be of significance in veterinary patients:

- **ATROPINE**: Atropine will antagonize the muscarinic effects of pyridostigmine but concurrent use should be used cautiously as atropine can mask the early clinical signs of cholinergic crisis
- **CORTICOSTEROIDS**: May decrease the anticholinesterase activity of pyridostigmine. After stopping corticosteroid therapy, drugs like pyridostigmine may cause increased anticholinesterase activity
- **DEXPANTHENOL**: Theoretically, dexpanthenol may have additive effects when used with pyridostigmine
- **DRUGS WITH NEUROMUSCULAR BLOCKING ABILITY**: (e.g., aminoglycoside antibiotics): May necessitate increased dosages of pyridostigmine in treating or diagnosing myasthenic patients
- **MAGNESIUM**: Anticholinesterase therapy may be antagonized by administration of parenteral magnesium therapy, as it can have a direct depressant effect on skeletal muscle
- **MUSCLE RELAXANTS**: Pyridostigmine may prolong the Phase I block of depolarizing muscle relaxants (e.g., succinylcholine, decamethonium) and edrophonium antagonizes the actions of non-depolarizing neuromuscular blocking agents (e.g., pancuronium, tubocurarine, gallamine, vecuronium, atracurium, etc.)

Doses

**DOGS:**

For myasthenia gravis (MG):

a) 1–3 mg/kg PO q8-12h. The dosage is titrated to effect to minimize adverse effects and maximize muscle strength. For animals that cannot tolerate oral medications, it may be used as an IV constant rate infusion at 0.01–0.03 mg/kg/hour. (Vernau 2009)
b) 0.5–3 mg/kg PO q8-12 hours with food. With high doses, weakness may occur as a result of a cholinergic crisis and therefore a low dose of pyridostigmine is initially given then slowly increased until weakness is resolved. A liquid formulation of pyridostigmine is recommended so dose can be easily adjusted to control clinical signs. An H2 antagonist (e.g., famotidine at 5 mg/kg/day) may reduce nausea and GI irritation associated with pyridostigmine. (Platt 2009)
c) For acquired MG: After oral regurgitation is abolished with parenteral therapy (neostigmine), may begin oral therapy with pyridostigmine at 7.5–30 mg PO two times a day. Once patient is stable and infections have resolved, begin corticosteroid therapy (antiinflammatory doses of prednisone) and continue concurrently with anticholinesterase drugs for 2 weeks, then pyridostigmine may be gradually reduced. (Pedroia 1989)
d) 0.5–3 mg/kg PO two to three times a day. If no response, add prednisone (0.5–1 mg/kg daily; increase to 1–2 mg/kg after a few days). (Kornegay 2006)
e) 0.5–1 mg/kg PO two to three times a day with or without prednisone (2 mg/kg PO twice daily). Not uncommon for dogs to fully recover without treatment (spontaneous remission). (LeCouteur 2005)

**CATS:**

For myasthenia gravis (MG):

a) 0.5–3 mg/kg daily PO in divided doses, dose depending on response. (Jones 2009)
b) 1–3 mg/kg PO q8-12h (Inzana 2000)
c) 0.5–3 mg/kg PO per day with corticosteroids (Wheeler 2006)

Monitoring

- Clients should be routinely monitored for clinical signs of cholinergic toxicity (see Overdosage section above) and efficacy of the therapy

Client Information

- Clients should be instructed to report to the veterinarian clinical signs of excessive salivation, GI disturbances, weakness, or difficulty breathing

Chemistry/Synonyms

An anticholinesterase agent, pyridostigmine bromide is a synthetic quaternary ammonium compound that occurs as an agreeable smelling, bitter tasting, hydrosopic, white or practically white, crystalline powder. It is freely soluble in water and in alcohol. The pH of the commercially available injection is approximately 5.

Pyridostigmine Bromide may also be known as: pyridostigmini bromidum, Distinon®, Kalymin®, Mestinon®, or Regonol®.

Storage/ Stability

Unless otherwise instructed by the manufacturer, store pyridostigmine products at room temperature. The oral solution and injection should be protected from light and freezing. Pyridostigmine tablets should be kept in tight containers. The extended-release tablets may become mottled with time, but this does not affect their potency.

Pyridostigmine injection is unstable in alkaline solutions.

Compatibility/ Compounding Considerations

Pyridostigmine is used in the treatment of myasthenia gravis (MG) in dogs (and rarely in cats). It is considered to be much more effective in acquired MG, than in congenital MG.
Pyridostigmine injection is reportedly physically compatible with glycopyrolate, heparin sodium, hydrocortisone sodium succinate, potassium chloride, and vitamin B-complex with C. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pyridostigmine Bromide Tablets: 60 mg; Mestinon® (ICN); generic, (Rx)

Pyridostigmine Bromide Extended-Release Tablets: 180 mg; Mestinon® (ICN); (Rx)

Pyridostigmine Bromide Syrup: 12 mg/mL in 480 mL; Mestinon® (ICN); (Rx)

Pyridostigmine Bromide Injection: 5 mg/mL in 2 mL amps; Mestinon® (ICN); (Rx)

References

Pyridostigmine Bromide Extended-Release Tablets: 180 mg; Mestinon® (ICN); (Rx)

Pyridostigmine Bromide Tablets: 60 mg; Mestinon® (ICN); generic, (Rx)

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.
Adverse effects in horses can include CNS stimulation (nervousness, insomnia, convulsions, tremors, ataxia), palpitation, GI disturbances, CNS depression (sedation), muscular weakness, anorexia, lassitude & incoordination.

Contraindications:

- None noted

Drug Interactions

- Injectable antihistamine
- Adverse Effects: Horses: CNS stimulation (nervousness, insomnia, convulsions, tremors, ataxia), palpitation, GI disturbances, CNS depression (sedation), muscular weakness, anorexia, lassitude & incoordination
- Drug Interactions

Uses/Indications

Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects; predominantly used in horses.

Pharmacology/Actions

Antihistamines (H1-receptor antagonists) competitively inhibit histamine at H1 receptor sites. They do not inactivate, nor prevent the release of histamine, but can prevent histamine’s action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). Pyrilamine is considered to be less sedating and have fewer anticholinergic effects when compared to most other antihistamines.

Pharmacokinetics

The pharmacokinetics of this agent have apparently not been extensively studied in cattle, dogs or cats. In horses, pyrilamine is poorly bioavailable (18%) after oral administration. After IV administration, elimination half-life was about 1.7 hours. After a single dose, pyrilamine principle metabolite, O-desmethylpyrilamine (O-DMP), can be detected in urine for at least two days, and possibly up to one week after dosing. (Dirikolu et al. 2009)

Contraindications/Precautions/Warnings

The manufacturer indicates that the use of this product “…should not supersede the use of other emergency drugs and procedures.”

Adverse Effects

Adverse effects in horses can include CNS stimulation (nervousness, insomnia, convulsions, tremors, ataxia), palpitation, GI disturbances, CNS depression (sedation), muscular weakness, anorexia, lassitude & incoordination.
Reproductive/Nursing Safety
At usual doses, pyrilamine is probably safe to use during pregnancy. Rats and mice treated with 10–20 times the human dose had an increased frequency of embryonic, fetal or perinatal death, but a study in pregnant women, showed no increase in teratogenic or fetocidal rates.

It is unknown if pyrilamine enters milk.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrilamine and may be of significance in veterinary patients:

- **ANTICOAGULANTS (heparin, warfarin):** Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin
- **CNS DEPRESSANT DRUGS:** Increased sedation can occur if pyrilamine is combined with other CNS depressant drugs
- **EPINEPHRINE:** Pyrilamine may enhance the effects of epinephrine

Laboratory Considerations
Antihistamines can decrease the wheal and flare response to antigen skin testing. In humans, it is suggested that antihistamines be discontinued at least 4 days before testing.

Doses

**DOGS:**

a) 12.5–25 mg PO four times a day; 25–125 mg IM (Swinyard 1975)

**CATTLE:**

a) 0.5–1.5 grams IM (Swinyard 1975)

b) For adjunctive treatment of aseptic laminitis: 55–110 mg/kg IV or IM (Berg 1986)

**HORSES:** (NOTE: ARCI UCGFS CLASS 3 DRUG)

a) 0.88–1.32 mg/kg (2–3 mL of 20 mg/mL solution per 100 lbs body weight) IV (slowly), IM or SC; may repeat in 6–12 hours if necessary. Fsaal: 0.44 mg/kg (1 mL of 20 mg/mL solution per 100 lbs. body weight) IV (slowly); IM or SC; may repeat in 6–12 hours if necessary. (Package Insert; Histaver-P®—Schering)

b) 1 mg/kg IV, IM or SC (Robinson 1987)

c) 0.5–1.5 grams IM (Swinyard 1975)

**SHEEP, SWINE:**

a) 0.25–0.5 gram IM (Swinyard 1975)

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms
An ethylenediamine antihistamine, pyrilamine maleate occurs as a white, crystalline powder with a melting range of 99–103°C. One gram is soluble in approximately 0.5 mL of water or 3 mL of alcohol.

Pyrilamine Maleate may also be known as: pyranisamine hydrochloride, pyrilamine hydrochloride, mepyramine hydrochloride, mepyramini maleas, myranisamine maleate, myrilamine maleate, mepyramine maleate, Anihist®, Alergitanil®, Antemey®, Antisani®, Antisani®, Equi-Phar® Equi-Hist®, Equine® Fluidase®, Histall®, Histagranules®, Histamed®, Histavet-P®, Histavet-P®, Hist-EQ® (Butler); (Rx). Labeled for use in horses. Do not use at least 72 hours before sporting events.

Anihist® (AHC); (OTC), Anthisan®, Anihist®, Alergitanil®, Antemey®, Antisani®, Antisani®, Equi-Phar® Equi-Hist®, Equine® Fluidase®, Histall®, Histagranules®, Histamed®, Histavet-P®, Histavet-P®, Hist-EQ®, Hist-EQ® (Butler); (Rx). Labeled for use in horses. Do not use at least 72 hours before sporting events.

Pyrilamine 600 mg/oz and Guaifenesin 2400 mg/oz Granules: in 20 oz, 5 lb and 25 lb containers; Anihist® (AHC), Hist-EQ® (Butler); (OTC). Labeled for use in horses. Do not use at least 72 hours before sporting events.

There are also combination cough syrups containing pyrilamine labeled for use in small animals.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

References

Pyrimethamine is a folic acid antagonist similar to trimethoprim. It acts by inhibiting the enzyme, dihydrofolate reductase that catalyzes the conversion of dihydrofolic acid to tetrahydrofolic acid.

**Pharmacology/Actions**

Pyrimethamine is a folic acid antagonist similar to trimethoprim. It acts by inhibiting the enzyme, dihydrofolate reductase that catalyzes the conversion of dihydrofolic acid to tetrahydrofolic acid.

**Pharmacokinetics**

No pharmacokinetic data was located for veterinary species. In humans, pyrimethamine is well absorbed from the gut after oral administration. It is distributed primarily to the kidneys, liver, spleen, and lungs, but does cross the blood-brain barrier. It has a volume of distribution of about 3 L/kg and is 80% bound to plasma proteins. Pyrimethamine enters milk in levels greater than those found in serum and can be detected in milk up to 48 hours after dosing.

**Uses/Indications**

In veterinary medicine, pyrimethamine is used to treat *Hepatozoon americanum* infections, and toxoplasmosis in small animals (often in combination with sulfonamides). In horses, it is used to treat equine protozoal myeloencephalitis, sometimes called equine toxoplasmosis. In humans, pyrimethamine is used for the treatment of toxoplasmosis and as a prophylactic agent for malaria.

**Contraindications/Precautions/Warnings**

Pyrimethamine is contraindicated in patients hypersensitive to it and should be used cautiously in patients with preexisting hematologic disorders. Some clinicians recommend avoiding its use in cats because of its adverse effect profile.

**Adverse Effects**

In small animals, anorexia, malaise, vomiting, depression, and bone marrow depression (anemia, thrombocytopenia, leukopenia) have been seen. Adverse effects may be more prominent in cats and noted 4–6 days after starting combination therapy. Some clinicians recommend avoiding its use in this species. Hematologic effects can develop rapidly and frequent monitoring is recommended, particularly if therapy persists longer than 2 weeks. Oral administration of folic acid at 1 mg/kg PO, folic acid 5 mg/day, or Brewer’s yeast 100 mg/kg/day have been suggested to alleviate adverse effects.

The drug is unpalatable to cats when mixed with food and the 25 mg tablet dosage size makes successful dosing a challenge. In horses, pyrimethamine has caused leukopenias, thrombocytopenia, and anemias when used in combination with sulfonamides. Baker’s yeast and folic acid have been suggested to antagonize these adverse effects. Alternatively, folic acid supplement may be used (an example is Folic Acid and Vitamin E Pak from Buckeye Feed Mills in Dalton, Ohio).

**Reproductive/Nursing Safety**

Pyrimethamine has been demonstrated to be teratogenic in rats. Fetal abnormalities have been seen in foals after mares have been treated, however, it has been used in treating women with toxoplasmosis during pregnancy. Clearly, the risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available (e.g., clindamycin in small animals). Concomitant administration of folic acid has been recommended if the drug is to be used during pregnancy by some, but others state that pregnant mares should not receive folic acid during therapy as it may exacerbate fetal abnormalities or mortality.

In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Pyrimethamine is excreted in maternal milk; consider using milk replacer.

**Overdosage/Acute Toxicity**

Reports of acute overdosage of pyrimethamine in animals were not located. In humans, vomiting, nausea, anorexia, CNS stimulation (including seizures), and hematologic effects can be seen. Recommendations for treatment include: standard procedures in emptying the gut or preventing absorption, parenteral barbiturates for seizures, folic acid for hematologic effects, and long-term monitoring (at least 1 month) of renal and hematopoietic systems.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving pyrimethamine and may be of significance in veterinary patients:

**AMINO BENZOIC ACID (PABA):** PABA is reportedly antagonistic towards the activity of pyrimethamine; clinical significance is unclear

**SULFONAMIDES:** Pyrimethamine is synergistic with sulfonamides in activity against toxoplasmosis (and malaria)

**TRIMETHOPRIM:** Use with pyrimethamine/sulfa is not recommended in humans as adverse effects may be additive, however, this combination has been used clinically in horses

**Doses**

**DOGS:**

For protozoal diseases:

- For toxoplasmosis: 0.5–1 mg/kg PO once daily for 2 days, then 0.25 mg/kg PO once daily for 2 weeks. Given with sulfadiazine at 30–50 mg/kg PO divided two to four times a day for 1–2 weeks (Murtaugh & Ross 1988)
- For Toxoplasmosis: 0.25–0.5 mg/kg PO once daily for 28 days; For Neospora (with trimethoprim sulfa): 1 mg/kg once daily for 28 days; For *Hepatozoon canis* (with trimethoprim sulfa and clindamycin): 0.25–0.5 mg/kg once daily for 2–4 weeks (Lappin, M. 2000)
- For *Hepatozoon americanum*: Trimethoprim/sulfa (15 mg/kg PO q12h), pyrimethamine (0.25 mg/kg PO q24h), and clindamycin (10 mg/kg q8h). Once remission attained, decoquinate (see monograph) can maintain. (Baneth 2007)
- For *Hepatozoon americanum*: Trimethoprim/sulfa (15 mg/kg PO q12h for 14 days), pyrimethamine (0.25 mg/kg PO q24h for 14 days), and clindamycin (10 mg/kg q8h for 14 days). Once remission attained, decoquinate (see monograph) can maintain.

For neosporosis: pyrimethamine (1 mg/kg PO daily) with trimethoprim/sulfa (15–30 mg/kg PO twice daily). (Blagburn 2005)

**CATS:** SEE WARNINGS ABOVE.

For toxoplasmosis:

- 0.5–1 mg/kg PO once daily for 2 days, then 0.25 mg/kg PO once daily for 2 weeks. Given with sulfadiazine at 30–50 mg/kg PO divided two to four times a day for 1–2 weeks (Murtaugh & Ross 1988)
- For enteritis epithelial cycle: 2 mg/kg, PO once daily. For extraintestinal cycle: 0.5–1 mg/kg PO divided two to three times daily combined with sulfonamides (e.g., triple sulfa, sulfadiazine) at 60 mg/kg PO or IM divided two to three times daily (Lappin, M.R. 1989)
- For protozoal myocarditis: Pyrimethamine 1 mg/kg PO once daily for 3 days, then decrease dose to 0.5 mg/kg PO once a day, with sulfadimethoxine 25 mg/kg PO, IV, or IM once a day (Ogburn 1988)
- Pyrimethamine: 0.5 mg/kg PO per day with sulfadiazine at 30 mg/kg, PO q12h for 7–10 days. Do not use continuously for longer than 2 weeks. Supplementation with folic acid 5 mg/day or folinic acid 1 mg/kg/day may alleviate toxicity. (Swango et al. 1989)

**HORSES:**

See also the next monograph (Pyrimethamine + Sulfadiazine)

For equine protozoal myeloencephalitis:

- Pyrimethamine 1 mg/kg PO once a day for 90–170 days (or longer). Given with a sulfa or potentiated sulfa (sulfadiazine 70 mg/kg PO once or twice a day). Monitor CBC’s. (MacKee et al. 2000)
During pregnancy, but others state that pregnant mares should not receive folic acid during therapy as it may exacerbate fetal abnormalities or mortality. In humans, the FDA categorizes pyrimethamine as category B. Pyrimethamine has been demonstrated to be teratogenic in rats. Fetal abnormalities have been seen in foals after mares have been treated; however, it has been used in treating women with toxoplasmosis during pregnancy. Risks associated with therapy must be weighed against the potential for toxicity, the severity of the disease, and any alternative therapies available.

**Storage/Stability**

Pyrimethamine tablets should be stored in tight, light-resistant containers. Pyrimethamine tablets may be crushed to make oral suspensions of the drug. Although stable in an aqueous solution, sugars tend to adversely affect the stability of pyrimethamine. If cherry syrup, corn syrup, or sucrose-containing liquids are used in the preparation of the suspension, it is recommended to store the suspension at room temperature and discard after 7 days.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

- Pyrimethamine Tablets: 25 mg; Daraprim® (GlaxoSmithKline); (Rx)

---

**PYRIMETHAMINE + SULFADIAZINE**

**(pyr’-i-meth-a-meen + sul-fa-deez) ReBalance®**

**ANTIPROTOZOAL**

Note: Also see the Pyrimethamine, and Sulfadiazine/Trimethoprim monographs

**Prescriber Highlights**

- Tetrahydrofolic acid inhibitor suspension labeled for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*
- May cause bone marrow suppression, GI effects, & “treatment crisis” (patient’s signs worsen after beginning therapy)
- Daily treatment may be required for 3–9 months

---

**Uses/Indications**

ReBalance® (pyrimethamine/sulfadiazine suspension in a 1:20 concentration) is labeled for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*. Some combine pyrimethamine and sulfadiazine with ponazuril or diclazuril in treating relapsing EPM.

Although not labeled for use in small animals it potentially could be useful for treating protozoal infections such as Toxoplasmosis in cats or Neosporosis in dogs.

**Pharmacology/Actions**

Sulfonamides inhibit the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA) by competing with PABA for dihydropteroate synthase. Pyrimethamine blocks the conversion of DFA to tetrahydrofolate by inhibiting dihydrofolate reductase. When sulfas and dihydrofolate reductase inhibitors (e.g., trimethoprim, pyrimethamine) are used together, synergistic effects can occur. When comparing pyrimethamine and trimethoprim, pyrimethamine is more active against protozoal dihydrofolate reductase and trimethoprim is more active against bacterial dihydrofolate reductase.

**Pharmacokinetics**

No specific information was located for the pharmacokinetics of this drug combination and dosage form (oral suspension) in horses. Previous reports in horses using other dosage forms reported pyrimethamine oral bioavailability of approximately 56% and elimination half-life of about 12 hours. CNS levels are approximately 25–50% of those found in plasma. Sulfadiazine is apparently well absorbed after oral administration to horses and enters the CSF. Volume of distribution is approximately 0.58 L/kg; elimination half-life is about 3–4 hours.

**Contraindications/Precautions/Warnings**

This drug combination is contraindicated in horses hypersensitive to either pyrimethamine or sulfadiazine. It should not be used in horses intended for human consumption. Because it may cause bone marrow suppression, use with caution in horses with preexisting hematologic abnormalities or those receiving other drugs that may cause bone marrow suppression.

**Adverse Effects**

Adverse effects in horses reported during field trials for pyrimethamine/sulfadiazine suspension include bone marrow suppression (anemia, leukopenia, neutropenia, thrombocytopenia), reduced appetite/anorexia, loose stools/diarrhea, and urticaria. CNS effects may be noted (seizures, depression), but are probably a result of the disease (EPM).

Baker’s yeast or folic acid have been suggested to antagonize the drug combination’s bone marrow depressive effects, but efficacy has not been proven.

During the initial period (first few days) of treatment, neurologic signs may worsen—so-called treatment crisis—and may persist up to 5 weeks. It is thought this may be the result of an inflammatory reaction secondary to dying parasites in the central nervous system.

**Reproductive/Nursing Safety**

The label for ReBalance® (pyrimethamine/sulfadiazine suspension) states that the safe use of this product in horses for breeding purposes, during pregnancy, or in lactating mares has not been evaluated.
A related compound for humans that contained Sulfadoxine & Pyrimethamine.

**HUMAN-LABELED PRODUCTS:**
not for use in horses intended for human consumption.

- **Sulfadiazine (as the sodium salt)** 250 mg/mL and Pyrimethamine 12.5 mg/mL Oral Suspension in quart (946.4 mL) bottles;
- **VETERINARY-LABELED PRODUCTS:**

**Dosage Forms/Regulatory Status**
ReBalance®

**Storage/Stability**
ReBalance® suspension should be stored at controlled room temperature (15–30°C) and protected from freezing.

**Doses**
**HORSES:**
For treatment of EPM:
- a) 20 mg/kg sulfadiazine with 1 mg/kg pyrimethamine; equivalent to 4 mL of ReBalance® suspension per 50 kg (110 lb) body weight PO once daily at least 1 hour before feeding with hay or grain. Administer using a suitable oral dosing syringe; insert nozzle through the interdental space and deposit the dose on the back of the tongue by depressing the plunger. Treatment duration is based upon clinical response, but usually ranges from 90–270 days. (Label information; ReBalance®—Phoenix)
- b) For horses that have had two relapses, intermittent sulfap-pyrimethamine may be effective in maintaining clinical remission. After completing regular therapy for EPM, give pyrimethamine/sulfadiazine twice weekly (first and fourth day of each week). (MacKay 2008)

**Laboratory Considerations**
The following laboratory alterations have been reported in humans taking sulfonamides and may be of significance in veterinary patients:
- **Urine glucose:** Sulfonamides may give false-positive results when using the Benedict’s method

**Chemistry/Synonyms**
Pyrimethamine is an aminopyrimidine agent structurally related to trimethoprim. It occurs as an odorless, white, or almost white, crystalline powder or crystals. It is practically insoluble in water and slightly soluble in alcohol.

Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.

Sulfadoxine and Pyrimethamine may also be known as Fansidar® and ReBalance®.

**Adverse Effects:**
Yellowing of skin & urine color, (not of clinical importance); GI (anorexia, nausea, vomiting, diarrhea), abnormal behaviors (“fly biting”, agitation), pruritus, & fever. Potentially:
- Hypersensitivity, hepatopathy, aplastic anemia, corneal edema, & retinopathy.
- Availability an issue
- Potential teratogen

**References**

**QUINACRINE HCL**
(prin-krihn)
**ANTIPROTOZOAL**

**Prescriber Highlights**
- Antiprotozoal that may be useful for treatment of Giardia, Leishmania, & coccidia. May improve clinical signs associated with giardial infection, but not eliminate infection
- Contraindications: Potentially, if hepatic dysfunction or pregnancy
- Adverse Effects: Yellowing of skin & urine color, (not of clinical importance); GI (anorexia, nausea, vomiting, diarrhea), abnormal behaviors (“fly biting”, agitation), pruritus, & fever. Potentially:
  - Hypersensitivity, hepatopathy, aplastic anemia, corneal edema, & retinopathy.

**References**
Uses/Indications
While quinacrine has activity against a variety of protozoans and helminths, its use against all but Giardia and Trichomonas has been superseded by safer or more effective agents. In humans, quinacrine may be used for treatment of mild to moderate discoid lupus erythematosus, transcervically as a sterilizing agent, or in powder form as an intrapleural sclerosing agent.

Pharmacology/Actions
Quinacrine’s mechanism of action for its antiprotozoal activity against Giardia is not understood, however, it does bind to DNA by intercalation to adjacent base pairs thereby inhibiting RNA transcription and transllocation. Additionally, quinacrine interferes with electron transport and inhibits succinate oxidation and cholinesterase. Quinacrine binds to nucleoproteins that (in humans at least) can suppress lupus erythromatosis (LE) cell factor.

Pharmacokinetics
Quinacrine is absorbed well from the GI tract or after intrapleural administration. It is distributed throughout the body, but CSF levels are only 1–5% of those found in plasma. Drug is concentrated in the liver, spleen, lungs, and adrenals. It is relatively highly bound to plasma proteins in humans (80–90%). Quinacrine crosses the placenta, but only small amounts enter maternal milk.

Monitoring
Efficacy (fecal exams, reduction in diarrhea)
Adverse effects

Client Information
Quinacrine should preferably be given after meals with plenty of liquids available.

Dosages

- **DOGS:**
  - a) 6.6 mg/kg PO q12h for 5 days (Papich 1992), (Sherding & Johnson 1994), (Blagburn 2003; Blagburn 2005)
  - b) 9 mg/kg PO q24h for 6 days. (Lappin 2006)

- **CATS:***
  - a) Giardia: 9 mg/kg PO once daily for 6 days; Coccidiosis: 10 mg/kg PO once daily for 5 days (Blagburn 2003), (Blagburn 2005)
  - b) Giardia: 11 mg/kg PO q24h for 12 days (Lappin 2006)
  - c) Coccidiosis: 10 mg/kg PO once daily for 5 days (Greene & Watson 1998)

- **REPTILES:**
  - a) For hemoprotozoal infections: 19–100 mg/kg PO q48h (every other day) for 2–3 weeks (de la Navarre 2003)

Overdosage/Acute Toxicity
Overdosage may be serious depending on the dose. In humans, a dose as low as 6.8 grams (administered intraduodenally) caused death. Clinical signs associated with acute toxicity include CNS excitation (including seizures), GI disturbances, vascular collapse, and cardiac arrhythmias. Treatment consists of gut emptying protocols, and supportive and symptomatic therapies. Urinary acidification with ammonium chloride and forced diuresis (with adequate fluid therapy) may be beneficial in enhancing urinary excretion of the drug.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving quinacrine HCl and may be of significance in veterinary patients:

- **ALCOHOL:** Quinacrine may cause a “disulfiram-reaction” if used with alcohol.
- **HEPATOTOXIC DRUGS:** Quinacrine concentrates in the liver and should be used with caution with hepatotoxic drugs (clinical significance unknown).
- **PRIMAQUINE:** Quinacrine increases the toxicity of primaquine (generally not used in veterinary medicine), and the two should not be used simultaneously.

Laboratory Considerations
When urine is acidic, quinacrine can cause it to turn a deep yellow color. By causing an interfering fluorescence, quinacrine can cause falsely elevated values of plasma and urine cortisol values.

Adverse Effects
In small animals, a yellowing of skin and urine color can occur, but is not of clinical importance (does not indicate jaundice). Additionally, gastrointestinal disturbances (anorexia, nausea, vomiting, diarrhea), abnormal behaviors (“fly biting”, agitation), lethargy, pruritus, and fever have been noted.

- Potentially hypersensitivity reactions, hepatopathy, aplastic anemia, corneal edema, and retinopathy could occur (all reported rarely in humans, primarily with high dose long-term use).

Contraindications/Precautions/Warnings
In humans, quinacrine is relatively contraindicated in patients with psychotic disorders, psoriasis, or porphyria as it may exacerbate these conditions. Veterinary relevance is unknown. The drug should be used with extreme caution in patients with hepatic dysfunction.

Overdosage/Acute Toxicity
When urine is acidic, quinacrine can cause it to turn a deep yellow color. By causing an interfering fluorescence, quinacrine can cause falsely elevated values of plasma and urine cortisol values.

Laboratory Considerations

- **DOGS:**
  - a) 6.6 mg/kg PO q12h for 5 days (Papich 1992), (Sherding & Johnson 1994), (Blagburn 2003; Blagburn 2005)
  - b) 9 mg/kg PO q24h for 6 days. (Lappin 2006)

- **CATS:**
  - a) Giardia: 9 mg/kg PO once daily for 6 days; Coccidiosis: 10 mg/kg PO once daily for 5 days (Blagburn 2003), (Blagburn 2005)
  - b) Giardia: 11 mg/kg PO q24h for 12 days (Lappin 2006)
  - c) Coccidiosis: 10 mg/kg PO once daily for 5 days (Greene & Watson 1998)

- **REPTILES:**

Monitoring
Efficacy (fecal exams, reduction in diarrhea)
Adverse effects

Client Information
Quinacrine should preferably be given after meals with plenty of liquids available.

Make sure clients understand the importance of compliance with directions and to watch for signs of adverse effects.

Chemistry/Synonyms
A synthetic acridine derivative anthelmintic, quinacrine HCl occurs as a bright yellow, odorless, crystalline powder having a bitter taste. It is sparingly soluble in water.

Quinacrine HCl may also be known as mequinacrine HCl.

Storage/Stability
Tablets should be stored in tight, light-resistant containers at room temperature. Quinacrine is not stable in solution for any length of time; however, it may be crushed and mixed with foods to mask its very bitter taste.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

There currently are no quinacrine products being marketed in the USA. It may be available from compounding pharmacies.
**QUINIDINE GLUCONATE**

**QUINIDINE POLYGALACTURONATE**

**QUINIDINE SULFATE**

***quin-deen* (Quinidex®)

**ANTIARRHYTHMIC**

**Prescriber Highlights**

- **Contraindications:** Hypersensitivity, myasthenia gravis; complete AV block with an AV junctional or idioventricular pacemaker; intraventricular conduction defects; digitalis intoxication with associated arrhythmias or AV conduction disorders; aberrant ectopic impulses; or abnormal rhythms secondary to escape mechanisms.

- **Extreme Caution:** Any form of AV block or if any clinical signs of digoxin toxicity are exhibited.

- **Caution:** Uncorrected hypokalemia, hypoxia, disorders or acid-base balance; hepatic or renal insufficiency.

- **Adverse Effects:**
  - Dogs: GI effects, weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex & QT intervals, AV block, & multiformal ventricular tachycardias hypotension. Horses: inappetence, depression, swelling of the nasal mucosa, ataxia, diarrhea, colic, hypotension & rarely, laminitis, paraphimosis & the development of urticarial wheals; cardiac arrhythmias including AV block, circulatory collapse & sudden death.

- **Consider monitoring blood levels.**

- **Administer at evenly spaced intervals throughout the day/night.**

- **GI upset may be decreased if administered with food.**

- **Do not allow animal to chew or crush sustained-release oral dosage forms.**

- **Many drug Interactions.**

**Uses/Indications**

Quinidine is used in small animal or equine medicine for the treatment of ventricular arrhythmias (VPCs, ventricular tachycardia), refractory supraventricular tachycardias, and supraventricular arrhythmias associated with anomalous conduction in Wolff-Parkinson-White (WPW) syndrome. Chronic use of quinidine for controlling ventricular arrhythmias and supraventricular tachycardia in dogs has diminished over the years as other drugs appear to be more effective. It is still used in dogs and horses to convert atrial fibrillation to sinus rhythm. Oral therapy is generally not used in cats.

**Pharmacology/Actions**

A class IA antiarrhythmic, quinidine has effects similar to that of procainamide. It depresses myocardial excitability, conduction velocity, and contractility. Quinidine will prolong the effective refractory period, which prevents the reentry phenomenon and increases conduction times. Quinidine also possesses antricholinergergic activity, which decreases vagal tone and may facilitate AV conduction.

**Pharmacokinetics**

After oral administration, quinidine salts are nearly completely absorbed from the GI, however, the actual amount that reaches the systemic circulation will be reduced due to the hepatic first-pass effect. The extended-release formulations of quinidine sulfate and glaconate, as well as the polygalacturonate tablets, are more slowly absorbed than the conventional tablets or capsules.

Quinidine is distributed rapidly to all body tissues except the brain. Protein binding varies from 82–92%. The reported volumes of distribution in various species are: horses 15.1 L/kg; cattle 3.8 L/kg; dogs 2.9 L/kg; cats 2.2 L/kg. Quinidine is distributed into milk and crosses the placenta.

Quinidine is metabolized in the liver, primarily by hydroxylolation. Approximately 20% of a dose may be excreted unchanged in the urine within 24 hours after dosing. Serum half-lives reported in various species are: horses 8.1 hours; cattle 2.3 hours; dogs 5.6 hours; cats 1.9 hours; swine 5.5 hours; goats 0.9 hours. Acidic urine (pH <6) can increase renal excretion of quinidine and decrease its serum half-life.

**Contraindications/Precautions/Warnings**

Quinidine is generally contraindicated in patients who have demonstrated previous hypersensitivity reactions to it; myasthenia gravis; complete AV block with an AV junctional or idioventricular pacemaker; intraventricular conduction defects (especially with pronounced QRS widening); digitalis intoxication with associated arrhythmias or AV conduction disorders; aberrant ectopic impulses; or abnormal rhythms secondary to escape mechanisms. It should be used with extreme caution, if at all, in any form of AV block or any clinical signs of digitalis toxicity are exhibited.

Quinidine should be used with caution in patients with uncorrected hypokalemia, hypoxia, or disorders or acid-base balance. Use cautiously in patients with hepatic or renal insufficiency as accumulation of the drug may result.

When using to cardiovert horses with atrial fibrillation, monitor the ECG throughout treatment. Heart rates above 80 bpm, a widening of QRS beyond 125% of baseline, and abnormal complexes are all indicators to discontinue medication (McGurrin 2010).

**Adverse Effects**

In dogs, gastrointestinal effects may include anorexia, vomiting, or diarrhea. Effects related to the cardiovascular system can include weakness, hypotension (especially with too rapid IV administration), negative inotropism, widened QRS complex and QT intervals, AV block, and multiformal ventricular tachycardias.

Horses may exhibit inappetence and depression commonly after quinidine therapy but this does not necessarily indicate toxicity. Signs of toxicity include swelling of the nasal mucosa, ataxia, diarrhea, colic, hypotension and, rarely, laminitis, paraphimosis and the development of urticarial wheals. Urticaria or upper respiratory tract obstruction can be treated by discontinuing the drug and administering corticosteroids if necessary. If obstruction persists, nasotracheal tube placement or tracheostomy may be required. Horses may develop cardiac arrhythmias including AV block, circulatory collapse, and sudden death.

Patients exhibiting signs of toxicity or lack of response may be candidates for therapeutic serum monitoring. The therapeutic range is thought to be 2.5–5 micrograms/mL in dogs. Toxic effects usually are not seen unless levels are >10 micrograms/mL.

**Reproductive/Nursing Safety**

In humans, the FDA classifies this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

Quinidine is excreted into maternal milk with a milk:serum ratio of approximately 0.71. Use caution when quinidine is administered to nursing patients. The American Academy of Pediatrics considers quinidine compatible with breastfeeding.
Overdosage/Acute Toxicity

Clinical signs of overdosage can include depression, hypotension, lethargy, confusion, seizures, vomiting, diarrhea, and oliguria. Cardiac signs may include depressed automaticity and conduction, or tachyarrhythmias. The CNS effects are often delayed after the onset of cardiovascular effects but may persist after the cardiovascular effects have begun to resolve.

If a recent oral ingestion, emptying of the gut and charcoal administration may be beneficial to remove any unabsorbed drug. IV fluids, plus metaraminol or norepinephrine, can be considered to treat hypotensive effects. A 1/6 molar intravenous infusion of sodium lactate may be used in an attempt to reduce the cardiotoxic effects of quinidine. Forced diuresis using fluids and diuretics along with reduction of urinary pH may enhance the renal excretion of the drug. Temporary cardiac pacing may be necessary should severe AV block occur. Hemodialysis will effectively remove quinidine, but peritoneal dialysis will not.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving quinidine and may be of significance in veterinary patients:

ACETAZOLAMIDE: May reduce quinidine clearance
AMIODARONE: May increase quinidine levels (significantly)
ANTACIDS: May delay oral absorption; separate dosages
ANTIARRHYTHMIC AGENTS: Use with caution with other antiarrhythmic agents, as additive cardiotoxic or other toxic effects may result
ANTICHOLINESTERASES (e.g., pyridostigmine, neostigmine): Quinidine may antagonize the effects of anticholinesterases in patients with myasthenia gravis
AUROTHIOPURIN: Increased risk for blood dyscrasias
CIMETIDINE: Cimetidine may increase the levels of quinidine by inhibiting hepatic microsomal enzymes
CISAPRIDE: Increased risk for QTc interval prolongation
COLCHICINE: Quinidine may increase colchicine levels
CLARITHROMYCIN: Increased risk for torsade de pointes
DEXAMETHASONE: In dogs, dexamethasone increased quinidine volume of distribution (49-78%) and elimination half-life (1.5-2.3X). (Zhang et al. 2006)
DIGOXIN: Digoxin levels may increase considerably in patients stabilized on digoxin who receive quinidine. Some cardiologists recommend decreasing the digoxin dosage by 1/3 when adding quinidine. Therapeutic drug monitoring of both quinidine and digoxin may be warranted in these cases.
DILTIAZEM: Possible decreased clearance; increased elimination half-life of quinidine
HYPOTENSIVE AGENTS: Quinidine may potentiate the effects of other drugs having hypotensive effects
FLUCONAZOLE: Increased risk for cardiotoxicity
FLUOROQUINOLONE ANTIBIOTICS (e.g., ciprofloxacin, enrofloxacin, etc): Increased risk for cardiotoxicity
ITRACONAZOLE: Increased risk for quinidine toxicity
KETOCONAZOLE: May reduce the metabolism of quinidine
NEUROMUSCULAR BLOCKING AGENTS: Quinidine may increase the neuromuscular blocking effects of drugs like succinylcholine, tubocurarine, or atracurium
PHENOBARBITAL, PHENYTOIN: May induce hepatic enzymes that metabolize quinidine thus reducing quinidine serum half-life by 50%
PHENTHALAZINES: Additive cardiac depressant effects may be seen
RESERPINE: Additive cardiac depressant effects may be seen
RIFAMPIN: May induce hepatic enzymes that metabolize quinidine thus reducing quinidine serum half-life by 50%
TRICYCLIC ANTIDEPRESSANTS (e.g., amitriptyline, clomipramine, doxepin, imipramine): Increased risk for QTc interval prolongation and tricyclic adverse effects
URINARY ACIDIFIERS (e.g., methionine, ammonium chloride): Drugs that acidify the urine (may increase the excretion of quinidine and decrease serum level)
URINARY ALKALINIZERS (carbonic anhydrase inhibitors, thiazide diuretics, sodium bicarbonate, antacids, etc): Drugs that alkaline the urine may decrease the excretion of quinidine, prolonging its half-life
VERAPAMIL: Possible decreased clearance; increased elimination half-life of quinidine; increased risk for hypotension
WARFARIN: Coumarin anticoagulants with quinidine may increase the likelihood of bleeding problems

Doses

DOGS:

a) For VPC’s or ventricular tachycardia:
   Quinidine gluconate: 6.6–22 mg/kg IM q2–4h or q8–12h PO (delayed dosage forms).
   Quinidine Sulfate: 6.6–22 mg/kg PO q6–8h; may be given initially q2h as a loading dose until arrhythmia is controlled or toxicity is induced (Ettinger 1989)
   b) 6–20 mg/kg IM q6h (loading dose 14–20 mg/kg); 6–16 mg/kg PO q6h; Sustained action oral preparations: 8–20 mg/kg PO q8h (Ware 2000)
   c) 6–16 mg/kg PO or IM q6h (q8h with sustained release products) (Fox 2003)
   d) For conversion of atrial fibr to sinus rhythm in dogs without underlying heart disease: Initially attempted with quinidine gluconate at 6–11 mg/kg IM q6h. Some dogs will convert in the first 24 hours of therapy. If rapid ventricular response occurs, may give either digoxin or a beta-blocker to slow rate of conduction across AV node. (Russell & Rush 1995), (Smith 2009)

CATS:

a) 6–16 mg/kg IM or PO q8h (Ware 2000)

HORSES: (Note: ARCI UCGEF Class 4 Drug

a) For atrial fibr without signs of heart failure: Keep horse quiet during dosing stage. Monitor ECG either continuously or before each dose. Horses with recent onset (<7 days) or whom develop atrial fibr during anesthesia: Quinidine gluconate 1.1–2.2 mg/kg IV every 10 minutes to a total dose of 8.8–11 mg/kg (or until conversion or toxicity develop).
   For horses who have had atrial fibr for >7 days: Give quinidine sulfate 22 mg/kg via NG tube every 2 hours for a total dose of 88–132 mg/kg (or until conversion or toxicity develop). If this fails to convert and no signs of toxicity are evident may continue at 22 mg/kg PO q6h for an additional 2–4 or more days. Discontinue if QRS duration is >125% of baseline. Rapid VT’s (>100 BPM) or ventricular arrhythmias may necessitate specific antiarrhythmic therapy.
   For V-Tach: Quinidine gluconate 0.5–2.2 mg/kg IV boluses every 10 minutes up to a total of 8.8–11 mg/kg (Mogg 1999)

b) For atrial fibrillation in a horse without heart failure:
   Oral (via NG tube) Dosing: give quinidine sulfate 22 mg/kg PO via nasogastric tube every two hours until cardiovascular, toxic effects, or six doses have been given. If AF remains continue administration every 6 hours until cardiovascular or adverse effects.
   Alternate IV dosing method: 0.5–2.2 mg/kg IV bolus every 5–10 minutes to effect or until adverse effects seen. Maximum IV dose is 12mg/kg. Conversion of ventricular tachycardia has occurred with a single 0.5 mg/kg dose.
   Monitor ECG throughout treatment. Heart rate in excess of 80 bpm, widening QRS complex >125% of baseline, ventricular arrhythmias or abnormal complexes are indicators to discontinue treatment.
   Toxic effects are variable. Mild signs include nasal edema, and mild depression. More severe signs include marked ataxia, hypotension, colic, diarrhea, seizures, sustained tachycardia, syncope and sudden death. Adverse effects not necessarily dose dependent. Hypokalemia increases risk for torsades de pointes. Therapeutic levels 3–5 micrograms/mL. (Kimberly & McGurrin 2006)

c) For atrial fibrillation:
   Oral (via NG tube) Dosing: give quinidine sulfate 22 mg/kg PO via nasogastric tube every two hours for 4–6 doses, followed by dosing q6h if needed for conversion. Withhold food for 12 hours prior to starting treatment to ensure maximum oral absorption. Quinidine dissolves poorly so 1–2 liters of water may be needed per dose. Oral ulcers can occur if attempting to administer by mouth. If nasal edema or urticaria occurs, discontinue immediately. Heart rate in excess of 100 bpm, widening QRS complex >125% of baseline, ventricular arrhythmias or abnormal complexes are indicators to discontinue treatment.
glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Chemistry/Synonyms
Used as an antiarrhythmic agent, quinidine is an alkaloid obtained from cinchona or related plants, or is prepared from quinine. It is available commercially in three separate salts: gluconate, polygalacturonate, or sulfate.

Quinidine gluconate occurs as a very bitter tasting, odorless, white powder. It is freely soluble in water and slightly soluble in alcohol. The injectable form has a pH of 5.5–7.

Quinidine polygalacturonate occurs as a bitter tasting, creamy white, amorphous powder. It is sparingly soluble in water and freely soluble in hot 40% alcohol.

Quinidine sulfate occurs as a very bitter tasting, odorless, fine, needle-like, white crystals that may cohere in masses. One gram is soluble in approximately 100 mL of water or 10 mL of alcohol.

Quinidine Gluconate Sustained-Release Tablets: 324 mg; generic; (Rx)
Quinidine Sulfate (contains 83% anhydrous quinidine alkaloid) Sustained-Release Tablets: 300 mg; generic; (Rx)
Quinidine Sulfate (contains 83% anhydrous quinidine alkaloid) Tablets: 100 mg, 200 mg & 300 mg; generic; (Rx)

Compatibility/Compounding Considerations
All quinidine salts darken upon exposure to light (acquire a brownish tint) and should be stored in light-resistant, well-closed containers. Use only colorless, clear solutions of quinidine gluconate for injection. Quinidine gluconate injection is usually administered intramuscularly, but may be given very slowly (1 mL/minute) intravenously. It may be diluted by adding 10 to 40 mL of DSW.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Quinidine Sulfate may also be known as: chinidini sulfas, chinidinsulfate, chinidinum sulfuricum, or quinidini sulfas; many trade names are available.
Quinidine Gluconate may also be known as: quinidinium gluconate, Quinaglute®, Cardioquin®, Cardura®, Cardioquin®, Galactoquin®, Naticardin®, or Neochinidin Ritmocor®.
Quinidine Polygalacturonate may also be known as: Cardioquin®, Cardioquin®, Cardura®, Cardioquin®, Galactoquin®, Naticardin®, or Neochinidin Ritmocor®.
Quinidine Polygalacturonate may also be known as: Cardioquin®, Cardioquin®, Cardura®, Cardioquin®, Galactoquin®, Naticardin®, or Neochinidin Ritmocor®.

Storage/Stability
All quinidine salts darken upon exposure to light (acquire a brownish tint) and should be stored in light-resistant, well-closed containers. Use only colorless, clear solutions of quinidine gluconate for injection. Quinidine gluconate injection is usually administered intramuscularly, but may be given very slowly (1 mL/minute) intravenously. It may be diluted by adding 10 to 40 mL of DSW.

Contraindications
Hypersensitivity to ACE inhibitors

ACE inhibitor used primarily as a vasodilator in the treatment of heart failure or hypertension; may be of benefit in the treatment of chronic renal failure or protein losing nephropathies
Not as much information or experience available as some other ACE inhibitors (e.g., enalapril) in dogs or cats
Contraindications: Hypersensitivity to ACE inhibitors
Caution: Pregnancy, patients with hyponatremia, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE)

ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Ramiprilat prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for ramiprilat than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased.

The cardiovascular effects of ramiprilat in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure with no change or decrease in heart rate. Increased cardiac index and output, stroke volume, and exercise tolerance also occur. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

ANGIOTENSIN CONVERTING ENZYME (ACE) INHIBITOR

Prescriber Highlights

- ACE inhibitor used primarily as a vasodilator in the treatment of heart failure or hypertension; may be of benefit in the treatment of chronic renal failure or protein losing nephropathies
- Not as much information or experience available as some other ACE inhibitors (e.g., enalapril) in dogs or cats
- Contraindications: Hypersensitivity to ACE inhibitors
- Caution: Pregnancy, patients with hyponatremia, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE)
- Adverse Effects: Appears well tolerated in both dogs & cats. GI effects (anorexia, vomiting, diarrhea) possible; potentially: weakness, hypotension, & hyperkalemia

Uses/Indications
Ramipril is a long-acting angiotensin converting enzyme (ACE) inhibitor that may be useful in treating heart failure or hypertension in dogs or cats. It is an approved product in the UK for treating heart failure in dogs. In cats, ramipril has been used for treating arterial hypertension. A recent study (MacDonald et al. 2006) did not show any significant benefit using ramipril in treating Maine Coon cats with hypertrophic cardiomyopathy without heart failure.

Like other ACE inhibitors, it may potentially be useful as adjunctive treatment in chronic renal failure and protein losing nephropathies. In dogs with moderate renal impairment (such as might be found with CHF), there is apparently no need to adjust ramipril dosage.

Pharmacology/Actions
Ramipril is a pro-drug that has little pharmacologic activity until converted into ramiprilat. Ramiprilat prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for ramiprilat than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased.

The cardiovascular effects of ramiprilat in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure with no change or decrease in heart rate. Increased cardiac index and output, stroke volume, and exercise tolerance also occur. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.
Pharmacokinetics

After oral administration to dogs, ramipril is rapidly converted via de-esterification into ramiprilat. Bioavailability of ramiprilat after a dose of 0.25 mg/kg per day of ramipril is about 6.7%. At this dose, ACE activity never exceeded 60% in either healthy dogs or those with experimentally induced renal dysfunction (GFR reduced 58%) (Lefebvre et al. 2006).

After oral administration to cats with ramipril doses ranging from 0.125 mg/kg to 1 mg/kg once daily for 9 days, ramipril peak concentrations occurred in about 0.5 hours. Ramipril is rapidly converted into its active metabolite ramiprilat, which peaks at 1 hour post-administration. Repeated doses of 0.125 mg/kg inhibited serum ACE activity by 94% at maximum to 55% 24 hours post-dose. At a dose of 1 mg/kg, ACE activity was 97% inhibited at maximum, and 83% inhibited 24 hours post-dose (Coulet & Burgaud 2002).

When cats were administered radio-labeled ramipril orally, 85–89% of the radioactivity was recovered in the feces. It is unclear how much of this represents unabsorbed drug or absorbed parent compound/metabolites eliminated in the feces. Approximately 10% of administered drug was recovered in the urine. Excretion of radio-labeled compounds was complete by 168 hours after dosing.

Contraindications/Precautions/Warnings

The labeling for the UK product approved for dogs (Vasotop®) states that it should not be used in clinical cases of vascular stenosis (e.g., aortic stenosis), obstructive hypertrophic cardiomyopathy, or with potassium-sparing diuretics (see Drug Interactions).

Adverse Effects

While information is limited, ramipril appears to be well tolerated in dogs and cats. Gastrointestinal effects are probably the most likely adverse effects to be noted. Weakness, hypotension, or hyperkalemia are possible.

Reproductive/Nursing Safety

The labeling for the product approved in the UK (Vasotop®) suggests not using in bitches during pregnancy or lactation. Weigh the potential risks associated with using this medication (see human data below) in veterinary patients with the potential benefits of therapy. Dosages of up to 500 mg/kg/day did not impair fertility in rats. While no teratogenic effects have been detected with ramipril in studies performed in mice, rats, rabbits, and cynomolgus monkeys, fetal risk is increased in humans.

If used in humans during the 2nd and 3rd trimesters increased rates of fetal death, neonatal hypopituitarism, skull hypoplasia, anuria, renal failure, oligohydramnios leading to fetal limb contractures, craniofacial deformation, and hypoplastic lung development were noted. In humans, ramipril has a “black box” warning regarding its use in pregnancy that states “When used in pregnancy during the second and third trimesters, angiotensin-converting enzyme (ACE) inhibitors can cause injury and even death to the developing fetus. When pregnancy is detected, ramipril should be discontinued as soon as possible.” For humans, the FDA categorizes ramipril as category D for use during the 2nd and 3rd trimesters of pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks) and as category C for use during the first trimester of pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is unknown whether ramipril (or ramiprilat) enters milk. Both the veterinary label (UK) and human label recommended not using the drug during nursing.

Overdosage/Acute Toxicity

In dogs, ramipril appears quite safe; dosages as high as 1 gram/kg induced only mild GI distress. Lethal doses in rats and mice were noted at 10–11 grams/kg. No information was located on overdoses in cats. In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug’s long duration of action, prolonged monitoring and treatment may be required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ramipril and may be of significance in veterinary patients:

- ASPIRIN: Aspirin may potentially negate the decrease in systemic vascular resistance induced by ACE inhibitors. However, in one study in dogs using low-dose aspirin, hemodynamic effects of enalapril (active metabolite of enalapril, a related drug) were not affected.

- ANTIDIABETIC AGENTS (insulin, oral agents): Possible increased risk for hypoglycemia; enhanced monitoring recommended

- DIURETICS (e.g., furosemide, hydrochlorothiazide): Potential for increased hypotensive effects

- DIURETICS, POTASSIUM Sparing (e.g., spironolactone, triamterene): Increased hyperkalemic effects, enhanced monitoring of serum potassium

- NSAIDS: Potential for increased risk of renal dysfunction or hyperkalemia

- POTASSIUM SUPPLEMENTS: Increased risk for hyperkalemia

Laboratory Considerations

- ACE inhibitors may cause a reversible decrease in localization and excretion of iodohippurate sodium 131I, or Technetium Tc 99 pententate renal imaging in the affected kidney in patients with renal artery stenosis, which could lead to confusion in test interpretation

Doses

- DOGS:
  a) For treatment of heart failure: Initially, 0.125 mg/kg PO once daily; depending on the severity of pulmonary congestion, dose may be increased to 0.25 mg/kg PO once daily (Label information; Vasotop®—Intervet UK)

- CATS:
  a) For treatment of arterial hypertension: 0.125 mg/kg PO once daily (Graff & Herve 2003)

- HORSES:
  a) For CHF: There is anecdotal evidence that ACE inhibitors may be beneficial in horses and ramipril at 0.2 mg/kg PO once daily has been used, but pharmacokinetic studies are lacking. (Giguere 2008)

Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential, periodic
- Blood pressure (if treating hypertension or clinical signs associated with hypotension arise)

Client Information

- For this drug to be maximally effective it must be given once daily at about the same time each day
- Do not abruptly stop or reduce therapy without veterinarian’s approval
- Contact veterinarian if vomiting or diarrhea persist, are severe, or if animal’s condition deteriorates

Chemistry/Synonyms

Ramipril occurs as a white to almost white, crystalline powder that is sparingly soluble in water and freely soluble in methyl alcohol.

Ramipril may also be known as Hoe-498, ramiprilis, or ramiprilium. There are many international trade names, including: Altace®, Cardase®, Delix®, Ramase®, Triatec®, and Triuace®.

Storage/Stability

Capsules should be stored at room temperature (15–30°C) protected from light in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None in the USA; in the UK and in other European countries: Ramipril Tablets: 0.625 mg, 1.25 mg, 2.5 mg, & 5 mg; Vasotop® (Intervet); (Rx). Approved for use in dogs.
Unlike cimetidine, ranitidine appears to have much less effect on the hepatic metabolism of drugs and is unlikely to cause clinically relevant drug interactions via this mechanism. The following drug interactions have either been noted to remove ranitidine from the body.

**Drug Interactions**

Dialysis have been noted to remove ranitidine from the body.

Clinical experience with ranitidine overdosage is limited. In laboratory animals, very high dosages (225 mg/kg/day) have been associated with muscular tremors, vomiting and rapid respirations. Single doses of 1 gram/kg in animals are lethal. In humans, 2-3 grams may cause death. Ranitidine overdosage has been associated with respiratory depression, hypotension, ECG changes and bradycardia. Management includes supportive care and atropine if indicated. Ranitidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and possibly at reduced dosage in patients with diminished renal function. Ranitidine has caused increased serum ALT levels after single oral doses in humans. Food does not appreciably alter the extent of absorption or the peak serum levels attained.

**Pharmacokinetics**

Approximately 1.1 L/kg and 1.5 L/kg in adults and foals, respectively. Clearance in adults is approximately 10 mL/min/kg and 13.3 mL/min/kg in foals. Pharmacokinetics are similar in dogs, cats, and other species other than horses. In horses, the oral bioavailability is approximately 81%, serum half-life is 2.2 hours and volume of distribution 2.6 L/kg. Pharmacokinetics of ranitidine are similar in dogs and cats. While ranitidine may cause gastric emptying times to be delayed, it more likely will stimulate GI motility by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors). Lower esophageal sphincter pressures may be increased by ranitidine. By decreasing the amount of gastric juice produced, ranitidine decreases the amount of pepsin secreted.

Ranitidine, unlike cimetidine, does not appear to have any appreciable effect on serum prolactin levels, although it may inhibit the release of vasopressin.

**Contraindications/Precautions/Warnings**

Ranitidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and possibly at reduced dosage in patients with diminished renal function. Ranitidine has caused increased serum ALT levels in humans receiving high, IV doses for longer than 5 days. The manufacturer recommends that with high dose, chronic therapy, serum ALT values be considered for monitoring.

**Adverse Effects**

Adverse effects appear to be very rare in animals at the dosages generally used. Potential adverse effects (documented in humans) that might be seen include mental confusion and headache. Rarely, agranulocytosis may develop and, if given rapidly IV, transient cardiac arrhythmias may be seen. Pain at the injection site may be noted after IM administration. IV boluses have been associated with vomiting in small animals.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.) Ranitidine is excreted in human breast milk with milk:plasma ratios of approximately 5:1 to 12:1. The drug is not recommended to be used in nursing humans; use with caution in nursing veterinary patients.

**Overdosage/Acute Toxicity**

Clinical experience with ranitidine overdosage is limited. In laboratory animals, very high dosages (225 mg/kg/day) have been associated with muscular tremors, vomiting and rapid respirations. Single doses of 1 gram/kg in rodents did not cause death. Treatment of overdoses in animals should be handled using standard protocols for oral ingestions of drugs; clinical signs may be treated symptomatically and supportively if necessary. Hemodialysis and peritoneal dialysis have been noted to remove ranitidine from the body.

**Drug Interactions**

Unlike cimetidine, ranitidine appears to have much less effect on the hepatic metabolism of drugs and is unlikely to cause clinically relevant drug interactions via this mechanism. The following drug interactions have either been reported or are theoretical in humans or animals receiving ranitidine and may be of significance in veterinary patients:

- **ACETAMINOPHEN**: Ranitidine (dose-dependent) may inhibit acetaminophen metabolism
- **ANTACIDS (high doses)**: May decrease the absorption of ranitidine; give at separate times (2 hours apart) if used concurrently
- **KETOCONAZOLE, ITRACONAZOLE**: Absorption may be reduced secondary to increased gastric pH
- **METOPROLOL**: Ranitidine may increase metoprolol half-life, and peak levels
- **NIFEDIPINE**: Ranitidine may increase nifedipine AUC by 30%
- **PROPANTheline**: Delays the absorption but increases the peak serum level of ranitidine; relative bioavailability of ranitidine may be increased by 23% when propantheline is administered concomitantly with ranitidine
- **VITAMIN B-12**: Long-term ranitidine use may decrease oral absorption of B-12
Laboratory Considerations

Ranitidine may cause a false-positive urine protein reading when using Multistix®. The sulfosalicylic acid reagent is recommended for determining urine protein when the patient is concomitantly receiving ranitidine.

Doses

**DOGS:**

- For esophagitis:
  - 1–2 mg/kg PO twice daily (Watrous 1989)
- For chronic gastritis:
  - 0.5 mg/kg PO twice daily (Hall, J.A. & Twedt 1989)
- For ulcer disease:
  - 0.5–2 mg/kg PO, IV or IM q8–12h (Haskins 2000)
  - 2 mg/kg PO, IV q8h (Matz 1995)
  - 1–2 mg/kg PO, IV, SC q12h (also used for esophagitis) (Sellon 2007)
  - 2 mg/kg PO, IV q12h (Waddell 2007)
- For gastrinoma:
  - 1–2 mg/kg PO, SC, IV q8–12h (Zerbe & Washabau 2000)
  - 0.5 mg/kg PO, IV or SC twice daily (Kay & Richter 1988)
- To treat hypergastrinemia secondary to chronic renal failure:
  - 1–2 mg/kg PO twice daily (Morgan 1988)
- To treat hyperhistaminemia secondary to mast cell tumors:
  - 2 mg/kg q12h (Fox 1995)
- As a prokinetic agent to stimulate gastric contractions:
  - 1–2 mg/kg PO q12h (Hall, J. & Washabau 2000)

**CATS:**

- For ulcer disease/esophagitis:
  - 2.5 mg/kg IV q12h or 3.5 mg/kg PO q12h (Matz 1995), (Johnson 1996)
  - 1–2 mg/kg PO, IV, SC q12h (Sellon 2007)
  - 2 mg/kg PO, IV q12h (Waddell 2007)
- As a prokinetic agent to stimulate colonic motility:
  - 1–2 mg/kg PO q8–12h (Washabau & Holt 2000)
  - 1–2 mg/kg PO q12h (Scherk 2003)

**FERRETS:**

- For *Helicobacter mustelae:* Ranitidine bismuth citrate (Note: Not available commercially in USA; must be compounded) at 24 mg/kg PO q8–12h and clarithromycin (12.5 mg/kg PO q8–12h). Treat with both for 14 days. (Johnson-Delaney 2008)

**HORSES:** (Note: ARCI UCGFS Class 5 Drug)

- Foals: 1.5 mg/kg IV q6h or 6.6 mg/kg PO q8h often used with omeprazole (4 mg/kg PO q24h). (Paradis 2008)
- Foals: 6.6 mg/kg IV q4h or 0.8–2.2 mg/kg IV four times a day; 5–10 mg/kg PO two to four times a day. (Wilkins 2004)
- 1.5–2 mg/kg IV or IM q6–8h; 6.6 mg/kg PO q8h (Sanchez 2004)

**SMALL MAMMALS:**

- As a prokinetic in rabbits: 0.5 mg/kg IV q24 with cisapride (0.5 mg/kg PO q8h). (Lichtenberger 2008)
- For suspected gastric ulceration in rabbits: 2–5 mg/kg PO twice daily. (Bryan 2009)

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in clinical signs, endoscopic examination, blood in feces, etc.

Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; symptoms may reoccur if dosages are missed.

Chemistry/Synonyms

An H₂ receptor antagonist, ranitidine HCl occurs as a white to pale-yellow granular substance with a bitter taste and a sulfur-like odor. The drug has pKas of 8.2 and 2.7. One gram is approximately soluble in 1.5 mL of water or 6 mL of alcohol. The commercially available injection has a pH of 6.7–7.3. Ranitidine HCl may also be known as: AH-19065, ranidini hydrochloridum; many trade names are available.

Storage/Stability

Ranitidine tablets should be stored in tight, light-resistant containers at room temperature. The injectable product should be stored protected from light and at a temperature less than 30°C. A slight darkening of the injectable solution does not affect the potency of the drug.

Compatibility/Compounding Considerations

Ranitidine injection is reportedly stable up to 48 hours when mixed with the commonly used IV solutions (including 5% sodium bicarbonate).

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

- Ranitidine HCl Oral Tablets: 75 mg, 150 mg & 300 mg; Zantac® (GlaxoSmithKline); Zantac® 75 (Boehringer Ingelheim); generic; (Rx or OTC)
- Ranitidine HCl Effervescent Oral Tablets: 25 mg & 150 mg; Zantac® EFFERdose (GlaxoSmithKline); (Rx)
- Ranitidine HCl Solution: 15 mg/mL in 473 mL & 480 mL; Zantac® (GlaxoSmithKline); generic; (Rx)
- Ranitidine HCl Injection: 1 mg/mL (premixed) & 25 mg/mL in 2 mL single-dose and 6 mL multi-dose vials; Zantac® (GlaxoSmithKline); generic (Bedford); (Rx)
REMIFENTANIL HCL
(rem-i-fen-tan-ill) Ultiva®
ULTRA-SHORT ACTING OPIOID ANALGESIC

Prescriber Highlights

- Opioid similar to fentanyl; used primarily as an anesthesia adjunct
- Degraded by esterases in plasma, red cells, and tissues; can be used for prolonged procedures in patients with renal or hepatic dysfunction
- Because of its short duration of action, may reduce recovery times
- Little veterinary clinical experience at present
- Currently much more expensive than fentanyl

Uses/Indications

Remifentanil is a mu-opioid structurally related to fentanyl. Because remifentanil is primarily metabolized by tissue and red cell esterases, it can safely be used in patients with either hepatic or renal impairment. Its very short duration of action also is beneficial, because if adverse effects occur (e.g., respiratory depression, bradycardia), reversal with naloxone should rarely be required. A possible advantage of using remifentanil versus fentanyl as an anesthesia adjunct is that recovery times may be faster with remifentanil. There is some remifentanil research on dogs and cats published, but there is little clinical experience in veterinary medicine with this agent.

Pharmacology/Actions

Remifentanil hydrochloride is a mu-opioid agonist with rapid onset of analgesic action and peak effect, and short duration of action. Mu-receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscles. The pharmacology of the opiate agonists is discussed in more detail in the monograph, Narcotic (opiate) Agonist Analgesics.

Unlike other opioids, remifentanil is rapidly metabolized by hydrolysis of the propanoic acid-methyl ester linkage by nonspecific blood and tissue esterases. Remifentanil is not appreciably metabolized by the liver or metabolized by plasma cholinesterase (pseudocholinesterase). Adverse effects (bradycardia, respiratory depression, hypotension) are dose dependent and similar to other mu opioids. When used as an anesthesia adjunct, remifentanil, like other opioids, has a ceiling effect (increased doses do not enhance analgesia).

Opioid activity of remifentanil is antagonized by antagonists such as naloxone.

In dogs, remifentanil is equally efficacious, but about half as potent, as fentanyl but recovery from remifentanil anesthesia is much more rapid, especially after continuous infusions maintained for 6+ hours (Michelsen et al. 1996). Remifentanil reduced sevoflurane MAC similarly to fentanyl in dogs, but allowed shorter recovery times (Martinez & Lepiz 2008). In another dog study, remifentanil given as a CRI reduced the dosage requirements of propofol for maintaining target-controlled infusion system-based anesthesia. (Beier et al. 2009) The principle carboxylic acid metabolite of remifentanil (GR90291) has been shown to be at least 4000 times less potent in dogs as the parent drug (Hoke et al. 1997).

In cats, remifentanil reduced isoflurane MAC similarly (about 25% reduction) at the three doses studied (Ferreira et al. 2009). However in another cat study, remifentanil did not alter the MAC thresholds for isoflurane, but did produce analgesia, reflected by increased thermal thresholds. The authors state that the extent or existence of an analgesic-MAC relationship cannot be assumed for all analgesics in all species. They concluded that measures of anesthetic immobility need not bear any relation to measures of analgesic efficacy. Consequently, MAC-saving effects should not be used to infer analgesic effects without prior validation of the nature of such a relationship for a specific agent and species (Brosnan et al. 2009).

Pharmacokinetics

In dogs, remifentanil is rapidly distributed into the CNS with a blood-brain equilibrium half-life of 2.3 – 5.2 minutes. It has a terminal elimination half-life of 6 minutes (Hoke et al. 1997). In cats, remifentanil has a moderately high volume of distribution (7.6 L/kg) and a high clearance (766 mL/min/kg) and a short terminal elimination half-life (17.4 minutes). In anesthetized (isoflurane) cats, volume of distribution of remifentanil is decreased (1.65 L/kg), but elimination half-life is not significantly altered (Pyependop et al. 2008).

In humans after IV doses, remifentanil is rapidly distributed into the CNS and has a peak effect 1-3 minutes after administration. Remifentanil is approximately 70% bound to plasma proteins with the majority bound to alpha-1-acid-glycoprotein. Remifentanil has an effective biological half-life of 3-10 minutes in human patients. The pharmacokinetics of remifentanil are not appreciably altered in patients with renal or hepatic failure.

Contraindications/Precautions/Warnings

Remifentanil is contraindicated in patients hypersensitive to it or other fentanyl analogs. As the injection contains glycerine, it is contraindicated for epidural or intrathecal administration.

Because of the possibility of significant respiratory depression or bradycardia, it should be administered only in a monitored anesthesia care setting. Continuous infusions should only be administered by an infusion device.

In morbidly obese patients, the drug dose should be based upon ideal body weight.

Adverse Effects

Remifentanil has an adverse effect profile similar to other mu-opioids. Respiratory depression, including apnea, bradycardiacs and hypotension are possible. Increased body temperatures in cats may be noted. Anaphylaxis is very rare, but possible.

Reproductive/Nursing Safety

Remifentanil appears to be relatively safe to use during pregnancy. No teratogenic effects were observed after administration of remifentanil at doses up to 5 mg/kg in rats and 0.8 mg/kg in rabbits. For humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) It is unknown if remifentanil is excreted into milk, but clinical effect in offspring seems unlikely. However, weigh the potential risks of using this medication versus the benefits for nursing or pregnant animals.

Overdosage/Acute Toxicity

As with all potent opioid analgesics, overdosage should manifest as enhancement of the drug’s non-analgesic pharmacological effects. Clinical signs may include: apnea, chest-wall rigidity, seizures, hypoxemia, hypotension, and bradycardia.

Discontinue drug administration and give supportive therapy including mechanical ventilation and oxygen administration. Oftentimes, this is all that is required since the drug is cleared so rapidly. Additional supportive therapy can include IV fluids, glycopyrrolate or atropine for bradycardia or hypotension. Naloxone may also be used to reverse the drug’s mu activity, but can lead to acute pain and sympathetic hyperactivity.

References

Beier W, et al. (2009). Principle carboxylic acid metabolite of remifentanil (GR90291) has been shown to be at least 4000 times less potent in dogs as the parent drug (Hoke et al. 1997). In cats, remifentanil reduced isoflurane MAC similarly (about 25% reduction) at the three doses studied (Ferreira et al. 2009). However in another cat study, remifentanil did not alter the MAC thresholds for isoflurane, but did produce analgesia, reflected by increased thermal thresholds. The authors state that the extent or existence of an analgesic-MAC relationship cannot be assumed for all analgesics in all species. They concluded that measures of anesthetic immobility need not bear any relation to measures of analgesic efficacy. Consequently, MAC-saving effects should not be used to infer analgesic effects without prior validation of the nature of such a relationship for a specific agent and species (Brosnan et al. 2009).

Drug Interactions

Remifentanil clearance is not altered by concomitant administration of thiopental, isoflurane, or propofol.

The following drug interactions have either been reported or are theoretical in humans or animals receiving fentanyl and may apply to remifentanil and be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER:** Additive CNS effects possible
- **DIURETICS:** Opiates may decrease efficacy in CHF patients
- **MONOAMINE OXIDASE INHIBITORS (e.g., amitraz, and possibly selegeline):** Severe and unpredictable opiate potentiation may be seen; fentanyl not recommended (in humans) if MAO inhibitor has been used within 14 days
- **MUSCLE RELAXANTS, SKELETAL:** Remifentanil may enhance neuromuscular blockade
- **NITROUS OXIDE:** High remifentanil doses may cause cardiovascular depression
- **TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.):** Fentanyl may exacerbate the effects of tricyclic antidepressants
- **WARFARIN:** Opiates may potentiate anticoagulant activity

**Laboratory Considerations**

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

**Doses**

**Note:** Do not confuse microgram/kg/HOUR and microgram/kg/MINUTE CRI rates

**DOGS:**

- As an analgesic adjunct to general anesthesia:
  - a) 4 micrograms/kg bolus IV, followed by 6–20 micrograms/kg/hr CRI. (Spelts 2009)
  - b) 1 microgram/kg IV loading dose slowly over 2–3 minutes, followed by a 0.1–0.2 microgram/kg/minute CRI. (Grint 2008)

**CATS:**

- As an analgesic adjunct to general anesthesia:
  - a) In the study, in propofol-anesthetized (0.3 micrograms/kg/minute) cats an infusion rate of remifentanil at 0.2 micrograms/kg/minute allowed ovariohysterectomies to be performed; an infusion rate of 0.3 micrograms/kg/minute was required to reduce the incidence of stimulus-induced movement after electrical noxious stimulation. (Correa et al. 2007)

**Monitoring**

- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia
- Blood pressure

**Chemistry/Synonyms**

Remifentanil hydrochloride has a pKa of 7.07 and partition coefficient n-octanol:water of 17.9 at pH 7.3. The commercially available injection has a pH of 2.5–3.5.

Remifentanil may also be known as: GI-87084B, remifentanilo, rémifentanil, or remifentanili. Trade names include: Ultiva® and Remiciti®.

**Storage/Stability**

Prior to reconstitution, store lyophilized powder for solution between 2°-25°C (36°-77° F). It is stable for 24 hours at room temperature after reconstitution and further dilution to concentrations of 20–250 micrograms/mL.

**Compatibility/Compounding Considerations**

To reconstitute solution, add 1 mL of diluent per mg of remifentanil. Shake well to dissolve. When reconstituted as directed, the solution contains approximately 1 mg of remifentanil activity per mL. It should then be further diluted to a final concentration of 20, 25, 50, or 250 micrograms per mL prior to administration. Do not administer remifentanil without dilution.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Remifentanil HCl Powder for reconstitution (IV use only): 1 mg (3 mL vial), 2 mg (5 mL vial), 5 mg (10 mL vial); Ultiva® (Bioniche); (Rx, C-II controlled substance)

**References**

**RIFAMPIN**

- *rifampin* (rifamycin, rifabutin, rifampicin, rifampin), *Rimactane*, *Rifadin*, *Rimactane*, *Rifadin*, *Rimactane*, *Rifadin*, *Rimactane*

**ANTIMICROBIAL**

**Prescriber Highlights**

- Antimicrobial with activity against a variety of microbes (Rhodococcus, mycobacteria, staphylococci); has some antifungal & antiviral activity as well.
- Contraindications: Hypersensitivity to it or other rifamycins
- Caution: Preexisting hepatic dysfunction (may need to reduce dosage)
- Adverse Effects: Uncommon; potentially rashes, GI distress, & increases in liver enzymes.
- Should not be used alone as resistance develops rapidly
- Preferably, give on an empty stomach
**May cause red/orange urine, tears, & sweat (harmless)**

**Drug Interactions, lab interactions**

---

**Uses/Indications**

The principle use of rifampin in veterinary medicine is in the treatment of *Rhodococcus equi* (*Corynebacterium equi*) infections (usually with erythromycin estolate) in young horses. It may also be useful to treat proliferative enteropathy caused by *Lawsinia intracellularis* in foals.

In small animals, the drug is sometimes used in combination with other antifungal agents (amphotericin B and 5-FC) in the treatment of histoplasmosis or aspergillosis with CNS involvement.

**Pharmacology/Actions**

Rifampin may act as either a bactericidal or bacteriostatic antimicrobial dependent upon the susceptibility of the organism and the concentration of the drug. Rifampin acts by inhibiting DNA-dependent RNA polymerase in susceptible organisms, thereby suppressing the initiation of chain formation for RNA synthesis. It does not inhibit the mammalian enzyme.

Rifampin is active against a variety of mycobacterium species and *Staphylococcus aureus*, *Neisseria*, *Haemophilus*, and *Rhodococcus equi* (*C. equi*). At very high levels, rifampin has activity against poxviruses, adenoviruses, and *Chlamydia trachomatis*. Rifampin has antifungal activity when combined with other antifungal agents.

**Pharmacokinetics**

After oral administration, rifampin is relatively well absorbed from the GI tract. Oral bioavailability is reportedly about 40–70% in horses and 37% in adult sheep. If food is given concurrently, peak plasma levels may be delayed and slightly reduced.

Rifampin is very lipophilic and readily penetrates most body tissues (including bone and prostate), cells and fluids (including CSF). It also penetrates abscesses and caseous material. Rifampin is 70–90% bound to serum proteins, is distributed into milk and crosses the placenta. Mean volume of distribution is approximately 0.9 L/kg in horses, and 1.3 L/kg in sheep.

Rifampin is metabolized in the liver to a deacetylated form that also has antibacterial activity. Both this metabolite and unchanged drug are excreted primarily in the bile, but up to 30% may be excreted in the urine. The parent drug is substantially reabsorbed in the gut, but the metabolite is not. Reported elimination half-lives for various species are: 6–8 hours (horses), 8 hours (dogs), 3–5 hour’s (sheep). Because rifampin can induce hepatic microsomal enzymes, elimination rates may increase with time.

**Contraindications/Precautions/Warnings**

Rifampin is contraindicated in patients hypersensitive to it or to other rifamycins. It should be used with caution in patients with preexisting hepatic dysfunction.

**Adverse Effects**

Rifampin can cause red-orange colored urine, tears, sweat, and saliva. There are no harmful consequences from this effect. In some species (e.g., humans) rashes, GI distress, and increases in liver enzymes may occur, particularly with long-term use.

Because resistance develops rapidly when rifampin is used alone, it should be used in combination with other effective antibiotics. Adverse effects in horses are apparently rare, but when combined with erythromycin, mild diarrhea (self-limiting) to severe enterocolitis in foals and mares, hyperthermia, and acute respiratory distress can occur. Although not commercially available, intravenous rifampin has caused CNS depression, sweating, hemolysis, and anorexia in horses.

**Reproductive/Nursing Safety**

Rifampin is excruted in maternal milk; use with caution in nursing veterinary patients.

**Overdosage/Acute Toxicity**

Clinical signs associated with overdosage of oral rifampin generally are extensions of the adverse effects outlined above (GI, orange-red coloring of fluids, and skin), but massive overdoses may cause hepatotoxicity.

There were 8 exposures to rifampin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 4 were dogs with 2 showing clinical signs and 3 were cats with all 3 showing clinical signs. Common findings in dogs included central nervous system depression. Common findings in cats included erythema. Should a massive oral overdosage occur, the gut should be emptied following standard protocols. Liver enzymes should be monitored and supportive treatment initiated if necessary.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving rifampin and may be of significance in veterinary patients:

- **FLUOROQUINOLONES**: *In vitro* antagonism has been reported when rifampin is used concurrently with fluoroquinolone antibiotics and concurrent use should be avoided.

- **BARBITURATES**

- **BENZODIAZEPINES** (e.g., diazepam)

- **CHLORAMPHENICOL**

- **CORTICOSTEROIDS**

- **DAPSONE**

- **KETOCONAZOLE**

- **PROPRANOLOL**

- **QUINIDINE**

- **WARFARIN**

**Laboratory Considerations**

- Microbiologic methods of assaying serum *folate* and vitamin B12 are interfered with by rifampin.

- Rifampin can cause false-positive *BSP* (*bromosulfophthalain*, sulfochromophthalain) test results by inhibiting the hepatic uptake of the drug.

**Doses**

**Note**: Because resistance develops rapidly when rifampin is used alone, it should be used in combination with other effective antibiotics.

**DOGS**

- a) For combination therapy of atypical Mycobacteria infections; treatment of resistant Staph endocarditis (in combination with amoxicillin/clavulanate or trimethoprim/sulfaxa): 10–20 mg/kg PO q8–12h (Trepanier 1999)

- b) As an alternate treatment for scarred pyogranulomatous pyoderma: 5–10 mg/kg PO q24h. Must be used with another antibiotic to reduce risk for resistance development. Author generally uses cephalixin or a potentiated sulfonamide. To monitor for potential toxicity, CBC’s, liver screens, and a urinalysis should be performed every 2 to 3 weeks. Rifampin is generally used for 4–8 weeks. (Rosenkrantz 2009)

- c) For actinomycosis: 10–20 mg/kg PO q12h PO (Hardie 1984)

**HORSES**

- For treatment of *Rhodococcus equi* (*C. equi*) infections in foals:
  - a) Rifampin 5 mg/kg PO two times daily with erythromycin 15–25 mg/kg, PO q12–24h. Conventional treatment, but erythromycin has numerous side effects including enterocolitis in foals and mares, hyperthermia,
Robenacoxib is a coxib class non-steroidal anti-inflammatory drug (NSAID) that is available for use in dogs and cats in some countries. Robenacoxib appears to be a selective inhibitor for COX-2 as compared to COX-1 when using an in vitro assay (Giraudel et al. 2010). In a non-inferiority field trial in cats that compared robenacoxib flavored tablets with ketoprofen, robenacoxib had equivalent (non-inferior) efficacy and tolerability, and better palatability. The primary adverse effects in both groups were GI-related and included diarrhea and vomiting.

Robenacoxib is a semi-synthetic zwitterion derivative of rifamycin B, rifampin occurs as a red-brown, crystalline powder with a pKa of 7.9. It is very slightly soluble in water and slightly soluble in alcohol. Robenacoxib is metabolized by the liver in dogs and cats. Robenacoxib appears to be relatively COX-2 specific in both species.

In acute synovitis model in dogs, robenacoxib had equivalent analgesic and antiinflammatory efficacy as meloxicam (Schmid, Spreng 2010). In a non-inferiority field trial in cats that compared robenacoxib in combination with ethambutol (30 mg/kg PO once daily) and one of the following: clofazimine (6 mg/kg PO once daily) or isoniazid (30 mg/kg PO once daily). (Pollock 2007)

**Uses/Indications**
Robenacoxib is a coxib class non-steroidal anti-inflammatory drug (NSAID) that is available for use in dogs and cats in some countries. Robenacoxib appears to be a selective inhibitor for COX-2 in cats (Giraudel et al. 2010). In an acute synovitis model in dogs, robenacoxib had equivalent analgesic and antiinflammatory efficacy as meloxicam (Schmid, Spreng 2010). In a non-inferiority field trial in cats that compared robenacoxib flavored tablets with ketoprofen, robenacoxib had equivalent (non-inferior) efficacy and tolerability, and better palatability. The primary adverse effects in both groups were GI-related and included diarrhea and vomiting (Giraudel et al. 2010).

**Pharmacokinetics**
In dogs, peak blood concentrations occur approximately 30 minutes after dosing; food decreases peak levels somewhat. It is highly bound to plasma proteins (>99%). Robenacoxib is metabolized by the liver in dogs and terminal half-life in blood is about 1.2-1.7 hours. Robenacoxib persists longer and at higher concentrations at sites of inflammation than in blood. In dogs, robenacoxib resides longer at inflamed joints compared to blood in both healthy and dogs with osteoarthritis (Silber et al. 2010). Excretion is primarily via the biliary route (~65%); remainder is excreted renally. Robenacoxib does not appear to induce hepatic enzymes in dogs. In cats, after oral administration peak blood concentrations of robenacoxib occur at about 30 minutes and the presence of small amount of food does not impact absorption. As in dogs, robenacoxib is highly bound to plasma proteins (>99%) and extensively metabolized by the liver. Terminal elimination half-life is about 1.7 hours. Elimination is 70% biliary and 30% renal.
Robenacoxib is contraindicated in patients with GI ulcers or that are hypersensitive to it (or any of its excipients). It is also contraindicated in dogs with hepatic disease.

Use with caution in dogs or cats with impaired cardiac or renal function or that are dehydrated, hypovolemic or hypotensive and in cats with hepatic dysfunction. If use cannot be avoided in these cases, careful monitoring is required.

Robenacoxib should not be used concurrently with corticosteroids or other NSAIDs. The manufacturer states that: Pre-treatment with other anti-inflammatory medicines may result in additional or increased adverse effects and accordingly a treatment-free period with such substances should be observed for at least 24 hours before the commencement of treatment with robenacoxib. The treatment-free period, however, should take into account the pharmacokinetic properties of the products used previously.

The UK label states: Use this product under strict veterinary monitoring in dogs or cats with a risk of gastrointestinal ulcers, or if the animal previously displayed intolerance to other NSAIDs.

The manufacturer recommends that robenacoxib be used cautiously with other drugs that may affect renal blood flow (e.g., diuretics, ACE inhibitors); additional clinical monitoring is recommended. They also recommend avoiding use with other potentially nephrotoxic drugs as there is a possibility for an increased risk for renal toxicity.

Adverse Effects
In pre-marketing field studies in dogs, GI effects (decreased appetite, vomiting, soft feces, diarrhea) were commonly reported, but were usually mild and self-limiting. Blood in the feces was seen in some patients.

In pre-marketing field studies in cats, transient, mild diarrhea, soft feces or vomiting were commonly reported. As there is limited clinical experience with this drug, the adverse effect profile will likely change.

Reproductive/Nursing Safety
Because the safety of robenacoxib has not been established during pregnancy and lactation in dogs or cats used for breeding, the manufacturer does not recommend its use in pregnant or lactating dogs or cats.

Overdosage/Acute Toxicity
No acute toxicity data was located. Acute overdoses may potentially cause GI, kidney, or liver toxicity. In chronic toxicity studies in healthy young dogs (doses of up to 10 mg/kg/day for 6 months) of robenacoxib did not produce any signs of toxicity. In healthy young cats aged 10 months, once daily doses of 4 mg/kg (2X) SC for 2 days and 10 mg/kg (5X) SC for 3 consecutive days did not produce any signs of toxicity.

Symptomatic, supportive therapy including administration of gastrointestinal protective agents and forced diuresis may be appropriate. Contact an animal poison center for more information.

Drug Interactions
See the Contraindications section above for the manufacturer’s warnings on use of robenacoxib with other medications. In addition, the following drug interactions have either been reported or are theoretical in humans or animals receiving NSAIDs and may be of significance in veterinary patients receiving robenacoxib:

ACE INHIBITORS (e.g., enalapril, benazepril): Some NSAIDs can reduce effects on blood pressure

ASPIRIN: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

CORTICOSTEROIDS (e.g., prednisolone): May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

DIGOXIN: NSAIDs may increase serum levels

FLUCONAZOLE: Administration has increased plasma levels of celecoxib in humans and potentially could also affect robenacoxib levels in dogs

FUROSEMIDE: NSAIDs may reduce the saluretic and diuretic effects

HIGHLY PROTEIN BINDING DRUGS (phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, sulfonylurea antidiabetic agents): As robenacoxib is highly bound to plasma proteins (>99%) in dogs and cats, it may displace other highly bound drugs or those agents could displace robenacoxib. Increased serum levels, duration of actions and toxicity could occur.

METHOTREXATE: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution

NEPHROTOXIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity development

Laboratory Considerations
None noted

Doses

DOGS:
For pain and inflammation associated with chronic osteoarthritis:
 a) 1 mg/kg with a range of 1–2 mg/kg PO once daily (at the same time every day). A clinical response is normally seen within a week; discontinue after 10 days if no clinical improvement seen. For long term treatment, can adjust to lowest effective dose for the patient. (Adapted from label information; Onsior®—Novartis. U.K.)

For treatment of pain and inflammation associated with orthopedic or soft tissue surgery:
 a) 2 mg/kg SC once approximately 30 minutes before the start of surgery. (Adapted from label information; Onsior Injection®—Novartis. U.K.)

CATS:
For the treatment of acute pain and inflammation associated with musculoskeletal disorders:
 a) 1 mg/kg; with a range of 1–2 mg/kg PO once daily (at the same time each day) for up to 6 days. Equates to 1 tablet for cats weighing 2.5–<6 kg and 2 tablets for cats weighing 6 kg–<12 kg. Give either without food or with a small amount of food; tablets should not be divided or broken. (Adapted from label information; Onsior®—Novartis. U.K.)

For pain and inflammation associated with chronic osteoarthritis:
 a) 2 mg/kg SC once approximately 30 minutes before the start of surgery. (Adapted from label information; Onsior Injection®—Novartis. U.K.)

Monitoring
Baseline and periodic physical exam including clinical efficacy and adverse effect queries
Baseline and periodic CBC, liver function, renal function, and electrolytes; urinalysis. For long term therapy in dogs, the manufacturer recommends that liver enzymes be monitored at the start of therapy, and after 2, 4 and 8 weeks; thereafter it is recommended to continue regular monitoring (every 3–6 months). Therapy should be discontinued if liver enzyme activities increase markedly or the dog shows clinical signs such as anorexia, apathy or vomiting in combination with elevated liver enzymes.

Client Information
Do not give with food to dogs; give at least 30 minutes before or after food
Give without or with a small amount of food to cats; do not divide, break or crush tablets
The manufacturer recommends washing hands after contact with tablets; pregnant women who are near term should wear gloves when handling the drug
If your animal shows signs of drug toxicity (collapse, listlessness, yellowing of the whites of the eyes) or if vomiting or diarrhea persist, are severe, or bloody, contact veterinarian immediately

Chemistry/Synonyms
A coxib-class NSAID, robenacoxib’s chemical name is 5-ethyl-2-[(2,3,5,6-tetrafluorophenyl)amino]phenyl acetic acid. The commercially available injection is a clear, colorless to slightly pink solution.
Robenacoxib may also be known as robenacoxibum or robenacoxib. Its trade name is Onsior®.

Storage/Stability
Store the flavored canine tablets at 25°C (77°F) or less and the feline flavored tablets at no more than 30°C (86°F). The injection should be stored in the refrigerator (2°-8°C) in its original outer carton.
ROCURONIUM BROMIDE
(ros-kyo-ron-ee-boh-myd) Zemuron®, Esmuron®
NON-DEPOLARIZING NEUROMUSCULAR BLOCKER

Prescriber Highlights

- Nondepolarizing neuromuscular blocking agent with a rapid to intermediate onset depending on dose and an intermediate duration of action (Alderson et al. 2007)
- Faster onset of action than vecuronium or atracurium and fewer adverse effects than succinylcholine
- Limited information and clinical experience in dogs, cats, or horses

Uses/Indications
Rocuronium bromide is an aminosteroidal, competitive, nondepolarizing neuromuscular blocking agent with a rapid to intermediate onset depending on dose and an intermediate duration of action. Rocuronium has minimal cardiovascular and histamine-releasing effects. It has a similar duration of action as vecuronium and atracurium but a faster onset of action (2–3 times faster than vecuronium). Unlike both vecuronium and atracurium, it is stable in aqueous solutions. Rocuronium’s onset of action is nearly as rapid as succinylcholine but it has fewer adverse effects. Clinical experience with rocuronium in veterinary patients is limited but potentially it can be used for rapid endotracheal intubation and to provide muscle relaxation during surgery.

Pharmacology/Actions
Rocuronium is a nondepolarizing neuromuscular blocking agent structurally similar to vecuronium, with a dose-dependent rapid to intermediate onset of action and an intermediate duration. Its mechanism of action is to compete for cholinergic receptors at the motor end plate. Effects are antagonized by acetylcholinesterase inhibitors (e.g., edrophonium or neostigmine). Rocuronium does not appear to induce malignant hyperthermia (MH) as it did not cause hyperthermia in (MH)-susceptible swine. Rocuronium is mildly vagolytic and a slight, transient tachycardia is occasionally seen in human patients. In dogs, a dose of 0.4 mg/kg IV produces complete neuromuscular blockade in about 2–3 minutes (Dugdale et al. 2002). Cats administered 0.6 mg/kg IV caused complete neuromuscular blockade in 90% of cats in the study within 30–60 seconds and did not significantly affect HR in any of the animals. At doses of 0.6 mg/kg, rocuronium appears to have a longer duration of action in dogs (20 minutes) and horses (55 minutes) than in cats (13 minutes) (Auer & Mosing 2006; Auer et al. 2007).

Pharmacokinetics
Specific pharmacokinetic parameters for dogs, cats, or horses were not located. Onset of effect and duration of action are noted above. It has been reported that rocuronium is eliminated primarily by the liver in dogs and cats. The principle metabolite, 17-desacetyl-rocuronium has approximately 1/20 th the neuromuscular-blocking potency of rocuronium in cats.

Contraindications/Precautions/Warnings
Rocuronium is contraindicated in patients hypersensitive to it or other neuromuscular blocking agents. It should only be used in settings where patients can be fully monitored and intubation, mechanical ventilation, oxygen therapy, and antagonist drugs are immediately available.

- Rocuronium use should only be undertaken in patients that are adequately anesthetized or sedated.
- There are conflicting reports whether rocuroinium should be used in patients with hepatic or renal impairment and some have stated that atracurium is preferred in these patients.

Adverse Effects
Other than the effects associated with pharmacologic neuromuscular blockade, rocuronium appears to be well tolerated in the limited number of animals studied. Changes in heart rate and blood pressure may be noted. A more accurate picture of the drug’s true adverse effect profile in veterinary patients may be forthcoming if it is more widely used.

In humans, the most common adverse reactions noted are effects on blood pressure (hypo- or hypertension). These are transient and usually mild and have been reported in only about 2% of patients. Severe anaphylaxis has been reported in humans. While rocuronium is thought to possess little histamine releasing effects, histaminoid reactions have been reported. Because the drug reportedly can cause a severe burning pain at the injection site, it is recommended that rocuronium be given only when a deep stage of anesthesia has been achieved.

Reproductive/Nursing Safety
When administered to pregnant laboratory animals, rocuronium did not demonstrate teratogenic effects and it is likely safe to use as long as the patient does not become hypoxic during use. For humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) The molecular weight of rocuronium is low enough for excretion into milk, but because the drug is ionized at physiologic pH, any clinical effect is thought to be unlikely. However, the weight of potential risks using this medication versus the benefits in humans or animals receiving rocuronium and to be of significance in veterinary patients:

| NON-DEPOLARIZING MUSCLE RELAXANT DRUGS, OTHER: May have a synergistic effect if used with rocuronium. |
Rocuronium Bromide for Injection 10 mg/mL in 5 mL & 10 mL multi-dose vials; HUMAN-LABELED PRODUCTS:

**Dosage Forms/Regulatory Status**

- cloxacillin, lorazepam, dexamethasone, methohexital, diazepam, methylprednisolone, erythromycin, thiopental, famotidine, trimethoprim, furosemide, and vancomycin.

**Compatibility/Compounding Considerations**

Rocuronium for injection is compatible in solution with: 0.9% NaCl, sterile water for injection, D5W, D5NS, and LRS. Rocuronium concentrations up to 5 mg/mL in these solutions are stable for 24 hours at room temperature in plastic bags, glass bottles, and plastic syringe pumps.

Rocuronium is physically incompatible when mixed with the following drugs: Amphotericin B, hydrocortisone sodium succinate, amoxicillin, insulin, azathioprine, lipid emulsion (Intralipid), cefazolin, ketorolac, cloxacillin, lorazepam, dexamethasone, methohexitol, dexamethasone, methylprednisolone, erythromycin, thiopental, famotidine, trimethoprim, furosemide, and vancomycin.

**Storage/Stability**

Store at 2°-8°C (36°-46°F). Do not freeze. When removed from refrigeration to room temperature storage conditions (25°C, 77°F), use within 60 days. Use opened vials of rocuronium within 30 days. Infusion solutions should be used within 24 hours of mixing. Unused portions of infusion solutions should be discarded.

**Compatibility/Compounding Considerations**

Rocuronium for injection is compatible in solution with: 0.9% NaCl, sterile water for injection, D5W, D5NS, and LRS. Rocuronium concentrations up to 5 mg/mL in these solutions are stable for 24 hours at room temperature in plastic bags, glass bottles, and plastic syringe pumps.

Rocuronium is physically incompatible when mixed with the following drugs: Amphotericin B, hydrocortisone sodium succinate, amoxicillin, insulin, azathioprine, lipid emulsion (Intralipid), cefazolin, ketorolac, cloxacillin, lorazepam, dexamethasone, methohexitol, dexamethasone, methylprednisolone, erythromycin, thiopental, famotidine, trimethoprim, furosemide, and vancomycin.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Rocuronium Bromide for Injection 10 mg/mL in 5 mL & 10 mL multi-dose vials; Zemuron® (Schering-Plough), generic; (Rx)

**References**

- Zemuron® or Esmeron®.
In dogs & cats, romifidine may cause bradycardia, cardiac arrhythmias, hypotension, transient hyperglycemia, & alterations in thermoregulation. Dogs may pant, salivate, vomit (less likely than in cats), & develop muscle twitching. Vomiting in cats may be a problem

Adjust dosage if used with other CNS depressant drugs

Romifidine is an alpha-2 agonist with sedative, muscle relaxant and analgesic effects. It is indicated (in the USA) for use in adult horses as a sedative and analgesic to facilitate handling, clinical examinations and procedures, minor surgical procedures, and as a preanesthetic prior to the induction of general anesthesia.

In certain European countries, it is approved for use in dogs and cats as a sedative/preanesthetic.

Although not approved, romifidine has been used in cattle and foals.

Pharmacology/Actions

A potent alpha-1adrenergic agonist, romifidine is classified as a sedative/analggesic with muscle relaxant properties. Alpha-2 receptors are found in the CNS and several tissues peripherally; both presynaptically and postsynaptically. In the CNS, the primary action is a feedback inhibition of norepinephrine release. Opioids and alpha-2 agonists may have synergistic analgesic effects.

Pharmacologic effects of romifidine include sedation, analgesia, and reduced catecholamine release from the CNS. Thermoregulatory mechanisms may be altered. Peripherally, an initial vasodilator response occurs with increases in blood pressure. Within minutes a hypotensive phase occurs. Heart rate can significantly decrease secondary to a vagal response to hypotension. A second-degree atrioventricular block may also occur.

Antimuscarnic agents can prevent bradycardia, but their use is controversial as they can potentially cause hypertension, increased myocardial oxygen demand, and decreased GI motility. Alpha-2 agonists can transiently slow duodenal motility and increase micturition in horses and can inhibit insulin release from pancreatic islet cells resulting in hyperglycemia. Other effects seen in horses include sweating, mydriasis, decreases in hematocrit, and increased urine output in non-pregnant mares.

In horses, when compared with other alpha-2 agonists (xylazine, detomidine, medetomidine), romifidine does not appear to cause as much ataxia at sedative dosages and has the longest duration of sedation. Duration of analgesia is shorter than the duration of sedation.

Pharmacokinetics

In horses, romifidine has a volume of distribution of approximately 2–3 L/kg, a clearance of about 100 mL/min/kg and an elimination half-life around 135 minutes (Wojskiak-Wypart et al. 2008).

In dogs and cats, bioavailability after IM administration is 86% and 95%, respectively. Bioavailability after subcutaneous injection in dogs is 92%. Peak levels after IM injection occur in approximately 50 minutes in dogs and 25 minutes in cats. After IV injection, volumes of distribution are about 3 L/kg in dogs, and 6 L/kg in cats. Romifidine is biotransformed in the liver. In dogs, about 80% of an administered dose is eliminated in the urine; 20% in the feces. Elimination half-lives are approximately 2 hours for dogs, 6 hours for cats.

Contraindications/Precautions/Warnings

Romifidine should not be used in animals hypersensitive to it or in combination with intravenous potentiated sulphonamides. The label states that this medication should not be used in horses with respiratory disease, hepatic or renal disease, or other systemic conditions of compromised health. It also states that the effects of this medication have not been evaluated in horses with colic, or in foals. Because of its effects on heart rate, changes in blood pressure, and use very cautiously in horses with preexisting cardiac conditions.

The manufacturer cautions that using with other sedatives, tranquilizers, or opioids may potentiate the adverse effects of romifidine and to avoid using epinephrine as it may potentiate the effects of alpha-2 agonists. Although animals may appear to be deeply sedated, some may respond (kick, etc.) to external stimuli; use appropriate caution.

When used in dogs and cats, the label for Romydil® (Virbac—Ireland) states: “Animals should be restrained to prevent injury, ensure that animals have sufficient fluid intake, and if undergoing prolonged sedation, animals should be prevented from becoming hypothermic. Additionally, care should be taken when used in animals in poor health, suffering from respiratory distress, or in cases of cardiovascular, renal, hepatic or pancreatic disease.” Cats with pancreatitis should be closely monitored. Because dogs and, particularly, cats may vomit after receiving romifidine, the manufacturer recommends not feeding for at least 12 hours prior to use.

When used epidurally in dogs, romifidine causes cardiovascular effects similar to when it is administered IV and equivalent monitoring must be performed (Martin-Bouyer et al. 2010).

This medication can be absorbed through the skin and via oral routes. Persons administering the medication should handle it carefully and avoid self-exposure.

Adverse Effects

In horses, romifidine may cause bradycardia (possibly profound), first- and second-degree atrioventricular heart block, and sinus arrhythmias (dose dependent). Initially, hypertension may occur followed by hypotension. Other adverse effects can include: ataxia, sweating, piloerection, salivation, muscle tremors, penile-relaxation, urination (occurs about one hour after dose), swelling of face, lips and upper airways, stridor, decreased GI motility, flatulence and mild colic. There is a possibility that horses may react paradoxically (excitation) to romifidine. Rarely, anaphylactic reactions to alpha-2 agonists have been reported in horses.

In dogs and cats romifidine may cause bradycardia, cardiac arrhythmias, hypotension, transient hyperglycemia, and alterations in thermoregulation (body temperature may increase or decrease depending on ambient temperature). Dogs may pant, salivate, vomit (less likely than in horses), and develop muscle twitching, while cats may vomit.

In cats, vomiting associated with romifidine use can be seen and persist up to 24 hours after dosing. Pancreatitis has been noted in some cats receiving the drug repeatedly every 2 days for 6 days; dose related increases in BUN have been observed. Localized injection site reactions have occurred in cats receiving the medication intramuscularly.

Reproductive/Nursing Safety

The label for the US product states that the effects of this medication have not been evaluated in pregnant mares, horses intended for breeding, or foals. The labeling for the equine and small animal products approved in Europe states that the drug is contraindicated in pregnant horses during the last month of pregnancy and during pregnancy in dogs and cats.

Overdosage/Acute Toxicity

Horses have received up to 600 micrograms/kg (3X) in experimental studies. Signs exhibited included sinus bradycardia, 2nd degree heart block, occasional apnea and mild respiratory stridor, deep sedation, frequent urination, and sweating. No clinically significant alterations in blood gases, acid-base, hemochromal or electrical parameters were noted. If necessary, a reversal agent such as atipamezole (at a dose of 30–80 micrograms/kg) or yohimbine may be used to reduce the duration and extent of adverse effects associated with acute toxicity.

Dogs have been administered doses of up to 1 mg/kg (approx. 8–10X) IV daily for up to 4 weeks with no serious adverse effects reported.

Drug Interactions

Intravenous Potentiated Sulfonamides (e.g., trimethoprim/sulfonamides): The manufacturer warns against using this agent with intravenous potentiated sulphonamides as fatal dysrhythmias may occur

Other Alpha-2 Agonists (e.g., xylazine, medetomidine, detomidine, clonidine and including epinephrine): Not recommended to be used together with romifidine as effects may be additive

Phenothiazines (e.g., acepromazine): Severe hypotension can result

The following drug interactions have either been reported or are theoretical in humans receiving a similar alpha-2 agonist, dexmetomidine and may be of significance in veterinary patients:

Anesthetics, Opiates, Sedative/Hypnotics: Effects may be additive; dosage reduction of one or both agents may be required; potential for increased risk for arrhythmias when used in combination with thiopental, ketamine or halothane

Laboratory Considerations

AdP-induced platelet aggregation: Can be inhibited in cats by medetomidine (a related alpha-2 agonist); not known if romifidine can have this effect

Doses

Horses (Adults):

a) For sedation and analgesia: 40–120 micrograms/kg IV slowly one time. This dose is equivalent to 0.4–1.2 mL per 100 kg (220 lb) body weight using the 1% (10 mg/mL) injection. Degree of sedation and analgesia is dose and time dependent. Onset of action occurs between 30 seconds to 5 minutes and gradually subsides during the next 2–4 hours. Duration of analgesia is shorter than the duration of sedation. See the package insert for expected onset and duration times for sedation and analgesia based upon dose.

As a preanesthetic: 100 micrograms/kg as slow, single IV injection. Induce anesthesia after maximal sedation is achieved. Mild to moderate sedation occurs in 2–4 minutes. Anesthetic doses may need to be

Uses/Indications

Romifidine is an alpha-2 agonist with sedative, muscle relaxant and analgesic effects. It is indicated (in the USA) for use in adult horses as a sedative and analgesic to facilitate handling, clinical examinations and procedures, minor surgical procedures, and as a preanesthetic prior to the induction of general anesthesia.
Nitroimidazole antibiotic/antiparasitic drug that appears to be useful in treating *Tritrichomonas foetus* infections in cats; also used for treating trichomoniasis infections in non-food birds

- Potentially carcinogenic; avoid human exposure
- Neurotoxicity (reversible): more likely at higher doses (50 mg/kg twice daily), but can occur at lower dosages as well; GI effects possible
- Many potential drug interactions
- Must be compounded from bulk powder (100%) & ideally, put in gelatin capsules

### Uses/Indications

Ronidazole is a nitroimidazole antibiotic/antiparasitic drug that appears to be useful in treating *Tritrichomonas foetus* infections in cats. The drug is not commercially available in the USA and must be compounded from bulk powder by a compounding pharmacy. The drug is also used for treating Trichomoniasis infections in non-food animal birds.

### Pharmacology/Actions

Ronidazole, like other 5-nitroimidazoles such as metronidazole is converted by hydrogenosomes (an organelle found in trichomonads) into polar autotoxic anion radicals. *Tritrichomonas foetus* resistance to nitroimidazoles has been documented (Gookin et al. 1998).
Ronidazole is a 5-nitroimidazole compound that occurs as a white to yellowish-brown, odorless or almost odorless, bitter-tasting, powder. It is very slightly soluble in water or alcohol.

**Client Information**

- **Monitoring**
  - Clinical efficacy (diarrhea improvement)
  - Adverse effects (neurotoxicity, vomiting, anorexia)
  - PCR testing (can be used to confirm infection, but negative results after treatment do not conclusively prove that infection has been eradicated)

- **Adverse Effects**
  - Reversible neurotoxicity similar to that reported with metronidazole, has been reported in cats with ronidazole. Initial signs may include lethargy, anorexia, ataxia, nystagmus, seizures or behavior changes. Should neurotoxicity be diagnosed, discontinue ronidazole, treat supportively, and if necessary, consider administering a benzodiazepine such as diazepam to competitively inhibit GABA receptors in the CNS. Incidence of neurotoxicity appears to be higher when using the 50 mg/kg twice daily dosage, but may occur at lower dosages as well. Potentially, gastrointestinal effects can occur (anorexia, vomiting). Ronidazole is very bitter and should be administered to cats in capsule form.

- **Drug Interactions**
  - In humans, the following drug interactions with metronidazole, a compound similar to ronidazole, have been reported or are theoretical and may be of significance in veterinary patients in patients receiving ronidazole:  
    - **ALCOHOL:** May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction  
    - **CIMETIDINE, KETOCONAZOLE:** May decrease the metabolism of ronidazole and increase the likelihood of dose-related side effects occurring  
    - **CYCLOSPORINE, TACROLIMUS (systemic):** Ronidazole may increase the serum levels of cyclosporine or tacrolimus  
    - **FLUOROURACIL (systemic):** Ronidazole may increase the serum levels of fluorouracil and increase risk for toxicity  
    - **LITHIUM:** Ronidazole may increase lithium serum levels and increase risk for lithium toxicity  
    - **OXYTETRACYCLINE:** Reportedly may antagonize the therapeutic effects of metronidazole (and presumably ronidazole)  
    - **PHENOBARBITAL, RIFAMPIN or PHENYTOIN:** May increase the metabolism of ronidazole thereby decreasing blood levels  
    - **WARFARIN:** Metronidazole (and potentially ronidazole), may prolong INR/PT in patients taking coumarin anticoagulants; avoid concurrent use if possible; otherwise intensify monitoring

- **Laboratory Considerations**
  - **AST, ALT, LDH (lactic dehydrogenase), Triglycerides, Hexokinase glucose:** A related compound, metronidazole can cause falsely decreased readings when determined using methods measuring decreases in ultraviolet absorbance when NADH is reduced to NAD. It is not known if ronidazole can also cause falsely decreased values.

- **Overdosage/Acute Toxicity**
  - No specific information was located. Cats receiving doses of 50 mg/kg twice daily appear to have greater incidences of neurotoxicity (see Adverse Reactions). A case report of an overdose causing neurotoxicity, hemorrhage and death in society finches after consuming ronidazole in drinking water has been published (Woods et al. 2010). If overdoses cause neurotoxicity, discontinue further therapy and treat supportively. Consider administering a GABA inhibitor such as diazepam, to competitively inhibit GABA receptors in the CNS.

- **Adverse Reactions**
  - Overdosage/Acute Toxicity
  - None in the USA; a 10% ronidazole powder to be added to drinking water for treating Trichomonas infections in pigeons is available in some countries, but these products are unsuitable for use in cats due to the dosage required and the unpalatability (very bitter) of the powder and solution. Capsules prepared from 100% bulk powder for an individual feline patient should be obtained from a compounding pharmacy that can prepare the capsules in a bio-safety hood that will protect the compounder from drug exposure.

**Pharmacokinetics**

- In cats, ronidazole is completely absorbed and bioavailable after oral dosing. Volume of distribution (steady state) is about 0.7 L/kg and clearance approximately 0.8 mL/kg/min. Elimination half-life is long at around 10 hours (LeVine et al. 2008).

**Contraindications/Precautions/Warnings**

- Ronidazole should not be used in patients hypersensitive to it or other 5-nitroimidazoles (e.g., metronidazole).

- The compound has been demonstrated to be carcinogenic in mice but not rats. While humans should avoid contact with this compound or with animal waste from treated patients, it can be safely compounded using a biological safety cabinet.

- The FDA prohibits this drug for use in food animals.

**Adverse Effects**

- Reversible neurotoxicity similar to that reported with metronidazole, has been reported in cats with ronidazole. Initial signs may include lethargy, anorexia, ataxia, nystagmus, seizures or behavior changes. Should neurotoxicity be diagnosed, discontinue ronidazole, treat supportively, and if necessary, consider administering a benzodiazepine such as diazepam to competitively inhibit GABA receptors in the CNS. Incidence of neurotoxicity appears to be higher when using the 50 mg/kg twice daily dosage, but may occur at lower dosages as well. Potentially, gastrointestinal effects can occur (anorexia, vomiting). Ronidazole is very bitter and should be administered to cats in capsule form.

- Ronidazole has been shown to increase the rate of benign mammary tumors in rats and increase the rates of benign and malignant pulmonary tumors in mice at dosages at or above 20 mg/kg/day.

- Dogs given 30 mg/kg per day for two years (40 mg/kg/day the first month) showed some testicular toxicity (type not specified), but no tumors.

**Storage/Stability**

- Compounded capsules should be stored in child-resistant, tight containers protected from light. Until further stability studies can be performed, capsules should be stored in the freezer.

**Adverse Effects**

- Adverse Effects
  - None in the USA; a 10% ronidazole powder to be added to drinking water for treating Trichomonas infections in pigeons is available in some countries, but these products are unsuitable for use in cats due to the dosage required and the unpalatability (very bitter) of the powder and solution. Capsules prepared from 100% bulk powder for an individual feline patient should be obtained from a compounding pharmacy that can prepare the capsules in a bio-safety hood that will protect the compounder from drug exposure.
S-ADENOSYL-METHIONINE (SAMe)  
ADEMETIONINE  
(hexahydro-4-oxo-4H-pyrido[1',2':5,6]pyrimido[4,5-b]pyrimidine-7-thione)

HEPATOPROTECTANT

Prescriber highlights

- “Nutraceutical” that can be used as an adjunctive treatment for liver disease (chronic hepatitis), osteoarthritis, or treatment of acetaminophen toxicity in small animals
- Well tolerated
- Not a regulated drug; choose products carefully

Uses/Indications

In small animal medicine, SAMe is most commonly used as an adjunctive treatment for liver disease (chronic hepatitis, hepatic lipidosis, cholangiobehapitis, feline triad disease, etc.). It may also be of benefit in osteoarthritis, age-related cognitive dysfunction, treatment of acute hepatotoxic-induced liver toxicity (e.g., acetaminophen, xylitol toxicity), and at-risk patients on long-term therapy using drugs with hepatotoxic potential.

In humans, SAMe is being used as a treatment for depression, osteoarthritis, AIDS-related myopathy, intrahepatic cholestasis, liver disease, alcoholic liver cirrhosis, fibromyalgia, adult ADHD, Alzheimer’s, migraines, etc.

Pharmacokinetics

S-adenosyl-methionine (SAMe) is an endogenous molecule synthesized by cells throughout the body. SAMe is formed from the amino acid methionine and ATP, in conjunction with SAMe synthetase enzyme (an enzyme manufactured in the liver, a rate-limiting step in the presence of liver compromise). SAMe is an essential component of three major biochemical pathways: transmethylation, transsulfuration, and aminopropilation. Normal function of these pathways is especially vital to the liver as many metabolic reactions occur there. In transmethylation pathway, SAMe serves as a methyl donor (necessary for many substances and drugs to be activated and/or eliminated). Transmethylation is essential in phospholipid synthesis important to membrane structure, fluidity, and function. In aminopropylation, SAMe donates aminopropyl groups and is a source of polyamines. Aminopropylation is important in producing substances that have antiinflammatory effects, protein and DNA synthesis, and promoting cell replication and liver mass regeneration. In transsulfuration, SAMe generates sulfur containing compounds important for conjugation reactions used in detoxification and as a precursor to glutathione (GSH). Glutathione is important in many metabolic processes and cell detoxification. The conversion of SAMe to glutathione requires the presence of folate, cyanocobalamin (B12), and pyridoxine (B6). Normaly, the liver produces ample SAMe, but in liver disease or in the presence of hepatotoxic substances, endogenous conversion to glutathione may be deficient. Exogenous SAMe has been shown to increase liver and red cell glutathione levels and/or prevent its depletion. SAMe inhibits apoptosis secondary to alcohol or bile acids in hepatocytes.

In humans, the mechanism for its antidepressant effects are not well understood, but it apparently increases serotonin turnover and increases dopamine and norepinephrine levels. Neuro-imaging studies in humans show that SAMe affects the brain similarly to other antidepressant medications.
Pharmacokinetics

Liver flukes and tapeworms do not use GABA as a peripheral nerve transmitter, selamectin would probably be ineffective against these parasites.

Neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, it causes paralysis of the parasite and eventual death. As a peripheral nerve transmitter, selamectin would probably be ineffective against these parasites.

Uses/Indications

Topical selamectin (Revolution®) is indicated for flea infestations (Ctenocephalides felis), prevention of heartworm disease (Dirofilaria immitis), and for ear mites (Otodectes cynotis) in both dogs and cats. Additionally in dogs, it is indicated for sarcoptic mange (Sarcoptes scabei), and tick infestations (Dermacentor variabilis). In cats it is indicated for hookworms (Ancylostoma tubaeforme) and roundworms (Toxocara cati). The product (Revolution®) is labeled as not effective against either adult heartworms or clearing circulating microfilaria, but it possibly may have some efficacy with prolonged, continuous administration (Atkins 2007).

Topical selamectin has been used off-label successfully to treat a variety of ectoparasites in small animals, including notoedric mange (Notoedres cati), nasal mites in dogs (Ancylostoma caninum), cheyletiellosis in dogs, cats and rabbits, and cordylobiosis (cutaneous myiasis, Cordylobia anthropophaga) in dogs. Selamectin has not been successful for treating generalized demodicosis.

Pharmacology/Actions

Like other compounds in its class, selamectin is believed to act by enhancing chloride permeability or enhancing the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, it causes paralysis of the parasite and eventual death. As a peripheral nerve transmitter, selamectin would probably be ineffective against these parasites.

Pharmacokinetics
After topical administration to dogs, about 5% of the drug is bioavailable and peak plasma levels occur about 3 days later. Selamectin bioavailability may be higher in female dogs. Elimination half-life after topical administration is about 11 days.

After topical administration to cats, about 75% of the drug is bioavailable and peak plasma levels occur about 15 hours later. Elimination half-life after topical administration is about 8 days. In cats, bioavailability is about 75% and peak levels may be 64 times those in dogs.

The persistence of the drug in the body is believed to be due to the drug forming reservoirs in skin sebaceous glands. It is secreted into the intestine to kill susceptible endoparasites in cats.

**Contraindications/Precautions/Warnings**

The manufacturer recommends caution when using in sick, underweight, or debilitated dogs or cats. It is not recommended for use in dogs under 6 weeks of age and in cats under 8 weeks of age.

At labeled doses of selamectin, dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc.) should tolerate the medication, but use cautiously. Higher doses may cause neurological toxicity in these dogs.

**Adverse Effects**

In field trials (limited numbers of animals) adverse effects were rare. Approximately 1% of cats showed a transient, localized alopecia at the area of administration. Other effects reported (< or = 0.5% incidence) include diarrhea, vomiting, muscle tremors, anorexia, pruritus/urticaria, erythema, lethargy, salivation and tachypnea. Very rarely, seizures and ataxia have been reported in dogs.

**Overdosage/Acute Toxicity**

Dogs: Oral overdoses of up to 15 mg/kg did not cause adverse effects (except for ataxia in one avermectin sensitive collie). Topical overdoses (10x) to puppies caused no adverse effects; topical overdoses to avermectin-sensitive Collies caused salivation. Cats: Oral ingestion may cause salivation and vomiting. Topical overdoses of up to 10x caused no observable adverse effects.

There were 97 exposures to selamectin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 48 were dogs with 12 showing clinical signs and 53 cases were cats with 28 showing clinical signs. The remaining 3 cases consisted of 2 lagomorphs and 1 ferret none of which had clinical signs. Common findings in dogs recorded in decreasing frequency included hypersalivation and polydipsia. Common findings in cats recorded in decreasing frequency included hypersalivation, licking, vomiting, anorexia, depression, and lethargy.

**Drug Interactions**

None documented, but caution is advised if using other drugs that can inhibit p-glycoprotein. Those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc “white feet”) should probably not receive selamectin with the following drugs, unless tested "normal": Drugs and drug classes involved include:

- AMIODARONE
- CARVEDILOL
- CLARITHROMYCIN
- CYCLOSPORINE
- DILTIAZEM
- ERYTHROMYCIN
- ITRAZONAZOLE
- KETOCONAZOLE
- QUINIDINE
- SPIRONOLACTONE
- TAMOXIFEN
- VERAPAMIL

**Laboratory Considerations**

None reported.

**Doses**

**DOGS:**

a) For prophylaxis and treatment of dirofilariasis, it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information: The recommended topical dose is 6 mg/kg. Dosing frequency: Heartworm prevention, flea control = monthly; Ticks = monthly (if heavy infestations, may repeat 2 weeks after the first dose); Ear Mites, Sarcoptes = once, repeat in one month if necessary. See the package for specific instructions on administration technique. (Label information; Revolution®—Pfizer)

b) For nasal mites in dogs (Pneumonyssoides caninum): In the study, dogs were dosed at 6–24 mg/kg for three times at 2-week intervals. (Gunnarsson et al. 2003)

c) For cheyletiellosis: 6–12 mg/kg topically every other week for a total of four treatments. (Mueller & Bettenay 2002)

d) For biting lice: 6 mg/kg topically once. (Shanks et al. 2003)

**CATS:**

a) For heartworm prevention: 18 mg/kg topically every 30 days. (Johnson 2006)

**FERRETS:**

a) For heartworm prevention: 18 mg/kg topically every 30 days. (Johnson 2006)

**RABBITS:**

a) For ear mites (P. cuniculi): 6–18 mg/kg topically (McTier et al. 2003)

**Monitoring**

- Clinical efficacy
- Owner compliance with treatment regimen

**Client Information**

- Follow label directions for administration technique; do not massage into skin, and do not apply if hair coat is wet. Because the product contains alcohol, do not apply to broken skin.
- Avoid contact with animal while the application site is wet.
- Wait two hours or more after applying to bathe the animal (or allow to go swimming).
- Avoid getting the product on human skin; if contact occurs, wash off immediately. Dispose of tubes in regular household refuse.
- Do not expose to flame as the product is flammable.
SELEGILINE HCL
L-DEPRENYL
se-de-jil-len-Antipyrin®; Eldepyr®
MONAMINE OXIDASE INHIBITOR
Prescriber Highlights

♦ MAO-B inhibitor that may be useful for cognitive dysfunction syndrome in dogs or cats or canine Cushing’s (efficacy in doubt for Cushing’s)

♦ Contraindications: Potentially in patients receiving opiates (see Drug Interactions)

♦ Adverse Effects: Vomiting & diarrhea; CNS effects manifested by restlessness, repetitive movements, or lethargy; salivation & anorexia. Diminished hearing/deafness, pruritus, licking, shivers/trembles/shakes possible

♦ Drug Interactions

Uses/Indications
Selegiline is FDA-approved for use in dogs for the treatment of Cushing’s disease and for Canine Cognitive Dysfunction (so-called “old dog dementia”). Its use for Cushing’s disease is somewhat controversial as clinical studies evaluating its efficacy have shown disappointing results. In humans, selegiline’s primary indication is for the adjunctive treatment of Parkinson’s disease. Selegiline may have a role in treating dogs with chronic anxiety, particularly those that have high prolactin levels (Page et al. 2007). Combined with a benzodiazepine and a beta-blocker such as propranolol, selegiline may be particularly useful in treating social or noise phobias. Selegiline may be of use in feline cognitive dysfunction syndrome.

Pharmacology/Actions
Selegiline’s mechanism of action for treatment of Cushing’s disease (pituitary dependent hyperadrenocorticism—PDH) is complex; a somewhat simplified explanation follows: In the hypothalamus, corticotropin-releasing hormone (CRH) acts to stimulate the production of ACTH in the pituitary and dopamine acts to inhibit the release of ACTH. As dogs age, there is a tendency for a decrease in dopamine production that can contribute to the development of PDH. As dopamine is metabolized by monamine oxidase-B (MAO-B) and selegiline inhibits MAO-B, dopamine levels can be increased at receptor sites after selegiline administration. In theory, this allows the levels of dopamine and CRH to be in balance in the hypothalamus, thereby reducing the amount of ACTH produced and ultimately, cortisol. While selegiline is labeled as a MAO-B inhibitor, at higher than labeled dosages, the drug loses its MAO-B specificity and also inhibits MAO-A. Two of these metabolites of selegiline are amphetamine and methamphetamine which may contribute to both the efficacy and the adverse effects of the drug.

Pharmacokinetics
There is only limited information on the pharmacokinetics of selegiline in dogs. A study done in 4 dogs showed that selegiline was absorbed rapidly and had an absolute bioavailability of about 10%. The volume of distribution of the central compartment was measured at approximately 7 L/kg. Terminal half-life was about one hour.

In humans, selegiline pharmacokinetics have wide interpatient variability. The drug has a high first pass effect where extensive metabolism to L-desmethylselegiline, methylamphetamine, and L-amphetamine occur. Each of these metabolites is active. While L-desmethyleselegiline does inhibit MAO-B, the others do not, but they are CNS stimulants. The drug is excreted in the urine, primarily as conjugated and unconjugated metabolites.

Contraindications/Precautions/Warnings
Selegiline is contraindicated in patients known to be hypersensitive to it. In human patients, it is contraindicated in patients receiving meperidine and possibly with other opioids as well. The manufacturer cautions to perform appropriate diagnostic tests to confirm the diagnosis before starting therapy and not to attempt to treat hyperadrenocorticism not of pituitary origin.

Adverse Effects
Adverse effects reported thus far in dogs include, vomiting, diarrhea, CNS effects manifested by restlessness, repetitive movements or lethargy, salivation, and anorexia. Should GI effects be a problem, discontinue the drug for a few days and restart at a lower dose. Diminished hearing/deafness, pruritus, licking, shivers/trembles/shakes have also been reported. The manufacturer advises to observe animals carefully for atypical responses.

Adverse effects that have been reported in human patients include nausea (10%), hallucinations, confusion, depression, loss of balance, insomnia, and hypersexuality. These effects are noted because of their “subjective” nature and they could help explain unusual or behavioral changes in canine patients, should they occur.
Selegiline HCl Tablets and Capsules: 1.25 mg (orally disintegrating) & 5 mg;
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

VETERINARY-LABELED PRODUCTS:
Commercially available veterinary tablets should be stored at controlled room temperature 20–25°C (68–77°F). The commercially available human-labeled tablets and capsules are recommended to be stored from 15–30°C.

Storage/Stability
Selegiline HCl, also commonly called l-deprenyl, occurs as a white to off-white crystalline powder that is freely soluble in water. It has a pKa of 7.5.

Chemistry/Synonyms
Selegiline HCl may also be known as: deprenyl, L-deprenyl, selegilini hydrochloridum; many trade names are available.

Client Information
Have clients monitor closely for adverse effects

Adverse effects. No correlation between low dose dexamethasone suppression test results and clinical efficacy of the drug. The manufacturer recommends physical exam and history as the primary methods to measure response to therapy.

Drug Interactions
Evaluating the potential for drug interactions for selegiline in dogs is problematic. There are a plethora of significant interactions with monoamine oxidase inhibitors in humans for selegiline, but because there are significant species differences in quantities and locations of MOA-A and B and selegiline’s effects at various dosages on these enzymes, they may not apply to dogs. However, the following drug interactions are some of the more significant interactions reported or are theoretical in humans or animals receiving selegiline and potentially could be of significance in veterinary patients; caution is advised particularly if using selegiline at higher than labeled dosages:

- Amitraz: The manufacturer recommends not using selegiline concurrently with amitraz (Mitaban®) in dogs
- BuPROPION: Potential for serotonin syndrome
- EphEDRINE: The manufacturer recommends not using selegiline concurrently with ephedrine in dogs
- MEPERIDINE/OPIOIDS: In humans, severe agitation, hallucinations and death have occurred in some patients receiving meperidine and an MAO inhibitor. Until the data can be clarified, it is recommended not to use selegiline and meperidine together. A separation of two weeks has been recommended. Other opioids (e.g., morphine) should be safer, but use with extreme caution, if at all.
- PHENYLPROPANOLAMINE, PSEUDOPHEDRINE: Possibility for increased risk for hypertension, hyperpyrexia
- SSRI’s (e.g., fluoxetine): Potentially, the so-called serotonin syndrome could occur if selegiline is used concurrently with selective serotonin reuptake inhibitors (SSRIs); several sources recommend a 5-week washout before administering selegiline in dogs after fluoxetine is discontinued and to wait 2 weeks if switching from selegiline to an SSRI.
- TRAMADOL: Use contraindicated in humans; serotonin syndrome, nausea, vomiting, cardiovascular collapse
- TRICYCLIC & TETRACYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.): Potentially, the so-called serotonin syndrome could occur if selegiline is used concurrently with these agents and use together is not advised at this time; a 2-week separation between these compounds and selegiline is recommended.

Doses

- DOGS:
  - For Cushing’s disease:
    - a) 1 mg/kg PO in the AM (with food as needed); Reevaluate clinically over next 2 mos.; if no improvement, may increase to 2 mg/kg once daily; if no improvement or signs increase, reevaluate diagnosis or consider alternate treatment (Package Insert; Anipryl®—Pfizer).
  - For Canine Cognitive Dysfunction:
    - a) 0.5–1 mg/kg, PO once daily, preferably in the AM. Initially, dose to the nearest whole tablet; adjustments should then be made based upon response and tolerance to the drug (Package Insert; Anipryl®—Pfizer).
    - b) 0.5 mg/kg PO q24h; if no response after 4 weeks give 1 mg/kg PO q24h. Also useful in some anxiety problems and sleep disorders. (Seksel 2008)

- CATS:
  - For Cognitive Dysfunction Syndrome:
    - a) 0.25–1 mg/kg PO once daily. There are no drugs licensed for the treatment of CDS in cats. However, a small open trial using selegiline showed a positive effect and the American Association of Feline Practitioners supports the use of this drug for the treatment of CDS. (Gunn-Moore 2008)
    - b) For anxiety, disturbed sleep wake cycles and excessive vocalization associated with aging: 0.5–1 mg/kg PO once daily. (Seksel 2008)

Monitoring

- Clinical efficacy
- Adverse effects. No correlation between low dose dexamethasone suppression test results and clinical efficacy of the drug. The manufacturer recommends physical exam and history as the primary methods to measure response to therapy.

HUMAN-LABELED PRODUCTS:

Selegiline HCl Tablets and Capsules: 1.25 mg (orally disintegrating) & 5 mg; Edepryl® (Somerset); Zelapar® (Valeant Pharmaceuticals); generic; (Rx)

Selegiline HCl Transdermal Patch: 6 mg/24 h (20 mg/20 cm²); 9 mg/24 h (30 mg/30 cm²) & 12 mg/24 hours (40 mg/40 cm²); Ensam® (Dey); (Rx)

Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.

It is not known whether selegiline is excreted in maternal milk.
SERTRALINE HCL  
(sir-tral-a-lyn) Zoloft®  
SELECTIVE SEROTONIN REUPTAKE INHIBITOR (SSRI)  
Prescriber Highlights

- A selective serotonin reuptake inhibitor that may be useful in treating a variety of behavior-related diagnoses in dogs & cats, including aggression, anxiety-related behaviors & other obsessive-compulsive behaviors
- Caution: geriatric patients or those with severe hepatic disease; dosages may need to be adjusted
- Adverse effect profile not well established. Potentially, Dogs: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Aggressive behavior in previously non-aggressive dogs possible. Cats: Sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), & changes in elimination patterns
- Drug-drug interactions
- Relatively inexpensive generic products now available

Uses/Indications
Sertraline may be considered for use in treating a variety of behavior-related diagnoses in dogs and cats, including aggression, and anxiety-related or other obsessive-compulsive behaviors.

Pharmacology/Actions
Sertraline is a highly selective inhibitor of the reuptake of serotonin (5-hydroxytryptamine) in the CNS thus potentiating its pharmacologic activity. Sertraline apparently has little effect on dopamine or norepinephrine, and apparently no effect on other neurotransmitters.

Pharmacokinetics
In dogs, sertraline’s volume of distribution is 25 L/kg and is 97% bound to plasma proteins. High first-pass metabolism occurs; clearance is greater than 35 mL/min/kg. Bile is the major route of excretion in the dog.

In humans, sertraline peak levels occur 30–45 minutes after oral dosing. It is 98% bound to plasma proteins. Sertraline appears to be highly metabolized primarily to N-desmethylsertraline, which is active. Elimination half-lives for sertraline and desmethylsertraline average 26 and 80 hours respectively.

Contraindications/Precautions/Warnings
Sertraline is contraindicated in patients hypersensitive to it or any SSRI, or receiving a monoamine oxidase inhibitor (MAOI) or cisapride. Use with caution in geriatric patients and those with hepatic impairment; dosages may need to be decreased or dosing interval increased.

Adverse Effects
Limited use of sertraline in dogs or cats makes it difficult to compare its adverse effect profile with other SSRIs (e.g., fluoxetine, paroxetine, fluvoxamine). In dogs, SSRIs can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously non-aggressive dogs has been reported. SSRI’s in cats can cause sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), and changes in elimination patterns.

Reproductive/Nursing Safety
In humans, the FDA categorizes sertraline as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In rats and rabbits, sertraline was implicated in causing delayed ossification. Sertraline decreased pup survival in rats exposed in utero.

It is unknown if sertraline enters maternal milk.

Overdose/Acute Toxicity
With overdoses, the SSRI’s can cause vomiting, diarrhea, hypersalivation, and lethargy. Serotonin syndrome may occur with signs that include muscle tremors, rigidity, agitation, hyperthermia, vocalization, hypertension or hypotension, tachycardia, seizures, coma, and death. Most dog exposures below 20 mg/kg are not serious. Human overdoses of as little of 2.5 grams have caused death, but one patient survived after taking 13.5 grams.

There were 345 exposures to sertraline reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 316 were dogs with 65 showing clinical signs and 27 were cats with 5 showing clinical signs. The remaining 2 cases were birds that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, tachycardia, somnolence, vomiting, and vocalization. Common findings in cats included hypersalivation.

Management of sertraline overdoses should be handled aggressively with supportive and symptomatic treatment. Veterinarians are encouraged to contact an animal poison control center for further guidance.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving sertraline and may be of significance in veterinary patients:

- BUSPIRONE: Increased risk for serotonin syndrome
- CIMITIDINE: May increase sertraline levels
- CYPROHEPTADINE: May decrease or reverse the effects of SSRIs
- Diazepam: Sertraline may decrease diazepam clearance
- Soniazid: Increased risk for serotonin syndrome
- MAO INHIBITORS (including amitraz and potentially, selegline): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing sertraline and a 2 week washout period is required if first discontinuing the MAO inhibitor
- PENTAZOCINE: Serotonin syndrome-like adverse effects possible
- TRAMADOL: SSRIs can inhibit the metabolism of tramadol to the active metabolites decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures)
- TRICYCLIC ANTIDEPRESSANTS (e.g., clomipramine, amitriptyline): Sertraline may increase TCA blood levels and may increase the risk for serotonin syndrome
- WARFARIN: Sertraline may increase the risk for bleeding

Laboratory Considerations
- No significant laboratory interactions or considerations were located.

Doses

- DOGS:
  a) For treatment of compulsive disorders: 2–4 mg/kg PO once daily or divided twice daily (Landsberg 2004)
  b) 1–2 mg/kg PO q24h (once daily) (allow 6–8 weeks for initial trial) (Virga 2005)
**Pharmacology/Actions**

**Uses/Indications**

**Dosage Forms/Regulatory Status**

**Chemistry/Synonyms**

A selective serotonin reuptake inhibitor, sertraline hydrochloride is a white crystalline powder that is slightly soluble in water and isopropyl alcohol; sparingly soluble in ethanol. The commercially available oral solution contains 1% ethanol and has a menthol scent.

Sertraline may also be known as: CP-51974-01; Abrucline®, Anilar®, Aremil®, Atencil®, Bexirat®, Bicromil®, Gladem®, Insertec®, Irradia®, Lustra®, Novavit®, Seadin®, Serel®, Serceor®, Serla®, Sera®, Tatig®, Tolber®, Tresleer® or Zolof®.

**Storage/Stability**

Store commercially available sertraline tablets and oral solution at controlled room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F). The manufacturer states to dilute the oral solution only in the following liquids: water, orange juice, ginger ale, lemonade or lemon/lime soda; use immediately after dilution.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Sertraline HCl Tablets: 25 mg, 50 mg & 100 mg (as base); Zoloft® (Pfizer); generic; (Rx)

Sertraline HCl Oral Solution Concentrate: 20 mg/mL in 60 mL; Zoloft® (Pfizer); generic; (Rx)

**References**

e) For treatment of compulsive disorders: 0.5–1 mg/kg PO once daily (Landsberg 2004)
b) For urine marking (spraying), aggression, anxiety—including anxiogenic house soiling, phobias, fears: 0.5–1 mg/kg PO q24h (once daily) (Virga 2002)
c) For treatment of behavioral diagnoses: 1 mg/kg PO q24h (once a day). Note: must treat for 3–5 weeks minimum to assess effects; then treat until “well” until either has no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Then treat for another 1–2 months (minimum), so that reliability of assessment is reasonably assured. If weaning off the drug do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)
d) For treatment of fear, affective or dominance aggression: 0.5–1 mg/kg PO once daily (Crowell-Davis, S. 2003b), (Crowell-Davis, S. 2003a). For generalized anxiety disorder: 0.5–1.5 mg/kg PO q24h. (Crowell-Davis, S.L. 2009)

e) For treatment of compulsive disorder, anxiety: 0.5–1 mg/kg PO q24h (once daily) (Seibert 2003)
f) 0.25–1.3 mg/kg PO q24h. (Curtis 2008)

c) 1–3 mg/kg PO once daily. Plan is to use the drug for a limited time (3–6 months) during which time behavioral modification is also employed. The animal should learn appropriate behavior in previously problematic situations. Then the animal should be weaned off the medication over a 2 to 4 week period by halving the dose weekly (Neilson 2002)
d) For treatment of behavioral diagnoses: 0.25–0.5 mg/kg PO q24h (once a day). Note: must treat for 3–5 weeks minimum to assess effects; then treat until “well” until either has no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Then treat for another 1–2 months (minimum), so that reliability of assessment is reasonably assured. If weaning off the drug do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)

**Storage/Stability**

Store commercially available sevelamine tablets and oral solution at controlled room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F). The manufacturer states to dilute the oral solution only in the following liquids: water, orange juice, ginger ale, lemonade or lemon/lime soda; use immediately after dilution.

**Uses/Indications**

Sevelamer may be useful for treating hyperphosphatemia associated with chronic renal failure, particularly when oral aluminum salts are not tolerated.

**Prescriber Highlights**

- Phosphorus binding agent (in the gut) for hyperphosphatemia associated with chronic renal failure
- May be useful if patient cannot tolerate aluminum salts or aluminum salts are commercially unavailable
- Expensive when compared to aluminum hydroxide or calcium carbonate products
- Drug-drug interactions including nutrients
**Pharmacology/Actions**
Sevelamer binds phosphorus in the gut; when combined with decreased phosphorus in the diet it can substantially reduce serum phosphorus levels. It also reduces serum low-density lipoproteins and total cholesterol.

**Pharmacokinetics**
Sevelamer is administered orally, but is not absorbed systemically.

**Contraindications/Precautions/Warnings**
Sevelamer is contraindicated in patients with hypophosphatemia, or bowel obstruction and in patients hypersensitive to it.

**Adverse Effects**
Adverse effects in humans are reported to be the same as placebo. Potentially some GI effects occur.

As oral vitamin absorption may be reduced by sevelamer, consider the addition of vitamin supplementation during therapy.

**Reproductive/Nursing Safety**
Safety during pregnancy is not established; because of the potential for binding vitamins, additional vitamins (both fat and water soluble) may be necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) There are no adequate and well-controlled studies in nursing mothers.

**Overdosage/Acute Toxicity**
As sevelamer is not absorbed, acute toxicity potential appears to be negligible.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving sevelamer and may be of significance in veterinary patients:

- **ANTICONVULSANTS (oral):** Sevelamer may reduce oral absorption; give at least one hour before or three hours after sevelamer capsules
- **ANTIARRHYTHMICS (oral):** Sevelamer may reduce oral absorption; give at least one hour before or three hours after sevelamer capsules
- **CIPROFLOXACIN:** Concurrent administration with sevelamer may decrease absorption by 50%; administer ciprofloxacin and other oral fluoroquinolones at least one hour before or 3 hours after sevelamer
- **ORAL MEDICATIONS:** There are only a few medications having documented reductions in oral administration when administered with sevelamer; consider dosing other oral drugs separately, particularly for drugs with narrow therapeutic indexes
- **VITAMINS:** Sevelamer may reduce vitamin absorption from food; consider administering vitamin supplements separately from sevelamer dose

**Doses**

**DOGS:**
- a) For medium to large sized dog: 400 mg PO with meals (Vaden 2007)

**CATS:**
- a) Has been used at 200 mg 2–3 times daily. Anecdotally appears to be safe and effective. (Sparkes 2006)

**Monitoring**
- Serum phosphorus (and other electrolytes calcium, bicarbonate, chloride)
- Consider a baseline coagulation screening test before and after sevelamer therapy implementation as vitamin K absorption may be impacted by the drug

**Chemistry/Synonyms**
A phosphorus binding agent, sevelamer HCl is a complex chemical that is hydrophilic, but insoluble in water.
Sevelamer may also be known as GT16-026A and Renagel®.

**Storage/Stability**
Sevelamer capsules should be stored at room temperature and protected from moisture.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**
- sevelamer HCl Oral Tablets: 400 mg & 800 mg; Renagel® (Genzyme); Renvela® (Genzyme); (Rx)
- sevelamer Powder for Oral Suspension: 0.8 grams/packet & 2.4 grams/packet; Renvela® (Genzyme); (Rx)

---

**SEVOFLURANE**

_(see-voe-flu-rahne) SevoFlo®, Ultane®_

**INHALATIONAL ANESTHETIC**

**Prescriber Highlights**

- Inhalational anesthetic similar to isoflurane, but with more rapid induction & recovery
- Currently much more expensive than isoflurane

**Uses/Indications**
Sevoflurane may be useful in a variety of species when rapid induction and/or rapid recoveries are desired with an inhalational anesthetic. The advantages of sevoflurane include rapid inductions and recoveries and the ability to change depth of anesthesia faster than with isoflurane. When mask inductions are necessary, sevoflurane is preferred over isoflurane or desflurane as it is better accepted and inductions are faster and smoother than with isoflurane. Sevoflurane may be of particular usefulness in debilitated or geriatric cats as it tends to cause less hypotension than isoflurane.

**Pharmacology/Actions**
While the precise mechanism that inhalant anesthetics exert their general anesthetic effects is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane.
Minimal Alveolar Concentration (MAC; %) in oxygen reported for sevoflurane in various species: Dog = 2.09–2.4; Cat = 2.58; Horse = 2.31; Sheep = 3.3; Swine = 1.97–2.66; Human (adult) = 1.71–2.05. Several factors may alter MAC (acid-base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

**Pharmacokinetics**

Because of its low solubility in blood, only small concentrations of sevoflurane in the blood are required to be dissolved in blood before alveolar partial pressures are in equilibrium with arterial partial pressures. This low solubility means that sevoflurane is rapidly removed from the lungs. It is unknown what percent sevoflurane is bound to plasma proteins. The majority of sevoflurane is excreted via the lungs, but about 3% is metabolized in the liver via the cytochrome P450 2E1 isoenzyme system.

**Contraindications/Precautions/Warnings**

Sevoflurane is contraindicated in patients with a history or predilection towards malignant hyperthermia. It should be used with caution (benefits vs. risks) in patients with increased CSF or head injury, or renal insufficiency.

Because of its rapid action, use caution not to overdose during the induction phase. Because of the rapid recovery associated with sevoflurane use caution (and appropriate sedation during the recovery phase), particularly with large animals.

Geriatric animals may require less inhalation anesthetic.

In rabbits, sevoflurane (and isoflurane) can cause breath holding and struggling; premedication and close observation are required. Sevoflurane may have a low margin of safety in guinea pigs.

Sevoflurane can react with carbon dioxide absorbents to produce "compound A", a nephrotoxin. After extensive clinical use in humans and dogs nephrotoxicity has not been demonstrated to be of clinical concern. However sevoflurane should be used with good maintenance of the carbon dioxide absorbent (i.e., should be changed regularly to prevent exhaustion or excessive drying) and should not be used with extremely low oxygen flows (i.e., less than 500 mL/min) (Mathews 2008).

**Adverse Effects**

Sevoflurane seems to be well tolerated. Hypotension may occur and is considered dose related. Dose-dependent respiratory depression and GI effects (nausea, vomiting, ileus) have been reported. While cardiodepression generally is minimal at doses causing surgical planes of anesthesia, it may occur; bradycardia is possible. Malignant hyperthermia may be triggered by this agent (like other inhalational anesthetics). Sevoflurane should be used in precision, agent-specific, out of circuit vaporizers.

In ferrets, sevoflurane (and isoflurane) can cause temporary decreases in erythrocyte and white cell counts and total protein. Within 45 minutes after discontinuation of sevoflurane, this effect begins to revert to normal and is reversed within 2 hours.

**Reproductive/Nursing Safety**

No overt fetotoxicity or teratogenicity has been demonstrated in lab animal studies, but definite safety has not been established for use during pregnancy.

**Overdosage/Acute Toxicity**

In the event of an overdose, discontinue sevoflurane; maintain airway and support respiratory and cardiac function as necessary.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving sevoflurane and may be of significance in veterinary patients:

- **AMINOLYCOXIDES, LINCOSAMIDES**: May enhance neuromuscular blockade
- **ARBITURATES (phenobarbital, pentobarbital, etc.)**: May increase concentrations of inorganic fluoride
- **ISONIAZID**: May increase concentrations of inorganic fluoride
- **MIDAZOLAM**: May potentiate sevoflurane effects; decrease MAC
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS (atracurium, pancuronium, vecuronium)**: Additive neuromuscular blockade may occur
- **OPIATES**: May potentiate sevoflurane effects; decrease MAC
- **ST. JOHNS WORT**: Increased risk for anesthetic complications; recommend discontinuing St. John’s Wort 5 days in advance of surgery
- **SUCCINYLCHOLINE**: Sevoflurane may enhance effects
- **SYMPATHOMIMETICS (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.)**: While sevoflurane sensitizes the myocardium to the effects of sympathomimetics less so than halothane, arrhythmias may still result; caution and monitoring is advised
- **TRAMADOL**: May decrease MAC requirements
- **VERAPAMIL**: May cause cardiodepression

**Laboratory Considerations**

Inhalational anesthetics may cause transient increases in liver function tests, WBCs, and glucose

**Doses**

Minimal Alveolar Concentration (MAC; %) in oxygen reported for sevoflurane in various species: Dog = 2.09–2.4; Cat = 2.58; Horse = 2.31; Sheep = 3.3; Swine = 1.97–2.66; Human (adult) = 1.71–2.05. Several factors may alter MAC (acid-base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

**DOGS/CATS:**

a) **Dogs**: Inspired Concentration: The delivered concentration of SevoFlo® (sevoflurane) should be known. Since the depth of anesthesia may be altered easily and rapidly, only vaporizers producing predictable percentage concentrations of sevoflurane should be used. Sevoflurane should be vaporized using a precision vaporizer specifically calibrated for sevoflurane. Sevoflurane contains no stabilizer. Nothing in the drug product alters calibration or operation of these vaporizers. The administration of general anesthesia must be individualized based on the patient’s response. When using sevoflurane, patients should be continuously monitored and facilities for maintenance of patient airway, artificial ventilation, and oxygen supplementation must be immediately available.

Replacement of Desiccated CO2 Absorbents: When a clinician suspects that the CO2 absorbent may be desiccated, it should be replaced. An exothermic reaction occurs when sevoflurane is exposed to CO2 absorbents. This reaction is increased when the CO2 absorbent becomes desiccated.

Premedication: No specific premedication is either indicated or contraindicated with sevoflurane. The necessity for and choice of premedication is left to the discretion of the veterinarian. Preanesthetic doses for premedicants may be lower than the label directions for their use as a single medication.

Induction: For mask induction using sevoflurane, inspired concentrations up to 7% sevoflurane with oxygen are employed to induce surgical anesthesia in the healthy dog. These concentrations can be expected to produce surgical anesthesia in 3 to 14 minutes. Due to the rapid and dose dependent changes in anesthetic depth, care should be taken to prevent overdosing. Respiration must be monitored closely in the dog and supported when necessary with supplemental oxygen and/or assisted ventilation.

Maintenance: SevoFlo® may be used for maintenance anesthesia following mask induction using sevoflurane or following injectable induction agents. The concentration of vapor necessary to maintain anesthesia is much less than that required to induce it. Surgical levels of anesthesia in the healthy dog may be maintained with inhaled concentrations of 3.7–4% sevoflurane in oxygen in the absence of premedication and 3.3–3.6% in the presence of premedication. The use of injectable induction agents without premedication has little effect on the concentrations of sevoflurane required for maintenance. Anesthetic regimens that include opioid, alpha2-agonist benzodiazepine or phenothiazine premedication will allow the use of lower sevoflurane maintenance concentrations. (Label directions; SevoFlo®—Abbott Animal Health)

b) **Dogs/Cats**: Where required, mask induction (particularly of cats) is achieved easily via a non-rebreathing system, usually starting at a concentration of around 4–4.5%. Maximum concentration (8%) is possible using the vaporizer and can be used for fresh gas flow for ‘chamber’ inductions as the concentrations in the box take time to reach high levels. However, concentrations administered must be reduced as soon as the animal loses consciousness (i.e., take animal out of the box). For maintenance, vaporizer settings with non-rebreathing systems depend on the fresh gas flow rates as well as the residual effects of injectable drugs; a maximum setting of 8% for a single system is a reasonable initial concentration. (Clarke 2008)
Sevoflurane setting of 3% for a circle system is a reasonable initial concentration. (Clarke 2008)

Monitoring
- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia

Chemistry/Synonyms
Sevoflurane is an isopropyl ether inhalational anesthetic with a molecular wt. of 200, saturate vapor pressure at 20°C of 160 mmHg and a boiling pt. of 58.5°C. It is reported to have a pleasant odor and is not irritating to airways. It is non-flammable and non-explosive. Sevoflurane is a clear, colorless liquid that is miscible with ethanol or ether and slightly soluble in water. It does not possess an objectionable odor.

Sevoflurane may also be known as: BAX-3084, MR-654, Sevocri®®, SevoFlo®, Sevorane®, or Ultane®.

Storage/Stability
Sevoflurane should be stored at room temperature. Sevoflurane does not react with metal.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Sevoflurane in 250 mL bts; SevoFlo® (Halocarbon Prod.); Petrem® (Minrad); (Rx). FDA-approved for use in dogs.

HUMAN-LABELED PRODUCTS:
Sevoflurane in 250 mL bts; Ultane® (Abbott); Sojour® (Minrad); (Rx)

References

SILDENAFIL CITRATE

(sil-den-a-fil) Viagra®, Revatio®
VASODILATOR; PHOSPHODIESTERASE TYPE 5 INHIBITOR
Prescriber Highlights
- Used in veterinary medicine for treating pulmonary hypertension
- Contraindicated if patients receiving organic nitrates
- Adverse effects not well-known; inguinal flushing, possible GI effects reported
- Treatment may be very expensive

Uses/Indications
Sildenafil may be of benefit in the adjunctive treatment of pulmonary hypertension in small animals.

In humans, sildenafil is indicated for erectile dysfunction or pulmonary hypertension.

Pharmacology/Actions
Sildenafil inhibits cyclic guanosine monophosphate (cGMP) specific phosphodiesterase type-5 (PDE5) found in the smooth muscle of the pulmonary vasculature, corpus cavernosum and elsewhere, where PDE5 is responsible for degradation of cGMP. Sildenafil increases cGMP thereby resulting in nitric oxide mediated vasodilatation within pulmonary vascular smooth muscle cells.

Pharmacokinetics
The pharmacokinetics of sildenafil has been reported in dogs (Walker et al. 1999). Oral bioavailability is approximately 50% (higher than humans); volume of distribution is about 5.2 L/kg (versus 1.2 L/kg in humans); elimination half-life approximately 6 hours (significant interpatient variability; average human half life is about 4 hours).

Contraindications/Precautions/Warnings
Sildenafil should not be used concurrently with nitrates (see drug interactions) or in patients documented hypersensitive to it.

Pulmonary vasodilators may significantly worsen the cardiovascular status of patients with pulmonary veno-occlusive disease (PVOD).

Use with extreme caution in patients with resting hypotension, fluid depletion, severe left ventricular outflow obstruction, or autonomic dysfunction.

Adverse Effects
Because of limited use in dogs, the adverse effect profile is not fully known. Cutaneous flushing of the inguinal region has been reported and GI effects are possible. In humans, headache, visual disturbances, dyspepsia, nasal congestion, myalgia, priapism, dizziness, and back pain have been reported.

Reproductive/Nursing Safety
No evidence of teratogenicity, embryotoxicity or fetotoxicity was observed in pregnant rats or rabbits, dosed at 200 mg/kg/day during organogenesis. In a rat pre- and postnatal development study, the no-observed-adverse-effect dose was 30 mg/kg/day. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is not known if sildenafil or its metabolites are excreted in milk.

Overdosage/Acute Toxicity
Little information is available. An adult woman ingested 2000 mg and survived but developed tachycardia, nonspecific ST-T changes on ECG, headache, dizziness, and flushing.

It is expected that overdoses in animals would mirror the drugs adverse effect profile; treat supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving sildenafil and may be of significance in veterinary patients:

- ALPHA-ADRENERGIC BLOCKERS (e.g., phentolamine, phentolamines, phenoxylenzamine): May increase hypotensive effects
- AMLODIPINE: Potential to increase hypotensive effects
- ANTHYPERTENSIVE HYPOTENSIVE DRUGS: Potentially could increase hypotensive effects
Antihypertensive/Hypotensive Drugs: Potentially could increase hypotensive effects

- Azole Antifungals (ketoconazole, itraconazole): May reduce sildenafil metabolism and increase AUC
- Cimetidine: May reduce sildenafil metabolism and increase AUC
- Erythromycin, Clarithromycin: May reduce sildenafil metabolism and increase AUC
- Heparin: May increase bleeding risks
- Nitrates (e.g., NTG, Isosorbide): Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- Nitroprusside Sodium: Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- Phenobarbital: May decrease sildenafil concentrations
- Rifampin: May decrease sildenafil concentrations

Laboratory Considerations
- None were noted.

Doses

**DOGS/CATS:**

For pulmonary hypertension:

a) Dogs: From a retrospective study: median dose was 1.9 mg/kg (range from 0.5–2.7 mg/kg) q8–24h. Dogs may have been also treated with oxygen, ACE inhibitors, furosemide, amlodipine, diltiazem, theophylline, phenobarbital and/or antibiotics. (Bach et al. 2006)
b) For pulmonary hypertension documented by Doppler, chronic pulmonary disease, right-sided heart failure (HW disease; congenital): 0.5–1 mg/kg PO two times daily (higher dose of 2–3 mg/kg three times a day may be tolerated and needed) (Tilley 2007)
c) In dogs and cats with moderate to severe PH secondary to either left heart disease or primary lung disease: 1 mg/kg PO q8h. (Henik 2007)
d) Dogs: 1–2 mg/kg PO three times daily. (Oyama 2009)

**Monitoring**

- Clinical efficacy (improved syncope, cough, respiratory effort)
- Pulmonary artery pressure, systemic blood pressure
- Adverse effects

**Client Information**

- Brief clients on the experimental nature of using this medication in small animals and the costs of therapy
- Report any adverse effects to the veterinarian

**Chemistry/Synonyms**

Sildenafil citrate occurs as a white to off-white crystalline powder with a solubility of 3.5 mg/mL in water and a molecular weight of 666.7.

Sildenafil may also be known as UK 92480, UK 92480-10, Aphrodil®, Revatio®, or Viagra®.

**Storage/Stability**

Sildenafil tablets should be stored at room temperature (25°C; 77°F); excursions permitted to 15–30°C (59–86°F).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Sildenafil Citrate Oral Tablets: 20 mg Revatio® (Pfizer); (Rx) and 25 mg, 50 mg & 100 mg (of sildenafil); Viagra® (Pfizer); (Rx)
- Sildenafil Injection Solution: 10 mg/12.5 mL (dextrose 50.5 mg/mL) in 12.5 mL single-use vials; Revatio® (Pfizer); (Rx)

**References**

**Silymarin**

**Mil克 Thistle**

**Nutraceutical Hepato-Protectant**

**Prescriber Highlights**

- Nutraceutical that may be useful for treatment of chronic & acute liver disease, cirrhosis; as a hepatoprotective agent when hepatotoxins (e.g., Aminita phalloide) ingested
- Appears well-tolerated; potentially could cause GI effects
- Do not confuse Milk Thistle with Blessed Thistle
- Potential drug interactions

**Uses/Indications**

While controlled studies demonstrating efficacy and a standardized form and concentration of silymarin are lacking, it is being used to treat a variety of liver diseases in humans and domestic companion animals (birds, dogs, cats, horses, rabbits). It is mostly of interest in treating chronic and acute liver disease, cirrhosis, and as a hepatoprotective agent when hepatotoxic agents are ingested (e.g., Aminita phalloide, “Death Cap Mushrooms”). There is laboratory data that silymarin may be beneficial in preventing certain cancers and in improving the efficacy and reducing the negative effects of chemotherapy for certain tumors.

**Pharmacology/Actions**

None were noted.
Silymarin has a variety of pharmacologic actions that may contribute to its apparent effects in treating liver disease. It inhibits lipid peroxidase and beta-glucuronidase and acts as an anti-oxidant and free radical scavenger. Silymarin also inhibits the cytotoxic, inflammatory, and apoptotic effects of tumor necrosis factor (TNF). It apparently can alter outer hepatocyte cell membranes that can prevent toxin penetration. Silymarin is thought to reduce hepatic collagen formation and increase hepatic glutathione content.

Pharmacokinetics
In humans, silymarin has an oral bioavailability of less than 50% and peak levels occur 2–4 hours post-dose. When silybin (silibin, silybin) is complexed with phosphatidylcholine, oral absorption can be increased. The drug undergoes extensive enterohepatic circulation and has significantly higher concentrations in liver cells and bile than in plasma. Elimination half-life in humans averages 6 hours. The majority of the drug is eliminated unchanged in the feces, but 20–40% is converted into glucuronide and sulfate conjugates which are eliminated in the feces; only about 8% is excreted in the urine.

Contraindications/Precautions/Warnings
There are no reported absolute contraindications to silymarin in animals. Extracts from the plant parts of Milk Thistle (not the seeds which are used to make the extract silymarin), may possess estrogen-like activity and should not be used in patients where exogenous estrogens would be contraindicated.

Adverse Effects
Silymarin is apparently well tolerated when administered orally. In humans, GI disturbances have been reported on occasion (nausea to diarrhea). Patients who have allergies to other members of the Asteraceae/Compositae plant family (includes ragweed, marigolds, daisies, etc.) may exhibit allergic reactions to Milk Thistle or Silybum species. Do not confuse Milk Thistle with Blessed Thistle.

Reproductive/Nursing Safety
Data on the safety of silymarin use during pregnancy or nursing is not available; its potential benefit must be weighed against the uncertainty of its safety.

Overdosage/Acute Toxicity
Overdoses are unlikely to cause significant morbidity. Gastrointestinal effects may be seen and treated in a supportive manner.

Drug Interactions
While no specific drug interactions have been reported, silymarin may inhibit cytochrome P450 isoenzyme 2C9 (CYP2C9). Drugs with narrow therapeutic indexes that are metabolized by this isoenzyme should be used with caution when using silymarin. Drugs that could be affected include: warfarin, amitriptyline, verapamil, etc.

Silymarin also may inhibit CYP3A4, but thus far this interaction does not appear to be clinically significant. Silymarin may increase the clearance of drugs that undergo hepatic glucuronidation (not cats), including: acetaminophen, diazepam, morphine, and lamotrigine. Clinical significance has not been determined for this interaction and the usefulness of silymarin for treating acetaminophen toxicity has not been determined.

Laboratory Considerations
- No interactions with laboratory tests are reported.

Doses
- **DOGS/CATS:**
  - a) Therapeutic dosage is unknown, but studies suggest silymarin doses range from 50–250 mg/day (Twedt 2004)
  - b) For adjunctive therapy for chronic liver disease: 20–50 mg/kg per day (extrapolated from human, monkey, rodent and dog research) (Center 2002)
  - c) For chronic liver disease and ameliorating the effects of anticonvulsants: Dosages vary from 50–200 mg given every 12–24 hours (Tams 2001)
  - d) For hepatotoxicity, hepatic recovery/regeneration, hepatic fibrosis: 20–50 mg/kg/day. (Webb 2007)
  - e) Cats: 4–8 mg/kg/day (Zoran 2006)

Monitoring
- Clinical efficacy

Client Information
- May cause diarrhea or vomiting. If these persist or are severe, contact veterinarian.
- These products are not evaluated or approved by the FDA

Chemistry/Synonyms
Milk Thistle, the common name for *Silybum marianum*, has been used as a medicinal agent for at least two thousand years. The medicinal extract from the seeds of the plant is silymarin that contains the four flavolignans: silichristin (sylrichristin), isoosilbin, silydianin (silydidianin), and the most biological active component, silybin (silibin, silybin, silybibe). Milk Thistle extract contains approximately 70% silymarin of which about 70% is silybin. Silymarin is reportedly fairly insoluble in water.

Silymarin or Milk thistle may also be known as *Carduus marianus*, Holy Thistle, Legalon, or Marian Thistle. Blessed Thistle is a different compound.

Storage/Stability
Unless otherwise labeled, commercially available products containing silymarin should be stored at room temperature in tight containers. Avoid storing the products in areas of high humidity.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**
Milk Thistle or silymarin is considered a nutritional supplement by the FDA. No standards have been accepted for potency, etc. by regulatory bodies. Supplements are available from a wide variety of sources and dosage forms include tablets and capsules in a variety of concentrations (150–1000 mg). When choosing a product it is recommended to purchase ones that state the concentration (usually 70–80%) of silymarin contained in the product.

- Silybin A+B 9 mg (in a phosphatidylcholine complex) & Vitamin E 50 Units Tablets: Marin® for Cats (Nutramax); Not considered a drug by the FDA.
- Silybin A+B 24 mg (in a phosphatidylcholine complex), Vitamin E 105 Units, & Zinc 17 mg Chewable Tablets: Marin® for Dogs (Nutramax); Not considered a drug by the FDA. Labeled for use in small to medium dogs.
- Silybin A+B 70 mg (in a phosphatidylcholine complex), Vitamin E 300 Units, & Zinc 45 mg Chewable Tablets: Marin® for Dogs (Nutramax); not considered a drug by the FDA. Labeled for use in large dogs.
- A combination product (Denamarin®, Nutramax) containing SAMe and silybin (silymarin) is also labeled for use in dogs and cats.

**HUMAN-LABELED PRODUCTS:** None as pharmaceuticals

References

Sodium Bicarbonate

*note: use with caution in hyperkalemic heart failure (Hardy)*
Sodium bicarbonate is indicated to treat metabolic acidosis and alkalinize the urine. It is also used as adjunctive therapy in treating hypercalcemic or hyperkalemia crises.

**Pharmacology/Actions**

Bicarbonate ion is the conjugate base component of bicarbonate: carbonic acid buffer, the principal extracellular buffer in the body.

**Contraindications/Precautions/Warnings**

Parenterally administered sodium bicarbonate is considered generally contraindicated in patients with metabolic or respiratory alkalosis, excessive chloride loss secondary to vomiting or GI suction, at risk for development of diuretic-induced hyperchloremic alkalosis, or with hypocalcemia where alkalosis may induce tetany.

Use with extreme caution and give very slowly in patients with hypocalcemia. Because of the potential sodium load, use with caution in patients with CHF, nephrotic syndrome, hypertension, oliguria, or volume overload.

**Adverse Effects**

Sodium bicarbonate therapy (particularly high-dose parenteral use) can lead to metabolic alkalosis, hypokalemia, hypocalcemia, “overshoot” alkalosis, hypernatremia, volume overload, congestive heart failure, shifts in the oxygen dissociation curve causing decreased tissue oxygenation, and paradoxical CNS acidosis leading to respiratory arrest. If used during CPR: hypercapnia, if the patient is not well ventilated; patients may be predisposed to ventricular fibrillation.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving sodium bicarbonate and may be of significance in veterinary patients:

- **SUCRALSE:*** Oral sodium bicarbonate may reduce the efficacy of sucralfate if administered concurrently
- **SALICYLATES:*** When urine is alkalinized by sodium bicarbonate, excretion of weakly acidic drugs may be increased
- **CIPROFLOXACIN; ENROFLOXACIN:*** The solubility of ciprofloxacin and enrofloxacin is decreased in an alkaline environment; patients with alkaline urine should be monitored for signs of crystalluria
- **CORTICOSTEROIDS:*** Patients receiving high dosages of sodium bicarbonate and ACTH or glucocorticoids may develop hyperkalemia
- **DIURETICS (e.g., thiazides, furomedil):*** Concurrent use of sodium bicarbonate in patients receiving potassium-wasting diuretics may cause hyperchloremic alkalosis
- **EPHEDRINE:*** When urine is alkalinized by sodium bicarbonate, excretion may be decreased
- **HISTAMINE2 BLOCKING AGENTS (e.g., cimetidine, ranitidine):*** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **IRON PRODUCTS:*** Concomitant oral sodium bicarbonate may reduce absorption; administer separately
- **ORAL MEDICATIONS:*** Because oral sodium bicarbonate can either increase or reduce the rate and/or extent of absorption of many orally administered drugs, it is recommended to avoid giving other drugs within 1–2 hours of sodium bicarbonate
- **QUINIDINE:*** When urine is alkalinized by sodium bicarbonate, excretion may be decreased
- **SALICYLATES:*** When urine is alkalinized by sodium bicarbonate, excretion of weakly acidic drugs may be increased
- **SUCRALFATE:*** Oral sodium bicarbonate may reduce the efficacy of sucralfate if administered concurrently
- **TETRACYCLINES:*** Concomitant oral sodium bicarbonate may reduce absorption; administer separately

**Doses**

For severe metabolic acidosis:

- **Main therapeutic goal should be to eliminate the underlying cause of acidosis. If causes are not readily reversible, arterial pH is <7.2 (7.1 if diabetic ketoacidosis), and ventilatory procedures have not reduced acidemia, bicarbonate therapy should be considered. mEq of bicarbonate required = 0.5 x body weight in kg x desired total CO2 mEq/L minus measured total CO2 mEq/L. Give ½ of the calculated dose slowly over 3–4 hours IV. Recheck blood gases and assess the clinical status of the patient. Avoid over-alkalinization.** (Schaer 2006)

b) For metabolic acidosis secondary to uremia: In the majority of patients, definitive treatment of the urinary tract disorder and fluid diuresis is usually all that is required. In the unstable dog or cat with a pH <7.0 due to metabolic acidosis, sodium bicarbonate administration should be considered. The formula often recommended is 0.3 x body weight (kilograms) x the base deficit. This gives an approximation for the total bicarbonate deficit. Administration of one third of this dose slowly IV and the rest placed in the intravenous fluids will correct the metabolic acidosis over several hours. If measurement of blood gas is not possible and it is believed that the animal is severely acidemic, 1–2 mEq/kg of bicarbonate can be given as a slow IV bolus. Rapid intravenous boluses of sodium bicarbonate should be avoided because of the production of carbon dioxide and its diffusion into the central nervous system making CSF acidosis even worse. Other disadvantages of sodium bicarbonate administration include shifting of the oxygen/hemoglobin dissociation curve to the left and increasing osmolarity. When monitoring the response to bicarbonate through the measurement of blood gases, remember that bicarbonate will increase initially in the intravascular space but then will be buffered by intracellular buffers. Immediate measurement of blood gases after bicarbonate administration may over-estimate the effect of the therapy. Diffusion and buffering of administered bicarbonate by intracellular buffers takes approximately 2-4 hours and a blood gas analysis should be performed after this time period as well. (Drobetz 2009)

c) For metabolic acidosis in acute critical situations (cardiac arrest): Sodium bicarbonate is generally not necessary unless a metabolic acidosis was present before the arrest or the CPR is extending beyond 10–20 minutes. It is definitely not given in those animals not being ventilated well. Both venous and arterial blood gas analysis is recommended to accurately determine if or how much bicarbonate is required. In most cases
Sodium Bicarbonate Neutralizing Additive Solution: 4% (0.48 mEq/mL) in 5 mL (2.4 mEq) vials; 4.2% (0.5 mEq/mL) in 5 mL fill in 6 mL vials (2.5 mEq).

Injectable Products:

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 50 mL (50 mEq/vial), 100 mL (100 mEq/vial) and 500 mL (500 mEq/vial) vials; available generically labeled.

Dosage Forms/Regulatory Status

(1) level teaspoon (5 mL) of commercially-available baking soda contains approximately 4.8–5.9 grams of sodium bicarbonate.

Sulfate, meperidine HCl, methadone HCl, metoclopramide HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, and succinylcholine chloride.

Cisplatin, codeine phosphate, corticotropin, dobutamine HCl, epinephrine HCl, glycopyrrolate, hydromorphone HCl, imipenem-cilastatin, regular insulin, isoproterenol HCl, labetolol HCl, levorphanol bitartrate, magnesium sulfate, meperidine HCl, methadone HCl, metoclopramide HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, and succinylcholine chloride.

Specialized references or a hospital pharmacist for more specific information.

Sodium bicarbonate for injection is reportedly physically compatible with the following intravenous solutions and drugs: Dextrose in water, dextrose/saline combinations, dextrose-Ringer’s combinations, sodium chloride injections, amikacin sulfate, aminophylline, amphotericin B, atropine sulfate, bretylium tosylate, cephalosporins, chloramphenicol sodium succinate, chlorothiazide sodium, cimetidine HCl, clindamycin phosphate, ergonovine maleate, erythromycin gluceptate/lactobionate, heparin sodium, hyaluronidase, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, metaraminol bitartrate, methotrexate sodium, oxytocin, penicillin G potassium, pentobarbital sodium, promazine HCl, promethazine HCl, quinidine sulfate, regular insulin, sodium bicarbonate, streptomycin sulfate, sucralfate, succinylcholine chloride, sucrose 50%, sulfadiazine sodium, and vancomycin HCl.

Compatibility/Compounding Considerations

Sodium bicarbonate for injection is reportedly physically incompatible with the following solutions or drugs: Alcohol 5%/dextrose 5%, D5 lactated Ringer’s, amrinone lactate, ascorbic acid injection, carmustine, cisplatin, codeine phosphate, corticotropin, dobutamine HCl, epinephrine HCl, glycopyrrolate, hydromorphone HCl, imipenem-cilastatin, regular insulin, isoproterenol HCl, labetolol HCl, levorphanol bitartrate, magnesium sulfate, meperidine HCl, methadone HCl, metoclopramide HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, and succinylcholine chloride.

Sodium bicarbonate for injection is reportedly physically incompatible with the following solutions or drugs: Alcohol 5%/dextrose 5%, D5 lactated Ringer’s, amrinone lactate, ascorbic acid injection, carmustine, cisplatin, codeine phosphate, corticotropin, dobutamine HCl, epinephrine HCl, glycopyrrolate, hydromorphone HCl, imipenem-cilastatin, regular insulin, isoproterenol HCl, labetolol HCl, levorphanol bitartrate, magnesium sulfate, meperidine HCl, methadone HCl, metoclopramide HCl, norepinephrine bitartrate, oxytetracycline HCl, pentazocine lactate, and succinylcholine chloride.

Because converting volume measurements into weights is not very accurate for powders, it is recommended to actually weigh powders when using them for pharmaceutical purposes. However, if this is not possible, one level teaspoon (5 mL) of commercially-available baking soda contains approximately 4.8–5.9 grams of sodium bicarbonate.

Sodium Bicarbonate may also be known as: baking soda, E500, monosodium carbonate, natrii bicarbonas, natrii hydrogenocarbonas, sal de vichy, sodium acid carbonate, NaHCO3, sodium hydrogen carbonate; many trade names are available.

Storage/Stability

Sodium bicarbonate tablets should be stored in tight containers, preferably at room temperature (15–30°C). Sodium bicarbonate injection should be stored at temperatures less than 40°C and preferably at room temperature; avoid freezing.

Sodium bicarbonate powder is stable in dry air, but will slowly decompose upon exposure to moist air.

Compatibility/Compounding Considerations

Sodium bicarbonate injection is reportedly physically compatible with the following intravenous solutions and drugs: Dextrose in water, dextrose/saline combinations, dextrose-Ringer’s combinations, sodium chloride injections, amikacin sulfate, aminophylline, amphotericin B, atropine sulfate, bretylium tosylate, cephalosporins, chloramphenicol sodium succinate, chlorothiazide sodium, cimetidine HCl, clindamycin phosphate, ergonovine maleate, erythromycin gluceptate/lactobionate, heparin sodium, hyaluronidase, hydrocortisone sodium succinate, kanamycin sulfate, lidocaine HCl, metaraminol bitartrate, methotrexate sodium, oxytocin, penicillin G potassium, pentobarbital sodium, promazine HCl, promethazine HCl, quinidine sulfate, regular insulin, sodium bicarbonate, streptomycin sulfate, sucralfate, succinylcholine chloride, sucrose 50%, sulfadiazine sodium, and vancomycin HCl.

Dosage Forms/Regulatory Status

VETERINARY-LAbeLED PRODUCTS:

Sodium Bicarbonate Injection: 8.4% (1 mEq/mL) in 50 mL (50 mEq/vial), 100 mL (100 mEq/vial) and 500 mL (500 mEq/vial) vials; available generically labeled; (Rx)

HUMAN-LAbeLED PRODUCTS:

Injectable Products:

Sodium Bicarbonate Neutralizing Additive Solution: 4% (0.48 mEq/mL) in 5 mL (2.4 mEq) vials; 4.2% (0.5 mEq/mL) in 5 mL fill in 6 mL vials (2.5 mEq); Neut® (Abbott); generic (American Pharmaceutical Partners); (Rx)
**SODIUM POLYSTYRENE SULFONATE**

*(conjunctive polyelectrolyte resin)*

**CATIONIC EXCHANGE RESIN (HYPERKALEMIA)**

### Prescriber Highlights

- **Cation exchange resin used to treat hyperkalemia**
- **Contraindications:** Patients who cannot tolerate a large sodium load
- **Cause of hyperkalemia must be addressed**
- **Adverse Effects:** Constipation, anorexia, vomiting, or nausea. Overdosage/overuse may lead to hypokalemia, hypocalcemia & hypomagnesemia.
- **If given PO, often mixed with sorbitol to expedite removal of resin (& potassium)**
- **Drug Interactions**

### Uses/Indications

SPS is indicated as adjunctive treatment of hyperkalemia. The cause of the hyperkalemia should be elucidated and corrected if possible.

### Pharmacology/Actions

SPS is a resin that exchanges sodium for other cations. After being given orally, hydrogen ions will be exchanged for sodium (in an acidic environment). As the resin travels through the intestinal tract, the hydrogen ions will be exchanged with other more concentrated cations. Primary exchange with potassium occurs predominantly in the large intestine. When given as a retention enema, SPS generally exchanges sodium for potassium directly in the colorectum. While theoretically, up to 3.1 mEq of potassium could be exchanged per gram of SPS, it is unlikely that more than one mEq will be exchanged per gram of resin administered.

### Pharmacokinetics

SPS is not absorbed from the GI tract. Its onset of action may be from hours to days; so severe hyperkalemia may require other treatments (e.g., dialysis) in the interim.

### Contraindications/Precautions/Warnings

Because large quantities of sodium may be released and absorbed, patients on severely restricted sodium diets (severe CHF, hypertension, oliguria) may benefit from alternative methods of treatment. Overdosage/overuse may lead to hypokalemia, hypocalcemia and hypomagnesemia.

### Adverse Effects

Large doses may cause constipation (faecal impactions have been reported rarely), anorexia, vomiting or nausea. Dose related hypokalemia, hyperkalemia and sodium retention have also been noted. To hasten the drug’s action and prevent constipation, SPS is generally mixed with 70% sorbitol (3–4 mL per one gram of resin) when doses orally.

### Reproductive/Nursing Safety

While reproductive studies have apparently not been performed, it is unlikely the drug carries much teratogenic potential. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

As SPS is not absorbed, it should be safe to use during nursing.

### Overdosage/Acute Toxicity

Overdosage may cause the adverse effects noted (above); treat symptomatically.

### Drug Interactions

-------

**References**

The following drug interactions have either been reported or are theoretical in humans or animals receiving SPS and may be of significance in veterinary patients:

**ANTACIDS, LAXATIVES (calcium- or magnesium-containing):** SPS may bind with magnesium or calcium found in laxatives (milk of magnesia, magnesium sulfate, etc.) or antacids which can prevent bicarbonate ion neutralization and lead to metabolic alkalosis. Concurrent use is not recommended during SPS therapy.

**Doses**

If dosed orally, to hasten the drug’s action and to prevent constipation SPS is generally mixed with 70% sorbitol (3–4 mL per one gram of resin); shake well before using.

**DOGS:**

a) For hyperkalemia: 2 grams of resin/kg of body weight (each gram should be suspended in 3–4 mL of water; or use commercially prepared suspension products) divided into 3 daily doses. If given orally, give with a cathartic. Do not use a cathartic if using as a retention enema as it must be in the colon for at least 30 minutes. To prepare a retention enema from the powder: add 15 grams per 100 mL of a 1% methylcellulose solution or 10% dextrose. If hyperkalemia is severe: 3–4 times the normal amount of resin may be given. (Willard 1986)

b) For mild hyperkalemia (<6 mEq/L): 2 grams/kg PO in 3–4 divided doses with 20% sorbitol; may also be given as an enema without sorbitol. (Cowgill & Francey 2005)

**HORSES:**

a) For life-threatening hyperkalemia in neonatal foals: 15 grams of resin in 100 mL of 10% dextrose via enema. Monitor serum potassium and sodium closely. (Madigan 2002)

**Monitoring**

- Serum electrolytes (sodium potassium (at least once a day), calcium, magnesium
- Acid/base status, ECG, if warranted

**Chemistry/Synonyms**

A sulfonated cation exchange resin, sodium polystyrene sulfonate (SPS) occurs as a golden brown, fine powder. It is odorless and tasteless. Each gram contains 4.1 mEq of sodium and has an in vitro exchange capacity of about 3.1 mEq of potassium (in actuality a maximum of 1 mEq is usually exchanged).

Sodium Polystyrene Sulfonate may also be known as: nutri polystyrenesulfonam, sodium polystyrene sulphonate, Elatit-Natrium®, K-Exit®, Kayexalate®, Kexelate®, Kionex®, Resinsodio®, Resonium®, Resonium A®, or SPS®.

**Storage/Stability**

Store products in well-closed containers at room temperature; do not heat. Suspensions made from powder should be freshly prepared and used within 24 hours.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Sodium Polystyrene Sulfonate Powder: Sodium content is approximately 100 mg (4.1 mEq) per g; in 1 lb. jars & 454 g; Kayexalate® (Sanofi Winthrop); Kionex® (Paddock); (Rx)
- Sodium Polystyrene Sulfonate Suspension: 15 grams/60 mL (sodium 1.5 grams, 65 mEq) in 60 mL, 120 mL, 200 mL, 480 mL, 500 mL and UD 60 mL; SPS® (Carolina Medical Products Co); generic (Roxane); (Rx)

**References**

**SODIUM STIBOGLUCONATE**

**SODIUM ANTIMONY GLUCONATE**

-sti-bo-glo-koe-nate; an-di-moe-nee
glu-koe-nate; Penstiban®

**ANTILEISHMANIAL**

Prescriber highlights

- Antimony compound for treatment of leishmaniasis in humans & dogs
- Not commercially available in USA (CDC distributes)
- Contraindicated in renal failure, pre-existing arrhythmias
- Many potential adverse effects, including some very serious

**Uses/Indications**

Sodium stibogluconate is used for the treatment of leishmaniasis in dogs.

**Pharmacology/Actions**

Sodium stibogluconate’s exact mode of action is unknown. It is believed that it may reduce ATP and GTP synthesis in susceptible amastigotes.

**Pharmacokinetics**

In dogs, stibogluconate’s volume of distribution (steady-state) was 0.25 L/kg, clearance 1.71 L/kg/hr, and terminal half-life ranged from 0.6–1.5 hours. The main route of excretion is via the kidneys; glomerular filtration rate determines excretion rate.

**Contraindications/Precautions/Warnings**

Stibogluconate is contraindicated in patients with pre-existing cardiac arrhythmias, or significantly impaired renal function. It should not be used in those that have had a serious adverse reaction to a previous dose.

**Adverse Effects**

Dogs given 40 mg/kg of stibogluconate developed increased AST levels. Other reported adverse effects (incidence unknown) include pain on injection, musculoskeletal pain, hemolytic anemia, leukopenia, vomiting, diarrhea, pancreatitis, myocardial injury and arrhythmias, renal toxicity, shock and sudden death. Intravenous administration can cause thrombophlebitis. Reportedly, the incidence of adverse effects increases if the drug is administered for longer than 2 months.

**Reproductive/Nursing Safety**

Sodium stibogluconate has not been shown to cause fetal harm, but the manufacturer states that the drug should be withheld during pregnancy unless the benefits outweigh the risks.

The use of this drug during nursing is controversial. Some (e.g., The American Academy of Pediatrics) say that it is usually compatible with breast-feeding, but the manufacturer states that it should not be used in
Sodium thiosulfate's topical antifungal activity is probably due to its slow release of colloidal sulfur.

Sodium thiosulfate has been used in humans to treat extravasation injuries secondary to carboplatin or cisplatin, for prophylaxis to prevent nephrotoxicity after cisplatin overdoses and ototoxicity with carboplatin overdoses. In combination with steroids, sodium thiosulfate may reduce the healing time associated with doxorubicin extravasation.

Uses/Indications
Sodium thiosulfate (alone or in combination with sodium nitrite) is useful in the treatment of cyanide toxicity. It has been touted for use in treating arsenic (and some other heavy metal) poisonings, but its efficacy is in question. Presumably, the sulfate moiety may react with and chelate the metal allowing its removal.

Uses/Indications
Sodium thiosulfate has been used in humans to treat extravasation injuries secondary to carboplatin or cisplatin, for prophylaxis to prevent nephrotoxicity after cisplatin overdoses and ototoxicity with carboplatin overdoses. 

Pharmacology/Actions
By administering thiosulfate, an exogenous source of sulfur is available to the body, thereby hastening the detoxification of cyanide using the enzyme rhodanese. Rhodanese (thiosulfate cyanide sulfurtransferase) converts cyanide to the relatively nontoxic thiocyanate ion; thiocyanate is then excreted in the urine.

Sodium thiosulfate has been used in humans to treat extravasation injuries secondary to carboplatin or cisplatin, for prophylaxis to prevent nephrotoxicity after cisplatin overdoses and ototoxicity with carboplatin overdoses.

Sodium thiosulfate’s topical antifungal activity is probably due to its slow release of colloidal sulfur.

While sodium thiosulfate has been recommended for treating arsenic (and some other heavy metal) poisoning, the proposed mechanism of action is not known and its efficacy is in question. Presumably, the sulfate moiety may react with and chelate the metal allowing its removal.
Sodium thiosulfate is relatively poorly absorbed from the GI tract. When substantial doses are given PO, it acts as a saline cathartic. When administered intravenously, it is distributed in the extracellular fluid and then rapidly excreted via the urine.

**Contraindications/Precautions/Warnings**

There are no absolute contraindications to the use of the drug.

**Adverse Effects**

The drug is relatively non-toxic. Large doses by mouth may cause profuse diarrhea. Injectable forms should be given slowly IV.

**Reproductive/Nursing Safety**

Safe use during pregnancy has not been established; use when benefits outweigh the potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

No lactation information was found.

**Drug Interactions/Laboratory Considerations**

- **No specific drug or laboratory interactions or considerations were noted.**

**Doses**

- **DOGS/CATS:**
  - a) For cyanide toxicity: Contact an animal poison control center for guidance.
  - b) For treating extravasation injuries secondary to doxorubicin, carboplatin, cisplatin infusions: *Note:* These are recommendations for human patients.
    
    - Doxorubicin: Subcutaneous sodium thiosulfate 2% added to therapy with subcutaneous hydrocortisone and topical betamethasone decreased the healing time by half for cytotoxic drug extravasation (including doxorubicin and epirubicin) when compared to therapy without sodium thiosulfate.
    
    - Carboplatin: Prepare a 0.17 moles/L solution by mixing 4 mL sodium thiosulfate 10% w/v with 6 mL sterile water for injection. Inject 5 mL into extravasation site.
    
    - Cisplatin: For extravasation of large amounts (greater than 20 mL) of highly concentrated (greater than 0.5 mg/mL) solutions: Prepare a 0.17 moles/L solution by mixing 4 mL sodium thiosulfate 10% w/v with 6 mL sterile water for injection. Inject into extravasation site. (*Drugdex* Evaluations. Micromedex Healthcare Series; Thompson, 2007)

- **HORSES:**
  - a) For cyanide toxicity: First give sodium nitrite at a dose of 16 mg/kg IV followed with a 20% solution of sodium thiosulfate given at a dose of 30–40 mg/kg IV. If repeating treatment, use sodium thiosulfate only. (Bailey & Garland 1992)
  - b) For cyanide toxicity: First give sodium nitrite in a 20% solution at a dose of 10–20 mg/kg IV followed with a 20% solution of sodium thiosulfate given at a dose of 30–40 mg/kg IV (Osweiler 2003)
  - c) For arsenic toxicity: Sodium thiosulfate at 20–30 grams in 300 mL of water orally with dimercaprol (BAL) 3 mg/kg IM q4h (Jones 2004)

- **RUMINANTS:**
  - a) In combination with sodium molybdate for the treatment of copper poisoning: In conjunction with fluid replacement therapy, 500 mg sodium thiosulfate in combination with 200 mg ammonium or sodium molybdate PO daily for up to 3 weeks will help decrease total body burden of copper (Thompson & Buck 1993)
  - b) For treatment of cyanide toxicity secondary to cyanogenic plants: 660 mg/kg IV sodium thiosulfate in a 30% solution given rapidly using a 12 or 14 gauge needle. (Post & Keller 2000)
  - c) For treatment of arsenic poisoning: 30–60 grams PO every 6 hours for 3–4 days and 30–60 grams as a 10–20% solution IV may be potentially useful in binding arsenic. Adjunctive fluid and electrolyte replacement is necessary. (Galey 1993)

**Chemistry/Synonyms**

- Sodium thiosulfate occurs as large, colorless crystals or coarse, crystalline powder. It is very soluble in water, deliquescent in moist air and effloresces in dry air at temperatures >33°C.

- Sodium thiosulfate may also be known as: natrii thiosulfas, natrium thiosulfuricum, sodium hyposulphite or sodium thiosulphate

**Storage/Stability**

- Unless otherwise stated by the manufacturer, store at room temperature. Crystals should be stored in tight containers.

- Sodium thiosulfate is not compatible mixed with cyanocobalamin.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Sodium Thiosulfate for Injection: 10% (100 mg/mL, as pentahydrate) & 25% (250 mg/mL as pentahydrate) preservative-free in 10 mL & 50 mL single-use vials; generic; (Rx)

**References**

- Note: When used in food animals, FARAD states that this salt is rapidly excreted and is not considered a residue concern in animal tissues; therefore, a 24 hour preslaughter withdrawal interval (WDI) would be sufficient. (Haskell et al. 2005)

**SOMATOTROPIN**

(GROWTH HORMONE)

- Used for canine hypopituitary dwarfism or growth hormone-responsive dermatosis (in adult dogs).
- May cause diabetes mellitus
- Availability & expense issues
Uses/Indications
Somatotropin may be useful in treating hypopituitary dwarfism or growth hormone-responsive dermatosis (in adult dogs).

Pharmacology/Actions
Growth hormone (somatotropin) is responsible for, or contributes to, linear and skeletal growth, organ growth, and cell growth. It also is a factor in protein, carbohydrate, lipid, connective tissue, and mineral metabolism.

Pharmacokinetics
No canine information was located. Both the liver and kidney are major elimination organs for somatotropin.

Contraindications/Precautions/Warnings
Growth hormone derived from other species is contraindicated in patients hypersensitive to it.

Adverse Effects
Growth hormone may cause diabetes mellitus in dogs. This may be transient or permanent even after discontinuing treatment. Blood and urine glucose should be routinely monitored. If blood glucose exceeds 150 mg/dL, therapy should be stopped. Hypersensitivity reactions are possible, but less so if using porcine origin product. Long-term treatment at high doses may cause acromegaly. Acromegaly in dogs can cause increased size of paws and head, increased skin folds around head and neck area, prognathism, and inspiratory stridor.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Overdosage/Acute Toxicity
Acute overdosage could cause hypoglycemia initially and then hyperglycemia. Blood glucose should be monitored and supportive treatment (glucose/insulin) performed.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving somatotropin and may be of significance in veterinary patients:

GLUCOCORTICOIDS: May inhibit the growth promoting effect of somatotropin. When concurrent adrenal insufficiency is diagnosed, adjust glucocorticoid dose carefully to avoid negative effects on growth.

Doses

**DOGS:**

a) For treatment of hypopituitary dwarfism: 0.1 Unit (0.05 mg)/kg SC three times per week for 4–6 weeks. **Note:** May also require life-long thyroid hormone supplementation and if secondary adrenal insufficiency present, glucocorticoid treatment. If after successful treatment, dermatologic signs recur, may dose as above (0.1 Unit/kg three times weekly for one week). Repeat these weekly regimens at intervals determined by the time lapse between treatments and relapse. (Feldman & Nelson 1996)

b) For treatment of growth hormone-responsive dermatosis in adult dogs: Dose as above (a), but thyroid and steroid supplementation not required (Feldman & Nelson 1996)

c) For Alopecia X: 0.15 Units/kg of porcine growth hormone SC 2 times weekly for 6 weeks. (Hillier 2006)

Monitoring

- Clinical efficacy
- Blood glucose (weekly)
- Urine glucose (daily)
- Thyroid function, adrenal function initially and then periodically (pituitary dwarfism pts.)

Client Information

- Clients should be instructed on the methods for SC injection and testing urine glucose
- May be expensive to treat and diabetes (permanent) can occur

Synonyms
Somatotropin may also be known as: CB-311, HGH, human growth hormone, LY-137998, somatropinum; many trade names are available.

Dosage Forms/Regulatory Status

There are several manufacturers of human recombinant DNA origin somatotropin products, but these are expensive, can cause immunogenicity reactions in dogs, and not sold for veterinary use.

The bovine recombinant growth hormone product (Posilac®—Monsanto) is not suitable for canine use as it is a sustained release formulation and not easily diluted down to the smaller doses required for dogs.

Porcine growth hormone appears to have little immunogenicity in dogs and reportedly can be obtained via: Dr A. F. Partlow at: 310-222-3537 E-Mail: Partlow@HUMC.edu WEBSITE: www.humc.edu/hormones

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

References

Sotalol may be useful in the treatment of ventricular tachycardias and, possibly, supraventricular tachycardias in dogs and cats. It is most often used in Boxers or in cases with ventricular tachycardia that are refractory to lidocaine.

**Pharmacology/Actions**

Sotalol is a non-selective beta-blocker and Class III antiarrhythmic agent. The beta blocking activity of sotalol is about 30% that of propranolol. Its primary usage in veterinary medicine is associated with its antiarrhythmic activity. Like other Class III drugs, it prolongs repolarization and refractoriness without affecting conduction. The pharmacologic action is believed caused by selectively inhibiting potassium channels.

**Pharmacokinetics**

Unlike propranolol, sotalol does not have any appreciable first pass effect after oral administration. Food may reduce the bioavailability of sotalol by approximately 20% (human data) and, if given on an empty stomach, bioavailability is 90–100%. The drug has relatively low lipid solubility and virtually no protein binding. Elimination is almost all via the kidney and most of the drug is excreted unchanged. In dogs, sotalol’s elimination half-life is 5 hours; in humans about 12 hours.

**Contraindications/Precautions/Warnings**

Sotalol is considered contraindicated in patients with asthma, sinus bradycardia, 2nd or 3rd degree heart block (unless artificially paced), long Q-T syndromes, cardiogenic shock or uncontrolled CHF. Because of the potential for negative inotropic effects, use with caution in CHF. Also, use with caution in patients with diabetes mellitus, or hyperthyroidism (may mask signs). Use with caution in patients with renal dysfunction; dosage intervals may need to be extended.

**Adverse Effects**

Primary concerns with sotalol in dogs are the potential for negative inotropic and proarrhythmic effects. These generally are not clinically important if dosage is not excessive. Other potential adverse effects include dyspnea/bronchospasm, fatigue/dizziness, and nausea/vomiting. Sotalol’s beta blocking effects can worsen syncope or cause lethargy, particularly if the ventricular tachyarrhythmia coexists with intermittent bradycardia (e.g., AV block).

**Reproductive/Nursing Safety**

Sotalol did not cause any fetotoxicity or teratogenicity when given to pregnant lab animals at high dosages, but clear safety in pregnancy has not been established. Sotalol enters maternal milk in concentrations up to 5X found in the serum; consider using milk replacer in nursing animals.

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Sotalol is excreted in milk; use with caution in nursing patients. It is not recommended for use in nursing humans.

**Overdosage/Acute Toxicity**

Overdoses may result in bradycardia, hypotension, CHF, bronchospasm, and hypoglycemia. Use gut evacuation (if not contraindicated) when significant risk of morbidity is possible. Treat adverse effects symptomatically and supportively.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving sotalol and may be of significance in veterinary patients:

- **AMIODARONE:** May prolong refractory periods; concurrent use not recommended in human patients
- **ANESTHETICS, GENERAL:** Additive myocardial depression may occur with the concurrent use of sotalol and myocardial depressant anesthetic agents
- **ANTACIDS:** May reduce oral sotalol absorption; separate doses by at least 2 hours
- **ANTIARRHYTHMICS, CLASS IA (quinidine, procainamide, disopyramide):** May prolong refractory periods; concurrent use not recommended in human patients; may also prolong QT interval
- **ANTIARRHYTHMICS, CLASS IB, IC (lidocaine, mexitelitne, phenytoin, flecainide etc.):** May prolong QT interval
- **CALCIUM CHANNEL BLOCKERS (verapamil, diltiazem, etc.):** Potential to increase hypotensive effects; may have additive effects on AV conduction or ventricular function; use with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **CISAPRIDE:** May prolong QT interval
- **CLONIDINE:** If clonidine is discontinued after concomitant therapy with sotalol, there is an increased risk for rebound hypertension
- **DIGOXIN:** Potential for increased risks for proarrhythmic events
- **ERYTHROMYCIN; CLARITHROMYCIN:** May prolong QT interval
- **LIDOCAINE:** Clearance may be impaired by sotalol
- **PHENOThIAZINES:** May prolong QT interval
- **RESERPINE:** May have additive effects (hypotension, bradycardia) with sotalol
- **SYMPATHOMIMETICS, BETA 2 AGONISTS (e.g., metaproterenol, terbutaline, albuterol):** May have their actions blocked by sotalol
- **TRICYCLIC ANTIDEPRESSANTS:** May prolong QT interval

**Laboratory Considerations**

- Beta-blockers may produce hypoglycemia and interfere with glucose or insulin tolerance tests
- Sotalol may falsely elevate urine metanephrine levels (pheochromocytoma screen) if using a fluorometric or photometric assay

**Doses**

- **DOGS:**
  a) 1–2 mg/kg PO q12h (Fox 2003), (Moise 2002), (Marks 2009; Smith 2007)
  b) 1–3 mg/kg PO twice daily. (Henik 2007)
  c) For ventricular tachycardia: 1–2 mg/kg PO twice daily (Atkins 2003)
  d) For ventricular tachyarrhythmias in Boxers in combination with mexiletine: Sotalol 1.5–3 mg/kg PO twice daily with mexiletine (5–7.5 mg/kg PO three times daily). (Prosek et al. 2006)
  e) In Boxers: 40–80 mg (total dose) PO q12h. (Mucha 2009)

- **CATS:**
  a) 2 mg/kg PO twice daily (Atkins 2003)
  b) For ventricular tachyarrhythmias: 2 mg/kg PO q12h (Cote 2010)
  c) 1–2 mg/kg PO q12h. (Marks 2009)
  d) ¼th of an 80 mg tablet PO twice daily, or approximately 2 mg/kg PO twice daily. (Henik 2007)

**Monitoring**

**Efficacy (ECG)**

**Adverse effects**
**Uses/Indications**

Although occasionally used in dogs, cats, and horses for susceptible infections, Spectinomycin only has FDA-approved dosage forms for cattle, chickens, turkeys, and swine. Refer to the Dosage section below for more information on FDA-approved uses.

**Pharmacology/Actions**

Spectinomycin is primarily a bacteriostatic antibiotic that inhibits protein synthesis in susceptible bacteria by binding to the 30S ribosomal subunit. Spectinomycin has activity against a wide variety of gram-positive and gram-negative bacteria, including *E. coli*, Klebsiella, Proteus, Enterobacter, Salmonella, Streptococci, Staphylococcus, and Mycoplasma. It has minimal activity against anaerobes, most strains of Pseudomonas, Chlamydia, or Treponema.

In human medicine, spectinomycin is used principally for its activity against *Neisseria gonorrhoeae*.

**Pharmacokinetics**

After oral administration only about 7% of the dose is absorbed, but the drug that remains in the GI tract is active. When injected SC or IM, the drug is reportedly absorbed well with peak levels occurring in about 1 hour. Tissue levels of absorbed drug are lower than those found in the serum. Spectinomycin does not appreciably enter the CSF or the eye and is not bound significantly to plasma proteins. It is unknown whether spectinomycin crosses the placenta or enters milk.

**Contraindications/Precautions/Warnings**

- **Contraindications:** Hypersensitive to it
- **Adverse Effects:** Appears to have minimal adverse effects at labeled dosages; probably less nephrotoxicity/ototoxicity than other aminocyclitols. Can cause neuromuscular blockade. May cause swelling at SC injection sites.

Drug Interactions

Antagonism has been reported when spectinomycin is used with chloramphenicol or tetracycline.

Doses

**DOGS:**

For susceptible infections:
- a) 5.5–11 mg/kg q12h IM or 22 mg/kg PO q12h (for enteric infections; not absorbed) (Kintzer & Peterson 1989)
- b) 5–10 mg/kg IM q12h (Davis 1985)
- c) For acute infectious gastroenteritis: 5–12 mg/kg IM q12h (DeNovo 1986)

**CATS:**

For susceptible infections:
- a) For acute infectious gastroenteritis: 5–12 mg/kg IM q12h (DeNovo 1986)

**CATTLE:**

For susceptible infections:
- a) For bronchopneumonia and fibrinous pneumonia: 33 mg/kg SC q6h. Suggested withdrawal time is 60 days. (Hjerpe 1986)
- b) 22–39.6 mg/kg/day IM divided three times daily (Upson 1988)
- c) For bovine respiratory disease: 10–15 mg/kg SC (in the neck; not more than 50 mL per site) once daily (q24h) for 3–5 consecutive days (Label directions; Adspec®)

**HORSES:**

For susceptible infections:
- a) 20 mg/kg, IM three times daily (Robinson 1987)
- b) For pneumonia: 20 mg/kg IM q8h; may cause local myositis. Insufficient data to comment on use. (Beech 1987)

**SWINE:**

For susceptible enteric infections:
- a) 10 mg/kg, PO q12h (Howard 1986)
- b) For bacterial enteritis (white scours) in baby pigs associated with E. coli susceptible to spectinomycin: 50 mg/10 lbs of body weight PO twice daily for 3–5 days (Label directions; Spectam Scour-Halt®—Ceva)
- c) 10 mg/kg, IM q12h (Baggot 1983)

**BIRDS:**

For air sacculitis associated with M. meleagridis or chronic respiratory disease associated with E. coli in turkey poult (1–3 days old): Inject 0.1 mL (10 mg) SC in the base of the neck.

For control and to lessen mortality due to infections from M. synoviae, S. typhimurium, S. infantis, and E. coli in newly hatched chicks: Dilute injection with normal saline to a concentration of 2.5–5 mg/0.2 mL and inject SC. (Label directions; Spectum® Injectable—Ceva)

For prevention and control of chronic respiratory disease associated with Mycoplasma gallisepticum in broilers: Add sufficient amount to drinking water to attain a final concentration of 2 grams/gallon.

For infections synovitis associated with Mycoplasma synoviae in broilers: Add sufficient amount to drinking water to attain a final concentration of 1 gram/gallon.

For improved weight gain/feed efficiency in floor-raised broilers: Add sufficient amount to drinking water to attain a final concentration of 0.5 grams/gallon. (Label directions; Spectum® Water-Soluble—Ceva)

Monitoring

**Clinical efficacy**

Chemistry/Synonyms

An aminocyclitol antibiotic obtained from Streptomyces spectabilis, spectinomycin is available as the dihydrochloride pentaheptahydrate and hexahydrate sulfate salts. It occurs as a white to pale buff, crystalline powder with pKas of 7 and 8.7. It is freely soluble in water and practically insoluble in alcohol.

Spectinomycin may also be known as: M-141, actinospectacin, spectinomycinii, U-18409AE, Adspec®, Amtech Spectum®, Kemprīt®, Kirit®, Spectoguard Scour-Chek®, Stanil®, Togamycin®, Trobicin®, Trobicinc®, or Vabicinc®.

Storage/Stability

Unless otherwise instructed by the manufacturer, spectinomycin products should be stored at room temperature (15–30°C). Protect from freezing.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:**

Spectinomycin Sulfate Injection: 100 mg/mL in 500 mL vials; Adspec®; (Pharmacia & Upjohn); (Rx). When used as labeled, slaughter withdrawal in cattle = 11 days; not to be used in veal calves or in dairy cattle 20 months of age or older.

Spectinomycin Injection: 100 mg/mL in 500 mL vials; Spectum® Injectable (Teva); (OTC). FDA-approved for use in 1–3 days old turkey poult and newly hatched chicks.

Spectinomycin Water Soluble Concentrate: 0.5 gram of spectinomycin per gram Spectum® Water Soluble (Bimeda); (OTC). FDA-approved for use in chickens (not layers). Slaughter withdrawal (at labeled doses) = 5 days.

Spectinomycin Oral Solution: 50 mg/mL in 240 mL pump bottle and 500 and 1000 mL without pump; Spectum Scour-Halt®, (Teva), Spectoguard Scour-Chek® (Bimeda), Spectum Scour-Halt®, (AgriPharm); (OTC). FDA-approved for use in swine (Weighing less than 15 lbs and not older than 4 weeks of age). Slaughter withdrawal (at labeled doses) = 21 days.

Spectinomycin Lincomycin in a 2:1 ratio

**LS 50 Water Soluble Powder® (Pharmacia & Upjohn); Sepclinx-50® (Bimeda);** generic in 2.65 oz packets. Each packet contains lincomycin 16.7 grams and spectinomycin 33.3 grams. FDA-approved for use in chickens up to 7 days age.

Lincomycin 50 mg/Spectinomycin 100 mg per mL in 20 mL vials; Linco-Spectin® Sterile Solution (Pharmacia & Upjohn); (OTC). FDA-approved for use in semen extenders only.

Prescriber Highlights

- Oral flea adulticide for dogs; labeled for one month prevention/treatment
- Rapid action
- Appears very safe and well tolerated in dogs
- Give with food

Spinosad is indicated for the prevention and treatment of flea (Ctenocephalides felis) infestations for one month in dogs. Advantages of this drug include: rapid response for a systemic once-monthly product, killing adult fleas before egg laying is initiated, efficacy is not affected by bathing or swimming, and FDA-approved (not EPA-approved as are many topical flea products) (Frick 2009).

While the drug is not labeled for use against ticks and it has been stated that it is not effective for this use, a pilot study evaluating the efficacy of spinosad dosed at 50 mg/kg (1.7X minimum flea dose) and 100 mg/kg (3.3X minimum flea dose) against adult brown dog tick (R. sanguineus) infestations in dogs, demonstrated high efficacy in killing ticks within 24 hours. The results suggested that some post-treatment residual tick control persisted up to 1 month. The authors concluded that the role of spinosad as a useful adjunct to currently marketed acaricidal products needs to be explored (Snyder et al. 2009).

In humans, spinosad is a topical suspension that has been used to treat pediculosis capitis (head lice).

Spinosad appears to be very well tolerated in dogs and most animals will not show any adverse effects after dosing. The following adverse reactions are possible and based on post-approval adverse drug event reporting; listed in decreasing order of frequency: vomiting, depression/lethargy, anorexia, ataxia, diarrhea, pruritus, trembling, hypersalivation and seizures.

The chewable tablets are beef flavored and while they do not contain beef proteins, pork proteins and hydrolyzed soy are used. Dogs with pork or soy allergies may react (Rosenkrantz 2010).

The product label cautions use in breeding females and dogs with pre-existing epilepsy at higher than labeled dosages may decrease seizure threshold.

The chewable tablets are beef flavored and while they do not contain beef proteins, pork proteins and hydrolyzed soy are used. Dogs with pork or soy allergies may react (Rosenkrantz 2010).

A study evaluating the safety of spinosad (doses up to 5X) with or without milbemycin (doses up to 10X) in Collies homozygous and heterozygous for the ABCB1 (MDR1) mutation did not cause signs of neurotoxicosis (Sherman et al. 2010).

Client Information

Chemistry/Synonyms
Spironolactone is a spironosyl class insecticide and contains two major factors, spironosyn A and spironosyn D that are derived from the naturally occurring bacterium, *Saccharopolyspora spinosa*. Spinosad may also be known as spironosyn A & B, DE-105, or XDE-105. Trade names include *Comfortis®* and *Natroba®* (human topical), or *Extinosad®*.

**Storage/Stability**
Chewable tablets should be stored at 20-25°C (68-77°F), excursions permitted between 15–30°C (59-86°F).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**
Spinosad Chewable Tablets: 140 mg, 270 mg, 560 mg, 810 mg, 1620 mg; *Comfortis®* (Lilly); (Rx). FDA- approved for use in dogs.

**HUMAN-LABELLED PRODUCTS:**
None for systemic use. There is a topical product (for head lice) Spinosad 0.9% topical suspension in 120 mL: *Natrobe®* (ParaPro; Pernix); (Rx)

**SPIRONOLACTONE** (spör-on-öl-aクト-n) *Aldaktone®* 

**ALDOSTERONE ANTAGONIST**

**Prescriber highlights**

- Aldosterone antagonist used as a potassium sparing diuretic or for adjunctive treatment for heart failure (use is somewhat controversial for CHF in dogs); should not be substituted for furosemide in CHF
- Contraindications: Hyperkalemia, Addison’s disease, anuria, acute renal failure or significant renal impairment
- Caution: Any renal impairment or hepatic disease
- **Adverse Effects:** Facial dermatitis in cats. Hyperkalemia, hyponatremia, & dehydration possible; increased BUN & mild acidosis in patients with renal impairment. GI distress (vomiting, anorexia, etc.), CNS effects (lethargy, ataxia, etc.), & endocrine changes possible

**Uses/Indications**
Spironolactone may be used in patients with congestive heart failure who do not adequately respond to furosemide and ACE inhibitors, who develop hypokalemia on other diuretics, and are unwilling or unable to supplement with exogenous potassium sources. It may also be effective in treating ascites as it has less potential to increase ammonia levels than other diuretics. Spironolactone may find a role in treating renal disease. In rats, it has been shown to decrease proteinuria and glomerulosclerosis in experimental models of renal disease.

**Pharmacology/Actions**
Aldosterone is competitively inhibited by spironolactone in the distal renal tubules with resultant increased excretion of sodium, chloride, and water, and decreased excretion of potassium, ammonium, phosphate, and titratable acid. Spironolactone has no effect on carbonic anhydrase or renal transport mechanisms and has its greatest effect in patients with hyperaldosteronism. When used alone in healthy dogs, spironolactone does not appear to cause significant diuresis (Jenness et al. 2004).

Spironolactone is not commonly used alone as most sodium is reabsorbed at the proximal tubules. Combining it with a thiazide or loop diuretic will yield maximum diuretic effect.

**Prodrug**
After cats received 2.7 mg/kg spironolactone twice daily for 7–9 days, the following serum values increased (on average) significantly: potassium 0.39 mEq/L, calcium 0.48 mg/dL, creatinine 0.22 mg/dL, phosphorus 0.63 mg/dL, and total protein 0.51 mg/dL. (Abbott & Saker 2006)

In humans, spironolactone can have antifibrotic effects on cardiac muscle. Whether this occurs in veterinary patients with heart failure is controversial. One study in Maine Coon cats with hypertrophic cardiomyopathy, but not in heart failure showed that spironolactone did not yield significant changes in diastolic function or left ventricular mass after 4 months of treatment (MacDonald et al. 2008). A study published in dogs with moderate to severe mitral regurgitation, concluded that spironolactone added to conventional therapy, decreased the risk for death, euthanasia or severe worsening of signs (Bernay et al. 2010). This study has met with skepticism by some who are unconvinced that the data supports this conclusion.

**Pharmacokinetics**
Because spironolactone is unstable if frozen and thawed, pharmacokinetic studies in animals are not readily performed. In fasted dogs, oral bioavailability of spironolactone (measured via its main metabolites) is approximately 50%, but increases up to 90% when given with food. About 70% of a dose is found in the feces and 18% in the urine. In a recent pharmacodynamic study done in 15 Beagles, the dose required to inhibit the aldosterone levels associated with CHF in dogs (Guyonnet et al. 2010).

In humans, spironolactone is >90% bioavailable and peak levels are reached within 1–2 hours. The diuretic action of spironolactone (when used alone) is gradually attained and generally reaches its maximal effect on the third day of therapy.

Spironolactone and its active metabolite, canrenone, are both about 98% bound to plasma proteins. Both spironolactone and its metabolites may cross the placenta. Canrenone has been detected in breast milk.

**Spironolactone is rapidly metabolized (half-life of 1–2 hours) to several metabolites, including canrenone, which has diuretic activity. Canrenone is more slowly eliminated, with an average half-life of around 20 hours.**

**Contraindications/Precautions/Warnings**
Spironolactone is contraindicated in patients with hyperkalemia. Addison’s disease, anuria, acute renal failure or significant renal impairment. It should be used cautiously in patients with hepatic disease, but is often used to treat ascites.

**Adverse Effects**
Adverse effects are usually considered mild and reversible upon discontinuation of the drug. Electrolyte (hyperkalemia, hyponatremia) and water balance (dehydration) abnormalities are the most likely effects with spironolactone therapy, but electrolytes in dogs do not appear to be significantly affected.

In a study in Maine Coon cats, approximately ⅔ of treated subjects developed severe facial dermatitis. Transient increases in BUN and mild acidosis may occur in patients with renal impairment. GI distress (vomiting, anorexia, etc.), CNS effects (lethargy, ataxia, headaches in humans, etc.), and endocrine changes (gynecomastia in human males) are all possible.

Spironolactone in patients with renal impairment may lead to hyperkalemia. Spironolactone reportedly inhibits the synthesis of testosterone and may increase the peripheral conversion of testosterone to estradiol.

**Long-term toxicity studies in rats have demonstrated that spironolactone is tumorigenic in that species.**

**Reproductive/Nursing Safety**
Spironolactone or its metabolites may cross the placental barrier. Feminization occurs in male rat fetuses. In humans, the FDA categorizes this drug as category D for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)
Spironolactone, a metabolite of spironolactone, appears in maternal milk. In humans, the estimated maximum dose to the infant is approximately 0.2% of the mother’s daily dose. Use with caution in nursing patients, but it is unlikely of clinical significance in veterinary patients.

**Overdosage/Acute Toxicity**

Information on overdosage of spironolactone is apparently unavailable. Should an acute overdose occur, it is suggested to follow the guidelines outlined in the chlorothiazide and furosemide monographs. Contact an animal poison control center for further guidance.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving spironolactone and may be of significance in veterinary patients:

- **DIGOXIN**: Spironolactone may increase the half-life of digoxin; enhanced monitoring of digoxin serum levels and effects are warranted when spironolactone is used with these agents.
- **MITOTANE**: Spironolactone may mute the effects of mitotane if given concurrently, but very limited information is available on this potential interaction; monitor carefully.
- **NEUROMUSCULAR BLOCKERS, NON-DEPOLARIZING**: Increase in neuromuscular blockade effects possible.
- **POTASSIUM-SPARING DIURETICS, OTHER (e.g., triamterene)**: Hyperkalemia possible.
- **POTASSIUM SUPPLEMENTS**: Hyperkalemia possible.
- **SALICYLATES**: Spironolactone’s diuretic effects may be decreased if aspirin or other salicylates are administered concomitantly.

**Laboratory Considerations**

- Spironolactone may give falsely elevated digoxin values, if using a radioimmune assay (RIA) method.
- Fluorometric methods of determining plasma and urinary 17-hydroxycorticosteroids (cortisol) may be interfered with by spironolactone.

**Doses**

- **DOGS**: As a diuretic in CHF:
  
  a) When furosemide and ACE inhibitors alone do not control fluid accumulation in refractory CHF: 1–2 mg/kg PO q12h (Ware & Keene 2000)
  
  b) With other diuretics when hypokalemia is an issue: 2–4 mg/kg PO once daily (Kittelson, 2000)
  
  c) To allow further reduction of furosemide dose (target dose for furosemide during maintenance phase: 1–2 mg/kg PO q24–48h): Spironolactone dose varies between 0.5 mg/kg PO once daily (aldosterone blockage, weak diuretic effect) to 2 mg/kg twice daily (stronger diuretic effect). (de Madron 2004)

  For treating ascites:
  
  a) Using the fixed dose combination with hydrochlorothiazide (Aldactazide®): The empirical dosage, based on the spironolactone component, is 0.5–1 mg/kg PO twice daily. (Trepanier 2008)
  
  b) Attempt at treating underlying abnormality. When ascites is caused by right-sided heart failure: Be sure owner is administering medication properly and the prescription is correct. Increase furosemide to 4–6 mg/kg PO q8h (generally speaking dose should be increased until all the abnormal accumulated fluid is eliminated or unacceptable azotemia develops). Optimize ACE inhibitor dose. Restrict dietary sodium. Add spironolactone at 1–2 mg/kg PO q12h. Initially (3 times weekly) substitute one of the oral furosemide doses with a SC dose. Consider adding hydrochlorothiazide initially at 2 mg/kg PO every other day. (Connolly 2006)

  For adjunctive treatment of hypertension:
  
  a) 1–2 mg/kg PO q12h (Stepan 2006)
  
  b) As a fourth step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after 1) enalapril/benzazepril (0.5 mg/kg q12h); 2) amloidipine (0.1 mg/kg q24h); 3) amloidipine (0.2 mg/kg q24h); 4) spironolactone (1–2 mg/kg twice daily); 5) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

- **CATS**: As a diuretic in CHF:
  
  a) When furosemide and ACE inhibitors alone do not control fluid accumulation in refractory CHF: 1–2 mg/kg PO q12h (Ware & Keene 2000)
  
  b) 1 mg/kg q12h PO when serum potassium is low (Bonagura 1989)

  For adjunctive treatment of hypertension:
  
  a) 1–2 mg/kg PO q12h (Stepan 2006)
  
  b) As a 3rd step drug when systolic BP >160 mmHg, diastolic >120 mmHg; 1) amlodipine (0.625 mg per cat q24h; if cat greater then 6 kg, 1.25 mg/cat q24h), add ACE inhibitor if proteinuric; 2) ACE inhibitor (benzazepril/enalapril 0.5 mg/kg q12h); 3) spironolactone (1–2 mg/kg twice daily); 4) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

  For adjunctive treatment of primary hyperaldosteronism:
  
  a) If potassium supplementation alone does not control clinical signs: 1–2 mg/kg PO twice daily. (Caney 2009)

**Monitoring**

- Serum electrolytes, BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema/ascites; patient weight, if indicated

**Client Information**

- Notify veterinarian if GI symptoms (e.g., vomiting, diarrhea, anorexia), lethargy, or other CNS effects are severe or persist.

**Chemistry/Synonyms**

A synthetically produced aldosterone antagonist, spironolactone occurs as a cream-colored to light tan, crystalline powder with a faint mercaptan-like odor. It has a melting range of 198°–207°, with decomposition. Spironolactone is practically insoluble in water and soluble in alcohol.

Spironolactone may also be known as: espironolactona, SC-9420, spirolactone, spironolactonum; many trade names are available.

**Storage/Stability**

Spironolactone tablets should be stored at room temperature in tight, light-resistant containers.

**Compatibility/Compounding Considerations**

An extemporaneously prepared oral suspension can be prepared by pulverizing commercially available tablets and adding cherry syrup. This preparation is reportedly stable for at least one month when refrigerated.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.
STANOZOLOL
(stablonor-l) Winstrol®-V
ANABOLIC STEROID

Prescriber Highlights

- Anabolic steroid; FDA-approved products no longer marketed in USA
- Contraindications: Pregnant animals, breeding stallions, food animals. Extreme Caution: Cats, hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, & during the nephrotic stage of nephritis. Caution: Cardiac & renal dysfunction with enhanced fluid & electrolyte monitoring.
- Adverse Effects: Potentially high incidence of hepatotoxicity in cats. Other possible effects: sodium, calcium, potassium, water, chloride, & phosphate retention; hepatotoxicity, behavioral (androgenic) changes, & reproductive abnormalities (oligosperma, estrus suppression)
- Category “X” for pregnancy; teratogenicity outweighs any possible benefit
- Controlled substance in the USA
- Drug Interactions; lab interactions

Uses/Indications

Labeled indications for the previously marketed veterinary stanozolol product Winstrol®-V (Winthrop-Upjohn) included “… to improve appetite, promote weight gain, and increase strength and vitality …” in dogs, cats and horses. The manufacturer also stated that: “Anabolic therapy is intended primarily as an adjunct to other specific and supportive therapy, including nutritional therapy.” In a review of the evidence supporting anabolic steroid use in horses, the authors conclude: “Level 1 evidence for the efficacy of anabolic steroids in horses for therapeutic uses is not found in the biomedical literature. Evidence in other species exists for the efficacy of anabolic steroids in treating anemia and increasing muscle mass after illness or injury, but that evidence is not unequivocal, and the applicability to horses has not been demonstrated. There is little evidence in other species for the efficacy of anabolic steroids for increasing appetite.” (Fujii & McCook 2008)

Like nandrolone, stanozolol has been used to treat anemia of chronic disease. Because stanozolol has been demonstrated to enhance fibrinolysis after parenteral injection, it may be efficacious in the treatment of feline aortic thromboembolism or thrombosis in nephrotic syndrome; however, clinical studies and/or experience are apparently lacking for this indication at present.

Pharmacology/Actions

Stanozolol possesses the actions of other anabolic agents but it may be less androgenic than other anabolics that are used in veterinary medicine. Refer to the discussion in the boldenone monograph for more information.

Pharmacokinetics

No specific information was located for this agent. It is generally recommended that the injectable suspension be dosed on a weekly basis in both small animals and horses.

Contraindications/Precautions/Warnings

Stanozolol is contraindicated in pregnant animals and in breeding stallions and should not be administered to horses intended for food purposes. Because of reported hepatotoxicity associated with this drug in cats, it should only be used in this species with extreme caution.

The manufacturer recommends using stanozolol cautiously in patients with cardiac and renal dysfunction with enhanced fluid and electrolyte monitoring.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, benign prostatic hypertrophy, during the nephrotic stage of nephritis, and in selected patients with breast carcinoma.

Adverse Effects

The manufacturer (Winthrop-Upjohn) lists as adverse effects in dogs, cats, and horses only “mild androgenic effects” and then only when used with excessively high doses for a prolonged period of time.

One study in cats demonstrated a very high incidence of hepatotoxicity associated with stanozolol use and the authors recommended that this drug not be used in cats until further toxicological studies are performed. Potentially (from human data), adverse reactions of the anabolic agents in dogs and cats could include: sodium, calcium, potassium, water, chloride, and phosphate retention, hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (oligosperma, estrus suppression).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity).

It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, use in nursing patients with extreme caution.

Overdosage/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving stanozolol and may be of significance in veterinary patients:

- ANTICOAGULANTS (heparin, warfarin): Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR/PT’s and dosage adjustment, if necessary, of the anticoagulant are recommended
- CORTICOSTEROIDS: Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- INSULIN: Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements
Laboratory Considerations

Concentrations of protein bound iodine (PBI) can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important. Androgen/anabolic agents can decrease amounts of thyroxine-binding globulin and decrease total T4 concentrations and increase resin uptake of T3 and T4. Free thyroid hormones are unaltered and there is no evidence of dysfunction.

- Both creatinine and creatine excretion can be decreased by anabolic steroids.
- Anabolic steroids can increase the urinary excretion of 17-ketosteroids.
- Androgenic/anabolic steroids may alter blood glucose levels.
- Androgenic/anabolic steroids may suppress clotting factors II, V, VII, and X.
- Anabolic agents can affect liver function tests (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase).

Doses

**DOGS:**

As an anabolic agent per labeled indications:

a) Small Breeds: 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly.

   Large Breeds: 2–4 mg PO twice daily; or 50 mg deep IM, may repeat weekly.

   Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; Winstrol®-V—Winthrop/Upjohn)

For anemia secondary to chronic renal failure:

a) 1–4 mg PO once daily (Ross et al. 1989)

b) For anemias secondary to uremia: 2–10 mg PO twice daily (Maggio-Price 1988)

As an anabolic/appetite stimulant:

a) 1–4 mg PO twice daily (Weller 1988)

b) 1–2 mg PO twice daily or 25–50 mg IM weekly (Bartges 2003; Macy & Ralston 1989)

For canine cognitive dysfunction:

a) 2 mg/kg IM for 4–6 weeks with 1–2 mg (total dose) PO once daily for dogs less than 23 kg and 4 mg (total dose) PO once daily for dogs greater than 23 kg. If drug has some positive effect, maintain oral dosing and gradually reduce injections to every 3–4 weeks. (Hoskins 1999)

**CATS:** NOTE: SEE WARNINGS ABOVE

As an anabolic agent per labeled indications:

a) 1–2 mg PO twice daily; or 25 mg deep IM, may repeat weekly. Treatment should continue for several weeks, depending on response and condition of animal. (Package Insert; Winstrol®-V—Winthrop/Upjohn)

**FERRETS:**

a) 0.5 mg/kg PO or SC twice daily; use with caution in hepatic disease (Williams 2000)

**RABBITS, RODENTS, SMALL MAMMALS:**

a) Rabbits: As an appetite stimulant: 0.5–2 mg PO once (Ivey & Morrisey 2000)

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)

As an anabolic agent per labeled indications:

a) 0.55 mg/kg (25 mg per 100 pounds of body weight) IM deeply. May repeat weekly for up to and including 4 weeks. (Package Insert; Winstrol®-V—Winthrop/Upjohn)

**SHEEP & GOATS:**

For acute or subacute aflatoxicosis in ruminants:

a) Stanozolol 2 mg/kg IM (plus activated charcoal 6.7 mg/kg as a 30% w/v slurry in M/15, pH 7 phosphate buffer). Do not combine with oxytetracycline therapy. (Hatch 1988)

**BIRDS:**

As an anabolic agent to promote weight gain and recovery from disease:

a) 0.5–1 mL/kg (25–50 mg/kg) IM once or twice weekly. Use with caution in birds with renal disease. (Clubb 1986)

**REPTILES:**

For most species post-surgically and in very debilitated animals:

a) 5 mg/kg IM once a week as needed (Gauvin 1993)

Monitoring

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- RBC count, indices, if indicated
- Weight, appetite

**Client Information**

- Tablets may be crushed and administered with food
- Because of the potential for abuse of anabolic steroids this agent is a controlled drug; it should be kept in a secure area and out of the reach of children

**Chemistry/Synonyms**

An anabolic steroid, stanozolol occurs as an odorless, nearly colorless, crystalline powder that can exist in two forms: prisms that melt at approximately 235°C, and needles that melt at about 155°C. It is sparingly soluble in alcohol and insoluble in water.

Stanozolol may also be known as: androstanazole, estanozolol, methylstanazole, NSC-43193, stanozololum, win-14833, Menabol®, Neurabol®, Stanol®, Stromba®, Strombaject® and Winstrol®.

**Storage/Stability**

Stanozolol tablets should be stored in tight, light-resistant packaging, preferably at room temperature.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None
STAPHYLOCOCCAL PHAGE LYSEATE
(staf'loyd-ko-kaf je-fur lye-yayt) Staphage Lyssate (SP)®, SPL

**IMMUNE STIMULANT**

**Prescriber Highlights**

- Injectable immune stimulant used to treat dogs with recurrent, idiopathic, staphylococcal pyoderma
- May cause hypersensitivity (local or systemic)

**Uses/Indications**
Staphylococcal phage lysate (SPL) is labeled for treatment of canine pyoderma and related staphylococcal hypersensitivity, or polymicrobial skin infections with a staphylococcal component. Veterinary dermatologists use SPL most commonly to treat recurrent, idiopathic, staphylococcal pyodermas in combination (at least initially) with an appropriate antibiotic.

**Pharmacology/Actions**
SPL apparently enhances cell-mediated immunity. It stimulates the production of tumor necrosis factor, interleukin-6, interleukin-γ, and γ-interferon.

**Pharmacokinetics**
No information was located.

**Contraindications/Precautions/Warnings**
The label states that "there are no known contraindications to the use of SPL® except that in highly allergic patients, reduced desensitizing doses may be indicated." However, use with extreme caution, if at all, in patients with prior systemic hypersensitivity reactions to it or documented hypersensitivity reactions to beef products (contains unfiltered beef heart infusion broth). Avoid administering subsequent doses at the same injection site. The product contains no preservative so it must be handled aseptically. It is recommended to use the entire contents when the vial is opened.

**Adverse Effects**
Adverse effects reported for SPL include post vaccine-type reactions (fever, malaise, etc.) and injection site reactions (redness, itching, swelling) that may occur in 2–3 hours after injection and persisting up to 3 days. If these effects are excessive, the manufacturer recommends dosage reduction. Systemic hypersensitivity reactions are thought to occur rarely. Signs could include weakness, vomiting, diarrhea, severe itching, rapid breathing, and/or fatigue/lassitude. Should an anaphylactic-type reaction occur, treat supportively; the manufacturer recommends epinephrine and atropine as antidotes.

**Reproductive/Nursing Safety**
Studies performed in rats and rabbits demonstrated no impaired fertility or fetal harm. No information was located on safety during nursing, but it is unlikely to be of concern.

**Overdosage/Acute Toxicity**
No specific information was located. Other than an increased risk for local or systemic hypersensitivity reactions, significant morbidity appears unlikely.

**Drug Interactions**
**CELL-MEDIATED IMMUNOSUPPRESSIVE DRUGS (e.g., corticosteroids, cyclosporine): These drugs may reduce the efficacy of SPL**

**Laboratory Considerations**
- No significant concerns noted.

**Doses**
**DOGS:**

a) For labeled indications: Highly allergic patients: Skin test with 0.05–0.1 mL intradermally. Therapy: Initially, 0.2 mL SC, then incremental increases of 0.2 mL once a week to 1 mL (a total of 5 injections). Then continue at 1 mL SC weekly for approximately 10–12 weeks.

For non-allergic patients: 0.5 mL SC twice weekly for 10–12 weeks, then 0.5–1 mL every 1–2 weeks.

Concomitant antibiotic therapy is recommended for an initial 4–6 week period.

Maximum dose should be decreased in small dogs and can be increased cautiously, if necessary, in large dogs to 1.5 mL. This dose is continued until improvement is demonstrated then the interval may be lengthened gradually to the longest interval that maintains adequate clinical control. (Label information; Staphage Lysate (SPL)®—Delmont Labs)

b) For idiopathic, recurrent pyoderma: Typically given 0.5 mL SC twice weekly for 10–12 weeks, then tapered to effect. This agent is rarely needed, because in most cases, an underlying cause can be identified and treated. (Gram 2005)

c) For chronic recurrent idiopathic pyoderma: Pyodermia needs to be under control as this product is not a substitute for antibiotics. Injections are administered twice weekly (0.5 mL) and slowly reduced to 0.5 mL every 2 weeks. (Watglass 2009)

**Monitoring**
- Clinical efficacy
- Local and systemic reactions (see adverse effects)

**Client Information**
- This medication should ideally be administered at a veterinary practice where suitable treatment can be instituted should a serious adverse effect (e.g., anaphylaxis) occur
- Report to veterinarian any adverse effects noted (e.g., local effects at injection site, itching, change in behavior or activity level, difficulty or unexplained rapid breathing, vomiting, diarrhea)

**References**
The following drug interactions have either been reported or are theoretical in humans or animals receiving streptozocin and may be of significance in veterinary patients:

**Drug Interactions**

Severe toxicity may result if acutely overdosed (see Adverse Effects); calculate dosages carefully.

**Overdosage/Acute Toxicity**

Additionally, GI effects (vomiting/nausea) often occur and can be severe or protracted. Less commonly, hematologic changes (mild myelosuppression) and increases in liver enzymes can occur. Injection site reactions (including severe necrosis) may occur if the drug extravasates.

**Streptozocin**

Streptozocin must be administered IV. Its distribution characteristics are not well known, but the drug does distribute to most tissues; concentrations in the pancreas are higher than those found in plasma. Streptozocin is considered an alkylating agent and it inhibits DNA synthesis, probably by inhibiting precursor incorporation into DNA.

**Pharmacology/Actions**

Streptozocin also exhibits a species-specific (in dogs, not humans) diabetogenic effect via reducing nicotinamide adenine dinucleotide (NAD) concentration in pancreatic beta cells. This effect is usually irreversible in animals with preexisting normal beta cell function.

**Uses/Indications**

At present the primary purpose for streptozocin use in veterinary medicine is as a treatment for insulinomas in dogs, particularly those with refractory hypoglycemia and when tumors are non-resectable or have metastasized.

Streptozocin potentially could be used for other oncologic conditions as well.

**Pharmacokinetics**

Streptozocin must be administered IV. Its distribution characteristics are not well known, but the drug does distribute to most tissues; concentrations in the pancreas are higher than those found in plasma. Streptozocin is metabolized, probably in the liver. Both unchanged and metabolized drug are excreted in the urine.

**Contraindications/Precautions/Warnings**

Should be used for recurrent insulinoma only in dogs that have undergone previous surgery in which all of the tumor could not be resected. Confirmed histologic diagnosis is mandatory.

Streptozocin must be used with extreme caution in patients with decreased renal, bone marrow, or hepatic function.

**Adverse Effects**

The primary concern when used for treating insulinomas in dogs is the potential for the development of serious, permanent renal toxicity. Aggressive saline diuresis during drug administration appears to reduce this concern. Additionally, GI effects (vomiting/nausea) often occur and can be severe or protracted. Less commonly, hematologic changes (mild myelosuppression) and increases in liver enzymes can occur. Injection site reactions (including severe necrosis) may occur if the drug extravasates.

**Reproductive/Nursing Safety**

Streptozocin has been shown to be teratogenic in rats; use during pregnancy when the benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether streptozocin is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if used in nursing patients.

**Overdosage/Acute Toxicity**

Severe toxicity may result if acutely overdosed (see Adverse Effects); calculate dosages carefully.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving streptozocin and may be of significance in veterinary patients:

- **DOXORUBICIN:** Streptozocin may prolong the half-life of doxorubicin; dosage adjustment may be required
- **MYELOSUPPRESSIVE DRUGS, OTHER:** When streptozocin is used with other myelosuppressive drugs (e.g., carmustine) additive or synergistic myelosuppression may occur
- **NEPHROTOXIC DRUGS, OTHER:** May cause additive nephrotoxicity when used with streptozocin
- **NIACINAMIDE (nicotinamide):** Can block the diabetogenic effects of streptozocin without altering its antineoplastic activity; this may be beneficial or detrimental depending on the reason for use
Doses

a) For “investigational” treatment of recurrent insulinoma after surgery: Begin saline diuresis: Give normal saline at 18–20 mL/kg/hour for 7–8 hours. Over the 4th–5th hour, give streptozocin in the saline solution at a dose of 500 mg/m² IV. Give an antiemetic (e.g., butorphanol) at the end of the 7-hour period. (Meleo & Caplan 2000)
b) Normal saline is given IV at 18.3 mL/kg/hr for 3 hours, then streptozocin is administered at 500 mg/m² over two hours with the saline diuresis continuing. After streptozocin infusion completed, continue saline diuresis for another 2 hours. Butorphanol is administered as an antiemetic immediately after streptozocin. May repeat at 3 week intervals until evidence of tumor progression, recurrence of hypoglycemia, or drug toxicity. Monitor for myelosuppression and nephrotoxicity. (Moore et al. 2002)

Monitoring

- Blood glucose (efficacy)
- Baseline renal function tests (including urinalyses) and after treatment
- CBC
- Baseline liver function tests and before retreatment
- Hydration status (especially for the first few days after treatment or if vomiting a problem).

Client Information

- Clients should understand the “experimental” nature of this treatment and the potential risks for serious adverse effects; follow-up monitoring is essential.

Chemistry/Synonyms

Streptozocin is an antineoplastic antibiotic produced by Streptomyces achromogenes, although the commercial product is prepared synthetically. It occurs as an ivory colored, crystalline powder. It is very soluble in water and has a pKa of 1.35.

Streptozocin may also be known as: NSC-85998, streptozotocin, U-9889 and Zanosar®.

Storage/Stability

The lyophilized powder for injection should be stored in the refrigerator and protected from light. It is stable for at least 3 years after manufacture. If stored at room temperature, it is stable for at least one year after manufacture.

After reconstitution, the lyophilized powder for injection has a pH of 3.5–4.5. Dextrose 5% or 0.9% sodium chloride are used to reconstitute the solution. Citric acid is added to buffer the solution at a concentration of 22 mg/mL. The solution is stable for 48 hours at room temperature and 96 hours if refrigerated, but as no preservative is added the manufacturer recommends using the drug within 12 hours of mixing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

- Streptozocin Powder for Injection: 1 gram (100 mg/mL) in vials; Zanosar® (Genesia Sicor); (Rx)

References

SUCCIMER

(su’-si-mir) Chemet®, DMSA, Dimercaptosuccinic acid

ANTIDOTE; CHELATOR

Prescriber highlights

- Oral heavy metal chelator
- Appears to be safe & effective despite limited experience
- Most likely adverse effects noted are GI in nature; may also cause increased liver enzymes, rash
- High doses may be fatal in birds
- Unpleasant odor of capsules; may give feces, urine, saliva, etc. a very unpleasant smell
- Cost is an issue

Uses/Indications

In veterinary medicine, succimer may be useful for the oral treatment of lead poisoning in small animals (including birds). Potentially, it also may be of benefit for the treatment of other toxic heavy metals such as arsenic or mercury, but more research must be done before this can be recommended.

Pharmacology/Actions

Succimer physically chelates heavy metals such as lead, mercury, and arsenic. These water-soluble chelates are then excreted via the kidneys.

Pharmacokinetics

No veterinary information was located. In humans, the drug is rapidly absorbed after oral ingestion, but only incompletely. Absorbed drug is excreted primarily through the kidneys into the urine. Half-life in humans is about 2 days.

Contraindications/Precautions/Warnings

Succimer is contraindicated in patients hypersensitive to it. Chelation therapy should only be attempted if the source of lead is removed to prevent further exposure.

Adverse Effects

Most common adverse reactions reported in humans are GI related effects (vomiting, diarrhea, etc.) or “flu-like” symptoms (body aches, fatigue, etc.). Increases in liver enzymes and rashes have also been reported.

Reproductive/Nursing Safety

It is unknown if succimer is safe to use during pregnancy. At high doses it was fetotoxic and teratogenic in mice. Mothers are discouraged from nursing when taking succimer. In humans, the FDA categorizes this drug as
Succimer Capsules: 100 mg;

HUMAN-LABELED PRODUCTS:

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status

 Unless otherwise labeled, store succimer capsules in tight containers at room temperature. Protect from light.

Storage/Stability

A heavy metal chelating agent also known as meso-2,3 dimercaptosuccinic acid (DMSA), succimer is an analog of dimercaprol. It has an unpleasant odor.

Chemistry/Synonyms

Client Information

Monitoring

Doses

DOGS:

For lead poisoning:

a) 10 mg/kg PO q8h for 10 days. Succimer has a good therapeutic index, few side effects, spares most other elements from being chelated and does not cause enhanced lead uptake from the gut. Blood lead levels should be rechecked a few days following the last dose of succimer; a second round of chelation therapy may be necessary to reduce the lead load. (Talcott 2008)

b) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

CATS:

For lead poisoning:

a) 10 mg/kg PO three times daily for 5 days, followed by 10 mg/kg PO twice daily for 2 weeks (Poppenga 2002)

b) See the dog dose referenced to Talcott above.

BIRDS:

For lead poisoning:

a) 15–35 mg/kg PO twice daily for 5 days (Calvert & Mieurs 2000)

b) 30 mg/kg PO twice daily for a minimum of 7 days. If severe neurologic signs, may supplement with one dose of CaEDTA (edetate calcium disodium; <50 mg/kg of body weight IM) (Hoogesteijn et al. 2003)

Overdosage/Acute Toxicity

In toxicology studies, doses of up to 200 mg/kg per day in dogs did not cause overt toxicity. Doses of 300 mg/kg/day did cause fatalities in Cockatiels (but 40 mg/kg q12h did not). If an overdose situation is encountered, standardized gut evacuation with subsequent activated charcoal protocols are recommended.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succimer and may be of significance in veterinary patients:

CHELATING AGENTS, OTHER (CaEDTA, dimercaprol, trientine, penicillamine, etc.); Concomitant use with other chelating agents is not recommended in humans

Laboratory Considerations

False positive urine ketones can be reported when using nitroprusside reagents (e.g., as in Ketostix®)

Falsely low measurements of CPK or serum uric acid can be caused by succimer

Doses

Succimer Capsules: 100 mg; Chemet® (Ovation); (Rx)

References

Kirk's Current Veterinary Therapy: XIII Small Animal Practice.
Specific recommendations for use in horses (see Contraindications below)

No analgesic or anesthetic effects

Uses/Indications

Succinylcholine chloride is indicated for short-term muscle relaxation needed for surgical or diagnostic procedures, to facilitate endotracheal intubation in some species, and reducing the intensity of muscle contractions associated with electro- or pharmacological-induced convulsions. Dogs, cats, and horses are the primary veterinary species where succinylcholine chloride has been used. Its use has been largely supplanted by newer agents (e.g., atracurium) with fewer adverse effects.

Pharmacology/Actions

An ultrashort-acting depolarizing skeletal muscle relaxant, succinylcholine bonds with motor end plate cholinergic receptors to produce depolarization (perceived as fasciculations). The neuromuscular block remains as long as sufficient quantities of succinylcholine remain, and is characterized by a flaccid paralysis. Other pharmacologic effects are discussed in the precautions and adverse effects sections.

Pharmacokinetics

The onset of action, with complete muscle relaxation, after IV administration is usually within 30-60 seconds. In humans, this effect lasts for 2–3 minutes and then gradually diminishes within 10 minutes. The very short duration of action after a single IV dose is thought to occur because the drug diffuses away from the motor end plate. If multiple injections or a continuous infusion is performed, the brief activity is a result of rapid hydrolysis by pseudocholinesterases at the site of action. After IM injection, the onset of action is generally within 2–3 minutes and may persist for 10-30 minutes. Dogs exhibit a prolonged duration of action (≈ 20 minutes); this species appears unique in this idiosyncratic response.

Succinylcholine is metabolized by plasma pseudocholinesterases to succinylmonocholine and choline; 10% is excreted unchanged in the urine. Succinylmonocholine is partially excreted in the urine and may accumulate in patients with impaired renal function. Succinylmonocholine has approximately 1/30 th the neuromuscular blocking activity of succinylcholine, but if it accumulates, prolonged periods of apnea may result.

Contraindications/Precautions/Warnings

Succinylcholine is contraindicated in patients with severe liver disease, chronic anemia, malnourishment (chronic), glaucoma or penetrating eye injuries, predisposition to malignant hyperthermia, and increased CPK values associated with rhabdomyolysis. As succinylcholine can exacerbate the effects of hyperkalemia, it should be used with extreme caution in patients who have suffered traumatic wounds or burns, are receiving quinidine or digoxin therapy, or have preexisting hyperkalemia or electrolyte imbalances as arrhythmias or cardiac arrest may occur. It should be used with caution in patients with pulmonary, renal, cardiovascular, metabolic, or hepatic dysfunction.

Succinylcholine should not be used if organophosphate agents have been given or applied recently. Succinylcholine chloride does not have analgesic effects; and should be used with appropriate analgesic, sedative, and anesthetic agents.

In horses, The American Association of Equine Practitioners have made the following additional recommendations:

1) Inform the owner that succinylcholine chloride is to be used as a restraining agent, not as an anesthetic.
2) Obtain history before use; do not use in horses if within 30 days they have received, an antibiotic ending in “mycin”, organophosphate insecticides or anthelmintics, any other cholinesterase inhibitor, or procaine.
3) Do not use in debilitated, excited, or exhausted horses.
4) If possible, withhold food for 4-6 hours before use.
5) Dosage of 0.088 mg/kg IV may be used to paralyze skeletal muscles without causing respiratory depression. Higher doses may cause apnea and death without respiratory support. Lower doses may be possible if used with a preanesthetic agent.
6) After administration, have someone hold the horse that is familiar with the actions of succinylcholine chloride so that the animal does not fall forward on its nose. Be prepared to administer oxygen and artificial respiration.
7) If death occurs, a necropsy should be performed.

Adverse Effects

Succinylcholine chloride can cause muscle soreness, histamine release, malignant hyperthermia, excessive salivation, hyperkalemia, rash, and myoglobinemia/myoglobinuria. Cardiovascular effects can include bradycardia, tachycardia, hypertension, hypotension, or arrhythmias.

Reproductive/Nursing Safety

It is unknown if succinylcholine can cause fetal harm. The drug does cross the placenta in low concentrations and a newly delivered neonate may show signs of neuromuscular blockade if the mother received high doses or prolong administration of the drug prior to delivery. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

It is not known whether this drug is excreted into milk; exercise caution when succinylcholine is administered to a nursing patient.

Overdosage/Acute Toxicity

Inadvertent overdoses, or standard doses in patients deficient in pseudocholinesterase may result in prolonged apnea. Mechanical ventilation with O2 should be used until recovery.

Repeated or prolonged high dosages may cause patients to convert from a phase I to a phase II block.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving succinylcholine and may be of significance in veterinary patients:

- AMPHOTERICIN B: May increase succinylcholine’s effects by causing electrolyte imbalances
- DIGOXIN: Succinylcholine may cause a sudden outflux of potassium from muscle cells, thus causing arrhythmias in digitalized patients
- OPIATES: Potential for increased incidences of bradycardia and sinus arrest
- THIAZIDE DIURETICS: May increase succinylcholine’s effects by causing electrolyte imbalances
- ANTIARRHYTHMICS (QUINIDINE, LIDOCAINE, PROCAINAMIDE)
- BETA-ADRENERGIC BLOCKERS
- CHLOROQUINE
- CLINDAMYCIN
- CORTICOSTEROIDS
- CYCLOPHOSPHAMIDE
- MAGNESIUM SALTS
- MAO INHIBITORS
- SULFONAMIDES
- THIOPHENE DERIVATIVES
METOCLOPRAMIDE
NEOSTIGMINE
ORGANOPHOSPHATES
OXYTOCIN
PANCURONIUM
PHENOTHIAZINES
PROCAINE (IV)
TERBUTALINE
THIOTIPE

**Doses**

**DOGS:**
- a) 0.07 mg/kg IV (Morgan 1988)
- b) 0.22 mg/kg IV (Mandsager 1988)

**CATS:**
- a) 0.06 mg/kg IV (Morgan 1988)
- b) 0.11 mg/kg IV (Mandsager 1988)

**HORSES:**
- See Precautions above. (Note: ARCI UCGFS Class 2 Drug)
  - a) 0.088–0.11 mg/kg IV, IM (Mandsager 1988)

**REPTILES:**
- a) To relax an animal to allow intubation: 0.5–1 mg/kg IM. Especially helpful with turtles and crocodilians. (Lewbart 2001)

**Monitoring**
- Level of muscle relaxation
- Cardiac rate/rhythm
- Respiratory depressant effect

**Client Information**
- This drug should only be used by professionals familiar with its use

**Chemistry/Synonyms**
- A depolarizing neuromuscular blocking agent, succinylcholine chloride occurs as an odorless, white, crystalline powder. The dihydrate form melts at 190°C and the anhydrous form at 160°C. Aqueous solutions are acidic with a pH of approximately 4. One gram is soluble in about 1 mL of water and about 350 mL of alcohol. Commercially available injections have a pH from 3–4.5.
- Succinylcholine chloride may also be known as: choline chloride succinate, succicurarium chloride, succinylole chloride, suxamethonii chlorideum, suxametetonklorid, suxamethonium chloride; many trade names are available.

**Storage/Stability**
- Commercial injectable solutions should be stored refrigerated (2°–8°C). One manufacturer (Anectine®—Glaxo Wellcome) states that multiple dose vials are stable up to 2 weeks at room temperature with no significant loss of potency.
- The powder forms of the drug are stable indefinitely when stored unopened at room temperature. After reconstitution with either D5W or normal saline, they are stable for 4 weeks at 5°C or 1 week at room temperature, but because they contain no preservative, it is recommended they be used within 24 hours.

**Compatibility/Compounding Considerations**
- Succinylcholine chloride is physically compatible with all commonly used IV solutions, amikacin sulfate, isoproterenol HCl, meperidine HCl, norepinephrine bitartrate, and scopolamine HBr. It may not be compatible with pentobarbital sodium and is physically incompatible with sodium bicarbonate and thiopental sodium.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None
- The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
- Succinylcholine Chloride Injection: 20 mg/mL in 10 mL vials and 5 mL Abboject syringes; Anectine® (GlaxoWellcome); Quelicin® (Hospira); (Rx)
- Succinylcholine Chloride Injection. Solution: 100 mg/mL in 5 mL & 10 mL single-use, preservative free vials & 20 mL multidose vials; Quelicin-1000® (Hospira); (Rx)
- Succinylcholine Chloride Powder for Infusion: 500 mg & 1 gram in vials; Anectine® Flo-Pak (GlaxoWellcome); (Rx)

**References**

**SUCRALFATE**
(*soo-kralfate*) Carafate®
GASTROPROTECTANT

**Prescriber Highlights**
- Locally-acting treatment for GI ulcers; may also protect somewhat against GI ulceration. Potentially could be useful for lowering serum phosphorus in renal patients.
- Contraindications: None, use with caution where decreased GI transit times may be harmful
- Adverse Effects: Unlikely; constipation possible. Vomiting reported in cats.
SUCRALFATE

**Uses/Indications**
Sucralfate has been used in the treatment of oral, esophageal, gastric, and duodenal ulcers. It has also been employed to prevent drug-induced (e.g., aspirin) gastric erosions, but efficacy for this is somewhat sporadic.

Sucralfate has been used in human patients with hyperphosphatemia secondary to renal failure and potentially could be useful for this in animals as well. In a study done in six healthy cats, sucralfate did not significantly change serum or urine phosphorus levels (Quimby & Lappin 2008).

**Pharmacology/Actions**
While the exact mechanism of action of sucralfate as an antulcer agent is not known, the drug has a local effect rather than a systemic one. After oral administration, sucralfate reacts with hydrochloric acid in the stomach to form a paste-like complex that will bind to the proteinaceous exudates that generally are found at ulcer sites. This insoluble complex forms a barrier at the site and protects the ulcer from further damage caused by pepsin, acid, or bile. Sucralfate can inactivate pepsin and bind bile acids.

Sucralfate may have some cytoprotective effects, possibly by stimulation of prostaglandin E2 and I2. Sucralfate also has some antacid activity, but it is believed that this is not of clinical importance.

Sucralfate does not significantly affect gastric acid output, or trypsin or pancreatic amylase activity. It may decrease the rate of gastric emptying.

As an aluminum salt, sucralfate can bind to gastrointestinal phosphorus.

**Pharmacokinetics**
Animal studies have indicated that only 3–5% of an oral dose is absorbed which it is excreted in the urine unchanged within 48 hours. By reacting with hydrochloric acid in the gut, the remainder of the drug is converted to sucrufate, which is excreted in the feces within 48 hours. The duration of action (binding to ulcer site) may persist up to 6 hours after oral dosing.

**Contraindications/Precautions/Warnings**
There are no known contraindications to the use of sucralfate. Because it may cause constipation, it should be used with caution in animals where decreased intestinal transit times might be deleterious.

**Adverse Effects**
Adverse effects are uncommon with sucralfate therapy. Constipation is the most prominent adverse effect reported in humans (2%) and dogs receiving the drug. Vomiting has been reported in cats.

**Reproductive/Nursing Safety**
It is unknown if sucralfate crosses the placenta and whether it may definitively be used safely during pregnancy. In rats, dosages up to 38 times those used in humans caused no impaired fertility and doses up to 50 times normal caused no symptoms of teratogenicity. In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)

It is not known whether this drug is excreted in milk, but it is unlikely to be of concern.

**Overdosage/Acute Toxicity**
Overdosage is unlikely to cause any significant problems. Laboratory animals receiving up to 12 grams/kg orally demonstrated no incidence of mortality.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving sucralfate and may be of significance in veterinary patients:

- AZITHROMYCIN
- CIPROFLOXACIN/ENROFLOXACIN (assume other oral fluoroquinolones as well)
- DICLOFENAC
- DIGOXIN
- DOXYCYCLINE
- ERYTHROMYCIN
- KETOCONAZOLE
- LEVOTHYROXINE
- PENICILLAMINE
- TETRACYCLINE
- THEOPHYLLINE
- VITAMINS (fat soluble)
- WARFARIN

**Doses**

**DOGS:**
- a) For esophagitis: 0.5–1 gram PO three times a day. Suspensions are more therapeutic than intact tablets. (Washabau 2000)
- b) For large dogs: 1 gram PO q4–6h; for smaller dogs: 0.5 gram PO q8h (Zerbe & Washabau 2000)
- c) 0.5–1 gram PO 2–4 times a day; patients with severe GI blood loss give an initial loading dose of 3–6 grams and then resume lower dose. If also using an H2 blocker, administer sucralfate 30–60 minutes later. (Hall 2000)
- d) For eliminating Helicobacter gastritis infections: Using triple therapy: Metronidazole 33 mg/kg once daily, amoxicillin 11 mg/kg q12h and either sucralfate (0.25–0.5 grams q8h) or omeprazole 0.66 mg/kg once daily (Hall 2000)
- e) In patients with severe hematemesis and anemia we sometimes give a loading dose of 3–6 grams initially and then decrease to 1 gram PO three to four times a day. May not always work in vomiting dogs. Suspensions may have less tendency to be vomited up in these patients. (Willard 2006)
- f) For gastric ulcers, esophagitis: 0.5–1 gram PO per dog q8–12h (Sellon 2007)
- g) For GI ulcers/esophagitis associated with acute renal failure: 1 gram per 30 kg body weight PO q6h (Waddell 2007)

**CATS:**
- a) 0.25–0.5 grams PO q8–12h (Zerbe & Washabau 2000)
- b) Empirical dosage of sucralfate is ¼ of a 1 gram tablet per cat PO three to four times a day. (Trepanier 2010c)
- For gastric ulcers, esophagitis: 0.25–0.5 grams PO per cat PO q8–12h (Sellon 2007)

**FERRETS:**
- a) 75 mg/kg PO q4–6h; give 10 minutes prior to feeding (Williams 2000)
**SUFTENANIL CITRATE**
(non-fen-ta-nil) Sufenta®
OPIATE AGONIST

Prescriber Highlights

- Injectable, extremely potent opiate that may be useful for adjunctive anesthesia or epidural analgesia
- Marginal veterinary experience & little published data available to draw conclusions on appropriate usage in veterinary species
- Dose-related respiratory & CNS depression most likely adverse effects
- Class-II controlled substance; expensive when compared to fentanyl

**Uses/Indications**
An opioid analgesic, sufentanil may be useful as an anesthesia adjunct or as an epidural analgesic. In humans, it has been used as the primary anesthetic in intubated patients with assisted ventilation, and as a post-operative analgesic.

**Pharmacology/Actions**
Sufentanil is a potent mu opioid with the expected sedative, analgesic, and anesthetic properties. When comparing analgesic potencies, 0.01-0.04 mg of sufentanil is equivalent to 0.4-0.8 mg of alfentanil, 0.1-0.2 mg of fentanyl, and approximately 10 mg of morphine, when all are injected IM. Like fentanyl, sufentanil appears to have less circulatory effects than does morphine. Sufentanil has a rapid onset of action (1–3 minutes) and a faster recovery time than fentanyl.

**Pharmacokinetics**
No information on the pharmacokinetics of sufentanil in domestic animals was located. In humans, the drug has rapid onset of action (1–3 minutes) after intravenous injection. The drug is highly lipid soluble and has volume of distribution in the central compartment of 0.1 L/kg. Approximately 93% is bound to plasma proteins; plasma concentrations rapidly decline due to redistribution. Terminal elimination half-life is about 2.5 hours. Plasma clearance has been reported to be 11.8 mL/min/kg. Sufentanil is metabolized primarily in the liver and small intestine via O-demethylation and N-dealkylation. The parent drug and these metabolites are excreted primarily in the urine. While the manufacturer states to use with caution in patients with impaired renal of hepatic function, limited pharmacokinetic studies in these patients, rarely showed any drug accumulation.

**Contraindications/Precautions/Warnings**
Sufentanil is contraindicated in patients hypersensitive to it or other opioids. It should be used with caution in debilitated or geriatric patients and those with severely diminished renal or hepatic function.
Sufentanil Citrate Injection: 50 micrograms/mL (as base) in 1 mL, 2 mL & 5 mL amps;

**HUMAN-LABELED PRODUCTS:**
The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

**VETERINARY-LABELED PRODUCTS:**

**Dosage Forms/Regulatory Status**

- Metoclopramide, midazolam, phenobarbital, and propofol. It is reportedly compatible with D5W and bupivacaine. For Y-site injection it is compatible with lorazepam, phenytoin and thiopental.
- Additive effects can occur if sufentanil is used concurrently with other drugs that can depress CNS or respiratory function (e.g., barbiturates, etc.).
- May increase bradycardia and hypotension

**Compatibility/Compounding Considerations**

- A phenylpiperidine derivative opioid related to fentanyl, sufentanil citrate occurs as a white or almost white powder that is soluble in water, sparingly soluble in alcohol, acetone, or chloroform. The commercially available injection has a pH (adjusted with citric acid) of 3.5–6. Sufentanil citrate may also be known as: R-33800, sufentanili citras, fentathienel citrate, sufentanyl citrate, sulfentanil citrate, Fastfen®, Sufenta® and Sufentan®.

**Storage/Stability**

- Unless otherwise labeled, sufentanil injection should be stored protected from light at room temperature. Sufentanil citrate is hydrolyzed in acidic solutions.

**Compatibility/Compounding Considerations**

- Sufentanil citrate is reportedly compatible with D5W and bupivacaine. For Y-site injection it is compatible with solutions containing: atropine, dexamethasone sodium phosphate, diazepam, diphenhydramine, etomidate, metoclopramide, midazolam, phenobarbital, and propofol. It is incompatible with lorazepam, phentoin and thiopental.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

- Sufentanil Citrate Injection: 50 micrograms/mL (as base) in 1 mL, 2 mL & 5 mL amps; Sufenta® (preservative free) (Taylor); generic; (Rx, C-II).

**References**

- Fastfen®, Sufenta® and Sufentan®.
• Contraindications: Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment
• Caution: Diminished renal or hepatic function, or urinary obstruction
• Adverse Effects: Can precipitate in the urine (especially with high dosages for prolonged periods, acidic urine or highly concentrated urine); Dogs: Keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting, & nonseptic polyarthritis possible
• Potentially teratogenic; weigh risk vs. benefit
• Too-rapid IV injection may cause muscle weakness, blindness, ataxia, & collapse; SC or IM injection may cause tissue irritation

Uses/Indications
Sulfachlorpyridazine is indicated for the treatment of diarrhea caused or complicated by *E. coli* in calves less than one month of age or colibacillosis in swine. It is also used parenterally as a general-purpose sulfonamide in adult cattle and other species.

Pharmacology/Actions
Sulfonamides are usually bacteriostatic agents when used alone. They are thought to prevent bacterial replication by competing with para-aminobenzoic acid (PABA) in the biosynthesis of tetrahydrofolic acid in the pathway to form folic acid. Only microorganisms that synthesize their own folic acid are affected by sulfas.

Microorganisms that are usually affected by sulfonamides include some gram-positive bacteria, including some strains of streptococci, staphylococcus, *Bacillus anthracis*, *Clostridium tetani*, *C. perfringens*, and many strains of *Nocardia*. Sulfas have in vitro activity against some gram-negative species, including some strains of *Shigella*, *Salmonella*, *E. coli*, Klebsiella, Enterobacter, Pasteurella, and Proteus. Sulfas also have activity against some rickettsia and protozoa (Toxoplasma, *Coccidia*). Unfortunately, resistance to sulfas is a progressing phenomenon and many strains of bacteria that were once susceptible to this class of antibacterial are now resistant. The sulfas are less efficacious in pus, necrotic tissue, or in areas with extensive cellular debris.

Pharmacokinetics
Very limited information is available on the specific pharmacokinetics for this agent. In general, sulfonamides are readily absorbed from the GI tract of non-ruminants, but absorption can vary depending on the drug, species, disease process, etc. Food delays the rate, but usually not the extent of absorption. Peak levels occur within 1–2 hours in non-ruminant (and young pre-ruminant) animals. Adult ruminants may have significant delays before the drug is absorbed orally.

Sulfonamides are well distributed throughout the body and some reach significant levels in the CSF. Levels of the drugs tend to be highest in liver, kidney, and lung, and lower in muscle and bone. The sulfas can be highly bound to serum proteins, but the extent of binding is species and drug dependent. When bound to proteins the sulfas is not active.

Sulfonamides are both renally excreted and metabolized. Renal excretion of unchanged drug occurs via both tubular secretion and glomerular filtration. Protein bound drug is not filtered by the glomeruli. Metabolism is performed principally in the liver, but extra-hepatic metabolism is also involved. Mechanisms of metabolism are usually acetylation and glucuronidation. The acetylated metabolites may be less soluble and crystallization in the urine can occur with some sulfonamides, particularly at lower pH. The serum half-life of sulfachlorpyridazine is approximately 1.2 hours in cattle.

Contraindications/Precautions/Warnings
Sulfonamides are contraindicated in patients hypersensitive to them, thiazides, or sulfonylurea agents. They are also considered contraindicated in patients with severe renal or hepatic impairment and should be used with caution in patients with diminished renal or hepatic function, or urinary obstruction.

Oral sulfonamides can depress the normal cellulytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Adverse Effects
Sulfonamides (or their metabolites) can precipitate in the urine, particularly when given at high dosages for prolonged periods. Acidic or highly concentrated urine may also contribute to increased risk of crystalluria, hematuria, and renal tubule obstruction. Different sulfonamides have different solubilities at various pH’s. Alkalinization of the urine using sodium bicarbonate may prevent crystalluria, but it also decreases the amount available for tubular reabsorption. Crystalluria can usually be avoided with most of the commercially available sulfonamides by maintaining an adequate urine flow. Normal urine pH in herbivores is usually 8 or more, so crystalluria is not frequently a problem. Sulfonamides can also cause various hypersensitivity reactions or diarrhea by altering the normal gut flora.

Too rapid intravenous injection of the sulfas can cause muscle weakness, blindness, ataxia, and collapse.

Sulfas are well distributed throughout the body and some reach significant levels in the CSF. Levels of the drugs tend to be highest in liver, kidney, and lung, and lower in muscle and bone. The sulfas can be highly bound to serum proteins, but the extent of binding is species and drug dependent. When bound to proteins the sulfas is not active.

In dogs, keratoconjunctivitis sicca has been reported with sulfonamide therapy. In addition, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported in dogs.

 Oral sulfonamides can depress the normal cellulytic function of the ruminoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

Reproductive/Nursing Safety
Sulfas cross the placenta and may reach fetal levels of 50% or greater those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

Sulfonamides are distributed into milk. Safe use during lactation cannot be assumed; use with caution.

Overdosage/Acute Toxicity
Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfachlorpyridazine and may be of significance in veterinary patients:

ANTACIDS: May decrease the oral bioavailability of sulfonamides if administered concurrently

Laboratory Considerations

Sulfonamides may give false-positive results for urine glucose determinations when using the Benedict’s method.

Doses

CATTLE:

In calves for labeled indications: 33–49.5 mg/kg PO, or IV twice daily for 1–5 days; suggest initiating therapy with intravenous preparation and then changing to oral if possible (Package insert; Vetisulid®—Fort Dodge)

SWINE:

For labeled indications: 44–77 mg/kg PO per day (divide dose and give twice daily if treating individual animals) for 1–5 days (Package insert; Vetisulid®—Fort Dodge)

BIRDS:

For enteric bacterial infections:

a) Using the oral powder: Mix ½ teaspoonful per liter of water and use as only supply of drinking water for 5–10 days. May be effective for many *E. coli* enteric infections. (Clubb 1986)

b) Using the oral powder: Mix ½ tsp. per 2 quarts of water. Fairly effective for enteric infections, particularly *E. coli*. Reserved for clients who are unable to give other medications by mouth or parenterally. (McDonald 1989)

c) For pigeons: 1200 mg per gallon of drinking water. Very effective for *E. coli* and it is a good coccidiostat. (Harlin 2006)
Pharmacokinetic parameters (absorption, distribution, elimination) in each species. Since different organisms have different MIC values and the optimal ratio of trimethoprim to sulfa differs from organism to organism, this species is: 2.5 hours (dogs), 1.91–3 hours (horses), 1.5 hours (cattle). The serum elimination half-lives for sulfadiazine in various species is: 9.84 hours (dogs), 2.71 hours (horses), and 2.5 hours (cattle). While trimethoprim is metabolized to oxide and hydroxylated metabolites. Trimethoprim may be more extensively metabolized in the liver in adult ruminants, than in other species. The serum elimination half-lives for trimethoprim in various species is: 1.02 L/kg.

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- To help reduce the possibility of crystalluria occurring, animals should have free access to water; avoid dehydration.

Chemistry/Synonyms

Sulfachlorpyridazine sodium is listed as a short to intermediate-acting, low lipid soluble sulfonamide antibacterial. It is reportedly very soluble in urine at usual pH’s.

Sulfachlorpyridazine may also be known as chloricul, sulfachlorpyridazine, or Vetisalid®.

Storage/Stability

The injection should be stored at room temperature and protected from light; avoid freezing. The oral suspension should be stored at room temperature; avoid freezing. The oral boluses and powder should be stored at room temperature; avoid excessive heat (above 40°; 104°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Sulfachlorpyridazine Sodium Oral powder: 54 grams per bottle; Vetisalid® Powder (BIVI); (OTC) FDA-approved for use in calves under one month of age and swine. Slaughter withdrawal (at labeled doses) = 4 days for swine. When used orally in the milk or milk replacer for ruminating calves, treated calves must not be slaughtered for food during treatment and for 7 days after the last treatment.

- Sulfachlorpyridazine Sodium Oral Suspension: 50 mg/mL in 180 mL bottles; Vetisalid® Oral Suspension (BIVI); (OTC). FDA-approved for use in swine. Slaughter withdrawal (at labeled doses) = 4 days for swine.

HUMAN-LABELED PRODUCTS: None

References

Sulfadiazone/Trimethoprim—See Pyrimethamine/Sulfadiazine

**SULFADIAZINE/TRIMETHOPRIM**

SULFAMETHOXAZOLE/TRIMETHOPRIM (sulfa-deoxy-a-zeen; sulfa-meth-ox-azole/trymeth-o-prim) (Co-trimoxazole, Trimobrisen®, Bactrim®, Septra®)

**POTENTIATED SULFONAMIDE ANTIMICROBIAL**

Note: In the USA, two separate combinations with trimethoprim are used clinically. There are trimethoprim/sulfadiazine products FDA-approved for use in dogs, cats, and horses in both parenteral and oral dosage forms. Many veterinarians also use the human FDA-approved, trimethoprim/sulfamethoxazole oral products. In Canada, sulfadoxine is available in combination with trimethoprim for veterinary use.

**Prescriber Highlights**

- Potentiated sulfonamide antimicrobial agent
- Contraindications: Hypersensitivity to sulfas, thiazides, or sulfonylurea agents; severe renal or hepatic impairment; Doberman pinschers
- Caution: Diminished renal or hepatic function, or urinary obstruction or urolithiasis
- Adverse Effects: Dogs: Keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritides, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemias, agranulocytosis, idiopathic hepatic necrosis in dogs. Cats: Anorexia, crystalluria, hematuria, leukopenias & anemias. Horses: Transient pruritic (after IV injection). Oral: diarrhea, hypersensitivity reactions & hematologic effects (anemias, thrombocytopenia, or leukopenias
- Local injection effects possible (check label for product recommendation for injection technique)
- Potentially teratogenic, weigh risk vs. benefit

**Uses/Indications**

Although only FDA-approved for use in dogs and horses, trimethoprim/sulfadiazine etc. is used in many species to treat infections caused by susceptible organisms. See Dosage section for more information.

Trimethoprim/sulfa can be effective for prostatic infections and for infections caused by many strains of methicillin-resistant staphylococci.

**Pharmacology/Actions**

Alone, sulfonamides are bacteriostatic agents and trimethoprim is bactericidal, but when used in combination, the potentiated sulfa is bactericidal. Potentiated sulfa sequentially inhibits enzymes in the folic acid pathway, inhibiting bacterial thymidine synthesis. The sulfonamide blocks the conversion of para-aminobenzoic acid (PABA) to dihydrofolic acid (DFA), and trimethoprim blocks the conversion of DFA to tetrahydrofolate acid by inhibiting dihydrofolate reductase. Infected tissue and cellular debris can inhibit the activity of trimethoprim/sulfa by secreting PABA and thymidine.

The in vitro optimal ratio for most susceptible bacteria is approximately 1:20 (trimethoprim:sulfa), but synergistic activity can reportedly occur with ratios of 1:1–1:40. The serum concentration of the trimethoprim component is considered more important than the sulfa concentration. For most susceptible bacteria, the MIC’s for trimethoprim are generally about 0.5 micrograms/mL.

The potentiated sulfa has a fairly broad spectrum of activity. Gram-positive bacteria that are generally susceptible include most streptococci, many strains of staphylococcus (including many strains of MRSA and MRSS), and Nocardia. In horses, approximately 30% of strains tested of Streptococcus coepedimicis are resistant to TMP/Sulf. Many gram-negative organisms of the family Enterobacteriaceae are susceptible to the potentiated sulfa, but not Pseudomonas aeruginosa. Some protozoa (Pneumocystis carinii, Coccidia, and Toxoplasma) are also inhibited by the combination. Potentiated sulfa reportedly have little activity against most anaerobes, but opinions on this vary.

Resistance will develop more slowly to the combination of drugs than to either one alone. In gram-negative organisms, resistance is usually plasmid-mediated.

**Pharmacokinetics**

Trimethoprim/sulfa is well absorbed after oral administration, with peak levels occurring about 1–4 hours after dosing; the drug is more slowly absorbed after subcutaneous absorption, however. In ruminants greater than 8 weeks old, trimethoprim is apparently trapped in the ruminoreticulum after oral administration and undergoes some degradation limiting its usefulness.

Trimethoprim/sulfa is both renally excreted unchanged via glomerular filtration and tubular secretion and metabolized by the liver. The sulfa are primarily acetylated and conjugated with glucuronic acid and trimethoprim is metabolized to oxide and hydroxylated metabolites. Trimethoprim may be more extensively metabolized in the liver in adult ruminants, than in other species. The serum elimination half-lives for trimethoprim in various species is: 7.5 hours (dogs), 2.25 hours (horses), 1.5 hours (cattle). The serum elimination half-lives for sulfadiazine in various species is: 9.84 hours (dogs), 2.71 hours (horses), and 2.5 hours (cattle).

While trimethoprim is rapidly eliminated from the serum, the drug may persist for a longer period of time in tissues.

Because of the number of variables involved, it is extremely difficult to apply pharmacokinetic values in making dosage recommendations with these combinations. Each drug (trimethoprim and the sulfa) has different...
The following drug interactions have either been reported or are theoretical in humans or animals receiving trimethoprim/sulfadiazine and may be of significance in veterinary patients:

- Suppression associated with chronic overdoses may be treated with folinic acid (leucovorin) if severe. Peritoneal dialysis is not effective in removing TMP or sulfas from the circulation.
- Manifestations of an acute overdosage can include clinical signs of GI distress (nausea, vomiting, diarrhea), CNS toxicity (depression, headache, and confusion), facial swelling, bone marrow depression and increases in liver enzymes (bilirubin, alkaline phosphatase).
- Infants with hyperbilirubinemia or G-6-PD deficiency are also at risk for adverse effects.
- There are no animal reproduction studies and no adequate studies in humans for evaluating the safety of trimethoprim/sulfadiazine for contraception. In humans, the FDA categorizes this drug as category C for use during pregnancy (see monograph). (Baneth 2006) For use in horses (or FDA-approved for other animals) intended for food, there is no data indicating it is safe for use during pregnancy.
- Safety of trimethoprim/sulfadiazine has not been clearly established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported. Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category C for use during pregnancy (see monograph) and class B for use in nursing animals (see monograph). (Baneth 2006)
- In horses, transient pruritus has been noted after intravenous injection. Oral therapy has resulted in diarrhea in some horses, but incidence is relatively low. Previous administration of potentiated sulfas has been implicated in increasing the mortality rate of associated with severe diarrhea. If the 48% injectable product is injected IM, SC, or extravasates after IV administration, swelling, pain and minor tissue damage may result. Hypersensitivity reactions and hematologic effects (anemia, agranulocytosis) are possible, but fairly rare. TMP/Sulfas may be a risk factor for developing acute pancreatitis, but cause and effect have not been definitively shown.
- Adverse effects noted in cats may include anorexia, leukopenias and anemias.

**Contraindications/Precautions/Warnings**

- The manufacturer states that trimethoprim/sulfadiazine should not be used in dogs or horses showing marked liver parenchymal damage, blood dyscrasias, or those with a history of sulfonamide sensitivity. It is not for use in horses (or FDA-approved for other animals) intended for food.
- Doses appear to be very susceptible to sulfonamide-induced poly-synthetic immune complex disease and most believe that these drugs are contraindicated in them.
- This combination should be used with caution in patients with pre-existing hepatic or renal disease.
- Because of its potential for crystallization in the urine, it may be wise to avoid the use of sulfadiazine in dogs known to have uroliths, at increased risk for developing uroliths or known to have highly concentrated (dehydration) or acidic urine.

**Adverse Effects**

- Adverse effects noted in dogs include: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria and cholestasis. Potential sulfonamides may cause hypothyroidism in dogs, particularly with extended therapy. Acute hypersensitivity reactions manifesting as Type I (anaphylaxis) or Type III reaction (serum sickness) can be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers appear to be more susceptible to sulfonamide-induced poly-synthetic immune complex disease and most believe that these drugs are contraindicated in them.

**Reproductive/Nursing Safety**

- Safety of trimethoprim/sulfadiazine has not been clearly established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported. Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category C for use during pregnancy (see monograph) and class B for use in nursing animals (see monograph). (Baneth 2006) For use in horses (or FDA-approved for other animals) intended for food, there is no data indicating it is safe for use during pregnancy.

Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category C for use during pregnancy (see monograph) and class B for use in nursing animals (see monograph). (Baneth 2006) For use in horses (or FDA-approved for other animals) intended for food, there is no data indicating it is safe for use during pregnancy.
- Safety of trimethoprim/sulfadiazine has not been clearly established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported. Studies thus far in male animals have not demonstrated any decreases in reproductive performance. In humans, the FDA categorizes this drug as category C for use during pregnancy (see monograph) and class B for use in nursing animals (see monograph). (Baneth 2006)

**Cats:**
For susceptible infections:
- a) For UTI: 30 mg/kg PO q24h for 7–14 days. (Greene et al. 2006)
- b) 30 mg/kg q12h (if treating Nocardia, double dose) (Ford & Aronson 1985)
- c) For toxoplasmosis: 15 mg/kg PO q12h for 28 days (Lappin 2000a)
- d) For bacterial UTI: 30 mg/kg q12h PO (Bartges 2007)

**Ferrets:**
For susceptible infections:
- a) 30 mg/kg PO twice daily (Williams 2000)
- b) For coccidiosis: 30 mg/kg PO once daily for 14 days. (Johnson 2006)

**Rabbits, Rodents, Small Mammals:**
- a) Rabbits: 15–30 mg/kg PO q12–24h; 30–48 mg/kg SC q12h. Sulfadiazine has a very short half-life (approx. 1 hour) in rabbits. (Ivey & Morrissey 2000)
- b) Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 15–30 mg/kg PO q12h or 30 mg/kg IM q12h (Adamcak & Otten 2000)
- c) Chinchillas: 30 mg/kg PO, SC or IM q12h (Hayes 2000)

**Cattle:**
For susceptible infections:
- a) 44 mg/kg once daily IM or IV using 48% suspension (Upson 1988)
- b) 25 mg/kg, IV or IM q24h (Burrows 1980)
- c) Calves: 48 mg/kg IV or IM q24h (Baggot 1983)

**Horses:**
For susceptible infections:
- a) For respiratory tract infections: 15–30 mg/kg PO q12h. Give 30 minutes prior to feeding hay (grain is OK) (Foreman 1999)
- b) Foals: 15 mg/kg IV q12h; 30 mg/kg PO q12h (Brunbaugh 1999)
- c) 22 mg/kg IV q24h or 30 mg/kg, PO q24h (Upson 1988)
- d) 30 mg/kg PO once daily or 21.3 mg/kg IV once daily (Package inserts; Tribriissen®—Coopers)
- e) Foals: 15 mg/kg PO or IV twice daily (Furr 1999)

**Swine:**
For susceptible infections:
- a) 48 mg/kg, IM q24h (Baggot 1983)

**Birds:**
For susceptible infections:
- a) Using TMP/SMX oral suspension (240 mg/5 mL): 2 mL/kg PO twice daily. Good for many gram-positive and negative enteric and respiratory infections, particularly in hand-fed babies. May cause emesis in Macaws. (McDonald 1989)
- b) For respiratory and enteric infections in psittacines using the 24% injectable suspension: 0.22 mL/kg IM once to twice daily. For coccidiosis in toucans and mynahs using TMP/SMX oral suspension (240 mg/5 mL): 2.2 mL/kg once daily for 5 days. May be added to feed. For respiratory and enteric infections in hand-fed baby psittacines using TMP/SMX oral suspension (240 mg/5 mL): 0.22 mL/30 grams twice daily to three times daily for 5–7 days. (Clubb 1986)
- c) Using oral suspension: 50–100 mg/kg (of combined product) PO q12h (Hoeffer 1995)
- d) Ratites: For Toxoplasma gondii: 30–50 mg/kg IM twice daily (Jenson 1998)

**Reptiles:**
For susceptible infections:
- a) For most species: 30 mg/kg IM (upper part of body) once daily for 2 treatments, then every other day for 5–12 treatments. May be useful for enteric infections. (Gauvin 1993)
- b) For all species: 30 mg/kg IM, first two doses 24 hours apart and then every other day (Jacobson 1999)
- c) 15–25 mg/kg/day IM for 7–14 days (Lewbart 2001)

**Monitoring**
- Clinical efficacy
- Adverse effects; with chronic therapy, periodic complete blood counts should be considered
- In dogs, monitor tear production (one suggestion is in 5 days and every 2–3 weeks)
- Thyroid function tests should be considered (baseline and ongoing) particularly in dogs receiving long-term treatment. Some do not feel this is necessary.

**Client Information**
- If using oral suspension, shake well before using; does not need to be refrigerated
- Animals must be allowed free access to water and must not become dehydrated while on therapy
- If dogs eyes are dry or become irritated contact veterinarian

**Chemistry/Synonyms**
Trimethoprim occurs as odorless, bitter-tasting, white to cream-colored crystals or crystalline powder. It is very slightly soluble in water and slightly soluble in alcohol. Sulfadiazine occurs as an odorless or nearly odorless, white to slightly yellow powder. It is practically insoluble in water and sparingly soluble in alcohol.
Sulfamethoxazole occurs as a practically odorless, white to off-white, crystalline powder. Approximately 0.29 mg are soluble in 1 mL of water and 20 mg are soluble in 1 mL of alcohol. In combination, these products may be known as: Co-trimoxazole, SMX-TMP, TMP-SMX, trimethoprim-sulfamethoxazole, sulfamethoxazole-trimethoprim, sulfadiazine-trimethoprim, trimethoprim-sulfadiazine, TMP-SDZ, SDF-TMP, Co-trimazine or by their various trade names.

**Storage/Stability**
Unless otherwise instructed by the manufacturer, trimethoprim/sulfadiazine and co-trimoxazole products should be stored at room temperature (15–30°C) in tight containers.

**Dosage Forms/Regulatory Status/Withdrawal Times**

**Veterinary-Labeled Products:**
Trimethoprim (TMP)/Sulfadiazine (SDZ) Oral Paste: Each gram contains 67 mg trimethoprim and 333 mg sulfadiazine. Available in 37.5 gram (total weight) syringes; Tribriissen® 400 Oral Paste (Schering-Plough); (Rx). FDA approved for use in horses not intended for food.
Sulfadimethoxine injection and tablets are FDA-approved for use in dogs and cats for respiratory, genitourinary, enteric and soft tissue infections caused by susceptible organisms. Sulfadimethoxine is used in the treatment of coccidiosis in poultry. In horses, sulfadimethoxine injection is FDA-approved for the treatment of respiratory infections caused by Streptococcus equi.

Sulfadimethoxine is added to drinking water to treat coccidiosis, fowl cholera, and infectious coryza in poultry. In horses, sulfadimethoxine injection is FDA-approved for the treatment of respiratory infections caused by Streptococcus equi.

Sulfadimethoxine injection and tablets are FDA-approved for use in dogs and cats for respiratory, genitourinary, enteric and soft tissue infections caused by susceptible organisms. Sulfadimethoxine is used in the treatment of coccidiosis in poultry. In horses, sulfadimethoxine injection is FDA-approved for the treatment of respiratory infections caused by Streptococcus equi.
Sulfastop

A long-acting sulfonamide, sulfadimethoxine occurs as an odorless or almost odorless, creamy white powder. It is very slightly soluble in water and slightly soluble in alcohol.

**Inhalation Considerations**

In dogs, keratoconjunctivitis sicca, bone marrow depression, hypersensitivity reactions (rashes, dermatitis), focal retinitis, fever, vomiting and nonseptic polyarthritis have been reported with sulfonamides.

Oral sulfonamides can depress the normal cellytic function of the rumenoreticulum, but this effect is generally temporary and the animal adapts.

Because solutions of sulfonamides are usually alkaline, they can cause tissue irritation and necrosis if injected intramuscularly or subcutaneously.

**Reproductive/Nursing Safety**

Sulfas cross the placenta and may reach fetal levels of 50% or greater of those found in maternal serum; teratogenicity has been reported in some laboratory animals when given at very high doses. They should be used in pregnant animals only when the benefits clearly outweigh the risks of therapy.

**Overdosage/Acute Toxicity**

Acute toxicity secondary to overdoses apparently occurs only rarely in veterinary species. In addition to the adverse effects listed above, CNS stimulation and myelin degeneration have been noted after very high dosages.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving sulfonamides and may be of significance in veterinary patients:

- **ANTACIDS**: May decrease the oral bioavailability of sulfonamides if administered concurrently.

**Laboratory Considerations**

- Sulfonamides may give false-positive results for urine glucose determinations when using the Benedict’s method.

**Doses**

- **DOGS**: For susceptible infections:
  - a) 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
  - b) 100 mg/kg PO, IV or IM once daily (Upson 1988)
  - c) 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; Albon®—Roche)

  For coccidiosis:
  - a) 55 mg/kg PO initially on the first day of therapy, then 27.5 mg/kg PO once daily for 9 days (Matz 1995)
  - b) 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007)
  - c) During the infant period (2–6 weeks): 50 mg/kg PO on the first day followed by a daily dose of 25 mg/kg PO until symptoms regress (Macintire 2004)

- **CATS**: For susceptible infections:
  - a) 25 mg/kg PO, IV, or IM once daily (Davis 1985), (Kirk 1989)
  - b) 100 mg/kg PO, IV or IM once daily (Upson 1988)
  - c) 55 mg/kg PO, or IV, or SC initially, then 27.5 mg/kg once daily thereafter (Package insert; Albon®—Roche)

  For coccidiosis:
  - a) 50 mg/kg once daily for 10–14 days will eliminate oocyst excretion in most dogs and cats. (Marks 2007)

- **FERRETS**: For susceptible infections:
  - a) 25 mg/kg PO, SC or IM once daily (Williams 2000)
  - b) For coccidiosis: 25 mg/kg PO once daily for 14 days. (Johnsson 2006)

- **RABBITS, RODENTS, SMALL MAMMALS**:
  - a) Rabbits: 10–15 mg/kg PO q12h (Ivey & Morrisey 2000)
  - b) Rabbits: For coccidiosis: 25 mg/kg PO once daily (Burke 1999)
  - c) Hedgehogs: 2–20 mg/kg/day IM, SC or PO (Smith 2000)
  - d) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: As a coccidiostat: 50 mg/kg PO once, then 25 mg/kg PO once daily for 10–20 days or 75 mg/kg PO for 7–14 days (Adamcak & Oten 2000)

- **CATTLE**:
  - For susceptible infections:
    - a) 110 mg/kg PO or IV once daily (Upson 1988)
    - b) 55 mg/kg IV initially, then 27.5 mg/kg IV once daily (Baggot 1983)
    - c) 110 mg/kg, PO Q24h (Burrows 1980)
    - d) 55 mg/kg PO or IV initially, then 27.5 mg/kg q24h (Jenkins 1986)
    - e) 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV or PO for up to 5 days. If using sustained release boluses: 137.5 mg/kg PO every 4 days (Package insert; Albon®—Roche)

- **HORSES**:
  - For susceptible infections:
    - a) 55 mg/kg, PO or IV q12h (Upson 1988)
    - b) 55 mg/kg IV or PO initially, then 27.5 mg/kg q24h IV (Package insert; Albon®—Roche)

- **CAMELIDS (NWC)**:
  - a) For coccidiosis (“regular” coccidia: *E. alpaca*, *E. lamae, E. punoensis, E. peruviana*): 15 mg/kg PO twice daily for 5 days; monitor for signs of polioencephalomalacia. (Walker 2009)
  - b) Treatment of Eimeria infection is generally directed at clinically affected animals using sulfadimethoxine at 110 mg/kg PO q24h (or amprolium). Treatments are effective only against the immature stages and therefore may not have a significant impact on fecal oocyst count initially. Given the long prepatent period, it is prudent to treat *E. macusaniensis* infections for 10-15 days. Treatment should be directly administered to the animal rather than by medicating water supplies. (McKenzie 2008)

- **REPTILES**:
  - For susceptible infections:
    - a) For coccidia: 90 mg/kg PO on day one and then 45 mg/kg PO on 5 successive days; may also be given IM or IV. Maintain adequate hydration. (Lewbart 2001)

**Chemistry/Synonyms**

A long-acting sulfonamide, sulfadimethoxine occurs as an odorless or almost odorless, creamy white powder. It is very slightly soluble in water and slightly soluble in alcohol.

Sulfadimethoxine may also be known as: solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, Albon®, Amtech®, Chemissal®, Deltin®, Di-Methox®, Ritarsulfa®, Ritarsulfa®, SDM®, Sulfadren®, Sulfastop®, or Sulfasol®, and Sulfathiazol.
**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Sulfadimethoxine Injection: 400 mg/mL (.4%) in 100 mL vials; Albon® Injection 40% (Pfizer); Di-Methox® Injection 40% (Agrin Labs), generic; (Rx) FDA-approved for use in dogs, cats, horses, swine and cattle. Not to be used in horses intended for food or calves to be processed for veal. Slaughter withdrawal (at labeled doses) = 5 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Tablets: 125 mg, 250 mg, and 500 mg; Albon® Tablets (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Sulfadimethoxine Oral Suspension: 50 mg/mL in 2 oz, and 16 oz. Bottles; Albon® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Sulfadimethoxine Oral Boluses: 5 grams, and 15 grams; Albon® (Pfizer); (OTC). FDA-approved for use in cattle. Not to be used in calves to be processed for veal. No withdrawal period has been established for this in pre-chemist calves. Slaughter withdrawal (at labeled doses) = 7 days (cattle); milk withdrawal (at labeled doses) = 60 hours.

Sulfadimethoxine Oral Boluses Sustained-Release: 12.5 g; Albon® SR (Pfizer); (Rx) FDA-approved for use in non-lactating cattle. Slaughter withdrawal (at labeled doses) = 21 days (cattle), a withdrawal period has not been established for pre-chemist calves. Not for use in calves intended to be processed for veal.

Sulfadimethoxine Soluble Powder: 94.6 grams/packet (for addition to drinking water); Albon® (Pfizer), generic; FDA-approved for use in dairy calves, dairy heifers, beef cattle, broiler and replacement chickens only, and meat-producing turkeys. Slaughter withdrawal (at labeled doses) = 7 days (cattle); 5 days (poultry—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

Sulfadimethoxine 12.5% Concentrated Solution (for addition to drinking water); Albon® (Pfizer), generic; (OTC). FDA-approved for use in chickens, turkeys and cattle. Slaughter withdrawal (at labeled doses) = 7 days (for dairy calves, dairy heifers and beef cattle only. Withdrawal for pre-chemist calves has not been established. Not to be used in calves to be processed for veal; 5 days (poultry)—do not use in chickens over 16 weeks old or in turkeys over 24 weeks old).

**HUMAN-LABELLED PRODUCTS:** None

**SULFADIMETHOXINE/ORMETOPRIM**

**Potentiated Sulfonamide Antimicrobial**

**Prescriber Highlights**

- Potentiated sulfa similar to trimethoprim/sulfa, but may have fewer adverse effects and is labeled for once daily dosing.
- Does not appear to be effective for prostate infections and is more expensive than generic trimethoprim/sulfa.
- The following apply to TMP/Sulfa & may apply to this agent as well:
  - Contraindications: Hypersensitive to sulfa's, thiazides, or sulfonurea agents; severe renal or hepatic impairment; Dobermans
  - Caution: Diminished renal or hepatic function, or urinary obstruction or urolithiasis
  - Adverse Effects: Dogs: Keratoconjunctivitis sicca, hypersensitivity (type 1 or type 3) acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polycythemia, facial swelling, polydipsia, crystalluria, hematuria, polyuria, cholestasis, hypothyroidism, anemias, agranulocytosis, idiosyncratic hepatic necrosis in dogs. Cats: Anorexia, crystalluria, hematuria, leukopenias & anemias
  - Potentially teratogenic, weigh risk vs. benefit

**Uses/Indications**

Sulfadimethoxine/ormetoprim is FDA-approved for the treatment of skin and soft tissue infections in dogs caused by susceptible strains of *Staphylococcus aureus* and *E. coli*. Some felt that it has fewer adverse effects in dogs than trimethoprim/sulfa and can be dosed once daily. It is more expensive than trimethoprim/sulfa and does not appear to penetrate into the prostate as well.

**Pharmacology/Actions**

Sulfadimethoxine/ormetoprim shares mechanisms of action and probably the bacterial spectrum of activity with trimethoprim/sulfa. Alone, sulfonamides are bacteriostatic agents, but in combination with either ormetoprim or trimethoprim, the potentiated sulfa is bactericidal. Potentiated sulfa's sequentially inhibit enzymes in the folic acid pathway, thereby inhibiting bacterial thymidine synthesis. The sulfonamide blocks the conversion of para-amino-benzoic acid (PABA) to dihydrofolic acid (DFA) and ormetoprim blocks the conversion of DFA to tetrahydrofolic acid by inhibiting dihydrofolate reductase.

The potentiated sulfa's have a fairly broad spectrum of activity. Gram-positive bacteria that are generally susceptible include most streptococci, many strains of staphylococcus, and Nocardia. Many gram-negative organisms of the family Enterobacteriaceae are susceptible to the potentiated sulfa's, but not *Pseudomonas aeruginosa*. Some protozoa (*Pneumocystis carinii*, Coccidia and Toxoplasma) are also inhibited by the combination. Potentiated sulfa's reportedly have little activity against most anaerobes, but opinions on this vary.

Resistance will develop more slowly to the combination of drugs, than to either one alone. In gram-negative organisms, resistance is usually plasmid-mediated.

**Pharmacokinetics**

The pharmacokinetics of sulfadimethoxine are outlined in the previous monograph. Pharmacokinetic data for ormetoprim is not available at the time of this writing, but the manufacturer states that therapeutic levels are maintained over 24 hours at recommended doses. Unlike trimethoprim/sulfa, ormetoprim does not apparently attain clinically effective levels in the prostate for treating bacterial prostatic infections.

**Contraindications/Precautions/Warnings**

The manufacturer states that ormetoprim/sulfadimethoxine should not be used in dogs showing marked liver parenchymal damage, blood dyscrasias, or in those with a history of sulfonamide sensitivity. Doberman pinschers appear to be very susceptible to sulfonamide-induced poly-systemic immune complex disease and most believe that these drugs are contraindicated in them.
Sulfasalazine is used for the treatment of inflammatory large bowel (colonic) disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs. It is not effective for small intestinal

Adverse Effects
This combination would be expected to exhibit an adverse reaction profile in dogs similar to that seen with trimethoprim/sulfa, including: keratoconjunctivitis sicca (which may be irreversible), acute neutrophilic hepatitis with icterus, vomiting, anorexia, diarrhea, fever, hemolytic anemia, urticaria, polyarthritis, facial swelling, polydipsia, polyuria, and cholestasis. Acute hypersensitivity reactions manifesting as Type I (anaphylaxis) or Type III reaction (serum sickness) can also be seen. Hypersensitivity reactions appear to be more common in large breed dogs; Doberman Pinschers may possibly be more susceptible to this effect than other breeds. Other hematologic effects (anemias, agranulocytosis) are possible, but fairly rare.

Long-term (8 weeks) therapy at recommended doses with ormetoprim/sulfadimethoxine (27.5 mg/kg once daily) resulted in elevated serum cholesterol, thyroid and liver weights, mild follicular thyroid hyperplasia, and enlarged basophilic cells in the pituitary. The manufacturer states that the principal treatment-related effect of extended or excessive usage is hypothyroidism.

Reproductive/Nursing Safety
Safety of ormetoprim/sulfadimethoxine has not been established in pregnant animals. Reports of teratogenicity (cleft palate) have been reported in some lab animals with trimethoprim/sulfa.

Overdosage/Acute Toxicity
In experimental studies in dogs, doses greater than 80 mg/kg resulted in slight tremors and increased motor activity in some dogs. Higher doses may result in depression, anorexia, or seizures.

It is suggested that very high oral overdoses be handled by emptying the gut using standard precautions and protocols and by treating clinical signs supportively and symptomatically.

Drug Interactions; Laboratory Considerations

Doses

DOGS:
For susceptible infections:

a) Initially 55 mg/kg (combined drug) PO on the first day of therapy, then 27.5 mg/kg PO once daily for at least 2 days after remission of clinical signs. Not approved for treatment longer than 21 days. (Package insert; Primor®—Pfizer)

Monitoring

- Clinical efficacy
- Adverse effects
- In dogs, monitor tear production (one suggestion is in 5 days after starting treatment and then every 2-3 weeks)

Client Information

- Animals must be allowed free access to water and must not become dehydrated while on therapy.

Chemistry/Synonyms

A diaminopyrimidine structurally related to trimethoprim, ormetoprim occurs as a white, almost tasteless powder. The chemistry of sulfadimethoxine is described in the previous monograph.

Sulfadimethoxine may also be known as: solfadimetossina, solfadimetossipirimidina, sulphadimethoxine, Chemiosal®b, Delitin®, Risulfir®, Ritarsulfa®, Sulfadren®, Sulfactiv®, Sulfadiazine®, or Sulfathior®.

Ormetoprim may also be known as NSC-95072, ormetoprima, ormétoprime, ormetoprimum, or Ro-5-9754.

Storage/Stability

Unless otherwise instructed by the manufacturer, store tablets in tight, light resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sulfadimethoxine/Ormetoprim Tablets (scored)
120’s: 100 mg Sulfadimethoxine, 20 mg Ormetoprim
240’s: 200 mg Sulfadimethoxine, 40 mg Ormetoprim
600’s: 500 mg Sulfadimethoxine, 100 mg Ormetoprim
1200’s: 1000 mg Sulfadimethoxine, 200 mg Ormetoprim; Primor® (Pfizer); (Rx) FDA-approved for use in dogs.

Sulfadimethoxine/Ormetoprim medicated premix: 113.5 grams sulfadimethoxine and 68.1 grams ormetoprim per pound in 50 lb bags. FDA-approved for use in chickens [broilers, replacements (breeders and layers)], turkeys, ducks, & Chukar partridges. Slaughter withdrawal (at labeled doses) = 5 days. Do not feed to chickens over 16 weeks or age, turkeys or ducks producing eggs for food.

1200’s: 200 mg Sulfadimethoxine, 40 mg Ormetoprim
120’s: 100 mg Sulfadimethoxine, 20 mg Ormetoprim

Sulfadimethoxine/Ormetoprim Tablets (scored)

**Uses/Indications**

Sulfasalazine is used for the treatment of inflammatory large bowel (colonic) disease in dogs and cats. It has also been suggested for adjunctive use in treating vasculitis in dogs. It is not effective for small intestinal...
**Contraindications/Precautions/Warnings**

Sulfasalazine is contraindicated in animals hypersensitive to it, sulfonamides or salicylates. It is also contraindicated in patients with intestinal or urinary obstructions. Doberman pinschers appear to be very susceptible to sulfonamide-induced polyneuropathic immune complex disease and most believe that these drugs are contraindicated in them.

It should be used with caution in animals with preexisting liver, renal or hematologic diseases. Because cats can be sensitive to salicylates (see the aspirin monograph), use caution when using this drug in this species.

**Adverse Effects**

Although adverse effects do occur in dogs, with keratoconjunctivitis sicca (KCS) reported most frequently, they are considered to occur relatively uncommonly. Other potential adverse effects include anorexia, vomiting, cholestatic jaundice, hemolytic anemia, leucopenia, vomiting, decreased sperm counts and an allergic dermatitis. Should decreased tear production be noted early, either reducing the dose or discontinuing the drug may prevent progression of KCS or increase tear production.

Cats can occasionally develop anorexia and vomiting which may be alleviated by use of the enteric-coated tablets. Anemias secondary to sulfasalazine are also potentially possible in cats.

**Pharmacology/Actions**

While the exact mechanism of action for its therapeutic effects in treating colitis in small animals has not been determined, it is believed that after sulfasalazine is cleaved into sulfapyridine and 5-aminosalicylic acid (5-ASA, mesalamine) by bacteria in the gut the antibacterial (sulfapyridine) and/or anti-inflammatory (mesalamine) activity alters the clinical signs/course of the disease. Levels of both drugs in the colon are higher then by giving them orally as separate agents.

**Pharmacokinetics**

Only about 10–33% of an orally administered dose of sulfasalazine is absorbed. Apparently, some of this absorbed drug is then excreted unchanged in the bile. Unabsorbed and biliary excreted drug is cleaved into 5-ASA and sulfapyridine in the colon by bacterial flora. The sulfapyridine component is rapidly absorbed, but only a small percentage of the 5-ASA is absorbed. Absorbed sulfapyridine and 5-ASA are heptatically metabolized and then renally excreted.

**Overdosage/Acute Toxicity**

Little specific information is available regarding overdoses with this agent, but because massive overdoses could cause significant salicylate and/or sulfonamide toxicity, standard protocols (empty stomach, cathartics, etc.) have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.

**Efficacy**

Clients should monitor for clinical signs of KCS (dry cornea, blepharospasm, bilateral mucopurulent discharge) and report them to the veterinarian immediately.

**Contraindications/Precautions/Warnings**

Sulfasalazine is contraindicated in animals hypersensitive to it, sulfonamides or salicylates. It is also contraindicated in patients with intestinal or urinary obstructions. Doberman pinschers appear to be very susceptible to sulfonamide-induced polyneuropathic immune complex disease and most believe that these drugs are contraindicated in them.

It should be used with caution in animals with preexisting liver, renal or hematologic diseases. Because cats can be sensitive to salicylates (see the aspirin monograph), use caution when using this drug in this species.

**Efficacy**

Clients should monitor for clinical signs of KCS (dry cornea, blepharospasm, bilateral mucopurulent discharge) and report them to the veterinarian immediately.
**Tadalafil**

**PHOSPHODIESTERASE TYPE 5 INHIBITOR**

**Prescriber Highlights**

- PDPS inhibitor that may be useful for treating pulmonary arterial hypertension in dogs
- Very limited clinical experience or published data for use in dogs
- Appears to have a longer duration action than sildenafil
- Contraindicated if patients receiving organic nitrates
- Adverse effects not well-known for dogs; inguinal flushing, GI effects reported with sildenafil
- Currently, very expensive

**Uses/Indications**

Tadalafil is a phosphodiesterase-5 inhibitor similar to sildenafil and may be useful for treating pulmonary arterial hypertension (PAH) in dogs. A pilot study done in dogs with PAH, showed that tadalafil (1 mg/kg PO) caused modest, but significant decreases in diastolic pulmonary arterial pressure (PAP), mean PAP and tricuspid regurgitation suggesting that oral tadalafil, when added to conventional heart failure therapy, decreases PAP in dogs with PAH. Because of its longer duration of action, tadalafil has some advantages over sildenafil but it is currently very expensive.

In humans, tadalafil is approved for use in treating pulmonary artery hypertension (Advair®) and erectile dysfunction (Cialis®). Off-label uses include treating Raynaud’s phenomenon.

**Pharmacology/Actions**

Tadalafil is a selective inhibitor of cyclic guanosine monophosphate (cGMP)–specific phosphodiesterase type 5 (PDE5). PDE5 is the enzyme responsible for the degradation of cGMP and is found (in humans) in the corpus cavernosum smooth muscle, pulmonary vascular and visceral smooth muscle, skeletal muscle, platelets, kidney, lung, cerebellum, and pancreas. In patients with PAH, vascular endothelium nitric oxide release is impaired with associated reduction of cGMP. PDE5 is the primary phosphodiesterase in pulmonary vasculature and tadalafil’s PDE5 inhibition increases cGMP thereby relaxing pulmonary vascular smooth muscle with resultant vasodilation.

**Pharmacokinetics**

No pharmacokinetic data for tadalafil for dogs was located.

In humans, after oral administration maximum plasma concentrations occur at around 4 hours in patients with PAH. Food does not alter the rate or extent of absorption. Tadalafil is 94% bound to human plasma proteins.

**Contraindications/Precautions/Warnings**

Tadalafil is contraindicated in human patients using (either regularly or intermittently) any form of organic nitrate, and in those with serious hypersensitivity to tadalafil. Dosage reductions may be required in patients with severe hepatic or renal impairment.

**Adverse Effects**

An adverse effect profile for dogs at suggested doses for PAH has not been determined. Cutaneous flushing of the inguinal region has been reported with sildenafil in dogs. GI effects are possible. In a 12-month tadalafil chronic toxicity study done in dogs, no disseminated arteritis was observed as was seen in rodent studies, but 2 dogs exhibited marked decreases in neutrophils and moderate decreases in platelets with inflammatory signs when dosed at approximately 4x to 18x the equivalent human dose. These effects were reversible within 2 weeks after discontinuing the drug.

Most common adverse effects of tadalafil reported in humans with PAH, include: dyspepsia, nausea, back pain, myalgia, nasal congestion, flushing and headache. Rare, but serious adverse effects include hypotension, optic neuropathy, seizures, Stevens-Johnson syndrome and exfoliative dermatitis, and deafness.

**Reproductive/Nursing Safety**

Tadalafil animal reproduction studies in rats and mice demonstrated no evidence of teratogenicity, embryotoxicity, or fetotoxicity when tadalafil was given to pregnant rats or mice at exposures of up to 11X (human equivalent dose). The FDA categorizes tadalafil as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

**References**

Tadalafil and/or its metabolites are secreted into the milk in lactating rats at concentrations approximately 2.4-fold found in the plasma. It is unlikely to pose much risk to nursing offspring. It is expected that overdoses in animals would mirror the drug’s adverse effect profile; treat supportively. Contact an animal poison control center for guidance, if necessary.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tadalafil and may be of significance in veterinary patients:

- **ALPHA-ADRENERGIC BLOCKERS** (e.g., phentolamine, phenothiazines, phenoxylbenzamine): May increase hypotensive effects
- **AMLODIPINE**: Potential to increase hypotensive effects
- **ANTIHYPERTENSIVE, HYPOTENSIVE DRUGS**: Potentially could increase hypotensive effects
- **AZOLE ANTIFUNGALS** (ketoconazole, itraconazole): May reduce tadalafil metabolism and increase AUC
- **CIMETIDINE**: May reduce tadalafil metabolism and increase AUC
- **ERYTHROMYCIN, CLARITHROMYCIN**: May reduce tadalafil metabolism and increase AUC
- **INHIBITORS** (e.g., NTG, Iso-sorbide): Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **NITROPRUSSIDE SODIUM**: Significant potentiation of vasodilatory effects; life-threatening hypotension possible
- **PHENOBARBITAL**: May decrease tadalafil concentrations
- **RIFAMPIN**: May decrease tadalafil concentrations

Laboratory Considerations
None noted

Doses

**DOGS:**

- For pulmonary arterial hypertension:
  - a) From a case report in a Yorkshire terrier: 1 mg/kg PO q48h (every other day) was added to the background treatment (furosemide, spironolactone, benazepril, dexamethasone and oxygen). Dog’s condition rapidly (≤24 hours) improved and 7-day follow-up showed a decrease (up to 26 mmHg) in systolic pulmonary arterial pressure and disappearance of all respiratory and cardiac signs of PAH (cyanosis, syncope and tachypnea). Authors recommend long-term studies in more animals. (Serres *et al.* 2006)
  - b) 1 mg/kg PO once daily. (Oyama 2009)

Monitoring
- Clinical efficacy (improved syncope, cough, respiratory effort)
- Pulmonary artery pressure, systemic blood pressure
- Adverse effects

Client Information
- Brief clients on the experimental nature of using this medication in small animals and the costs of therapy
- Report any adverse effects to the veterinarian

Chemistry/Synonyms
Tadalafil has a molecular weight of 389.41. It is insoluble in water and slightly soluble in ethanol.

Tadalafil may also be known as: GF-196960, IC-351, tadalafil fil, tadalafil, or tadalafilum. Cialis® and Adcirca® are trade names for tadalafil.

Storage/Stability
Tadalafil tablets should be stored at room temperature between 59°-86°F (15° and 30°C).

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Tadalafil Oral Tablets: 2.5 mg, 5 mg, 10 mg, 20 mg: Cialis® and Adcirca® (Lilly); (Rx)

References

**TAURINE**

*tor*-een

**AMINO ACID NUTRITIONAL**

Prescriber Highlights

- Amino acid used primarily for the treatment of taurine deficiency cardiomyopathies in cats & dogs
- May also be useful for many other conditions (e.g., seizures, hepatic lipidosis), but little supporting data available
- Very low toxic potential
- Laboratory considerations

Uses/Indications
Taurine has proven beneficial in preventing retinal degeneration and the prevention and treatment of taurine-deficiency dilated cardiomyopathy in cats. Although modern commercial feline diets have added taurine, some cats still develop taurine-deficiency associated dilated cardiomyopathy. It may also be of benefit in taurine (carnitine) deficient cardiomyopathy in dogs. In vivo, taurine is synthesized from methionine. Cysteinylsulfenic acid decarboxylase (CSAD) and vitamin B6 are involved with this synthesis. Deficiencies of either will depress taurine synthesis. Cats are particularly susceptible to taurine deficiency as they have low CSAD activity and use taurine almost exclusively for bile acid conjugation.

Additionally taurine is important in the modulation of calcium flux, thereby reducing platelet aggregation, stabilizing neuronal membranes, and affecting cardiac function. Taurine’s effects on cardiac function include positive inotropic activity without affecting resting potential and modulating ionic currents across the cell membrane. Taurine is important for normal development of the CNS and it has a GABA-like effect that may make it useful for treating some seizure disorders.

Pharmacology/Actions
While classically considered a “non-essential” nutrient, taurine has been found to play several “essential” roles in various mammalian species. Taurine is important for bile acid conjugation, especially in cats and dogs. In vivo, taurine is synthesized from methionine. Cysteinylsulfenic acid decarboxylase (CSAD) and vitamin B6 are involved with this synthesis. Deficiencies of either will depress taurine synthesis. Cats are particularly susceptible to taurine deficiency as they have low CSAD activity and use taurine almost exclusively for bile acid conjugation.

Monitoring
Clinical efficacy
Taurine levels (if possible and affordable; whole blood levels preferable to plasma/serum levels)

Chemistry/Synonyms
Taurine, an amino acid also known as 2-aminoisulphonic acid, has a molecular wt. of 125. Solubility in 100 mL of water at 20°C is 8.8 grams.

Storage/Stability
Unless otherwise labeled, store taurine tablets or capsules at room temperature. Protect from light and moisture.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
The following products are labeled (not FDA-approved drugs) for use in animals:
Taurine Tablets: 250 mg: *Formula V® (PetAg); Labeled for use in cats.
Taurine Liquid: 375 mg/4 mL (one pump); *Dyna-Taurinet® (Harlmen); Labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:
There are several oral dosage form products available for taurine. Technically considered a “nutrient” they are all OTC and may need to be obtained from health food stores. Most dosage forms available range from 125 mg to 500 mg.

References

TEPOXALIN
(te-pox-a-lin/Zuberta®)
Uses/Indications
Tepoxalin is indicated for the treatment of pain and inflammation associated with osteoarthritis in dogs. Because of the drug’s inhibitory effects on leukotrienes, there is interest in seeing if it would be beneficial in the adjunctive treatment of allergic conditions in dogs.

Pharmacology/Actions
Tepoxalin is a dual inhibitor of both cyclooxygenase (COX) and 5-lipoxygenase (LOX). It inhibits both COX-1 and COX-2 enzymes, but it is not clear if it is COX-2 preferential in the dog (it is not COX-2 preferential in sheep utrine cells) or if its LOX inhibition reduces the adverse effects associated with COX-1 inhibition. LOX inhibition in dogs persists for only about 6 hours after dosing. By inhibiting COX-2 enzymes, tepoxalin reduces the production of prostaglandins associated with pain, hyperpyrexia and inflammation. Its inhibition of LOX potentially reduces the production of leukotrienes, including leukotriene B4. As leukotriene B4 may contribute to increased GI tract inflammation by increasing cytokine production, neutrophil longevity and release of proteases, inhibition may reduce the GI effects routinely seen in dogs with COX-1 inhibitors. Leukotrienes may also contribute to inflammatory responses seen in osteoarthritic conditions and their inhibition could reduce clinical signs seen with the condition.

Pharmacokinetics
After oral administration to dogs, tepoxalin is readily absorbed and peak levels occur between 2–3 hours post-dose. The presence of food in the gut increases bioavailability. Tepoxalin is rapidly metabolized to several metabolites, including one that it active (tepoxalin pyrazole acid). Tepoxalin and tepoxalin pyrazole acid are highly bound to plasma proteins (98–99%). Elimination half-lives for tepoxalin and tepoxalin pyrazole acid are about 2 hours and 13 hours, respectively. Metabolites are eliminated in the feces; only 1% of the drug is eliminated in the urine.

Contraindications/Precautions/Warnings
Tepoxalin is contraindicated in dogs demonstrating prior hypersensitivity reactions to tepoxalin. It should be used with caution in patients with impaired hepatic, cardiovascular or renal function, or at risk for developing nephrotoxic affects associated with NSAIDs (i.e., dehydrated or on concomitant diuretic therapy). Patients with active gastrointestinal ulcers should probably not receive this drug.

Adverse Effects
Adverse effects most likely seen in dogs include diarrhea, vomiting, anorexia/appetence, enteritis, and lethargy. In one study where dogs received labeled doses for 4 weeks, 22% of dogs developed diarrhea and 20% vomited. It is unknown if giving the drug with food will decrease vomiting incidence. Other adverse effects reported (incidences <1%) include incoordination, incontinence, increased appetite, eating grass, flatulence, hair loss, and trembling. While all NSAIDs can potentially cause renal dysfunction, a study done in healthy dogs did not show that tepoxalin altered renal blood flow or renal function when used alone or with benazepril (for 7 days) or with enalapril (for 28 days) (Fusellier et al. 2005).

Reproductive/Nursing Safety
Safety of this drug has not been determined in pregnant, breeding, or lactating dogs; use with caution and with informed consent of client.

Overdosage/Acute Toxicity
Information on acute overdosage of tepoxalin was not located. Dogs receiving 300 mg/kg/day for 6 months showed decreases in total protein, albumin and calcium concentrations. At necropsy, all dogs showed gastric lesions. An acute overdose may cause significant GI distress and ulceration with GI bleeding. It is suggested to treat supportively and monitor CBC, hydration, renal function, and for evidence of GI bleeding. Contact an animal poison control center for more information.

Contraindications/Precautions/Warnings
Tepoxalin is contraindicated in dogs demonstrating prior hypersensitivity reactions to tepoxalin. It should be used with caution in patients with impaired hepatic, cardiovascular or renal function, or at risk for developing nephrotoxic affects associated with NSAIDs (i.e., dehydrated or on concomitant diuretic therapy). Patients with active gastrointestinal ulcers should probably not receive this drug.

Adverse effects most likely seen in dogs include diarrhea, vomiting, anorexia/appetence, enteritis, and lethargy. In one study where dogs received labeled doses for 4 weeks, 22% of dogs developed diarrhea and 20% vomited. It is unknown if giving the drug with food will decrease vomiting incidence. Other adverse effects reported (incidences <1%) include incoordination, incontinence, increased appetite, eating grass, flatulence, hair loss, and trembling. While all NSAIDs can potentially cause renal dysfunction, a study done in healthy dogs did not show that tepoxalin altered renal blood flow or renal function when used alone or with benazepril (for 7 days) or with enalapril (for 28 days) (Fusellier et al. 2005).

The manufacturer warns to discontinue the drug if signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus, or lethargy are observed. Safety studies in dogs less than 6 months of age have not been completed.

Reproductive/Nursing Safety
Safety of this drug has not been determined in pregnant, breeding, or lactating dogs; use with caution and with informed consent of client.

Overdosage/Acute Toxicity
Information on acute overdosage of tepoxalin was not located. Dogs receiving 300 mg/kg/day for 6 months showed decreases in total protein, albumin and calcium concentrations. At necropsy, all dogs showed gastric lesions. An acute overdose may cause significant GI distress and ulceration with GI bleeding. It is suggested to treat supportively and monitor CBC, hydration, renal function, and for evidence of GI bleeding. Contact an animal poison control center for more information.

Drug Interactions
A study in normal dogs showed no significant changes in renal function when enalapril was used with tepoxalin.

The following drug interactions have either been reported or are theoretical in human or animals receiving tepoxalin and may be of significance in veterinary patients:

-**ASPIRIN:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
-**CORTICOSTEROIDS:** As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tepoxalin
-**DIGOXIN:** NSAIDs may increase serum levels
-**FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans, it is unknown if fluconazole affects tepoxalin levels in dogs
-**FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
-**METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
-**NEPHROTOXIC DRUGS** (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity
-**NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
-**WARFARIN:** The manufacturer cautions to closely monitor patients also receiving drugs that are highly bound to plasma proteins (e.g., warfarin), as tepoxalin and its active metabolite are 98–99% protein bound in the dog

Laboratory Considerations
- No specific laboratory interactions or considerations noted

Doses
-**DOGS:**
  a) On first day of treatment give 20 mg/kg PO (or 10 mg/kg PO); subsequently give 10 mg/kg PO once daily. Duration of treatment should be based on clinical response and patient tolerance to therapy. (Package insert; Zubrin®—Schering-Plough)

Monitoring
- Clinical efficacy
- Baseline and periodic CBC, chemistry panel (including bilirubin and serum creatinine)
- Signs associated with adverse effects (GI effects, appetite, vomiting, diarrhea, etc.)
Client Information

- When dosing, the person administering the tablet should place it in dog’s mouth and hold mouth closed for approximately 4 seconds to assure tablet disintegration.
- Absorption may be enhanced (and vomiting reduced?) if given with food.
- Owners should be instructed to discontinue the drug and contact their veterinarian if diarrhea is severe or persists, or signs such as inappetence, vomiting, fecal abnormalities, anemia, icterus or lethargy are observed.
- Dogs should have access to water; dehydration should be avoided.
- The manufacturer provides a client information sheet and states to “Always provide client information sheet …”

Chemistry/Synonyms
A non-steroidal antiinflammatory agent (NSAID), tepoxalin occurs as a white, tasteless, crystalline material that is insoluble in water and soluble in alcohol and most organic solvents. The commercially available tablets contain a micronized form of the drug in a highly porous matrix that rapidly disintegrates in the mouth. Drug particles are released into the saliva and swallowed by the dog where it is absorbed in the intestines.

Tepoxalin may also be known as ORF-20485, RWJ-20485 and Zubrin®.

Storage/Stability
Tables should be kept in their foil blister packs until used and stored at temperatures between 2–30°C (36–86°F).

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:

Tepoxalin Oral (rapidly-disintegrating) Tablets: 30 mg, 50 mg, 100 mg, 200 mg in foil blisters containing 10 tablets in boxes of 10 foil blisters; Zubrin® (Schering-Plough); (Rx). FDA-approved for use in dogs.

HUMAN-LABELED PRODUCTS: None

TERBINAFINE HCL
(ter-bin-ah-fin) Lamisil®
ANTIFUNGAL

Prescriber Highlights

- Oral & topical antifungal; used primarily for dermatophytic infections, but may be useful for other fungi (e.g., aspergillus), especially in birds
- Comparatively (withazole antifungals) few drug interactions
- Appears to be very well tolerated, but limited experience; vomiting most likely adverse effect
- Caution if liver or renal disease
- Treatment is relatively expensive, but generics are now available.

Uses/Indications
Terbinafine may be useful for treating dermatophytic and other fungal infections in dogs and cats.

Terbinafine may also be useful for treating birds for systemic mycotic (e.g., aspergillus) infections.

Pharmacology/Actions

Terbinafine is an inhibitor of the synthesis of ergosterol, a component of fungal cell membranes. By blocking the enzyme squalene monoxygenase (squalene 2,3-epoxidase), terbinafine inhibits the conversion of squalene to sterols (especially ergosterol) and causes accumulation of squalene. Both these effects are thought to contribute to its antifungal action. Terbinafine’s mechanism for inhibiting ergosterol is different from the azole antifungals.

Unlike the azole agents, terbinafine’s actions are not mediated via the cytochrome P-450 enzyme system, and, therefore, do not have the concerns of drug interactions or altering testosterone or cortisol.

Terbinafine primarily has clinical activity (fungalidal) against dermatophytic organisms (Microsporum spp., Trichophyton spp., etc.). It may only be fungistatic against the yeasts (Candida spp.). Terbinafine has activity against Aspergillus, Blastomyces, and Histoplasma but is usually not used clinically for infections caused by these organisms.

Pharmacokinetics

Little small animal specific information is available. In cats dosed at 34–46 mg/kg PO once daily for 14 days, terbinafine persisted in hair above MIC for several weeks. (Foust et al. 2005).

In horses, orally administered terbinafine pharmacokinetic values have been reported. The maximum plasma concentration was 0.31 (range: 0.21–0.61) micrograms/mL and occurred at 1.7 (range: 0.75–4) hours after dosing. Mean half-life was about 8 hours, but ranged widely (range: 3.9–11.6 hours); volume of distribution (Vd/F) was about 131 L/kg (range: 50–266 L/kg); clearance was 187 mL/min/kg (range: 132–282 mL/min/kg).

As intravenous terbinafine was not administered, volume of distribution, and clearance are reported per fraction of drug available (Kuchanich et al. 2009).

In humans, terbinafine given orally is greater than 70% absorbed; after first pass, metabolism bioavailability is about 40%. Food may enhance absorption somewhat. Terbinafine is distributed to skin and into the sebum. Over 99% of drug in plasma is bound to plasma proteins. Drug in the bloodstream is metabolized in the liver and the effective elimination half-life is about 36 hours. The drug may persist in adipose tissue and skin for very long periods.

Contraindications/Precautions/Warnings

Terbinafine is contraindicated in patients hypersensitive to it. The manufacturer does not recommend its use in patients with active or chronic liver disease or with significantly impaired renal function. If terbinafine is to be used in veterinary patents with markedly impaired liver or renal function, do so with extreme caution; dosage adjustments should be considered.

Adverse Effects

Because of limited usage in veterinary patients the adverse effect profile is not well defined, but thus far, the drug appears to be well tolerated. GI effects (vomiting, inappetence, diarrhea) are possible. In case report in two cats, one cat developed lethargy (Nuttall et al. 2008).

Very rarely in humans, liver failure, neutropenia or serious skin reactions (e.g., TEN, Stevens-Johnson syndrome) have occurred after terbinafine use.

Reproductive/Nursing Safety

High dose studies in pregnant rabbits and rats have not demonstrated overt fetotoxicity or teratogenicity, but definitive safety in pregnancy has not been determined. Use with caution (manufacturer recommends NOT using in pregnant women). In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

The drug enters maternal milk at levels 7 times that found in plasma; the manufacturer recommends that mothers not nurse while taking this drug. Use with caution in nursing veterinary patients.

Overdosage/Acute Toxicity

When overdosage occurs (animals consuming more than intended) or acute toxicity is suspected (when unintended overdosage occurs), the following should be performed:

- Discontinue drug
- Induce vomiting
- Administer activated charcoal
- Administer a cathartic
- Supportive care (including dialysis)
- Supportive care for hypotension
- Monitor closely when refeeding
- If signs of encephalopathy occur (e.g., seizures), consider administration of diazepam (0.2–0.5 mg/kg IV)

In humans, acute toxicities may be manifested by nausea, vomiting, diarrhea, abdominal pain, anorexia, rash, pruritus, headache, elevated liver function tests, and hyperglycemia. The effects of acute toxicities are not well defined due to limited usage in humans.

Veterinary Labeled Products

HUMAN-LABELED PRODUCTS:

Tepoxalin Oral (rapidly-disintegrating) Tablets: 30 mg, 50 mg, 100 mg, 200 mg in foil blisters containing 10 tablets in boxes of 10 foil blisters in boxes of 10 foil blisters; Zubrin® (Schering-Plough); (Rx). FDA-approved for use in dogs.

Zubrin® (Schering-Plough); (Rx). FDA-approved for use in dogs.

None

Storage/Stability

Tablets should be kept in their foil blister packs until used and stored at temperatures between 2–30°C (36–86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Tepoxalin Oral (rapidly-disintegrating) Tablets: 30 mg, 50 mg, 100 mg, 200 mg in foil blisters containing 10 tablets in boxes of 10 foil blisters; Zubrin® (Schering-Plough); (Rx). FDA-approved for use in dogs.

HUMAN-LABELED PRODUCTS: None
Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving terbinafine and may be of significance in veterinary patients:

**CYCLOSPORINE:** Terbinafine may increase the elimination of cyclosporine

**rifampin:** May increase terbinafine clearance
As it shares the same metabolic pathway (CYP2D6), terbinafine could affect the metabolism of:

**beta-blockers**
**MAO inhibitors** (amitraz, selegiline)
**SSRI's** (fluoxetine, etc.)
**tricyclic antidepressants**

Laboratory Considerations
- No apparent issues

Doses
**HUMANS/CATS:**
For dermatophytic infections:
- a) Using pulse therapy in cats: In the study, cats given 20 mg/kg PO once daily for 7 days and then 21 days off had clinical and mycological cures and terbinafine concentrations in hair were maintained above therapeutic concentrations. Cats given higher doses (40 mg/kg) or continuous administration accumulated higher concentrations, but some developed emesis in the first week of therapy, and higher hepatic enzyme serum activities. There were no alterations in the values of ALT and AF in the pulse therapy group. (Balda & Larsson 2009)
- b) 10–20 mg/kg PO once daily; appears to be better tolerated than either ketoconazole or itraconazole. (MacDonald 2008)
- c) In cases where other drugs are not tolerated: 25 mg/kg PO q24h. (Rosenkranz 2006)
- d) For dermatophyte (M. canis) mycetomas in cats (from a case report in two cats): Both cats achieved clinical and mycological cure after 12–14 weeks therapy with 26–31 mg/kg PO q24h. (Nuttall et al. 2008)
For adjunctive treatment (with topical therapy) of nasal Aspergillus infections if the cribiform plate is penetrated:
- a) 5–10 mg/kg PO q12h for 3–6 months (Kuehn 2007)
For pythiosis where advanced disease precludes complete surgical excision:
- a) 10 mg/kg PO q24h with itraconazole (10 mg/kg PO twice daily) (Marks 2007)
For lagendiosis where disease precludes complete surgical excision:
- a) 5–10 mg/kg PO q24h with itraconazole (10 mg/kg PO q24h) with repeated aggressive surgical resection was effective in one dog with multifocal cutaneous lesions, but no systemic lesions. (Grooters 2007)
For cryptococcal infections in cats that have become resistant to the azoles:
- a) 10 mg/kg PO per day can rectify the clinical signs though cats with CNS cryptococcus usually require treatment for life. (Legendre 2010)

**HORSES:**
For avian mycotic infections:
- a) For Aspergillus: 10–15 mg/kg PO every 12-24 hours and appears to be well tolerated by a number of avian species. It can also be administered by nebulization as a 1 mg/mL aqueous solution. (Black 2008)
- b) 10–15 mg/kg PO q12–24h (suspend a 250 mg tablet in 25 mL water); Nebulization: 1 mg/mL (500 mg terbinafine plus 1 mL Mucomyst® plus 500 mL of distilled water). Terbinafine can be used in combination with itraconazole. (Flammer 2003)
- c) Aspergillus: Birds suspected of aspergillosis (leukocytosis and pulmonary nodules) should be treated with terbinafine at 10–15 mg/kg PO q12h for 4 weeks. (Lichtenberger & Orosz 2007)

Monitoring
- Clinical efficacy
- Costs of treating can be considerable
- Give with food, particularly if vomiting is a problem

Client Information
- Baseline liver enzymes and then as needed (especially if treating long-term)

Chemistry/Synonyms
A synthetic allylamine antifungal, terbinafine HCl occurs as a white to off-white, fine, crystalline powder. It is slightly soluble in water and soluble in ethanol.

Terbinafine HCl may also be known as:
- Lamisil®
- Daktarin®
- DesenexMax®
- Finex®, Lamisil®, Maduric®, Micossi®, or Terekol®

Storage/Stability
Terbinafine tablets should be stored at room temperature, in tight containers; protect from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Terbinafine HCl Oral Tablets: 250 mg; Lamisil® (Novartis); Terbines® (JSJ); generic; (Rx)
Terbinafine HCl Oral Granules (film-coated): 125 mg/packet & 187.5 mg/packet (as base); Lamisil® (Novartis); (Rx)
A topical cream and spray (1%) are also available (Rx)

References

Limited information; humans have taken doses of up to 5 grams without serious effects.
The following drug interactions have either been reported or are theoretical in humans or animals receiving terbutaline and may be of significance in veterinary patients:

Drug Interactions

- Blocking agent
  Clinical signs of significant overdose after systemic administration may include arrhythmias (bradycardia, tachycardia, heart block, extrasystoles), hypertension, fever, vomiting, mydriasis, and CNS stimulation. If a recent

Overdosage/Acute Toxicity

In humans, the FDA categorizes this drug as category

Reproductive/Nursing Safety

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents, including increased heart rate, tremors, CNS excitation (nervousness) and dizziness. These effects are generally

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or
dami ony. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or
dami ony. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or
dami ony. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Adverse Effects

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents, including increased heart rate, tremors, CNS excitation (nervousness) and dizziness. These effects are generally

Pharmacology/Actions

Terbutaline stimulates beta-adrenergic receptors found principally in bronchial, vascular, and uterine smooth muscles (beta2); bronchial and vascular smooth muscle relaxation occurs with resultant reduced airway resistance. At usual doses it has little effect on cardiac (beta1) receptors and usually does not cause direct cardiotonic effects. Occasionally, a tachycardia develops which may be a result of either direct beta stimulation or a reflex response secondary to peripheral vasodilation. Terbutaline has virtually no alpha-adrenergic activity.

Pharmacokinetics

The pharmacokinetics of this agent have apparently not been thoroughly studied in domestic animals. In humans, only about 33–50% of an oral dose is absorbed; peak bronchial effects occur within 2–3 hours and activity persists up to 8 hours. Terbutaline is well-absorbed following SC administration with an onset of action occurring within 15 minutes, peak effects at 30–60 minutes, and duration of activity up to 4 hours.

In horses, terbutaline is very poorly absorbed after oral administration with a bioavailability <1%. When given IV, mean residence time is about 30 minutes in horses and the drug probably needs to be given as a constant rate infusion if used therapeutically.

Terbutaline is distributed into milk at levels approximately 1% of the oral dose given to the mother. Terbutaline is principally excreted unchanged in the urine (60%), but is also metabolized in the liver to an inactive sulfate conjugate.

Contraindications/Precautions/Warnings

Terbutaline is contraindicated in patients hypersensitive to it. One veterinary school formulary (Schultz 1986) states that terbutaline is contraindicated in dogs and cats with heart disease, especially with CHF or
dami ony. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Adverse Effects

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents, including increased heart rate, tremors, CNS excitation (nervousness) and dizziness. These effects are generally

Overdosage/Acute Toxicity

Clinical signs of significant overdose after systemic administration may include arrhythmias (bradycardia, tachycardia, heart block, extrasystoles), hypertension, fever, vomiting, mydriasis, and CNS stimulation. If a recent

Drug Interactions

The following drug interactions have either been reported or are theoretic in humans or animals receiving terbutaline and may be of significance in veterinary patients:

- ANESTHETICS, INHALATION (e.g., halothane, isoflurane, methoxyflurane): Use with inhalation anesthetics may predispose the patient to ventricular arrhythmias, particularly in patients with preexisting cardiac
disease—use cautiously

- BETA-ADRENERGIC BLOCKING AGENTS (e.g., propranolol): May antagonize the actions of terbutaline

- DIGOXIN: Use with digitalis glycosides may increase the risk of cardiac arrhythmias

- MONOAMINE OXIDASE INHIBITORS: May potentiate the vascular effects of terbutaline

- SYMPATHOMIMETICS, OTHER: Use of terbutaline with other sympathomimetic amines may increase the risk of developing adverse cardiovascular effects

- TRICYCLIC ANTIDEPRESSANTS: May potentiate the vascular effects of terbutaline

Doses

- DOGS:
  a) For a trial to treat intrathoracic tracheal collapse, expiratory cough or dyspnea and marked exercise intolerance: 1.25–5 mg (total dose) PO two to three times daily (Johnson, LR 2004)
  b) As a bronchodilator in chronic bronchitis: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h (Johnson, L 2000)
  c) For bradyarrhythmias: 0.2 mg/kg PO q8–12h; improvement usually partial and often temporary (Rishniw & Thomas 2000)
  d) For treatment of premature labor: The initial dose is 0.03 mg/kg PO or SC q6h. The drug should be discontinued 48 hours prior to the calculated delivery date to permit normal labor and delivery to occur. Exogenous progesterone may be added if myometrial contractility cannot be controlled with tocolytics. (Davisson 2008)
  e) For tracheal collapse: Small dogs: 0.625–1.25 mg (total dose) PO q12h; medium-sized dogs: 1.25–2.5 mg (total dose) PO q12h; large dogs: 2.5–5 mg PO q12h; 0.01 mg/kg IV, IM or SC (Ettinger & Kantrowitz 2005)

- CATS:
  a) For acute exacerbations of feline asthma treated at home: 0.01 mg/kg SC or IM; Beneficial response (decrease of respiratory rate or effort by 50%) occurs in 15–30 minutes. A heart rate that approaches 240 BPM indicates that the drug has been absorbed. (Pariad 2000)
  b) For feline asthma: 0.312–0.625 mg (total dose) per cat PO two to three times daily; may adjust dose up to 1.25 mg in larger cats if needed (Noone 1999)
HORSES: (Note: ARCI UCGFS Class 3 Drug)

a) For use as a quantitative intradermal terbutaline sweat test (QITST) to identify anhidrosis (preliminary study): In the study a 6 cm wide strip of skin was clipped parallel with and 3 cm below the dorsal margin of the neck on the left side. Beginning at the caudal aspect of this strip, eight 0.1 mL intradermal injections of serial 10-fold dilutions of terbutaline sulfate in 0.9% saline were made through a 25 gauge needle at approximately 5 cm intervals as follows: 0 (control), 0.001, 0.01, 0.1, 1, 10, 100 and 1000 mg/mL. Individual sections of absorbent pad (3 x 3 cm; Stayfree® UltraThin regular pads) were preweighed within plastic bags. Pads were then taped over each injection site. Thirty minutes later, they were removed, replaced in plastic bags and reweighed. Sweat weights at saline control sites were, in all cases, ≤8 mg. Sweat weights increased significantly at each successive terbutaline concentration up to a mean weight of 491 mg at the 1000 mg/mL dose. The lower one-sided 95% confidence limits for sweat weights were 19, 57, 96, 195 and 267 mg for terbutaline concentrations of 0.1, 1, 10, 100 and 1000 mg/mL, respectively. (MacKay 2008)

b) 0.0033 mg/kg IV (Robinson 1987)

Monitoring

- Clinical symptom improvement; auscultation
- Cardiac rate, rhythm (if indicated)
- Serum potassium, early in therapy if animal susceptible to hypokalemia

Client Information

- Contact veterinarian if animal’s condition deteriorates or if it becomes acutely ill

Chemistry/Synonyms

A synthetic sympathomimetic amine, terbutaline sulfate occurs as a slightly bitter-tasting, white to gray-white, crystalline powder that may have a faint odor of acetic acid. One gram is soluble in 1.5 mL of water or 250 mL of alcohol. The commercially available injection has its pH adjusted to 3–5 with hydrochloric acid.

Terbutaline Sulfate may also be known as: KWD-2019, terbutaline sulphate, terbutalini sulfas; many trade names are available.

Storage/Stability

Terbutaline tablets should be stored in tight containers at room temperature (15–30°C) and protected from light. The injection has an expiration date of 2 years after the date of manufacture.

Terbutaline injection should be stored at room temperature (15–30°C) and protected from light. The injection has an expiration date of 2 years after the date of manufacture.

Terbutaline injection is stable over a pH range of 1–7. Discolored solutions should not be used.

Compatibility/Compounding Considerations

Terbutaline injection is physically compatible with DSW and aminophylline.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELLED PRODUCTS:

- Terbutaline Sulfate Tablets: 2.5 mg & 5 mg; Brethine® (aaiPharma); generic; (Global) (Rx)
- Terbutaline Injection: 1 mg/mL in 1 mL vials & 2 mLamps with 1 mL fill; Brethine® (aaiPharma); generic; (Rx)

References

Brethine® (aaiPharma); generic; (Rx)

d) 0.01 mg/kg IV (Robinson 1987)

c) For bradyarrhythmias: 0.625 mg PO q8–12h; improvement usually partial and often temporary (Rishniw & Thomas 2000)

d) For acute bronchoconstriction (initial crisis): 0.01 mg/kg IV, SC, IM (Cohn 2007)

TESTOSTERONE CYPIONATE

TESTOSTERONE ENANTHATE

TESTOSTERONE PROPIONATE

(testosterone-decanoate)

ANDROGENIC HORMONE

Prescriber Highlights

- Principle endogenous androgen used primarily for the treatment of testosterone-responsive urinary incontinence in neutered male dogs/cats; in bovine medicine to produce an estrus-detector animal
- Contraindications: Known hypersensitivity to the drug; prostate carcinoma. Caution: Renal, cardiac, or hepatic dysfunction
- Adverse Effects: Uncommon, but perianal adenomas, perineal hernias, prostatic disorders, & behavior changes possible
- Testosterone products are controlled substances (C-III)

Uses/Indications

The use of injectable esters of testosterone in veterinary medicine is limited primarily to its use in dogs (and perhaps cats) for the treatment of testosterone-responsive urinary incontinence in neutered males. Testosterone has been used to treat a rare form of dermatitis (exhibited by bilateral alopecia) in neutered male dogs. These drugs are also used in bovine medicine to produce an estrus-detector (teaser) animal in culled cows, heifers, and steers.

The effectiveness of testosterone to increase libido, treat hypogonadism, aspermia, and infertility in domestic animals has been disappointing.

Pharmacology/Actions

The principle endogenous androgenic steroid, testosterone is responsible for many secondary sex characteristic of the male as well as the maturation and growth of the male reproductive organs and increasing libido.

Testosterone has anabolic activity with resultant increased protein anabolism and decreased protein catabolism. Testosterone causes nitrogen, sodium, potassium and phosphorus retention and decreases the urinary excretion of calcium. Nitrogen balance is improved only when an adequate intake of both calories and protein occurs.

By stimulating erythropoietic stimulating factor, testosterone can stimulate the production of red blood cells. Large doses of exogenous testosterone can inhibit spermatogenesis through a negative feedback mechanism inhibiting luteinizing hormone (LH).

Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.

Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.
Testosterone may help maintain the normal urethral muscle tone and integrity of the urethral mucosa in male dogs. It may also be necessary to prevent some types of dermatoses.

**Pharmacokinetics**

Orally administered testosterone is rapidly metabolized by the GI mucosa and the liver (first-pass effect); very little reaches the systemic circulation. The esterified compounds, testosterone enanthate and cypionate are less polar than testosterone and more slowly absorbed from lipid tissue after IM injection. The duration of action of these compounds may persist for 2–4 weeks after IM injection. Testosterone propionate reportedly has a much shorter duration of action than the enanthate or cypionate esters. Because absorption is dependent upon several factors (volume injected, perfusion, etc.), duration of action may be variable.

Testosterone is highly bound to a specific testosterone-estradiol globulin (98% in humans). The quantity of this globulin determines the amount of drug that is in the free or bound form. The free form concentration determines the plasma half-life of the hormone.

Testosterone is metabolized in the liver and is, with its metabolites, excreted in the urine (>90%) and the feces (<6%). The plasma half-life of testosterone has been reported to be between 10–100 minutes in humans. The plasma half-life of testosterone cypionate has been reported to be 8 days.

**Contraindications/Precautions/Warnings**

Testosterone therapy is contraindicated in patients with known hypersensitivity to the drug or prostate carcinoma. It should be used with caution in patients with renal, cardiac or hepatic dysfunction.

**Adverse Effects**

Adverse effects are reportedly uncommon when injectable testosterone products are used in male dogs to treat hormone-responsive incontinence. Perianal adenosmas, perineal hernias, prostatic disorders, and behavior changes (aggression) are all possible, however. Behavioral changes have been reported in cats. Polycythemia has been reported in humans receiving high dosages of testosterone. High dosages or chronic usage may result in oligospermia or infertility in intact males.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

It is not known whether androgens are excreted in milk; consider using milk replacer if using testosterone in nursing patients.

**Overdosage/Acute Toxicity**

No specific information was located; refer to the Adverse Effects section for further information.

**Drug Interactions**

No specific information was located; refer to the Adverse Effects section for further information.

**Pharmacokinetics**

Testosterone propionate occurs as odorless, creamy white to white, crystals or crystalline powder. It is insoluble in water, freely soluble in alcohol and soluble in vegetable oils. Testosterone propionate melts between 118–123°C.

Testosterone enanthate occurs as an odorless to having a faint odor, creamy white or white, crystalline powder. It is soluble in vegetable oils, insoluble in water and melts between 34–39°C.
**Storage/Stability**

The commercially available injectable preparations of tetracycline propionate and tetracycline enanthate should be stored at room temperature; avoid freezing or exposing to temperatures greater than 40°C. If exposed to low temperature a precipitate may form, but should redissolve with shaking and rewarming. If a wet needle or syringe is used to draw up the parenteral solutions, cloudy solutions may result, but will not affect the drug's activity.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

No known tetracycline products (with the exception of combinations with estradiol as growth promotant implants) FDA-approved for use in veterinary species were located. Tetracycline propionate (200 mg) is available in combination with estradiol benzoate (20 mg) as a growth promotant. Trade names include Component E-HB (VetLife); (OTC) and Synovex-HB (Fort Dodge); (OTC). For use in heifers weighing 400 or more pounds.

Tetracycline propionate (200 mg) with estradiol benzoate (28 mg); Synovex-Plan (Fort Dodge); (OTC); for steers.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Tetracycline Cypionate (in oil) Injection: 100 mg/mL & 200 mg/mL in 1 mL & 10 mL vials; Depo-Testosterone® (Pfizer); generic; (Rx, C-III)

Tetracycline Enanthate (in oil) Injection: 200 mg/mL in 5 mL multi-dose vials; Delatestryl® (Indevus); generic (Paddock); (Rx, C-III)

Tetracycline Pellets Implant for subcutaneous implantation: 75 mg in 1 pellet/vials; Testopel® (Bartor Pharmacal); (Rx, C-III)

Tetracycline Transdermal System: Release Rates: 5 & 2.5 mg/24 hour, total testosterone contents: 24.3 mg & 12.2 mg (respectively): Androderm® (Watson Pharma); (Rx, C-III)

Tetracycline Gel: 1% (50 mg testosterone) in unit-dose packets and tubes or 75 gram metered multiple dose pumps; AndroGel® 1% (Solvay); Testim® (Auxilium); (Rx, C-III)

Tetracycline, Buccal System: 30 mg testosterone in blister packs; Striant® (Columbia); (Rx, C-III)

**References**

**TETRACYCLINE ANTIBIOTIC**

(Tet-ra-sy-klin)

**TETRACYCLINE ANTIBIOTIC**

**Prescriber Highlights**

- Prototype tetracycline antibiotic; many bacteria are now resistant, but still may be very useful to treat mycoplasma, rickettsia, spirochetes, & Chlamydia
- Dosing frequency may be an issue for small animals
- Extreme Caution: Pregnancy
- Caution: Liver or renal insufficiency
- Adverse Effects: GI distress, staining of developing teeth & bones, superinfections, photosensitivity; long-term use may cause uroliths.

**Uses/Indications**

While tetracycline is still used as an antimicrobial, most small animal clinicians prefer doxycycline and large animal clinicians prefer oxytetracycline when a tetracycline is indicated to treat susceptible infections. The most common use of tetracycline HCl today is in combination with niacinamide for the treatment of certain immune-mediated skin conditions in dogs, such as pemphigus.

**Pharmacology/Actions**

Tetracyclines generally act as time-dependent antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminocycl transfer-RNA. Tetracyclines have been deemed bacteriostatic antibiotics, but this nomenclature is more of historical importance than descriptive of their antibacterial actions. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococcus and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines include Actinomyces spp., Bacillus anthracis, Clostridium perfringens and tetani, Listeria monocytogenes, and Nocardia. Among gram-negative bacteria that tetracyclines usually have in vitro and in vivo activity include Bordetella spp., Brucella, Bartonella, Haemophilus spp., Pasteurella multocida, Shigella, and Yersinia pestis. Many or most strains of E. coli, Klebsiella, Bac teroides, Enterobacter, Proteus and Pseudomonas aeruginosa are resistant to the tetracyclines. While most strains of Pseudomonas aeruginosa show in vitro resistance to tetracyclines, those compounds attaining high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism. Hemoglobin at the site of the infection can reduce the antimicrobial activity of tetracycline.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance and a tetracycline susceptibility disk is usually used for in vitro testing for oxytetracycline susceptibility. Tetracyclines have antiflammatory and immunomodulating effects. They can suppress antibody production and chemotaxis of neutrophils; inhibit lipases, collagenases, prostaglandin synthesis, and activation of complement component 3.

**Pharmacokinetics**

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailability are approximately 60–80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration, tetracycline is erratically and poorly absorbed with serum levels usually lower than those attainable with oral therapy.

Tetracyclines as a class, are widely distributed to heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF, and therapeutic levels may not be achievable. While all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into skin.
Contraindications/Precautions/Warnings
Tetracyclines are contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than doxycycline or minocycline.

Tetracyclines in high levels can exert an antianabolic effect that can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and rumenoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiosuppressive effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

In small animals, tetracyclines may cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well, and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs.

Horses that are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrhea after receiving tetracyclines (especially with oral administration). Tetracycline therapy (especially long-term) may result in overgrowth of non-susceptible bacteria or fungi (superinfections).

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity, formation of anti-nuclear antibodies, or blood dyscrasias.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

Tetracyclines are excreted in milk, but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals.

Overdose/Acute Toxicity
Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and rumenoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tetracyclines and may be of significance in veterinary patients:

**ATOVQUEONE:** Tetracyclines have caused decreased doxavquake levels

**BETA-LACTAM OR AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, have been historically thought to interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides but the actual clinical significance of this interaction is doubtful.

**BIOGENIN:** Tetracyclines have increased the bioavailability of digoxin in a small percentage of human patients and caused digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.

**DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products.

**METHOXYFLURANE:** Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline not recommended

**SUCRALATE:** Sucralfate may impair the oral absorption of tetracycline; separate dosing by at least 2 hours to minimize this effect

**WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment

Laboratory Considerations

**Tetracyclines (not minocycline):** may cause falsely elevated values of urine catecholamines when using fluorometric methods of determination.

Tetracyclines reportedly can cause false-positive urine glucose results if using the cupric sulfate method of determination (Benedict’s reagent, Clinistix®, but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (Clinistix®, Tes-Tape®).

Doses

**DOGS:**

For systemic bacterial, brucellosis: 22–50 mg/kg PO q8h for 28 days. (Greene et al. 2006)

For Rocky Mountain Spotted Fever: 22 mg/kg q8h for 14–21 days (Sellon & Breitschwerdt 1995)

c) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden & Papich 1995)

For susceptible UTI's: 18 mg/kg PO q8h (Dowling 2009)

For Lyme disease: 22 mg/kg PO q8h for 14 days (Breitschwerdt 2000)

f) For small intestinal bacterial overgrowth: 5–10 mg/kg PO q8h for 28 days; has been effective for uncomplicated cases (Ludlow & Davenport 2000)
Tetracycline HCl Capsules: 250 mg & 500 mg; HUMAN-LABELED PRODUCTS:
An oral combination product containing tetracycline, novobiocin and prednisone (may be available in several sizes; may be FDA-approved for use in swine, cattle, or poultry. Withdrawal time may vary depending on age of animal and product.

There are a variety of Tetracycline HCl Soluble Powder (as a water additive) products that are available in various concentrations and sizes. Usual concentrations are either 25 grams/lb or 324 grams/lb and these products be stored at room temperature; avoid freezing the oral suspension.

Storage/Stability
- Chloride, procaine HCl and ascorbic acid.
- Water and 10 mg/mL soluble in alcohol. Tetracycline base has a solubility of about 0.4 mg per mL of water and 20 mg per mL of alcohol. Commercially available tetracycline HCl for IM injection also contains magnesium chloride, procaine HCl and ascorbic acid.

Client Information
- Avoid giving this drug orally within 1–2 hours of feeding, giving milk or other dairy products
- Avoid giving with a small amount of food may help, but this may also reduce the amount of drug absorbed

Clinical efficacy
- For susceptible infections in calves:
  - 11 mg/kg orally (Howard 1986)
  - 11 mg/kg, PO twice daily for up to 5 days (Label directions; Polystic®—American Cyanamid)

Chemistry/Synonyms
- An antibiotic obtained from Streptomyces aureofaciens or derived semisynthetically from oxytetracycline, tetracycline HCl occurs as a moderately hygroscopic, yellow, crystalline powder. About 100 mg/mL is soluble in water and 10 mg/mL soluble in alcohol. Tetracycline base has a solubility of about 0.4 mg per mL of water and 20 mg per mL of alcohol. Commercially available tetracycline HCl for IM injection also contains magnesium chloride, procaine HCl and ascorbic acid.
- Tetracycline may also be known as: tetracyclini hydrochloridum; many trade names are available.

Dosage Forms/Regulatory Status
- VETERINARY-LABELED PRODUCTS:

**THIAMINE HCI**

**VITAMIN B1**

**NUTRITIONAL; B VITAMIN**

**Prescriber Highlights**

- A “B” vitamin used for treatment or prevention of thiamine deficiency. May be useful for adjunctive treatment of lead poisoning & ethylene glycol toxicity
- **Adverse Effects:** hypersensitivity/anaphylactic reactions (rarely); tenderness, or muscle soreness after IM injection
- **Drug Interactions; lab interactions**

**Uses/Indications**

Thiamine is indicated in the treatment or prevention of thiamine deficiency states. Clinical signs of thiamine deficiency may be manifested as gastrointestinal (anorexia, salivation), neuromuscular/CNS signs (ataxia, seizures, loss of reflexes), or cardiac effects (brady- or tachyarrhythmias). Deficiency states may be secondary to either a lack of thiamine in the diet or the presence of thiamine destroying compounds in the diet (e.g. bracken fern, raw fish, amprollum, thiamine-producing bacteria in ruminants). Thiamine may be supplemented in camels and other species when long-term amprollum is used.

Thiamine has also been used in the adjunctive treatment of lead poisoning and ethylene glycol toxicity (to facilitate the conversion of glyoxylate to nontoxic metabolites).

**Pharmacology/Actions**

Thiamine combines with adenosine triphosphate (ATP) to form a compound (thiamine diphosphate/thiamine pyrophosphate) that is employed for carbohydrate metabolism, but does not effect blood glucose concentrations.

Absence of thiamine results in decreased transketolase activity in red blood cells and increased pyruvic acid blood concentrations. Without thiamine triphosphate, pyruvic acid is not converted into acetyl-CoA; diminished NADH results with anaerobic glycolysis producing lactic acid. Lactic acid production is further increased secondary to pyruvic acid conversion; lactic acidosis may occur.

**Pharmacokinetics**

Thiamine is absorbed from the GI tract and is metabolized by the liver. Elimination is renal, the majority of the drug is eliminated as metabolites.

**Contraindications/Precautions/Warnings**

Thiamine injection is contraindicated in animals hypersensitive to it or to any component of it.

**Adverse Effects**

Hypersensitivity reactions have occurred after injecting this agent. Rarely, a vasovagal anaphylactic response (cardiac arrest or severe bradycardia, cardiac arrhythmias, apnea, hypotension, collapse, seizure, and protracted neuromuscular weakness), has been observed in a small number of cats when thiamine hydrochloride was administered subcutaneously. Some tenderness or muscle soreness may result after IM injection.

**Reproductive/Nursing Safety**

In humans, the FDA categorizes this drug as category A for use during pregnancy (Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) If used in doses greater than the RDA, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in milk, but it should not be of clinical concern.

**Overdosage/Acute Toxicity**

Very large doses of thiamine in laboratory animals have been associated with neuromuscular or ganglionic blockade, but the clinical significance is unknown. Hypotension and respiratory depression may also occur with massive doses. A lethal dose of 350 mg/kg has been reported. Generally, no treatment should be required with most overdoses.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiamine and may be of significance in veterinary patients:

- **NEUROMUSCULAR BLOCKING AGENTS:** Thiamine may enhance the activity of neuromuscular blocking agents; clinical significance is unknown

**Laboratory Considerations**

- Thiamine may cause false-positive serum uric acid results when using the phosphotungstate method of determination or urobilinogen urine spot tests using Ehrlich’s reagent
- The Schack and Wester method of determining theophylline concentrations may be interfered with by large doses of thiamine

**Doses**

**DOGS:**

- For thiamine deficiency:  
  a) 5–50 mg IM, SC, or IV (depending on formulation) (Phillips 1988)
  b) 1–2 mg IM (Greene & Braund 1989)
Thiamine HCl Injection: 100 mg/mL in 1 mL in 2 mL

Thiamine Enteric Coated Tablets: 20 mg; Thiamine Tablets: 50 mg, 100 mg & 250 mg; generic; (OTC)

HUMAN-LABELLED PRODUCTS:
There are several B-complex vitamin preparations available that may also have thiamine included.

Thiamine HCl Supplement: 500 mg/oz in 1.5 lb, 4 lb and 20 lb containers; Thiamine HCl Dietary Supplement: 8,200 mg per lb.

VETERINARY-LABELLED PRODUCTS:
Dosage Forms/Regulatory Status
Thiamine HCl is reportedly physically
 Compatibility/Compounding Considerations
Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Do not mix thiamine with alkaline drugs or alkalinizing agents (barbiturates, citrates, carbonates, acetates, copper ions) or oxidizing/reducing agents (e.g., sulfites).

Chemistry/Synonyms
A water-soluble “B” vitamin, thiamine HCl occurs as bitter-tasting, white, small hygroscopic crystals, or crystalline powder that has a characteristic yeast-like odor. Thiamine HCl is freely soluble in water, slightly soluble in alcohol and has pKas of 4.8 and 9.0. The commercially available injection has a pH of 2.5–4.5.

Storage/Stability
Thiamine HCl for injection should be protected from light and stored at temperatures less than 40°C and preferably between 15–30°C; avoid freezing.
Thiamine HCl is unstable in alkaline or neutral solutions or with oxidizing or reducing agents. It is most stable at a pH of 2.

Thiamine HCl is reportedly physically compatible with all commonly used intravenous replacement fluids.

Client Information
Efficacy
Thiamine HCl may also be known as: aneurine hydrochloride, thiamin hydrochloride, thiamine chloride, thiamini hydrochloridum, thiamini chlorideum, vitamin B-1; many trade names available.

Monitoring
Thiamine HCl for use in horses, dogs and cats.

CAMELIDS (NWC):
a) For prophylaxis when animals with E. marasmius treated with amprolium for >5 days (from a retrospective study): 10 mg/kg SC q24h after the 5th day of amprolium. (Cebra, C.K. et al. 2007)

For thiamine deficiency:
a) 100–250 mg parenterally twice a day (experimentally, as little as 1 mg is effective) (Armstrong & Hand 1989)
b) 10–20 mg/kg IM for several days. (Abramson 2009)
c) For adjunctive treatment of hepatic lipodisosis: If neck ventroflexion is present, consider electrolyte or thiamine insufficiency; check electrolytes (potassium, phosphate, and magnesium); provide supplements as appropriate. Give 100 mg of thiamine in one liter of crystalloid fluids with additional soluble B vitamins (riboflavin, niacinamide, D-panthenol, pyridoxine, and cyanocobalamin). (Center 2005)
d) 100–250 mg SC twice daily for several days until regression of symptoms with complete recovery (Hoskins 1988)
e) 10–20 mg/kg IM or SC two to three times daily until signs abate, then 10 mg/kg PO once daily for 21 days (Morgan 1988)

CATTLE:
For thiamine deficiency:
a) For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)
b) 10–20 mg/kg IM or SC 3 times daily; if giving IV dilute in isotonic saline or isotonic dextrose. (Walz 2006)
c) 10 mg/kg up to 4 times a day; first dose may be given via slow IV and subsequent doses IM. Less severely affected animals may respond to lower or less frequent dosing. Severely affected animals may benefit from corticosteroids (dexamethasone 1–2 mg/kg) and mannitol (1 gram/kg in a 20% solution IV through a filtered IV set). (Cebra, C. 2005)

Thiamine for adjunctive therapy of lead poisoning:
a) 2 mg/kg IM (at same time as CaEDTA therapy); total daily dose 8 mg/kg (Barratt & Kowalczyk 1989)

HORSES:
For thiamine deficiency:
a) 0.5–5 mg/kg IV, IM or PO (Robinson 1987)
b) 100–1000 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):
Feeds: 1 gram in one liter of fluids IV once a day (Slovos 2003)

As part of a parenteral nutrition (PN) formula:
A) Complex vitamins (thiamine 12.5 mg/mL; niacinamide 12.5 mg/mL; pyridoxine 5 mg/mL; d-panthenol 5 mg/mL; riboflavin 2 mg/mL; cyanocobalamin 5 mg/mL) should be supplied at a rate of 1–2 mL/kg daily, diluted in fluids or PN. Vitamin C should be supplied at a rate of 20 mg/kg/day enteral whenever possible. (Magdesian 2010)

For thiamine deficiency:
a) 5–100 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

SHEEP & GOATS:
For thiamine deficiency:
a) For polioencephalomalacia: Initially, 10 mg/kg IV; then, 10 mg/kg IM twice daily for 2–3 days. If no improvement within 4 days, may be advisable to recommend slaughter. (Dill 1986)
b) Sheep: 20–200 mg IM, SC, or IV (depending on formulation) (Phillips 1988)

CAMELIDS (NWC):
a) For prophylaxis when animals with E. marasmius treated with amprolium for >5 days (from a retrospective study): 10 mg/kg SC q24h after the 5th day of amprolium. (Cebra, C.K. et al. 2007)

For thiamine deficiency:
a) 10 mg/kg IM; total daily dose 8 mg/kg (Barratt & Kowalczyk 1989)

For thiamine deficiency:
a) 100–250 mg parenterally twice a day (experimentally, as little as 1 mg is effective) (Armstrong & Hand 1989)
b) 10–20 mg/kg IM for several days. (Abramson 2009)
c) For adjunctive treatment of hepatic lipodisosis: If neck ventroflexion is present, consider electrolyte or thiamine insufficiency; check electrolytes (potassium, phosphate, and magnesium); provide supplements as appropriate. THIOGUANINE
(thye-oh-gwah-nin)
ANTINEOPLASTIC
Prescriber Highlights

- Oral purine analog antineoplastic that may be useful as adjunctive treatment for acute lymphocytic or granulocytic leukemia in dogs or cats
- Contraindications: Hypersensitivity to thioguanine
- Caution: Hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or history of urate urinary stones
- Potentially mutagenic & teratogenic; use milk replacer if nursing
- Adverse Effects: GI effects, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, & dermatologic reactions
- Cats may be more susceptible than dogs to adverse effects
- Low therapeutic index; monitoring mandatory

Uses/Indications
Thioguanine may be useful as adjunctive therapy for acute lymphocytic or granulocytic leukemia in dogs or cats.

Pharmacology/Actions
Intracellularly, thioguanine is converted to ribonucleotides that cause the synthesis and utilization of purine nucleotides to be blocked. The drug’s cytotoxic effects are believed to occur when these substituted nucleotides are inserted into DNA and RNA. Thioguanine has limited immunosuppressive activity. Extensive cross-resistance usually occurs between thioguanine and mercaptopurine.

Pharmacokinetics
Thioguanine is administered orally, but absorption is variable. In humans, only about 30% of a dose is absorbed. Thioguanine is distributed into the DNA and RNA of bone marrow, but several doses may be necessary for this to occur. It does not apparently enter the CNS, but does cross the placenta. It is unknown whether it enters maternal milk.

Thioguanine is rapidly metabolized primarily in the liver to a methylate derivative that is less active (and toxic) than the parent compound. This and other metabolites are eliminated in the urine.

Contraindications/Precautions/Warnings
Thioguanine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thioguanine has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

Adverse Effects
At usual doses, GI effects (nausea, anorexia, vomiting, diarrhea) may occur in small animals. However, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, and dermatologic reactions are potentially possible. Cats may be particularly susceptible to the hematologic effects of thioguanine.

Reproductive/Nursing Safety
Thioguanine is potentially mutagenic and teratogenic and not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) Although it is unknown whether thioguanine enters milk, use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity
Toxicity may be acute (GI effects) or delayed (bone marrow depression, hepatotoxicity, gastroenteritis). It is suggested to use standard protocols to empty the GI tract if ingestion was recent and treat supportively.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving thioguanine and may be of significance in veterinary patients:

- **HEPATOTOXIC DRUGS** (e.g., halothane, ketoconazole, valproic acid, phenobarbital, primidone, etc.): Thioguanine should be used cautiously with other drugs that can cause hepatotoxicity
- **IMMUNOSUPPRESSIVE DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection
- **MYELOSUPPRESSIVE DRUGS** (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- **VACCINES, LIVE**: Live virus vaccines should be used with caution during therapy, if at all

Laboratory Considerations
- Thioguanine may increase serum uric acid levels in some patients

Doses

**DOGS:**
Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] are strongly recommended.

a) For acute lymphocytic and granulocytic leukemia: 40 mg/m² PO once daily (q24 hours) for 4–5 days, then every 3rd day thereafter (Jacobs et al. 1992)
Pharmacology

**Actions**

The rapid onset of action of thiopental is a result of its high lipid solubility. The drug rapidly enters the CNS producing profound hypnosis and anesthesia. Due to its short duration of action, thiopental is referred to as an ultrashort-acting barbiturate.

**Pharmacokinetics**

Thiopental is rapidly distributed throughout the body after IV administration. Most of the drug is metabolized in the liver and excreted unchanged in the urine. Due to its high lipid solubility, thiopental readily penetrates body fat and muscle stores. Thiopental is a C-III controlled substance.

**Uses/Indications**

- Thiopental is used for induction of general anesthesia in dogs, cats, and horses.
- It is also used for induction of short-term immobilization for diagnostic procedures.
- Thiopental is not recommended for long-term maintenance anesthesia.

**Contraindications**

- Thiopental is contraindicated in cats with preexisting cardiac or pulmonary disease.
- Thiopental should be used with caution in dogs with preexisting cardiac disease.
- Thiopental should not be used in horses with hepatic disease.

**Warnings**

- Thiopental should not be administered intravenously at rates greater than 1 mg/kg/min.
- Hypotension may occur with thiopental administration.
- Excessive sedation or depression may occur with thiopental administration.

**Monitoring**

- Postanesthetic monitoring is recommended for cats, dogs, and horses.
- Heart rate and rhythm should be monitored closely.
- Blood pressure should be monitored in high-risk patients.

**Client Information**

- Clients should be informed of the short duration of action of thiopental.
- Clients should be informed of the potential for hypotension with thiopental administration.

**Dosage Forms/Regulatory Status**

- Thiopental is available in tablets and intravenous injectable forms.
- Thiopental is a Schedule III controlled substance in the United States.

**Storage/Stability**

- Thiopental tablets should be stored at room temperature.
- Thiopental injectable solution should be stored at room temperature.

**References**

**Efficacy**

- Thiopental is highly effective for induction of general anesthesia.
- Thiopental is not recommended for long-term maintenance anesthesia.

**Efficacy in Dogs**

- Thiopental is highly effective for induction of general anesthesia in dogs.
- Thiopental is not recommended for long-term maintenance anesthesia.

**Efficacy in Cats**

- Thiopental is highly effective for induction of general anesthesia in cats.
- Thiopental is not recommended for long-term maintenance anesthesia.

**Efficacy in Horses**

- Thiopental is highly effective for induction of general anesthesia in horses.
- Thiopental is not recommended for long-term maintenance anesthesia.

**Toxicity**

- Thiopental toxicity is rare in dogs, cats, and horses.
- Thiopental toxicity is more common in horses than in dogs and cats.

**Preparation and Administration**

- Thiopental should be administered IV slowly to avoid hypotension.
- Thiopental should be administered slowly to avoid hypotension.

**Thiopental Tablets**

- Thiopental tablets should be stored at room temperature.
- Thiopental tablets should be administered slowly to avoid hypotension.

**Thiopental Sodium (Pentothal)**

- Thiopental sodium is available as a solution for IV administration.
- Thiopental sodium should be administered slowly to avoid hypotension.

**THIOPENTAL SODIUM**

- Thiopental sodium is available as a solution for IV administration.
- Thiopental sodium should be administered slowly to avoid hypotension.

**Prescriber Highlights**

- Ultra-short acting thiobarbiturate
- Contraindications: Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, & conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). Greyhounds ( & other sight hounds) metabolize thiobarbiturates much more slowly than other breeds; consider using methohexital instead. Horses: preexisting leukopenia; thiopental alone may cause excessive ataxia & excitement
- Avoid: Extravasation, intra-carotid or intra-arterial injections, & use of concentrations of less than 2% in sterile water. Too rapid IV administration can cause significant vascular dilatation & hypoglycemia
- Adverse Effects: Dogs: Ventricular bigeminy Cats: Apnea after injection, mild arterial hypotension. Horses: Excitement & severe ataxia (if used alone); transient leukopenias, hyperglycemia, apnea, moderate tachycardia, mild respiratory acidosis
- Severe CNS toxicity & tissue damage has occurred in horses receiving intra-carotid injections of thiobarbiturates
- C-III controlled substance

**Uses/Indications**

- Because of its rapid action and short duration, in young, healthy animals, thiopental is excellent induction agent (rapid IV bolus) for general anesthesia with other anesthetics or as the sole anesthetic agent for very short procedures. In sick or debilitated animals, thiopental may be used in a more cautious manner (IV, slowly to effect).

**Pharmacology/Actions**

- Because of their high lipid solubility, thiobarbiturates rapidly enter the CNS and produce profound hypnosis and anesthesia. They are also known as ultrashort-acting barbiturates. See the monograph Barbiturates, Pharmacology of, for additional information.

**Pharmacokinetics**

- Following IV injection of therapeutic doses, hypnosis and anesthesia occur within one minute and usually within 15-30 seconds. The drug rapidly enters the CNS and then redistributes to muscle and adipose tissue in the body. The short duration of action (10–30 minutes) after intravenous dosing of thiopental is due less to rapid metabolism than to this redistribution out of the CNS and into muscle and fat stores. Greyhounds and other sight hounds may exhibit longer recovery times than other breeds. This may be due to these breeds low body fat levels or differences in the metabolic handling of the thiobarbiturates. Although anesthesia is short, recovery periods may require several hours.

- Thiopental is metabolized by the hepatic microsomal system and several metabolites have been isolated. The elimination half-life in dogs has been reported as being approximately 7 hours and in sheep, 3–4 hours. Very little of the drug is excreted unchanged in the urine (0.3% in humans), so dosage adjustments are not necessary in patients with chronic renal failure.
The following are considered absolute contraindications to the use of thiopental: absence of suitable veins for IV administration, history of hypersensitivity reactions to the barbiturates, and status asthmaticus. Relative contraindications include: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). These relative contraindications do not preclude the use of thiopental, but dosage adjustments must be considered and the drug must be given slowly and cautiously.

Patients with renal dysfunction or acidaemia may show increased sensitivity to thiopental. Because greyhounds (and other sighthounds) metabolize thiothepinates much more slowly than methohexital, many clinicians recommend using methohexital instead. In horses, thiopental should not be used if the patient has preexisting leukopenia. Some clinicians feel that thiopental should not be used alone in the horse as it may cause excessive ataxia and excitement. Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. Extravasation and intra-arterial injections should be avoided because of the high alkalinity of the solution. Severe CNS toxicity and tissue damage has occurred in horses receiving intra-carotid injections of thiothepinates.

**Adverse Effects**

In dogs, thiopental has an approximate arhythmogenic incidence of 40%. Ventricular bigeminy is the most common arrhythmia seen; it is usually transient and generally responds to additional oxygen. Administration of catecholamines may augment the arhythmogenic effects of the thiothepinates, while lidocaine may inhibit it. Cardiac output may also be reduced, but is probably only clinically significant in patients experiencing heart failure. Dose-related apnea and hypotension may be noted.

Cats are susceptible to developing apnea after injection and may develop a mild arterial hypotension. Horses can exhibit clinical signs of excitement and severe ataxia during the recovery period if the drug is used alone. Horses can develop transient leukopenias and hyperglycemia after administration. A period of apnea and moderate tachycardia and a mild respiratory acidosis may also develop after dosing.

Too rapid IV administration can cause significant vascular dilatation and hypoglycemia. Repeated administration of thiopental is not advised as recovery times can become significantly prolonged. Parasympathetic side effects (e.g., salivation, bradycardia) may be managed with the use of anticholinergic agents (atropine, glycopyrrolate). Prolonged recoveries may occur when repeated doses of thiopental are administered.

Thiopental’s high pH (10–11) can cause significant tissue irritation and necrosis if administered perivascularly; administration through an IV catheter is advised.

**Reproductive/Nursing Safety**

Thiopental readily crosses the placental barrier and should be used with caution during pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Small amounts of thiopental may appear in milk following administration of large doses, but is unlikely to be of clinical significance in nursing animals.

**Overdosage/Acute Toxicity**

Treatment of thiopental overdosage consists of supporting respirations (O2, mechanical ventilation) and giving cardiovascular support (do not use catecholamines, e.g., epinephrine, etc.).

**Drug Interactions**

A fatal interaction has been reported in a dog receiving the proprietary product, Diathal® (no longer marketed; contained procaine penicillin G, dihydrostreptomycin sulfate, diphemanil methylsulfate, and chlorpheniramine) and the related compound thiamylal. The following drug interactions have either been reported or are theoretical in humans or animals receiving thiopental and may be of significance in veterinary patients:

- **CLONIDINE:** IV clonidine prior to induction may reduce thiopental dosage requirements by up to 37%

- **CNS DEPRESSANTS, OTHER:** May enhance respiratory and CNS depressant effects

- **DIAZOXIDE:** Potential for hypotension

- **EPINEPHRINE, NOREPINEPHRINE:** The ventricular fibrillatory effects of epinephrine and norepinephrine may be potentiated when used with thiothepinates and halothane

- **METOCLOPRAMIDE:** Given prior to induction may reduce thiopental dosage requirements

- **MIDAZOLAM:** May potentiate hypnotic effects

- **OPIATES:** Given prior to induction may reduce thiopental dosage requirements

- **PHENOTHIAZINES:** May potentiate thiopental effects; hypotension possible

- **PROBENECID:** May displace thiopental from plasma proteins

- **SULFONAMIDES:** Thiopental and sulfas may displace one another from plasma proteins

**Doses**

**Note:** Atnorepine (or glycopyrrolate) is often administered prior to thiothepinate anesthesia to prevent parasympathetic side effects; however, some clinicians question whether routine-administration of anticholinergic agents is necessary. Thiothepinates are administered strictly to effect; doses are guidelines only.

**DOGS:**

a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; Pentothal®—Ceva Laboratories)

b) 15–17 mg/kg IV for brief (7–10 minutes) anesthesia; 18–22 mg/kg IV for moderate (10–15 minutes) duration; 22–29 mg/kg IV for longer (15–25 minutes) duration (Booth 1988)

c) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)

d) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005)

**CATS:**

a) 13.2–26.4 mg/kg IV depending on duration of anesthesia required (Package insert; Pentothal®—Ceva Laboratories)

b) 22 mg/kg IV; or 15.4 mg/kg IV after tranquilization; or 11 mg/kg IV after narcotic premedication (Mandsager 1988)

c) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005)

**RABBITS, RODENTS, SMALL MAMMALS:**

a) Rabbits: 15–30 mg/kg IV to effect (Ivey & Morrissey 2000)

b) For chemical restraint: Mice: 50 mg/kg IP; Rats: 40 mg/kg IP; Hamsters/Gerbils: 30–40 mg/kg IP; Guinea pigs: 15–30 mg/kg IV; Rabbits: 15–30 mg/kg IV (Burke 1999)

c) For anesthesia in rabbits: 10–12 mg/kg IV to effect. (Kaiser-Klingler 2009)

c) Usually dosed at 12–15 mg/kg, with one-third of the drug administered rapidly and any additional amount administered to effect. Repeated doses will accumulate resulting in prolonged recoveries; residual effect may last several hours. (Hellyer 2005)

**HORSES:**

a) 8.14–15.4 mg/kg IV; for unweaned calves from which food has been withheld for 6–12 hours: no more than 6.6 mg/kg IV for deep surgical anesthesia (Pentothal® package insert; Ceva Laboratories)

b) For calves under 2 weeks of age: 15–22 mg/kg IV slowly until complete muscular relaxation takes place, duration of anesthesia usually lasts 10–12 minutes (Booth 1988)

c) 5.5 mg/kg IV after sedation and administration with guaifenesin; or 8.8–11 mg/kg IV after tranquilization (Mandsager 1988)

**PENTOTHAL®—Ceva Laboratories)**

May potentiate hypnotic effects

May displace thiopental from plasma proteins

May enhance respiratory and CNS depressant effects

May displace thiopental from plasma proteins

May potentiate hypnotic effects

May displace thiopental from plasma proteins

May displace thiopental from plasma proteins

May displace thiopental from plasma proteins

May potentiate thiopental effects; hypotension possible

May displace thiopental from plasma proteins

**Thiopental’s high pH (10–11) can cause significant tissue irritation and necrosis if administered perivascularly; administration through an IV catheter is advised.**
A thiobarbiturate, thiopental occurs as a bitter tasting, white to off-white, crystalline powder or a yellow-white hygroscopic powder. It is soluble in water (1 gram in 1.5 mL) and alcohol. Thiopental has a pKa of 7.6 and is a weak organic acid. Thiopental solutions are very alkaline (pH>10).

Thiopental sodium may also be known as: thiopentone sodium, natrium isopentylaethylthiobarbituricum, penticobarbitale sodique, thiomebumalnatrium cum natrii carbonate, thioentobarbitalam soluble, tiopenol sodico, Anesthala® Bensul®l, Farmafast®, Higlovento®, Inductala®, Intraval®, Nesdonal®, Pensodital®, Pentothala®, Pentothal®, Sodipental®, Sodiembutal®, Thiopentacal®, Trubartial®, or Trupanal®.

Storage/Stability
When stored in the dry form, thiopental sodium is stable indefinitely. Thiopental should be diluted with only sterile water for injection, sodium chloride injection, or D5W. Concentrations of less than 2% in sterile water should not be used as they may cause hemolysis. After reconstitution, solutions are stable for 3 days at room temperature and 7 days if refrigerated; however, as no preservative is present, it is recommended be used within 24 hours after reconstitution. After 48 hours, the solution has been reported to attack the glass bottle in which it is stored. Thiopental may also adsorb to plastic IV tubing and bags. Do not administer any solution that has a visible precipitate.

Compatibility/Compounding Considerations
Preparation of Solution for Administration:

The following agents have been reported to be physically compatible when mixed with thiopental: aminophylline, chloramphenicol sodium succinate, hyaluronidase, hydrocortisone sodium succinate, neostigmine methylsulfate, oxytocin, pentobarbital sodium, phenobarbital sodium, potassium chloride, propofol (1:1 mixture), scopolamine HBr, sodium iodide, and tubocurarine chloride (recommendations conflict with regard to tubocurarine; some clinicians recommend not mixing with thiopental).

The following agents have been reported to be physically incompatible when mixed with thiopental: Ringer’s injection, Ringer’s injection lactate, amikacin sulfate, atropine sulfate, chlorpromazine, codeine phosphate, dimenhydrinate, diphenhydramine, ephedrine sulfate, glycopyrrolate, hydromorphone, insulin (regular), levorphanol bitartrate, meperidine, metaraminol, morphine sulfate, norepinephrine bitartrate, penicillin G potassium, procyclidine hydrochloride, promazine HCl, promethazine hydrochloride, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

VETERINARY-LABELED PRODUCTS:

None presently being marketed in USA.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

At the time of writing (February 2011), thiopental is not available for the US market.

Thiopental Sodium Powder for Injection: 2% (20 mg/mL) in 1 gram, 2.5 grams and 5 grams kits; 400 mg Min-I-Mix vials with Min-I-Mix injector, Ready-to-Mix and Ready-to-MixLifeShield syringes; 2.5% (25 mg/mL) in 250 & 500 mg Min-I-Mix vials, 500 mg, 1 gram, 2.5 grams, 5 grams & 10 grams kits, 250 mg and 500 mg Ready-to-Mix syringes and Ready-to-Mix LifeShield syringes; Pentothala® (Abbott); generic; (Rx, C-III)

References

References

Vaccine indications for thiopeta include: systemic use for adjunctive therapy against carcinomas, and intracavitary use for neoplastic effusions. In dogs with transitional cell bladder carcinoma, intravesical instillation of thiopeta had significantly less efficacy (mean survival time = 75 days) when compared to a systemic doxorubicin/cyclophosphamide protocol (mean survival time = 259 days).

Pharmacology/Actions

Thiopeta is an alkylating agent, thereby interfering with DNA replication and RNA transcription. It is cell cycle non-specific. Thiopeta has some immunosuppressive activity. When given via the intracavitary route, thiopeta is thought to control malignant effusions by a direct antineoplastic effect.

Pharmacokinetics

Thiopeta is poorly absorbed from the GI tract. Systemic absorption is variable from the pleural cavity, bladder, and after IM injection. Some studies in humans have shown that absorption from bladder mucosa ranges from 10–100% of an administered dose. Distribution characteristics are not well described; it is unknown if the drug enters maternal milk. Thiopeta is extensively metabolized and then excreted in the urine.

Contraindications/Precautions/Warnings

Thiopeta is contraindicated in patients hypersensitive to it. The drug should be used cautiously (weight risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, tumor cell infiltration of bone marrow, renal function impairment (adjust dosage) or with a history of urate urinary stones. Thiopeta has a very low therapeutic index and should only be used by clinicians with experience in the use of cytotoxic agents and able to monitor therapy appropriately.

Adverse Effects

When used systemically, leukopenia is the most likely adverse effect seen in small animals. Other hematopoietic toxicity (thrombocytopenia, anemia, pancytopenia) may be noted. Intracavitary or intravesical instillation of thiopeta may cause hematologic toxicity. GI toxicity (vomiting, diarrhea, stomatitis, intestinal ulceration) may be noted and human patients have reported dizziness and headache as well.

Reproductive/Nursing Safety

Thiopeta is potentially mutagenic and teratogenic and is not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.)

Although it is unknown whether thiopeta enters milk, use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity

There is no specific antidote for thiopeta overdose. Supportive therapy, including transfusions of appropriate blood products, may be beneficial for treatment of hematologic toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving thiopeta and may be of significance in veterinary patients:

- IMMUNOSUPPRESSIVE DRUGS (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection
- MYELOSUPPRESSIVE DRUGS (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive
- VACCINES, LIVE: Live virus vaccines should be used with caution during therapy, if at all

Laboratory Considerations

- Thiopeta may increase serum uric acid levels in some patients

Doses

DOGS:

Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references (e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)) are strongly recommended.

a) For intracavitary use neoplastic effusions or systemically for adjunctive therapy of carcinomas: 0.2–0.5 mg/m² intracavitary; IV. (Jacobs et al. 1992)

Monitoring

- Efficacy
- CBC with platelets

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality
- Clients should contact veterinarian should the animal exhibit clinical signs of abnormal bleeding, bruising, anorexia, vomiting, jaundice, or infection

Chemistry/Synonyms

An ethylene derivative alkylating agent antineoplastic, thiopeta occurs as fine, white crystalline flakes. The drug has a faint odor and is freely soluble in water or alcohol.

Thiopeta may also be known as: NSC-6396, TESPA, thiophosphamide, triethylenethiophosphoramide, TSPA, WR-45312, L

Storage/Stability

Store both the powder and the reconstituted solution refrigerated (2–8°C) and protected from light. Do not use solution that is grossly opaque (slightly opaque is OK) or if a precipitate is present. If refrigerated, reconstituted solutions are stable for up to 5 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Thiopeta Lyophilized Powder for Injection: 15 mg & 30 mg in vials; Thiopeta® (Amgen); generic, (Sicor); (Rx)

References

Adapted from the U.S. Pharmacopeia and the 2006 American Academy of Veterinary Internal Medicine, Philadelphia, PA.

Managing the Canine Cancer Patient: A Practical Guide to Compassionate Care, Philadelphia, PA.

Withrow and MacEwen’s Small Animal Clinical Oncology 4th Ed, Philadelphia, PA.
Uses/Indications
The labeled indications for the formerly available bovine-source veterinary product Dermamycin® (Mallinckrodt) was for “the treatment of acanthosis nigricans and for temporary supportive therapy in hypothyroidism in dogs.” In actuality however, TSH is used in veterinary medicine principally as a diagnostic agent in the TSH stimulation test to diagnose primary hypothyroidism.

Pharmacology/Actions
Thyrotropin increases iodine uptake by the thyroid gland and increases the production and secretion of thyroid hormones. With prolonged use, hyperplasia of thyroid cells may occur.

Pharmacokinetics
No specific information was located; exogenously administered TSH apparently exerts maximal increases in circulating T₄ approximately 4-8 hours after IM or IV administration.

Contraindications/Precautions/Warnings
A previous veterinary manufacturer (Coopers), listed adrenocortical insufficiency and hyperthyroidism as contraindications to TSH use for treatment purposes in dogs. In humans, TSH is contraindicated in patients with coronary thrombosis, untreated Addison’s disease, or hypersensitive to bovine thyrotropin.

Adverse Effects
Because the commercially available product is derived from human sources, hypersensitivity reactions may occur in patients sensitive to human proteins, particularly with repeated use.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether the drug is excreted in milk, but is unlikely to be clinically significant when used for diagnostic purposes.

Overdosage/Acute Toxicity
Chronic administration at high dosages can produce clinical signs of hyperthyroidism. Massive overdoses can cause clinical signs resembling thyroid storm. Refer to the levothyroxine monograph for more information on treatment.

Drug Interactions: Laboratory Considerations
Refer to the information listed in the Levothyroxine monograph for more information.

Doses

**DOGS:**
For TSH stimulation test:

- a) Using the human recombinant product. From a study where dogs received 75 micrograms (total dose) IV. Blood samples were taken before and 6 hours after rhTSH administration for determination of total serum thyroxine (T₄) concentration. The authors concluded: The TSH-stimulation test with rhTSH is a valuable diagnostic tool to assess thyroid function in selected dogs in which a diagnosis of hypothyroidism cannot be based on basal T₄ and canine TSH concentrations alone. (Boretti et al. 2006)

- b) Using the human recombinant product: 50-100 micrograms (0.05–0.1 mg) IV; Measure serum T₄ at 0 hours (pre-sample) and 4 hours post. Product may be frozen for at least 8 weeks with no loss of potency. (Scott-Moncrieff 2006)

**BIRDS:**
For TSH stimulation test:

- a) Draw pre-dose baseline sample. Administer 1 Unit/kg IM. Collect sample for T₄ 6 hours after dose. (Greenacre 2009)

Chemistry/Synonyms
Commercially available thyrotropin (human; rhTSH) is now available only as a lyophilized powder for reconstitution obtained via DNA recombinant technology. Originally obtained from bovine anterior pituitary glands, thyrotropin is a highly purified preparation of thyroid-stimulating hormone (TSH). Thyrotropin is a glycoprotein and has a molecular weight of approximately 28,000–30,000. Thyrotropin is measured in International Units (IU), which is abbreviated as Units in this reference. 7.5 micrograms of thyrotropin are approximately equivalent to 0.037 Units.

Thyrotropin may also be known as: thyroid-stimulating hormone, thyrotrophic hormone, thyrotropin, TSH, 

**Storage/Stability**
Thyrotropin alfa (unreconstituted) should be stored between 2–8°C (36–46°F). If necessary, the reconstituted solution can be stored up to 24 hours between 2–8°C (36–46°F), while avoiding microbial contamination. However, it is reportedly stable if kept refrigerated (2–8°C) up to 4 weeks and up to 8 weeks if frozen (-20°C).

After reconstitution visually inspect each vial for particulate matter or discoloration before use. Do not use any vial exhibiting particulate matter or discoloration. Do not use after the expiration date on the vial. Protect from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Recombinant (human) Thyrotropin (Thyroid Stimulating Hormone) Powder for Injection, Lyophilized: 1.1 mg per vial; Thyrogen® (Genzyme); (Rx)

TIAMULIN (tye-am-myoo-lin) Denagard®

DITERPINE PLEUROMUTILIN ANTIBIOTIC

Prescriber Highlights

- Antibiotic used primarily in swine
- Contraindications: Access to feeds containing polyether ionophores (e.g., monensin, lasalocid, narasin, or salinomycin); swine over 250 pounds
- Adverse Effects are unlikely
- Variable withdrawal times depending on dosage

Uses/Indications
Tiamulin is FDA-approved for use in swine to treat pneumonia caused by susceptible strains of *Haemophilus pleuropneumoniae* and swine dysentery caused by *Treponema hyodysenteriae*. As a feed additive, it is used to cause increased weight gain in swine.

Pharmacology/Actions
Tiamulin is a pleuromutilin antibiotic that is usually bacteriostatic, but can be bactericidal in very high concentrations against susceptible organisms. The drug acts by binding to the 50S ribosomal subunit, thereby inhibiting bacterial protein synthesis.

Tiamulin has good activity against many gram-positive cocci, including most Staphylococci and Streptococci (not group D streps). It also has good activity against Mycoplasma and spirochetes. With the exception of *Haemophilus* spp. and some *E. coli* and Klebsiella strains, the drug’s activity is quite poor against gram-negative organisms.

Pharmacokinetics
Tiamulin is well absorbed orally by swine. Approximately 85% of a dose is absorbed and peak levels occur between 2–4 hours after a single oral dose. Tiamulin is apparently well distributed, with highest levels found in the lungs.

Tiamulin is extensively metabolized to over 20 metabolites, some having antibacterial activity. Approximately 30% of these metabolites are excreted in the urine with the remainder excreted in the feces.

Contraindications/Precautions/Warnings
Tiamulin should not be administered to animals having access to feeds containing polyether ionophores (e.g., monensin, lasalocid, narasin, or salinomycin) as adverse reactions may occur. Not for use in swine over 250 pounds.

Reproductive/Nursing Safety
Teratogenicity studies done in rodents demonstrated no teratogenic effects at doses up to 300 mg/kg. The manufacturer has concluded that the drug is not tumorigenic, carcinogenic, teratogenic, or mutagenic.

Adverse Effects
Adverse effects occurring with this drug at usual doses are considered unlikely. Rarely, redness of the skin, primarily over the ham and underline, has been observed. It is recommended to discontinue the medication, provide clean drinking water, and hose down the area or move affected animals to clean pens.

Overdosage/Acute Toxicity
Oral overdoses in pigs may cause transient salivation, vomiting, and CNS depression (calming effect). Discontinue drug and treat symptomatically and supportively if necessary.

Drug Interactions
- POLYETHER IONOPHORES (e.g., monensin, lasalocid, narasin, or salinomycin): Tiamulin should not be administered to animals having access to feeds containing polyether ionophores as adverse reactions may occur
- LINCOSAMIDES, MACROLIDES (e.g., clindamycin, lincomycin, erythromycin, tylosin): Although not confirmed with this drug, concomitant use with other antibiotics that bind to the 50S ribosome could lead to decreased efficacy secondary to competition at the site of action

Doses
**SWINE:**

a) For swine dysentery: 7.7 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; Denagard® Liquid Concentrate)

b) For swine pneumonia: 23.1 mg/kg PO daily in drinking water for 5 days. See package directions for dilution instructions. (Package insert; Denagard® Liquid Concentrate)

c) For use as a medicated premix: See the label for the product.

Monitoring
- Clinical efficacy

Client Information
- Prepare fresh medicated water daily
- Avoid contact with skin or mucous membranes as irritation may occur

Chemistry/Synonyms
A semisynthetic diterpene-class antibiotic derived from pleuromulin, tiamulin is available commercially for oral use as the hydrogen fumarate salt. It occurs as white to yellow, crystalline powder with a faint but characteristic odor. Approximately 60 mg of the drug are soluble in 1 mL of water.

Tiamulin may also be known as: 81723-hfu, SQ-14055, SQ-22947 (tiamulin fumarate), and Denagard®.

Storage/Stability
Protect from moisture; store in a dry place. In unopened packets, the powder is stable up to 5 years. Fresh solutions should be prepared daily when using clinically.

Dosage Forms/Regulatory Status

**VETERINARY APPROVED PRODUCTS:**

Tiamulin Medicated Premix: 10 grams/1 lb in 35 lb bags. FDA-approved for use in swine not weighing over 250 lbs. Slaughter withdrawal period at the 35 grams/ton use is 2 days and at the 200 grams/ton dose is 7 days. *Denagard® 10 (Novartis); (OTC).

Tiamulin Solution: 12.3% tiamulin hydrogen fumarate in an aqueous base in 32 oz bottles. FDA-approved for use in swine. Slaughter withdrawal: treatment at 3.5 mg/lb = 3 days, at 10.5 mg/lb = 7 days. *Denagard® Liquid Concentrate (Boehringer Ingelheim); TiaGard® (Teva); (OTC)
Ticarcillin/clavulanate is used systemically to treat serious infections such as sepsis or nosocomial pneumonias in dogs, cats and horses. By adding clavulanate, enhanced spectrum of activity against beta-lactamase producing bacteria can be obtained. This drug combination is sometimes used to treat Pseudomonas otitis in dogs.

**Pharmacokinetics**

Ticarcillin is eliminated primarily by the kidneys, via both tubular secretion and glomerular filtration. Concurrent probenecid administration can slow elimination and increase blood levels. In humans, about 10–15% of the drug is metabolized by hydrolysis to inactive compounds. The half-life in dogs and cats is reportedly 45–80 minutes; about 54 minutes in the horse. Clearance is 4.3 mL/kg/min in the dog and 2.8–3.2 mL/kg/min in the horse. There is no evidence to suggest that the addition of clavulanic acid alters ticarcillin pharmacokinetics.

Ticarcillin/clavulanate can induce chromosomal beta-lactamases. Like the aminopenicillins, these agents are susceptible to inactivation by beta-lactamases.

Synergy against *Pseudomonas aeruginosa* can occur when used with an aminoglycoside, but the drugs cannot be mixed together (see Drug Interactions).

**Contraindications/Precautions/Warnings**

Do not use this medication in patients with documented hypersensitivity reactions to penicillins or other beta-lactams.

Dosage adjustments should be made in patients with significantly impaired renal function.

**Adverse Effects**

Although clinical experience with this medication in veterinary patients is limited, it appears to be well tolerated; potentially, hypersensitivity reactions can occur. In humans, high dosages (particularly in patients with renal insufficiency) have caused platelet dysfunction and bleeding, and CNS effects (headache, giddiness, hallucinations, seizures). Intramuscular administration can cause pain, but reconstituting with 1% lidocaine (see Drug Interactions).

Although penicillins can be distributed into milk, it is unlikely that ticarcillin/clavulanate would be of significant clinical concern for nursing veterinary patients.

**Reproductive/Nursing Safety**

Penicillins have been shown to cross the placenta and safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes ticarcillin/clavulanate as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Although penicillins can be distributed into milk, it is unlikely that ticarcillin/clavulanate would be of significant clinical concern for nursing veterinary patients.

**Overdosage/Acute Toxicity**

A single inadvertent overdose is unlikely to cause significant morbidity. In humans, very high dosages of parenteral penicillins such as ticarcillin, especially in patients with renal disease, have induced CNS effects (hallucinations, headaches, seizures) and alterations in platelet function (bleeding).

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving ticarcillin/clavulanate and may be of significance in veterinary patients:

- *Pseudomonas* spp., *Klebsiella*, and *Proteus*. Clavulanic acid acts by competitively and irreversibly binding to beta-lactamases, including types II, III, IV, and V, and penicillinases produced by *Staphylococcus*. Type I beta-lactamases that are often associated with *Pseudomonas aeruginosa* are resistant to many beta-lactamases. However, clavulanic acid can induce chromosomal beta-lactamases.

- *Pseudomonas aeruginosa* can occur when used with an aminoglycoside, but the drugs cannot be mixed together (see Drug Interactions).
Ticarcillin Disodium Powder for Injection (contains 4.75 mEq sodium/g) and Clavulanate Potassium (contains 0.15 mEq potassium/g): 3 grams ticarcillin and 0.1 gram clavulanic acid in 3.1 gram vials, piggyback bottles.

Telazol® is indicated for restraint or anesthesia combined with muscle relaxation in cats, and for restraint and minor procedures of short duration (=30 minutes) which require mild to moderate analgesia in dogs. Although not officially FDA-approved, it has been used also in horses and many exotic and wild species.

Pharmacology/Actions

Tranquilization is a state of altered consciousness in which the patient is usually free of pain but may experience some degree of sensory and motor inhibition. 

Telazol® is indicated for restraint or anesthesia combined with muscle relaxation in cats, and for restraint and minor procedures of short duration (=30 minutes) which require mild to moderate analgesia in dogs. Although not officially FDA-approved, it has been used also in horses and many exotic and wild species.

Pharmacology/Actions

Tranquilization is a state of altered consciousness in which the patient is usually free of pain but may experience some degree of sensory and motor inhibition. Telazol® is contraindicated in large, exotic cats (contraindicated in tigers) as it may cause seizures, permanent neurologic abnormalities, or death. Cats’ eyes remain open after receiving Telazol®, and they should be protected from injury and an ophthalmic lubricant (e.g., Lactrilube®) should be applied to prevent excessive drying of the cornea. Cats reportedly do not tolerate endotracheal tubes well with this agent. Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.

Contraindications/Precautions/Warnings

Telazol® is contraindicated in animals with pancreatitis and it may cause hypothermia, susceptible animals (small body surface area, low ambient temperatures) should be monitored carefully and supplemental heat applied if needed. Like ketamine, Telazol® does not abolish pinnal, palpebral, pedal, laryngeal, and pharyngeal reflexes and its use (alone) may not be adequate if surgery is to be performed on these areas. It has been reported that this drug is contraindicated in rabbits due to renal toxicity. Telazol® is generally avoided for use in large, exotic cats (contraindicated in tigers) as it may cause seizures, permanent neurologic abnormalities, or death. Cats’ eyes remain open after receiving Telazol®, and they should be protected from injury and an ophthalmic lubricant (e.g., Lactrilube®) should be applied to prevent excessive drying of the cornea. Cats reportedly do not tolerate endotracheal tubes well with this agent. Dosages may need to be reduced in geriatric, debilitated, or animals with renal dysfunction.

Adverse Effects

Respiratory depression is a definite possibility, especially with higher dosages of this product. Apnea may occur; observe animal carefully. Pain after IM injection (especially in cats) has been noted which may be a result of the low pH of the solution. Athetoid movements (constant succession of slow, writhing, involuntary movements of flexion, extension, pronation, and other movements) may occur; do not give additional Telazol® in the attempt to diminish these actions. Large doses given SC or IM, versus small doses given IV, may result in longer, rougher recoveries.

In dogs, tachycardia may be a common effect and last for 30 minutes. Insufficient anesthesia after recommended doses has been reported in dogs. Telazol® has been implicated in causing nephropathy in lagomorphs (rabbits/hares) and is usually not recommended for use in these species.

Other adverse effects listed by the manufacturer include: emesis during emergence, excessive salivation and bronchial/tracheal secretions (if atropine not administered beforehand), transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertension, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, and either hypertension or hypotension.

Reproductive/Nursing Safety

Telazol® crosses the placenta and may cause respiratory depression in newborns; the manufacturer lists its use in cesarean section as being contraindicated. The teratogenic potential of the drug is unknown, and it is not recommended for use during any stage of pregnancy.

Overdosage/Acute Toxicity

Some adverse effects listed by the manufacturer include: emesis during emergence, excessive salivation and bronchial/tracheal secretions (if atropine not administered beforehand), transient apnea, vocalization, erratic and/or prolonged recovery, involuntary muscular twitching, hypertension, cyanosis, cardiac arrest, pulmonary edema, muscle rigidity, and either hypertension or hypotension.

Telazol® has been implicated in causing nephropathy in lagomorphs (rabbits/hares) and is usually not recommended for use in these species.

In dogs, tachycardia may be a common effect and last for 30 minutes. Insufficient anesthesia after recommended doses has been reported in dogs. Telazol® has been implicated in causing nephropathy in lagomorphs (rabbits/hares) and is usually not recommended for use in these species.
Drug Interactions

Little specific information is available presently on drug interactions with this product.

- **ANESTHETICS, INHALATIONAL**: Dosage may need to be reduced when used concomitantly with Telazol®
- **BARBITURATES**: Dosage may need to be reduced when used concomitantly with Telazol®
- **CHLORAMPHENICOL**: In dogs, chloramphenicol apparently has no effect on recovery times with Telazol®, but in cats, anesthesia is prolonged on average of 30 minutes by chloramphenicol.

- **PHENOTHIAZINES**: Can cause increased respiratory and cardiac depression. For potential additional interactions from the related compounds, ketamine and midazolam:

**Ketamine**:

- **NEUROMUSCULAR BLOCKERS** (e.g., succinylcholine and tubocurarine): May cause enhanced or prolonged respiratory depression.

- **THYROID HORMONES**: When given concomitantly with ketamine, thyroid hormones have induced hypertension and tachycardia in humans; beta-blockers (e.g., propranolol) may be of benefit in treating these effects.

**Midazolam**:

- **ANESTHETICS, INHALATIONAL**: Midazolam may decrease the dosages required.

- **AZOLE ANTIMICROBIALS** (ketoconazole, itraconazole, fluconazole): May increase midazolam levels.

- **CALCIUM CHANNEL BLOCKERS** (diltiazem, verapamil): May increase midazolam levels.

- **CIMETIDINE**: May increase midazolam levels.

- **CNS DEPRESSANTS, OTHER**: May increase the risk of respiratory depression.

- **MACROLIDES** (erythromycin, clarithromycin): May increase midazolam levels.

- **OPIATES**: May increase the hypnotic effects of midazolam and hypotension has been reported when used with meperidine.

- **PHENOBARBITAL**: May decrease peak levels and AUC of midazolam.

- **RIFAMPIN**: May decrease peak levels and AUC of midazolam.

- **THIOPENICAL**: Midazolam may decrease the dosages required.

**Doses**

- **DOGS**:
  a) For diagnostic purposes: 6.6–9.9 mg/kg IM
    For minor procedures of short duration: 9.9–13.2 mg/kg IM;
    If supplemental doses are necessary, give doses less than the initial dose and total dosage should not exceed 26.4 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert: Telazol®—Robins)
  b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002)
  c) For aggressive (difficult to handle) dogs that require more sedation and only if insufficient sedation from opioid, higher dose medetomidine, and midazolam: 1–2 mg/kg IM. (Moffat 2008)

- **CATS**:
  a) 9.7–11.9 mg/kg IM for procedures such as dentistry, abscess treatment, foreign body removal, etc. For procedures that require mild to moderate levels of analgesia (lacerations, castration, etc.) use 10.6–12.5 mg/kg IM.
    For ovariohysterectomy and onychectomy use 14.3–15.8 mg/kg IM.
    If supplemental doses are necessary, give doses less than the initial dose and total dosage should not exceed 72 mg/kg. Atropine 0.04 mg/kg should be used concurrently to control hypersalivation. (Package Insert: Telazol®—Robins)
  b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002)

- **RUMINANTS**:
  As an induction agent for cattle, llamas/alpacas, goats, sheep:
  a) Xylazine at 0.05–0.1 mg/kg IV, IM, then
  b) Based upon the combination of drugs: 3–10 mg/kg IM or SC or 2–5 mg/kg IV (Mama 2002)

- **RABBITS, RODENTS, SMALL MAMMALS**:
  For chemical restraint:
  a) Gerbils: 20 mg/kg IP (in combination with xylazine 10 mg/kg) (Huerkamp 1995)
  b) Mice: 80–100 mg/kg IM.
    - Rats: 20–60 mg/kg IM.
    - Hamsters/Gerbils: 20–80 mg/kg IM.
    - Guinea pig: 10–80 mg/kg IM.
    - Rabbits: Not recommended (Burke 1999)
  c) Chinchillas: 20–40 mg/kg IM.
  d) Small rodents:6–10 mg/kg IM is adequate prior to inhalation anesthesia. Advantages over ketamine include better muscle relaxation, small volume of injection, rapid induction time and a wide margin of safety. Disadvantages of this drug combination are increased respiratory secretions, variability in recovery times, and short self-life after reconstitution. (Bennett 2009)

- **FERRETS**:
  As a sedative/analgescic:
  a) 22 mg/kg IM combined with glycopyrrolate (0.01 mg/kg IM). Rapid onset, but slow and rough recovery (3–4 hours) (Finkler 1999)
  b) Telazol® alone: 22 mg/kg IM;
    - Telazol® (1.5 mg/kg) plus xylazine (1.5 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM)
    - Telazol® (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)
  c) Xylazine at 0.05–0.1 mg/kg IV, IM, then

**Monitoring**

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Monitor eyes to prevent drying or injury
- Body temperature

**Client Information**

Should only be administered by individuals familiar with its use.

**Chemistry/Synonyms**

Tiletamine is an injectable anesthetic agent chemically related to ketamine. Zolazepam is a diazepinone minor tranquilizer. The pH of the injectable product, after reconstitution, is 2.2–2.8.

**Storage/Stability**

After reconstitution, solutions may be stored for 4 days at room temperature and 14 days if refrigerated. Do not use solutions that contain a precipitate or are discolored.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Tiletamine HCl (equivalent to 250 mg free base) and Zolazepam HCl (equivalent to 250 mg free base) as lyophilized powder/vial in 5 mL vials. When 5 mL of sterile diluent (sterile water) is added a concentration of 50 mg/mL of each drug (100 mg/mL combined) is produced; Telazol® at 1.65–2.2 mg/kg IV (Hubbell et al. 1989)

**HUMANS-LABELLED PRODUCTS:** None

**ThilMICOSIN**

**MACROLIDE ANTIBIOTIC**

**Prescriber Highlights**

- Macrolide antibiotic used in cattle, sheep, & sometimes rabbits; used in swine as a medicated feed article
- Contraindications: Not to be used in automatically powered syringes or to be given IV, camels(?)
- May be fatal in swine (when injected) & non-human primates; potentially in horses
- Adverse Effects: IM injections may cause a local tissue reaction resulting in trim loss; edema is possible at SC injection site
- Avoid contact with eyes
- In case of human injection, contact physician immediately
Tilmicosin is indicated for the treatment of bovine or ovine respiratory diseases (BRD) caused by *Mannheimia (Pasteurella) haemolytica*.

**Pharmacology/Actions**

Like other macrolides, tilmicosin has activity primarily against gram-positive bacteria, although some gram-negative bacteria are affected and the drug reportedly has some activity against mycoplasma. Preliminary studies have shown that 93% of studied isolates of *Pasteurella haemolytica* are sensitive. Bacterial isolates susceptible to tilmicosin at concentrations of 8 micrograms/mL or less are reported as susceptible to tilmicosin. The MIC90 value reported for *M. haemolytica* and *P. multocida* in cattle with BRD is 32 micrograms/mL.

**Pharmacokinetics**

Tilmicosin apparently concentrates in lung tissue. At 3 days post injection, the lung:serum ratio is about 60:1. MIC95 concentrations (3.12 micrograms/mL) for *P. Haemolytica* persist for a minimum of 3 days after a single injection.

**Contraindications/Precautions/Warnings**

Not to be used in automatically powered syringes or to be given intravenously as fatalities may result. Tilmicosin has been shown to be fatal in swine (when injected), non-human primates and potentially, in horses. Avoid contact with eyes.

There have been anecdotal reports of severe reactions in some cameldids.

**Adverse Effects**

If administered IM, a local tissue reaction may occur resulting in trim loss. Edema may be noted at the site of subcutaneous injection.

Accidental self-injection can be fatal in humans. Do not use in automatically powered syringes. Emergency treatment includes applying ice to injection site and contacting a physician immediately. Emergency medical telephone numbers are 1-800-722-0987 or 1-317-276-2000.

**Reproductive/Nursing Safety**

Safe use in pregnant animals or animals to be used for breeding purposes has not been demonstrated.

**Overdosage/Acute Toxicity**

The cardiovascular system is apparently the target of toxicity in animals. In cattle, doses up to 50 mg/kg IM did not cause death, but SC doses of 150 mg/kg did cause fatalities, as well as IV doses of 5 mg/kg. Doses as low as 10 mg/kg in swine caused increased respiration, emesis and seizures; 20 mg/kg IM caused deaths in most animals tested. In monkeys, 10 mg/kg administered once caused no signs of toxicity, but 20 mg/kg caused vomiting; 30 mg/kg caused death.

In cases of human injection, contact physician immediately. The manufacturer has emergency telephone numbers to assist in dealing with exposure: 1-800-722-0987 or 1-317-276-2000.

**Drug Interactions**

In swine, epinephrine increased the mortality associated with tilmicosin. No other specific information was noted; refer to the erythromycin monograph for possible interactions.

**Doses**

**CATTLE:**

For susceptible infections (subcutaneous injection under the skin in the neck, if not accessible, behind the shoulders and over the ribs is suggested).

a) For treatment of pneumonic pasteurellosis: 10 mg/kg SC every 72 hours (Shewen & Bateman 1993)

b) 10 mg/kg SC (not more than 15 mL per injection site. (Package insert; Micotil® 300—Elanco)

**SHEEP:**

For susceptible infections:

a) 10 mg/kg SC (not more than 15 mL per injection site). Subcutaneous injection under the skin in the neck, or if not accessible, behind the shoulders and over the ribs is suggested. Do not use in lambs less than 15 kg of body weight. (Package insert; Micotil® 300—Elanco)

**RABBITS, RODENTS, SMALL MAMMALS:**

a) **Rabbits:** Two regimens:

1) 25 mg/kg SC once; repeat in 3 days if necessary.

2) 5 mg/kg SC on day 0, if no reaction, give 10 mg/kg SC on days 7 and 14. Can cause weakness, pallor, tachypnea and sudden death. May cause acute death if given IV. SC injections can cause local swelling and necrosis. (Ivey & Morrissey 2000)

**Monitoring**

- Efficacy
- Withdrawal times

**Client Information**

- If clients are administering the drug, they should be warned about the potential toxicity to humans, swine, and horses if accidentally injected
- Carefully instruct in proper injection techniques
- Avoid contact with eyes

**Chemistry/Synonyms**

A semi-synthetic macrolide antibiotic, tilmicosin phosphate is commercially available in a 300 mg/mL (of tilmicosin base) injection with 25% propylene glycol.

Tilmicosin may also be known as EL-870, LY-177370, *Micotil*® or *Pulmotil*®.

**Storage/Stability**

Store the injection at or below room temperature. Avoid exposure to direct sunlight.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Tilmicosin for Subcutaneous Injection: 300 mg/mL in 50 mL, 100 mL and 250 mL multi-dose vials; *Micotil® 300 Injection* (Elanco); (Rx). FDA-approved for use in cattle and sheep. Not FDA-approved for use in female dairy cattle 20 months or older. Do not use in lactating ewes if milk is to be used for human consumption. Do not use in veal calves. Slaughter withdrawal (at labeled doses) = 28 days.

Tilmicosin Feed Medication: 90.7 grams/lb. *Pulmotil® 90* (Elanco); (OTC). FDA-approved for veterinary use in swine only. Slaughter withdrawal (at labeled doses) = 7 days.

**HUMAN-LABELED PRODUCTS:** None

**References**

None
**TILUDRONATE DISODIUM**

**TILUDRONIC ACID**

(til-yoo-dro-nate) Tildren®, Skelid®

BISPHOSPHONATE BONE RESORPTION INHIBITOR

**Prescriber Highlights**

- Bisphosphonate bone resorption inhibitor available in some countries for the intravenous treatment of navicular disease in horses
- Adverse effects: Signs of colic, muscle tremor (hypocalcemia), fatigue/lassitude, sweating, injection site effects, salivation, tail hypertonia
- Must be legally imported into the USA

**Uses/Indications**

Tiludronate disodium (tiludronic acid) is a bisphosphonate bone resorption inhibitor that is available in some countries for the intravenous treatment of navicular disease in horses. It may be beneficial in managing lameness associated to the navicular bone and distal tarso/metatarsal arthritis by decreasing bone resorption and inflammation (Kamm et al. 2008). Treatment earlier in the course of the disease apparently results in greater efficacy.

For humans, there is an orally administered FDA-approved product for treating Paget’s disease (osteitis deformans).

**Pharmacology/Actions**

Tiludronate, like other bisphosphonates, inhibit osteoclastic bone resorption by inhibiting osteoclast function after binding to bone hydroxyapatite thereby helping to regulate bone remodeling.

**Pharmacokinetics**

After intravenous injection in horses the drug is rapidly distributed to bone. Binding is greater to cancellous bone than cortical bone. Plasma protein binding is reported to be approximately 85% and elimination half-life is approximately 4.5 hours. Repeated daily doses do not result in accumulation in plasma. Unbound drug is eliminated unchanged in the urine. Approximately 25–50% of a single IV dose is eliminated in the urine over 96 hours.

**Contraindications/Precautions/Warnings**

The labeling for Tildren® states that the drug should not be used in horses with renal dysfunction or those producing milk for human consumption. Because there is an absence of data on the effects the drug may have on the skeleton of young animals, the manufacturer states to not administer to horses less than 3 years old.

Since the safety of tiludronate has not been established in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

Use with caution in horses with hypocalcemia or cardiac dysfunction. If used in these patients, slow the rate of injection and watch these patients carefully for the first few hours post-injection.

**Adverse Effects**

Acute adverse effects reported in horses include colic (reduced appetite, abdominal discomfort, pawing/scratching at ground, restlessness), muscle tremor, fatigue/lassitude and sweating. The incidences of these effects are reported at 5% or less and are postulated to be due to a mild hypoglycemic effect. The onset of colic signs appear within a few hours of treatment and generally resolve without treatment. Should they persist, conventional colic treatments are recommended. Muscle tremors may be treated with intravenous calcium if required.

Up to 9% of patients develop local reactions at the injection site (e.g., phlebitis), particularly after the 4th injection.

Other adverse effects reported include salivation and tail hypertonia.

**Reproductive/Nursing Safety**

Studies performed in male and female rats at dosages as high as 75 mg/kg/day demonstrated no effects on fertility.

Studies in pregnant rabbits given 2X–5X human dosages showed no skeletal abnormalities. Pregnant mice given 7X human dosages showed some adverse effects (decreased litter size, malformed paws in 6 fetuses from one litter). Rat studies have shown decreased litter sizes, but no teratogenic effects. In humans, the FDA categorizes tiludronate as category C for use during pregnancy. (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

As the safety of tiludronate has not been studied in pregnant or lactating mares, the manufacturer recommends not using it during pregnancy or lactation.

**Overdosage/Acute Toxicity**

Limited information is available. The manufacturer reports that doses of 3X in horses caused an increased frequency of adverse effects, particularly signs of colic and muscle tremor. Intravenous calcium administration may be considered for signs associated with hypocalcemia.

**Drug Interactions**

- **CALCIUM- or MAGNESIUM-CONTAINING INTRAVENOUS FLUIDS:** May complex with tiludronate and reduce its availability; do not mix with fluids or administer with fluids such as Lactated Ringer’s, Ringer’s, Plasma-Lyte®, Normasol®, etc.

**Laboratory Considerations**

No specific concerns were noted.

**Doses**

- **HORSES:**
  - For navicular disease:
    - 0.1 mg/kg tiludronic acid slow IV (over 20–30 seconds per 10 mL given) once daily for 10 days. Alternate injection sites from day to day. (Label information; Tildren®—Ceva/ Sanofi)

**Monitoring**

- Clinical Efficacy
- Serum Calcium
- Adverse Effects (particularly within first 4 hours after dosing)

**Client Information**

- This medication should be administered by a veterinary professional
- Patient should be observed for up to 4 hours post-administration for signs of hypocalcemia (muscle tremors, etc.) or colic

**Chemistry/Synonyms**

Tiludronate disodium is a bisphosphonate that occurs as a white powder having a molecular weight of 380.6. Commercially available products contain the disodium salt of tiludronic acid. 120 mg of tiludronate disodium is equivalent to 100 mg of tiludronic acid.

Tiludronate disodium or tiludronic acid may also be known as ME-3737, SR-41319, acidum tiludronicum, Tildren® or Skelid®

**Storage/Stability**

Unless otherwise indicated, store the unreconstituted powder and diluent at room temperature (15–30°C) in the outer carton.

Shell life of properly stored unreconstituted product is generally 3 years. Reconstitute the powder by aseptically adding 10 mL of the provided diluent and mix gently. The resulting solution contains 5 mg/mL of tiludronic acid.
TINIDAZOLE
(tye-ni-dah-zole) Tindamax®

NITROIMIDAZOLE ANTIPROTOZOAAL/ANTIBIOTIC

Prescriber Highlights

- Drug similar to metronidazole, potentially useful for treating anaerobic infections (especially in the mouth), trichomoniasis, amebiasis and balantidiasis
- Little experience in veterinary medicine
- Adverse effects most likely GI-related; like metronidazole and ronidazole, tinidazole could cause neurotoxicity
- Many potential drug interactions

Uses/Indications
Little information is presently available on the use of tinidazole in dogs, cats, or horses. It potentially could be useful for treating anaerobic infections, particularly associated with dental infections in small animals. Because of its antiprotozoal effects, it has been used as an alternative for treating giardiasis in small animals, and it could have efficacy against amebiasis, trichomoniasis or balantidiasis in veterinary species, but documentation of efficacy is not available. Tinidazole has a longer duration of action in dogs and cats than does metronidazole. In a small study done in cats experimentally infected with T. foetus, tinidazole doses at 30 mg/kg PO once daily for 14 days, decreased fecal shedding of T. foetus but failed to eradicate the infection from 2 of 4 cats (Gookin et al. 2007).

In humans, oral tinidazole is FDA-approved for treating extraintestinal and intestinal amebiasis, (Entamoeba histolytica), giardiasis (Giardia duodenalis/lambda), and trichomoniasis (T. vaginalis).

Pharmacology/Actions
Tinidazole is a 5-nitroimidazole similar to metronidazole. It is bactericidal against susceptible bacteria. Its exact mechanism of action is not well understood; it is taken-up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible for the drug’s antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria. Tinidazole has activity against many obligate anaerobes and Helicobacter pylori. It has excellent activity against Porphyromonas spp. found in canine gingiva. Tinidazole is also trichomonacidal and amebicidal. Its mechanism of action for its antiprotozoal activity is not well understood. It has therapeutic activity against Entamoeba histolytica, Trichomonas, and Giardia.

Pharmacokinetics
In dogs and cats, tinidazole is practically completely absorbed after oral administration. Apparent volumes of distribution are 0.66 L/kg in dogs and 0.54 L/kg in cats. Dogs clear the drug about twice as fast as cats; elimination half-lives are about 4.4 hours in dogs, 8.4 hours in cats.

In horses, tinidazole is practically completely absorbed after oral administration. Apparent volume of distribution is 0.66 L/kg an elimination half-life of about 5.2 hours.

Contraindications/Precautions/Warnings
Tinidazole should not be used in patients documented to be hypersensitive to it or other 5-nitroimidazoles (e.g., metronidazole).

Tinidazole is metabolized by the liver; use with caution in patients with hepatic dysfunction.

As other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats and seizures have been reported rarely with tinidazole use in humans, use with caution in animals susceptible to seizures.

The human labeling for tinidazole carries a “black box warning” stating: “Carcinogenicity has been seen in mice and rats treated chronically with another agent in the nitroimidazole class (metronidazole). Although such data have not been reported for tinidazole, avoid unnecessary use of tinidazole. Reserve its use for the conditions for which it is indicated.”

Adverse Effects
The adverse effect profiles for dogs, cats or horses are not well described since clinical use of this medication has been limited. Gastrointestinal effects including vomiting, inappetence, and diarrhea are most likely. Giving the medication with food may help alleviate these effects. Other 5-nitroimidazoles (metronidazole, ronidazole) have been associated with neurotoxic signs in dogs and cats; seizures have been reported rarely with tinidazole use in humans.

Tinidazole reportedly is very bitter tasting. If using compounded products, consider using capsules or having a flavored suspension prepared.

Reproductive/Nursing Safety
In studies performed on male rats tinidazole decreased fertility and caused testicular histopathology. Tinidazole crosses the placenta. While studies in mice and rats have not demonstrated significant fetal effects, because of its mutagenic potential, it is stated that it should not be used in women during the first trimester of pregnancy. In humans, the FDA categorizes tinidazole as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Tinidazole is distributed into maternal milk at levels approximating those found in serum. It is suggested that milk replacer be used if tinidazole is necessary for treating a nursing dam.

Overdosage/Acute Toxicity
Very limited information is available. In studies done in rats and mice, the oral LD50 was >3.6 grams/kg for mice and >2 grams/kg for rats. Treatment of acute overdoses of tinidazole is symptomatic and supportive. Gastric lavage or induction of emesis may be helpful. Hemodialysis can remove approximately 43% of the amount in the body (human) in a 6 hour session.

Drug Interactions
After reconstitution, use immediately. Any remaining product should be discarded.

Do not mix or administer with intravenous fluids containing calcium or magnesium (e.g., LRS, Ringer’s, etc.).

References
Drug Interactions
In humans, the following drug interactions with metronidazole have been reported or are theoretical and may be of significance in veterinary patients receiving tinidazole:

- **ALCOHOL:** May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction
- **CIMETIDINE, KETOCONAZOLE:** May decrease the metabolism of tinidazole and increase the likelihood of dose-related side effects occurring
- **CYCLOSPORINE, TACROLIMUS (systemic):** Tinidazole may increase the serum levels of cyclosporine or tacrolimus
- **FLUOROURACIL (systemic):** Tinidazole may increase the serum levels of fluorouracil and increase the risk of toxicity
- **LITHIUM:** Tinidazole may increase lithium serum levels and increase the risk for lithium toxicity
- **OXYTETRACYCLINE:** Reportedly, may antagonize the therapeutic effects of metronidazole (and presumably tinidazole)
- **PHENOBARBITAL, RIFAMPIN OR PHENYTOIN:** May increase the metabolism of tinidazole thereby decreasing blood levels
- **WARFARIN:** Metronidazole (and potentially tinidazole) may prolong the prothrombin time (PT) in patients taking warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

Laboratory Considerations

**AST, ALT, LDH, Triglycerides, Hexokinase glucose:** Tinidazole, like metronidazole may interfere with enzymatic coupling of the assay to oxidation-reduction of nicotinamide adenine. Falsely low values, including zero, may result.

Doses

**DOGS:**
- a) For stomatitis, anaerobic infections: 15–25 mg/kg PO q12h for 7 days. (Greene et al. 2006)
- b) For giardiasis: 44 mg/kg PO q24h for 6 days. Potentially may be useful for treating trichomoniasis, amebiasis and balantidiasis, but efficacy data lacking for animals. (Barr 2006)

**CATS:**
- a) For stomatitis, anaerobic infections: 15 mg/kg PO q24h for 7 days. (Greene et al. 2006)

**HORSES:**
- a) For susceptible anaerobic infections: 10–15 mg/kg PO q12h (Pvorala et al. 1990)

Monitoring

- Clinical efficacy in treating the infection

Client Information

- Give this medication with food
- Animals should not have access to alcohol when receiving this medication
- If gastrointestinal signs (vomiting, lack of appetite, diarrhea) are severe or persist, contact veterinarian
- Contact veterinarian immediately if animal shows signs of behavior changes, eyes moving back and forth (nystagmus), convulsions, or if patient has difficulty walking, climbing stairs, etc. (ataxia); these could be signs that drug toxicity is occurring

Chemistry/Synonyms

Tinidazole occurs as an almost white or pale yellow, crystalline powder. It is practically insoluble in water, soluble in acetone, and sparingly soluble in methyl alcohol.

Tinidazole may also be known as CP-12574 or tinidazolum. International trade names include: Estovyn-T®, Fasigyn®, Tindamax®, Tinib®, Tiniameb®, or Tinidazol®.

Storage/Stability

Store tinidazole tablets at controlled room temperature (20–25°C) protected from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

As tinidazole is a nitroimidazole, its use is prohibited in animals to be used for food.

**HUMAN-LABELED PRODUCTS:**
- Tinidazole Tablets (scored): 250 mg & 500 mg; Tindamax® (Mission Pharmacal); generic; (Rx)

References

**TIOPRONIN**

(“tye-oh-proe-nin”) Thiola®, 2-MPG

ANTIULROTIBC (CYSTINE) AGENT

Prescriber Highlights

- Drug for prevention (& treatment) of cystine urolithiasis
- Cautions: Agranulocytosis, aplastic anemia, thrombocytopenia or other significant hematologic abnormality, impaired renal or hepatic function, or sensitivity to either tiopronin or penicillamine
- Adverse Effects: Coombs’-positive regenerative spherocytic anemia, aggressiveness, proteinuria, thrombocytopenia, elevations in liver enzymes, dermatologic effects, & myopathy
- Relatively expensive

Uses/Indications

Tiopronin is indicated for the prevention of cystine urolithiasis in patients where dietary therapy combined with urinary alkalization is not completely effective. It may also be useful in combination with urine alkalization and dietary (ultra-low protein diet) modification to dissolve stones.
Tiopronin is considered an antiurolithic agent. It undergoes thiol-disulfide exchange with cystine (cysteine-cystine disulfide) to form tiopronin-cystine disulfide. This complex is more water-soluble and is readily excreted thereby preventing cystine calculi from forming.

**Pharmacology/Actions**

Tiopronin has a rapid onset of action and in humans, up to 48% of a dose is found in the urine within 4 hours of dosing. Tiopronin has a relatively short duration of action and its effect in humans disappears in about 10 hours. Elimination is primarily via renal routes.

**Pharmacokinetics**

Tiopronin has a molecular weight of 163.2. It occurs as a white crystalline powder that is freely soluble in water.

**Chemistry/Synonyms**

Tiopronin may also be known as: SF 522, N-(2-Mercaptopropionyl)-glycine (MPG), 2-MPG, thiopronine, Captimer®, Epatiol®, Mucolysin®, Mucosyl®, Sutilan®, Thiole®, Thiosol®, or Tioglis®.

**Tobramycin Sulfate**

(tor-bra-my-sulfate; Necitab®, TOBI®)

**Aminoglycoside Antibiotic**

**Prescriber Highlights**

- Parenteral aminoglycoside antibiotic that has “good” activity against a variety of bacteria, predominantly gram-negative aerobic bacilli, also in ophthalmic preps
- Because of potential adverse effects usually reserved for serious infections when given systemically, may be less nephrotoxic than gentamicin
Doses

Uses/Indications
While most veterinarians use gentamicin or amikacin and there are no FDA-approved veterinary tobramycin products in the U.S., tobramycin can be useful clinically to treat serious gram-negative infections in most species. It is often used in settings where gentamicin-resistant bacteria are a clinical problem. The inherent toxicity of the aminoglycosides limit their systemic use to serious infections when there is either a documented lack of susceptibility to other less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Whether tobramycin is less nephrotoxic than either gentamicin or amikacin when used clinically is controversial. Laboratory studies indicate that in a controlled setting in laboratory animals, it may indeed be so.

Pharmacokinetics
Tobramycin, like the other aminoglycosides, is not appreciably absorbed after oral or intraarterial administration, but it is absorbed from topically applied solutions. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. Subcutaneous injection results in slightly delayed peak levels and more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

The pharmacokinetics of tobramycin in horses has been reported (Hubenov et al. 2007). Approximate values are (Note: First value is calculated value from a microbiologic assay and second from an HPLC assay): volume of distribution (steady-state): 0.24-0.55 L/kg; clearance: 101–130 mL/h; elimination half-life: 2.5–4 hours.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids, and high levels are found in sputum, bronchial secretions and bile. Aminoglycosides (other than streptomycin) are minimally protein bound (<20%) to plasma proteins. Aminoglycosides do not readily cross the blood-brain barrier nor penetrate ocular tissue. CSF levels are unpredictable and range from 0–50% those found in the serum. Therapeutic levels are found in bone, heart, gallbladder and lung tissues after parental dosing. Aminoglycosides tend to accumulate in certain tissues such as the inner ear and kidneys, which may help explain their toxicity. Aminoglycosides cross the placenta and fetal concentrations range from 15–50% those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

Contraindications/Precautions/Warnings
Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections, there are no other absolute contraindications to their use; however, they should be used with extreme caution in patients with preexisting renal disease with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis, and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs (e.g., “seeing-eye”, herding, dogs for the hearing impaired, etc.).

Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are generally considered contraindicated in rabbis/hares as they adversely affect the GI flora balance in these animals.

Adverse Effects
The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity normally manifests by increases in BUN, creatinine, nonprotein nitrogen in the serum and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest with either auditory and/or vestibular clinical signs and may be more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but either form can occur with any of the drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain or inflammation at the injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs, hemolysis, and hepatic effects have been reported.

Reproductive/Nursing Safety
Tobramycin can cross the placenta and concentrate in fetal kidneys and while rare, cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Total irreversible deafness has been reported in some human babies whose mothers received tobramycin during pregnancy. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Small amounts of aminoglycoside antibiotics are excreted in milk, but are unlikely to cause clinically significant effects in nursing offspring.

Overdosage/Acute Toxicity
Should an inadvertent overdosage be administered, three treatments have been recommended: 1) Hemodialysis is very effective in reducing serum levels of the drug, but is not a viable option for most veterinary patients; 2) Peritoneal dialysis also will reduce serum levels, but is much less efficacious; 3) Complexation of drug with either carbenicillin or ticarcillin (12–20 grams/day in humans) is reportedly nearly as effective as hemodialysis.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tobramycin and may be of significance in veterinary patients:

**BETA-LACTAM ANTIBIOTICS** (penicillins, cephalosporins): May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides in vitro (do not mix together) and in vivo (patients in renal failure)

**CEPHALOSPORINS**: The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with the aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).

**DIURETICS, LOOP (e.g., furosemide, torsemide) or OSMOTIC (e.g., mannitol)**: Concurrent use with loop or osmotic diuretics may increase the nephrototoxic or ototoxic potential of the aminoglycosides

**NEPHROTOXIC DRUGS, OTHER** (e.g., cispatin, amphoterin B, polymyxin B, or vancomycin): Potential for increased risk for nephrotoxicity

**NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL**: Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

Laboratory Considerations
Tobramycin serum concentrations may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough level.

**Doses**
**Chemistry/Synonyms**

An aminoglycoside derived from Streptomyces tenebrarius, tobramycin occurs as a white to off-white, hygroscopic powder that is freely soluble in water and very slightly soluble in alcohol. The sulfate salt is formed during the manufacturing process. The commercial injection is a clear, colorless solution and the pH is adjusted to 6–8 with sulfuric acid and/or sodium hydroxide.

**Compatibility/Compounding Considerations**

The following drugs or solutions are reportedly incompatible:

- inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented; see the information in the Drug Interaction and Laboratory Consideration sections.
- Other aminoglycosides, most now recommend dosing mammals one daily; consider giving the total daily dose as a single dose (e.g., if dose listed is 2 mg/kg q8h, give 6 mg/kg once daily).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS: None**

**HUMAN-LABELED PRODUCTS:**

- Tobramycin Sulfate Injection: 0.8 mg/mL and 1.2 mg/mL (as sulfate) in 100 mL & 50 mL (respectively) single-dose containers; Solution for Injection: 10 mg/mL in 2 mL vials and 40 mg/mL in 1.5 mL & 2 mL syringes, & 2 mL and 30 mL vials; generic. (Rx)
- Tobramycin Sulfate Powder for Injection: 1.2 grams (40 mg/mL after reconstitution), preservative free in 50 mL bulk package vial; generic. (Rx)
Toceranib Solution for inhalation: 60 mg/mL in 5 mL amps; TOBI® (Novartis); (Rx)
Also available in ophthalmic preparations.

References

Toceranib Phosphate
(Toe-er-a-nil) Palladia®
TYROSINE KINASE INHIBITOR ANTEOPLASTIC
Prescriber Highlights

Tyrosine kinase inhibitor FDA-approved for grades II or III canine mast cell tumors
Most common adverse effects are: diarrhea, decreased/loss of appetite, lameness, weight loss and blood in the stool
Adverse effects can be serious and require treatment pause or dose reduction
Monitoring essential

Uses/Indications
Toceranib is indicated for the treatment of Patnaik grade II or III, recurrent, cutaneous mast cell tumors with or without regional lymph node involvement in dogs.
Toceranib may prove useful for treating a variety of tumors in dogs, including sarcomas, carcinomas, melanomas, and myeloma. Toceranib can be part of metronomic therapy (using low doses of chemotherapy and/or other anti-cancer agents to inhibit tumor angiogenesis and growth) is being investigated.

Pharmacokinetics/Actions
Toceranib is a small molecule tyrosine kinase inhibitor (TKIs) that selectively inhibits the tyrosine kinase activity of several split kinase receptor tyrosine kinases (RTK), including VEGFR-2 (vascular endothelial growth factor receptor-2), PDGFR-Beta (platelet-derived growth factor receptor-Beta), KIT (stem cell growth factor receptor), among others. These kinases are believed to be involved in growth, pathologic angiogenesis, and metastatic processes of certain tumors. By inhibiting TKIs, toceranib competitively inhibits ATP, preventing receptor phosphorylation and subsequent downstream signal transduction. Toceranib exerts an antiproliferative effect on endothelial cells (in vitro) and can induce cell cycle arrest and subsequent apoptosis in tumor cells lining expressing activating mutations in KIT. As canine mast cell tumor growth can be enhanced by activating mutations in KIT, toceranib inhibition can reduce angiogenesis and subsequent growth of these cells.
Calcitol may enhance the antiproliferative activity of toceranib in dogs with mast cell tumors and investigations exploring this potential are ongoing (Malone et al. 2010).

Pharmacokinetics
Oral bioavailability of toceranib phosphate in dogs is about 77%. The presence of food does not significantly impact absorption. Binding to canine plasma proteins is around 94% and the volume of distribution is very large (>20 L/kg). Terminal elimination half-life is about 17 hours (after IV) and 31 hours (oral). While the metabolic fate of toceranib has not been completely determined, it appears that the drug is metabolized via cytochrome P450 and/or flavin monooxygenase to an N-oxide metabolite.

Contraindications/Precautions/Warnings
The label lists toceranib contraindications as breeding, pregnant or lactating bitches. Safe use has not been evaluated in dogs less than 24 months of age or weighing less than 5 kg. Because toceranib can cause vascular dysfunctions leading to edema and thromboembolism (including pulmonary emboli), wait at least 3 days after stopping drug before performing surgery.

Use caution when handling this medication. See drug company’s Client Information Sheet for more details.

Toceranib may cause clinical signs similar to those seen with aggressive mast cell tumors, when these occur, the drug should be stopped and the patient re-evaluated (Johannes 2010). The package insert has specific monitoring requirements with dosage adjustment or therapy pause guidelines when certain adverse effects (severe diarrhea, GI bleeding) occur or when laboratory monitoring indicates toxicity. Refer to the Monitoring section below, or the package insert for more information.

Adverse Effects
Most common adverse effects seen with toceranib in dogs include: diarrhea, decreased/loss of appetite, lameness, weight loss and blood in the stool. Severe diarrhea or GI bleeding require immediate treatment and dictate dose interruption or dose reduction (see monitoring below). Other potential adverse effects include muscle cramping, neutropenia, hypoalbuminemia, thromboembolic disease, vasculitis, pancreatitis, nasal depigmentation, change in coat or skin color, epistaxis, seizures and pruritus.

One author (London 2010) suggests starting certain drugs 4-7 days prior to staring toceranib to reduce the likelihood of toxicity. These include antacids (famotidine, omeprazole), an antihistamine (diphenhydramine) and prednisone (to reduce tumor inflammation and possibly decrease mast cell mediator’s effects) and sulfa (if dog has a positive stool hemoccult). Additionally, dogs that experience inappetence or vomiting after therapy has begun, either metoclopramide, ondansetron, or maropitant may be effective. Loperamide can be given on toceranib dosing days help prevent or lessen diarrhea. Others have found metronidazole useful. Another author states that prednisone can be continued after treatment has begun, but should only be given on days when toceranib is not given and that NSAIDs and prednisone should never be used together (Garrett 2010).

Reproductive/Nursing Safety
Toceranib is a likely teratogen and should not be used in pregnant females. It is labeled as contraindicated in breeding, pregnant, or lactating bitches.

Overdosage/Acute Toxicity
No acute toxicity data was located, but toceranib has a narrow margin of safety. In the event of an acute overdose, consider immediate gut decontamination; contact an animal poison center for further guidance.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving toceranib and may be of significance in veterinary patients:

NSAIDs: The package insert states to use NSAIDs with caution in conjunction with toceranib due to an increased risk of gastrointestinal ulceration or perforation. However, NSAIDs (e.g., piroxicam) are often sometimes used with toceranib as part of metronomic drug protocols, they should be used with extreme caution in dogs receiving toceranib; and should never be given on the same day as GI toxicity can be exacerbated (London 2010).

CYP3A4 INHIBITORS (e.g., ketoconazole, fluconazole, itraconazole, grapefruit juice, clarithromycin, verapamil): May increase toceranib concentrations. This interaction with toceranib has not been documented in dogs to date and presently is speculative. However, use caution.

Laboratory Considerations
None noted.
**DOGS:**

For Patnaik grade II or III, recurrent, cutaneous mast cell tumors with or without regional lymph node involvement:

- a) Initial dose 3.25 mg/kg PO every other day (q48h). Dose reductions of 0.5 mg/kg (to a minimum dose of 2.2 mg/kg every other day and dose interruptions (cessation of treatment) for up to two weeks may be required, if needed, to manage adverse reactions. May be administered with or without food. Do not split tablets. The package insert has a dosage table to determine the appropriate strength and number of tablets to use for a given dog’s weight. (Adapted from label information; Palladia®—Pfizer)

- b) Recent clinical experience with toceranib in dogs suggests that dosing at 2.5-2.75 mg/kg every other day is better tolerated than the higher dose, resulting in less toxicity, better owner compliance, and fewer drug holidays. Some dogs do not tolerate this dosing regimen even at the 2.5 mg/kg dose rate. The author and some other medical oncologists have found that a Monday/Wednesday/Friday schedule of dosing may be better tolerated by some dogs. This may be particularly useful when toceranib is combined with other drugs, such as cyclophosphamide or NSAIDs as part of a metronomic treatment protocol. When a dog cannot tolerate the M/W/F schedule, every third day dosing may be attempted, but this is not ideal and may result in sub-therapeutic drug exposure. (London 2010)

**Monitoring**

- CBC, Hematocrit, Serum Albumin, Creatinine, Serum Phosphate. Manufacturer recommends weekly (approximately) veterinary assessment for the first 6 weeks of therapy and every 6 weeks (approximately) thereafter.

- The package insert states: Temporarily discontinue drug if anemia, azotemia, hypoalbuminemia, and hyperphosphatemia occur simultaneously. Resume treatment at a dose reduction of 0.5 mg/kg after 1 to 2 weeks when values have improved and albumin is >2.5 g/dL. Temporary treatment interruptions may be needed if any one of these occurs alone: hematocrit <26%, creatinine ≥2 mg/dL or albumin <1.5 g/dL. Then resume treatment at a dose reduction of 0.5 mg/kg once the hematocrit is >30%, the creatinine is <2.0 mg/dL, and the albumin is >2.5 g/dL. Temporarily discontinue the use of toceranib if neutrophil count is ≤1000/microl.. Resume treatment after 1 to 2 weeks at a dose reduction of 0.5 mg/kg, when neutrophil count has returned to >1000/microl. Further dose reductions may be needed if severe neutropenia reoccurs.

- Other laboratory tests that have been suggested for monitoring early (first 6 weeks) include urinalysis, and full chemistry panels

- Adverse Effects (Diarrhea): If ≥4 watery stools/day or ≥ 2 days stop drug until formed stools and institute supportive care. When dosing is resumed, decrease dose by 0.5 mg/kg.

- Adverse Effects (GI-Bleeding): If fresh blood in stool or black tarry stool for > 2 days or frank hemorrhage or blood clots in stool. Stop drug and institute supportive care until resolution of all clinical signs of blood in stool, then decrease dose by 0.5 mg/kg.

- Tumor Size

**Client Information**

- In the package insert, the manufacturer states to: “Always provide Client Information Sheet with prescription.” In addition, it is highly recommended to verbally reiterate some of the key points found on the client information sheet, including the sections: “How do I give Palladia to my dog?”; “Stop Palladia immediately and contact your veterinarian if you notice any of the following changes in your dog”; and “Handling Instructions”.

- May be given with or without food; do not split or crush tablets

**Chemistry/Synonyms**

Toceranib phosphate is an idolinone with a molecular weight of 494.46. Toceranib may also be known as: PHA-291639, SU-11654, UNII-59L7Y0530C, toceranibum, or tocéranib.

**Storage/Stability**

Toceranib phosphate tablets should be stored at controlled room temperature 20–25°C (68–77° F).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Toceranib Phosphate Oral Tablets: 10 mg, 15 mg, 50 mg; Palladia® (Pfizer); (Rx)

**TOLAZOLINE HCL**

(tol-az-oh-leen) Tolazine®

**ALPHA-ADRENERGIC BLOCKER**

**Prescriber Highlights**

- Alpha-adrenergic blocker used primarily as a reversal agent for xylazine

- Contraindications: Horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia or shock, hypersensitivity, or with coronary artery or cerebrovascular disease

- Adverse Effects: Horses: Transient tachycardia; peripheral vasodilatation presenting as sweating & injected mucous membranes of the gingiva & conjunctiva; hyperalgesia of the lips (licking, flipping of lips); piloerection; clear lacrimal & nasal discharge; muscle fasciculations; apprehensiveness

**Uses/Indications**

Tolazoline is FDA-approved and indicated for the reversal of effects associated with xylazine in horses. It has also been used for this purpose in a variety of other species as well, but less safety and efficacy data is available. In humans, the primary uses for tolazoline are: treatment of persistent pulmonary hypertension in newborns, adjunctive treatment and diagnosis of peripheral vasospastic disorders, and as a provocative test for glaucoma after subconjunctival injection.

**Pharmacology/Actions**

By directly relaxing vascular smooth muscle, tolazoline has peripheral vasodilating effects and decreases total peripheral resistance. Tolazoline also is a competitive alpha1 and alpha2-adrenergic blocking agent, explaining its mechanism for reversing the effects of xylazine. Tolazoline is rapid acting (usually within 5 minutes of IV administration), but has a short duration of action and repeat doses may be required.

**Pharmacokinetics**

After IV injection in horses, tolazoline is widely distributed. Animal studies have demonstrated that tolazoline is concentrated in the liver and kidneys. Half-life in horses at recommended doses is approximately 1 hour.

**Contraindications/Precautions/Warnings**

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established and some believe it should not be used in foals. as adverse reactions and fatalities have been reported.

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established and some believe it should not be used in foals. as adverse reactions and fatalities have been reported.

The manufacturer does not recommend use in horses exhibiting signs of stress, debilitation, cardiac disease, sympathetic blockage, hypovolemia, or shock. Safe use for foals has not been established and some believe it should not be used in foals. as adverse reactions and fatalities have been reported.
Tolazoline should be considered contraindicated in patients known to be hypersensitive to it, or with coronary artery or cerebrovascular disease. Humans having any of the above-contraindicated conditions should use extra caution when handling the agent.

Adverse Effects
In horses adverse effects that may occur include: transient tachycardia; peripheral vasodilatation presenting as sweating and injected mucous membranes of the gingiva and conjunctiva; hyperalgesia of the lips (licking, flapping of lips); piloerection; clear lacrimal and nasal discharge; muscle fasciculations; apprehensiveness. Adverse effects should diminish with time and generally disappear within 2 hours of dosing. The potential for adverse effects increases if tolazoline is given at higher than recommended dosages or if xylazine has not been previously administered.

Reproductive/ Nursing Safety
Safety during pregnancy, in breeding or lactating animals has not been established. It is unknown if the drug enters maternal milk.

Overdosage/Acute Toxicity
In horses given tolazoline alone (no previous xylazine), doses of 5X recommended resulted in gastrointestinal hypermotility with resultant flatulence and defecation or attempt to defecate. Some horses exhibited mild colic and transient diarrhea. Intraventricular conduction may be slowed when horses are overdosed, with a prolongation of the QRS-complex noted. Ventricular arrhythmias may occur resulting in death with higher overdoses (5X). In humans, ephedrine (NOT epinephrine or norepinephrine) has been recommended to treat serious tolazoline-induced hypotension.

A llama that received 4.3 mg/kg IV and again 45 minutes later (approximately a 5X overdose) developed signs of anxiety, hyperesthesia, profuse salivation, GI tract hypermotility, diarrhea, convulsions, hypotension, and tachypnea. Treatment including IV diazepam, phenylephrine, IV fluids, and oxygen was successful. (Reed et al. 2000).

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tolazoline and may be of significance in veterinary patients:

**ALCOHOL:** Accumulation of acetadylede can occur if tolazoline and alcohol are given simultaneously

**EPINEPHRINE, NOREPINEPHRINE:** If large doses of tolazoline are given with either norepinephrine or epinephrine, a paradoxical drop in blood pressure can occur followed by a precipitous increase in blood pressure

**DOGS/CATS:**

For reversal of xylazine effects:

a) 4 mg/kg IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; Tolazine®—Lloyd Laboratories; New Zealand)

Note: If reversal is warranted, the high concentration (100 mg/mL) of the veterinary drug may make accurate dosing difficult; yohimbine or the human-labeled tolazoline product (25 mg/mL) may be safer alternatives than Tolazine® (100 mg/mL). Note: Tolazine is not FDA-approved for use in dogs and cats in the USA and the US manufacturer does not recommend its use.

**HORSES:**

For reversal of xylazine effects:

a) 4 mg/kg slow IV (4 mL/220 lb. of body weight); administration rate should approximate 1 mL/second (Package Insert; Tolazine®—Lloyd Laboratories)

**LAMAS/ALPACAS:**

For reversal of xylazine effects:

a) 1–2 mg/kg IM or give 50% of initial dose slowly IV or IM and then determine if more is needed. Use with caution IV in camelds. (Wolff 2009)

b) 1–2 mg/kg IV or IM; Caution: acute death has been reported after rapid IV administration of tolazoline at high dosages. (Anderson 2005)

**BIRDS:**

As a reversal agent for alpha2-adrenergic agonists (e.g., xylazine, detomidine, etc.):

a) 15 mg/kg IV (Clyde & Paul-Murphy 2000)

**DEER:**

Note: Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; Tolazine®—Lloyd Laboratories; New Zealand)

**CATTLE:**

Note: Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; Tolazine®—Lloyd Laboratories; New Zealand)

b) The amount of reversal agent used depends on the dose and time elapsed after administering xylazine. Emergency doses of yohimbine (0.1 mg/kg IV) or tolazoline at 2 mg/kg IM can be administered, but tolazoline should not be administered IV rapidly as this can result in cardiac asystole. When dosed properly the effects of reversal should start to become evident about 10 minutes following IM administration. (Anderson & Abrahamsen 2008)

**SHEEP & GOATS:**

Note: Not FDA-approved in the USA for use in food animals

For reversal of xylazine effects:

a) 2–4 mg/kg slow IV; titrate to effect; Slaughter withdrawal: 30 days (Label Directions; Tolazine®—Lloyd Laboratories; New Zealand)

b) Small Ruminants: 1–2 mg/kg IM. Give 50% of initial dose slow IV or IM and then determine if more is needed. (Snyder 2009)

Monitoring/Client Information

- **Reversal effects (efficacy)**
- **Adverse effects (see above).** Because of the risks associated with the use of xylazine and reversal by tolazoline, these drugs should be administered and monitored by veterinary professionals only.

Chemistry/Synonyms

An alpha-adrenergic blocking agent, tolazoline HCl is structurally related to phentolamine. It occurs as a white to off-white, crystalline powder possessing a bitter taste and a slight aromatic odor. Tolazoline is freely soluble in ethanol or water. The commercially available (human) injection has pH between 3–4.

Tolazoline HCl may also be known as: benzazoline hydrochloride, tolazolinium chlorotatum, Prisco®, Priscoline®, Tolazine® or Vaso-Dilatan®.

Storage/Stability

Commercially available injection products should be stored between 15–30°C and protected from light.

Compatibility/Compounding Considerations

The drug is reportedly physically compatible with the commonly used IV solutions.

Dosage Forms/Regulatory Status

Not FDA-approved in the USA for use in food animals

- Reversal of xylazine with tolazoline comes with extra caution when handling the agent.
Tolfaone HCl Injection: 100 mg/mL in 100 mL multi-dose vials; Tolazine® (Lloyd); (Rx). FDA-approved for use in horses; not to be used in food-producing animals.

HUMAN-LABELED PRODUCTS: None

References

VETERINARY-LABELED PRODUCTS:

Tolfenamic Acid
(tol-fer-na-mik); Tolfofin®
NONSTEROIDAL ANTI-INFLAMMATORY AGENT

Prescriber Highlights

- NSAID approved for dogs & cats in Canada, Europe
- Available (not in USA) in both oral & injectable dosage forms
- Relatively safe for short-term use

Uses/Indications

Tolfenamic acid may be useful for the treatment of acute or chronic pain and/or inflammation in dogs and acute pain/inflammation in cats. In Europe, it is also approved for use in cattle.

Pharmacology/Actions

Tolfenamic acid exhibits pharmacologic actions similar to those of aspirin. It is a potent inhibitor of cyclooxygenase, thereby inhibiting the release of prostaglandins. It also has direct inhibition of prostaglandin receptors. Tolfenamic acid has significant anti-thromboxane activity and is not recommended for use pre-surgically because of its effects on platelet function.

Pharmacokinetics

Tolfenamic acid is absorbed after oral administration. In dogs, peak levels occur from 2–4 hours after dosing. Enterorehepatic recirculation is increased if given with food. This can increase the bioavailability, but also creates more variability in bioavailability than when given to fasted dogs. The volume of distribution in dogs is reported to be 1.2 L/kg and it has an elimination half-life of about 6.5 hours. Duration of antiinflammatory effect is 24–36 hours. Dogs with experimentally induced renal failure had significantly increased clearances of the drug presumably via increasing hepatic metabolism or enterohepatic recycling of tolfenamic acid (Lefebvre et al. 1997).

Contraindications/Precautions/Warnings

Tolfenamic acid is contraindicated in animals hypersensitive to it or to other drugs in its class (i.e., meclofenamic acid). Like other NSAIDs, it should not be used in animals with active GI bleeding or ulceration. Use with caution in patients with decreased renal or hepatic function.

Adverse Effects

Tolfenamic acid is relatively safe when given as recommended in dogs and cats. Vomiting and diarrhea have been reported after oral use. Experimental studies did not demonstrate significant renal or GI toxicity until doses were more than 10 times labeled. Because of its anti-thromboxane activity and resultant effects on platelet function, tolfenamic acid is not recommended for use pre-surgically.

Reproductive/Nursing Safety

No specific information was located; like other NSAIDs, tolfenamic acid should be used with caution in pregnancy.

Overdosage/Acute Toxicity

No specific information was located. It is suggested that if an acute, overdose occurs treatment follows standard overdose procedures (empty gut following oral ingestion, etc.). Supportive treatment should be instituted as necessary and IV dexamethasone used to help control seizures. Monitor for GI bleeding. Because tolfenamic acid may cause renal effects, monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tolfenamic acid or other NSAIDs and may be of significance in veterinary patients:

- ASPIRIN: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- CORTICOSTEROIDS: As concomitant corticosteroid therapy may increase the occurrence of gastric ulceration, avoid the use of these drugs when also using tolfenamic acid
- DIGOXIN: NSAIDs may increase serum levels
- FLUCONAZOLE: Administration has increased plasma levels of celecoxib in humans and potentially could also affect tolfenamic acid levels in dogs
- FUROSEMIDE: NSAIDs may reduce sulferic and diuretic effects
- METHOTREXATE: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- NEPHROTIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.): May enhance the risk of nephrotoxicity
- NSAIDS, OTHER: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- WARFARIN: Closely monitor patients also receiving drugs that are highly bound to plasma proteins (e.g., warfarin), as tolfenamic acid and its active metabolite are 98–99% protein bound in the dog

Doses

- DOGS:
  a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days.
  b) For chronic pain: 4 mg/kg, PO once daily for 3–5 consecutive days per week. The injectable is suggested for the first dose only. (Dowling 2000)
- CATS:
  a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days. The injectable is suggested for the first dose only. (Dowling 2000)

HUMAN-LABELLED PRODUCTS: (not in USA) Available in both oral & injectable dosage forms

NSAID approved for dogs & cats in Canada, Europe

Available (not in USA) in both oral & injectable dosage forms

Relatively safe for short-term use

Uses/Indications

Tolfenamic acid may be useful for the treatment of acute or chronic pain and/or inflammation in dogs and acute pain/inflammation in cats. In Europe, it is also approved for use in cattle.

Pharmacology/Actions

Tolfenamic acid exhibits pharmacologic actions similar to those of aspirin. It is a potent inhibitor of cyclooxygenase, thereby inhibiting the release of prostaglandins. Doses

- DOGS:
  a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days.
  b) For chronic pain: 4 mg/kg, PO once daily for 3–5 consecutive days per week. The injectable is suggested for the first dose only. (Dowling 2000)
- CATS:
  a) For acute pain: 4 mg/kg once daily SC, IM or PO for 3–5 days. The injectable is suggested for the first dose only. (Dowling 2000)
  b) 4 mg/kg PO once daily for 3–5 days or as recommended by the veterinarian. (Label information; Tolfedine®—Vetoquinol Canada)
**CATTLE:**

- As registered for use in Australia: As an aid in the treatment of pneumonia and acute mastitis in cattle. Pneumonia: 2 mg/kg by IM injection high in the neck. Treatment may be repeated once only after 48 hours. Mastitis: 4 mg/kg as a single intravenous injection. DO NOT inject cattle other than into muscle tissues high on the side of the neck. Meat withdrawal = 10 days (IM), 4 days (IV); Milk withdrawal = 12 hours (1 milking). (Label Information; Tolfiejec®—Troy Labs, Australia)

**SWINE:**

- As registered for use in Australia: As an aid in the treatment of metritis-mastitis-agalactia in pigs: 2 mg/kg IM once. Meat withdrawal = 6 days. (Label Information; Tolfiejec®—Troy Labs, Australia)

**Monitoring**

- Clinical efficacy
- Adverse effects

**Client Information**

- The weekly dosing regimen (3–5 consecutive days per week for dogs) is important to follow to minimize risks of adverse effects
- Report any changes in appetite, water consumption, or GI distress to veterinarian

**Chemistry/Synonyms**

A non-steroidal antiinflammatory agent in the anthranilic acid (fenamate) category, tolfenamic acid is related chemically to meclofenamic acid.

Tolfenamic Acid may also be known as: acidum tolfenamicum, Bifenac®, Clotam®, Clotan®, Fenamic®, Fluscour®, Ganti®, Migear®, Polmonin®, Purfalcro®, Rociclyn®, Tolfamico®, Tolfedine®, Tolfedine® or Turbaund®.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None in the USA.

In Canada, New Zealand, Australia and Europe: Tolfenic Acid Tablets: 6 mg, 30 mg, 60 mg and Tolfenic Acid Injection 40 mg/mL are available. Common trade name is Tolfedine® (Vetoquinol).

**HUMAN-LABELED PRODUCTS:** None in the USA

**Uses/Indications**

Toltrazuril is an antiprotozoal agent that may be considered as an alternative treatment for coccidiosis in dogs and cats, Isospora or Hepatazoon infections, or for treating the oocyst shedding stage of toxoplasmosis in cats. It has also been used as a treatment for overwhelming parasitic loads in lizards (Bearded Dragons).

Toltrazuril has activity against parasites of the genus Hepa to zoon, but other drugs (e.g., imidocarb, primaquine, doxycycline) are generally used. Toltrazuril can induce initial excellent clinical responses in dogs with American canine hepatozoonosis (ACH), but cannot completely eliminate the parasites, and remission is transient in most dogs.

While toltrazuril has been used to treat equine protozoal myeloencephalitis (EPM) caused by Sarcocystis neurona, use of FDA-approved products now available (e.g., ponazuril, pyrimethamine/sulfadiazine) is preferred. Toltrazuril has been used in some countries to treat Isospora suis in pigs.

**Pharmacology/Actions**

Toltrazuril is the parent compound to ponazuril (toltrazuril sulfone). Its mechanism of action is not well understood, but it appears to inhibit protozoal enzyme systems.

Toltrazuril has activity against Hepa to zoon, Isospora, Sarcocystis, Toxoplasma, and all intracellular stages of coccidia.

**Pharmacokinetics**

Little information is available. Toltrazuril is about 50% absorbed after oral consumption in poultry. Highest concentrations are found in the liver; it is rapidly metabolized into the sulfone derivative (ponazuril).

**Contraindications/Precautions/Warnings**

Toltrazuril should not be used in patients who have had prior hypersensitivity reactions to it or other triazine (triazine) antiprotozoals (e.g., ponazuril, diclazuril).

The principle metabolite of toltrazuril reportedly persists in the environment and can contaminate groundwater, however there appears to be little risk for significant environmental contamination when toltrazuril is used in dogs, cats, horses, or other companion animals (pet birds, reptiles).

**Adverse Effects**

Toltrazuril appears to be well tolerated in birds. An adverse effect profile in mammals is not well described. Potentially, GI signs could occur. Some horses receiving the related drug ponazuril, developed blisters on their nose and mouth, and some, a rash or hives during field trials.

**Reproductive/Nursing Safety**

No reproductive or nursing safety information was located; weigh potential risks versus benefits of use during pregnancy or lactation.

**Overdosage/Acute Toxicity**

Very limited information is available. Doses of up to 10X in horses were tolerated without significant adverse effects. 5X overdoses in poultry have been tolerated without clinical signs noted. Decreased water intake has been seen if overdoses are greater than 5X.
Topiramate may be useful for treating seizures in dogs, particularly partial seizure activity. It may also be of benefit in treating cats, but little information is available.

Uses/Indications

PADIS-LABELED PRODUCTS:

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the Instructions for Legally Importing Drugs for Compassionate Use in the USA found in the appendix.

REFERENCES

HUMAN-LABELED PRODUCTS:

The 2.5% solution should be stored at temperatures at 25°C or below.

Storage/Stability

Dilutions in drinking water more concentrated than 1:1000 (1 mL of the 2.5% solution to 1 liter of water) may precipitate. After dilution, the resulting solution is stable for 24 hours. It is recommended that medicated drinking water not consumed after 24 hours be discarded.

REFERENCES

COMMON SYNTHETIC

Related to other antiprotozoals such as ponazuril, toltrazuril is a triazinone (triazine) antiprotozoal (anticoccidial) agent. The commercially available (in Europe) 2.5% oral solution is an alkaline, clear, colorless to yellow brown solution that also contains triethanolamine 30 mg/mL and polyethylene glycol 80.7 mg/mL. Toltrazuril has a molecular weight of 425.4.

Toltrazuril may also be known as Bay-Vi-9142, toltrazurilo, toltrazurilum and Baycox®.

Client Information

Avoid direct contact with this medication; the manufacturer recommends wearing synthetic rubber gloves when handling the 2.5% solution. Wash exposed skin after use.

Chemistry/Synonyms

Clinical efficacy

Drug Interactions

- None reported

Laboratory Considerations

- No issues were noted.

Doses

- DOGS:
  
a) For coccidiosis (Cystoisosporiosis): 10–20 mg/kg PO one time to all puppies at 3–4 weeks of age will help prevent problems associated with intestinal coccidiosis (Daugschies et al. 2000)
  
b) For coccidiosis: 15 mg/kg PO once daily for 3–6 days (Dubey, J. & Greene 2006)
  
c) For Isospora spp. infections: 10–30 mg/kg PO once daily for 1–3 days. (Dubey, J.P. et al. 2009)
  
d) For coccidiosis: 20 mg/kg PO once daily for 3 days. (Marks 2007)

- CATS:
  
a) For enteropathelial cycle of toxoplasmosis (oocyst shedding): 5–10 mg/kg PO once daily for 2 days (Dubey, J. & Lappin 2006)
  
b) For coccidiosis: 30 mg/kg PO once daily for 2–3 days (Greene et al. 2006)
  
c) For coccidiosis: 20 mg/kg PO once daily for 3 days. (Marks 2007)

- SHEEP:
  
a) For ovine coccidiosis (Eimeria ovinaoidalis): Controlled study comparing efficacy against dichloran: 20 mg/kg PO once. (Mundt et al. 2009)

- BIRDS:
  
a) For coccidiosis in raptors: 7 mg/kg PO once daily for 2–3 days (Jones 2004)

- REPTILES:
  
a) For parasitism in Bearded Dragons: 5–15 mg/kg PO once daily for 3 days (Kramer 2006)

Monitoring

Prescriber Highlights

- Antiseizure medication that may be useful for seizure disorders in dogs, particularly partial seizure activity; may be of benefit in treating cats, but little information available

- Very short half-life in dogs (2–4 hours), but therapeutic activity may persist secondary to high affinity for receptors in brain

- Adverse effect profile may include GI distress, inappetence, & irritability in dogs; in cats, sedation & inappetence have been noted

- Expense may be an issue; generics now available

Uses/Indications

Topiramate may be useful for treating seizures in dogs, particularly partial seizure activity. It may also be of benefit in treating cats, but little information is available.
Topiramate Tablets: 25 mg, 50 mg & 100 mg; Sprinkle Capsules: 15 mg & 25 mg;
The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

Pharmacology/Actions
While the exact mechanism for its antiseizure action is not known, topiramate possesses three properties that probably play a role in its activity: Topiramate blocks in a time-dependent manner action potentials elicited repetitively by a sustained depolarization of neurons; it increases the frequency that GABA activates GABAA receptors; and it antagonizes the kainite/AMPA receptors without affecting the NMDA receptor subtype. Topiramate’s actions are concentration-dependent; effects can first be seen at 1 mcg/mL and maximize at 200 microMoles. Topiramate is a weak inhibitor of carbonic anhydrase isoenzymes CA-II and CA-Iv, but it is believed that this effect does not contribute significantly to its antiepileptic actions.

Pharmacokinetics
In dogs, topiramate is rapidly absorbed after oral administration, but absolute bioavailability varies between 30–60%. Half-life ranges from 2–4 hours after multiple doses (Streeter et al. 1995). Comparatively, the half-life in humans is about 21 hours in adults, but shorter in children. In humans, the drug is not extensively metabolized and about 70% is excreted unchanged in the urine.

Contraindications/Precautions/Warnings
Topiramate is contraindicated in patients hypersensitive to it. It should be used with caution (in humans) with impaired hepatic or renal function.

Adverse Effects
Because this drug rarely has been used in veterinary patients, an accurate adverse effect profile is not known. In dogs, most prevalent adverse effects reported include GI distress, inappetence, and irritability. In cats, sedation and inappetence have been noted.

In humans, the most likely adverse effects include somnolence, dizziness, nervousness, confusion, and ataxia. Very rarely, acute myopia with secondary angle closure glaucoma has been reported. Incidence of kidney stones is about 2–4 times higher in patients taking topiramate than in the general population. Topiramate can cause a hyperchloremic metabolic acidosis and reduce citrate excretion in the urine thus increasing urine pH leading to calcium phosphate renal calculi.

Reproductive/Nursing Safety
In humans, the FDA categorizes topiramate as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) Teratogenic effects were noted in mice and rats given topiramate at dosages equivalent to those used in humans.

Topiramate enters maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity
Overdoses in humans have caused convulsions, drowsiness/lethargy, slurred speech, blurred and double vision, impaired mentation/ stupor, ataxia, metabolic acidosis, hypotension, agitation, and abdominal pain.

There were 140 exposures to topiramate reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 129 were dogs with 16 showing clinical signs and 11 were cats with 5 showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia and lethargy.

Treatment consists of gut emptying protocols if the ingestion was recent, and supportive therapy. Hemodialysis is effective in enhancing the elimination of topiramate from the body.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving topiramate and may be of significance in veterinary patients:

- **AMITRIPTYLINES**: Topiramate may increase levels
- **CARBONIC ANHYDRAZE INHIBITORS** (acetazolamide, dichlorphenamide, etc.): Used concomitantly with topiramate, may increase the risk of renal stone formation
- **CNS DEPRESSANT DRUGS, OTHER**: Other CNS depressant drugs may exacerbate the adverse effects of topiramate
- **LAMOTRIGINE**: May increase topiramate levels
- **PHENYTOIN**: May decrease topiramate levels; phenytoin levels may increase
- **VALPROIC ACID**: May decrease topiramate and VPA levels

Laboratory Considerations
- No specific laboratory interactions or considerations were noted. Plasma concentrations of topiramate are usually not monitored in human patients, but therapeutic levels are thought to range from 2–25 mg/L.

Doses
- **DOGS**:
  - a) As an alternative second line anticonvulsant: 5–10 mg/kg PO q12h (Shell 2003)
  - b) As an alternative treatment for refractory generalized and focal seizures: 5–10 mg/kg PO twice daily (Smith 2002)
  - c) Initial dose of 2–10 mg/kg PO q12h. (Podell 2006)
  - d) 5–10 mg/kg PO twice daily; start at the lower dosage to reduce adverse effects. (Kortz 2005)
  - e) For refractory epilepsy: Presently, the author is using this drug at 2.5–5 mg/kg PO three times daily, but at this stage there is not enough data to know how effective this treatment will be. (Platt 2008)
- **CATS**:
  - a) 12.5–25 mg PO (total dose) q8–12h. In author’s experience, topiramate has been most useful in treat automatisms (especially running fits) and focal seizure activity. Gradual adaptation in dosing is recommended. Inappetence is a major adverse effect with higher doses. (Podell 2006; Podell 2008)

Monitoring
- **Efficacy**
- **Adverse effects**

Client Information
- Clients must understand that the clinical use of this agent is relatively “investigational” in veterinary patients, that it must be dosed often in dogs, and the potential costs
- Caution clients not to stop therapy abruptly or “rebound” seizures may occur
- Have clients maintain a seizure diary to help determine efficacy

Chemistry/Synonyms
A sulfamate-substituted derivative of D-fructose antiepileptic, topiramate occurs as a white crystalline powder with a bitter taste. Its solubility in water is 9.8 mg/mL; it is freely soluble in alcohol.

Topiramate may also be known as: McN-4853, RWJ-17021, Epitomax®, Topamac®, Topamax®, or Topiragen®.

Storage/Stability
Topiramate tablets should be stored in tight containers at room temperature (15–30°C; 59–86°F); protect from moisture. Topiramate sprinkle capsules should be stored in tight containers at temperatures below 25°C (76°F); protect from moisture.

Dosage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS**: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**
- Topiramate Tablets: 75 mg, 50 mg & 100 mg; Sprinkle Capsules: 15 mg & 75 mg: Topamax® (Janssen); Topiragen® (Janssen); generic: (Rx)
- Topiramate capsules: 100 mg, 200 mg: Topamax® (Janssen); Topiragen® (Janssen); generic: (Rx)
The following drug interactions have either been reported or are theoretical in humans or animals receiving torsemide and may be of significance in veterinary patients:

- Potent loop diuretic potentially useful for adjunctive treatment of CHF in dogs & cats; very little information available on clinical use in veterinary medicine
- Approximately 10X more potent, longer diuretic action, & more potassium-sparing (in dogs) than furosemide
- May be more expensive than furosemide, but tablets are now available generically

Uses/Indications
Torsemide is a loop diuretic similar to furosemide, but it is more potent, its diuretic effects persist for a longer period, and it does not cause as much potassium excretion (in dogs). While clinical use in dogs and cats thus far has been minimal, it potentially may be a useful adjunctive treatment for congestive heart failure in dogs and cats, particularly in patients that have become refractory to furosemide. Torsemide could be considered for use as an alternative to furosemide particularly in those patients that have become refractory to furosemide therapy. Torsemide is approximately 10 times more potent than furosemide, so a starting dose of 10% of the furosemide dose could be considered. As torsemide has a more persistent diuretic effect (approximately 12 hours), dosing frequency may also be reduced. A study comparing furosemide (2 mg/kg PO twice daily) with torsemide (0.2 mg/kg PO twice daily) demonstrated that diuretic resistance developed after 14 days of furosemide, but not torsemide. But both drugs were associated with increased BUN and plasma creatinine concentrations, compared with values before treatment (Hori et al. 2007).

Pharmacology/Actions
Torsemide, like furosemide inhibits sodium and chloride reabsorption in the ascending loop of Henle via interference with the chloride-binding site of the 1Na+, 1K+, 2Cl- cotransport system.

Torsemide increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate. In dogs, excretion of potassium is affected much less than is sodium (20:1); this is approximately twice the ratio of Na+/K+ excreted than with furosemide. In cats, torsemide’s effects on potassium excretion appear to be similar to that of furosemide. In dogs, torsemide appears to have differing effects on aldosterone than furosemide. When compared to furosemide, torsemide increases plasma aldosterone levels and inhibits the amount of receptor-bound aldosterone, however, additional research must be performed to determine the clinical significance of these effects.

Pharmacokinetics/Pharmacodynamics
Limited information is available. Oral bioavailability has been reported to be between 80–100% in dogs and cats. Elimination half-life in dogs is about 8 hours which is longer than furosemide. In dogs, diuretic activity begins within one hour of dosing, peaks at about 2 hours and persists for approximately 12 hours. In cats, peak diuresis occurs about 4 hours post-dose and persists for 12 hours.

Contraindications/Precautions/Warnings
Torsemide should not be used in patients with known hypertensivity to it or other sulfonlureas, or in anuric patients. Use torsemide cautiously in patients with significant hepatic dysfunction, hyperuricemia (may increase serum uric acid), or diabetes mellitus (may increase serum glucose). The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance when used in horses.

The injection should be administered IV slowly over a period of 2 minutes. Ototoxicity has occurred in human patients receiving rapid IV administration of other loop diuretics.

Adverse Effects
Adverse effect profiles for dogs and cats have not been established due to the limited use of this drug in veterinary medicine. Furosemide, a related drug, can induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium, magnesium and sodium). Prenatal azotemia may result if moderate to severe dehydration occurs. Hypotonatremia is probably the greatest concern, but hypokalemia, hypocalcemia, and hypomagnesemia may all occur. Animals with normal food and water intake are much less likely to develop water and electrolyte imbalances than those that do not.

Other potential adverse effects include gastrointestinal disturbances, hematologic effects (anemia, leukopenia), weakness, and restlessness. Torsemide, unlike furosemide, apparently only rarely causes significant ototoxic effects in humans; very high doses in laboratory animals have induced ototoxicity.

Reproductive/Nursing Safety
No effects on fertility were noted when female and male rats were administered up to 25 mg/kg/day.

No adverse teratogenic effects were seen when pregnant rats and rabbits were administered up to 15X (human dose) and 5X (human dose), respectively. Larger doses did increase fetal resorptions, decreased average body weight, and delayed fetal ossification. In humans, the FDA categorizes torsemide as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

It is unknown if torsemide enters milk, but furosemide is distributed in milk. Clinical significance for nursing offspring is unknown.

Overdosage/Acute Toxicity
In dogs, the oral LD50 is >2 grams/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. Consider gut emptying protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation with fluid, electrolyte and acid-base monitoring; supportive treatment should be initiated if required.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving torsemide and may be of significance in veterinary patients:

- ACE INHIBITORS (e.g., enalapril, benazepril): Increased risks for hypotension, particularly in patients who are volume or sodium depleted secondary to diuretics.
- AMINOGLYOSIDES (gentamicin, amikacin, etc.): Other diuretics have been associated with increasing the ototoxic or nephrotoxic risks of aminoglycosides. It is unknown if torsemide can also have these effects and if so, what the clinical significance may be.
- AMPHOTERICIN B: Loop diuretics may increase the risk for nephrotoxicity development.
- DIGOXIN: Can increase the area under the curve of torsemide by 50%, but is unlikely to be of significance clinically; torsemide-induced hypokalemia may increase the potential for digoxin toxicity.
- LITHIUM: Torsemide may reduce lithium clearance.
- NSAIDS: Some NSAIDs may reduce the natriuretic effects of torsemide.
- PROBENECID: Can reduce the diuretic efficacy of torsemide.
- SALICYLATES: Torsemide can reduce the excretion of salicylates.
Torsemide can affect serum electrolytes, glucose, uric acid, and BUN concentrations.

**Doses**
- **DOGS/CATS:**
  a) For adjunctive treatment of refractory congestive heart failure: Injectable furosemide can restore a diuresis in some animals, and torsemide (now only available PO in the USA) can also be tried at approximately 0.2–0.3 mg/kg q12-24 hours when other diuretics have become ineffective. (Rush 2008)
  b) 0.2 mg/kg PO once a day to three times a day. (Atkins 2008)

**Monitoring**
- Serum electrolytes, BUN, creatinine, glucose (if diabetic)
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated

**Client Information**
- Contact veterinarian if clinical signs of water or electrolyte imbalance occur. Signs such as excessive thirst, lethargy, restlessness, increased urination, GI distress or rapid heart rate may indicate electrolyte or water balance problems.

**Chemistry/Synonyms**
Torsemide is a pyridyl sulfonylurea loop diuretic that occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol. The injection (no longer marketed in USA) has a pH >8.3.
Torsemide may also be known as torasemide, AC-3525, AC 4464, and Demadex®. International trade names include Torem® and Unat®.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Torsemide Oral Tablets: 5 mg, 10 mg, 20 mg, & 100 mg; Demadex® (Meda); generic; (Rx)

**References**

**TRAMADOL HCL**

(Opiate-like (mu-receptor) agonist)

**Prescriber Highlights**
- Synthetic mu-receptor opiate-like agonist that also inhibits reuptake of serotonin & norepinephrine
- May be useful as an analgesic or antitussive. May take up to two weeks for full analgesic activity in chronic pain states.
- Not a controlled drug in USA, but has some potential for human abuse
- Appears well tolerated in dogs; sedation most likely adverse effect
- Avoid use with SSRIs (e.g., fluoxetine) or MAOIs (e.g., selegiline)
- Relatively inexpensive

**Uses/Indications**
Tramadol may be a useful alternative or adjunct for the treatment of post-operative or chronic pain or cough in dogs and potentially, other species. When used in combination with NSAIDs, or other analgesic drugs (e.g., amantadine, gabapentin, alpha-2 agonists) it may be particularly useful for chronic pain conditions. Epidurally administered tramadol may also be useful as an analgesic in horses, but no appropriate commercial dosage forms are presently available in the USA.

**Pharmacology/Actions**
Tramadol is a centrally acting opiate-like agonist that has primarily mu-receptor activity, but also inhibits reuptake of serotonin and norepinephrine. These pharmacologic actions all contribute to its analgesic properties. At least one metabolite (O-desmethyltramadol; ODT; M1) has activity. When compared to tramadol in lab animal studies, M1 is 6 times more potent an analgesic and has 20 times more potency in binding to mu-receptors. Naloxone only partially antagonizes the analgesic effects of tramadol.

**Pharmacokinetics**
In dogs after oral administration of immediate-release tablets, bioavailability is about 65%, but there is significant interpatient variability. Rectal bioavailability is only about 10%. Volume of distribution is approximately 3.8 L/kg. Total body clearance and half-life are about 35 mL/kg/min and 1.7 hours, respectively. Tramadol is extensively metabolized via several metabolic pathways. At least one metabolite (M1) has agonist activity, but is a minor metabolite in dogs; M1 has a half-life of about 2 hours after oral tramadol administration in dogs.

One study in 8 cats using the immediate release oral tablet, showed high interpatient variability in absorption (with two cats there was not enough data to analyze). The elimination half-life for the parent compound was about 2.5 hours; for the M1 metabolite, 4.5 hours. Neurologic effects (mydriasis, dysphoria) were seen in 25% of cats (2 of 4 females) in the study group and the drug was observed to be unpalatable to cats (Papich & Bledsoe 2007). Another study in 6 cats demonstrated approximate values of: oral bioavailability—66%, volume of distribution (steady-state)—2 L/kg, clearance—12 mL/min/kg, and terminal half-life—191 minutes.
Terminal half-life for ODT after oral administration was about 290 minutes (Pypendop & Ilkiw 2007).

In neonatal and weaned foals, tramadol has different pharmacokinetics. After oral administration, higher bioavailability (53% vs. 20%), shorter time to peak concentration (1 hr. vs. 1.25 hr.), and peak levels occurred earlier (1.25 hr. vs. 2 hr. respectively) than in adult horses.
### Contraindications/Precautions/Warnings

Tramadol is contraindicated in patients hypersensitive to it or other opioids. The combination product containing acetaminophen is contraindicated in cats.

Use with caution in conjunction with other drugs that can cause CNS or respiratory depression. Because tramadol has caused seizures in humans, it should be used with caution in animals with preexisting seizure disorders or receiving other drugs that may reduce the seizure threshold. Like other opiate-like compounds, tramadol should be used with caution in geriatric or severely debilitated animals. Patients with impaired renal or hepatic function may need dosage adjustments.

While the risk of physical dependence occurring is less than that of several other opiates, it has been reported in humans. The drug should be withdrawn gradually in animals that have received it chronically. While not a controlled substance in the USA, humans can potentially abuse tramadol and significant diversion of the drug reportedly occurs. Veterinarians should be alert to “clients” seeking tramadol for their animals.

### Adverse Effects

Tramadol appears to be well tolerated in dogs. Potentially, it could cause a variety of adverse effects associated with its pharmacologic actions, including: CNS effects (excitation, agitation, anxiety, tremor, dizziness), or GI (nausea, vomiting, constipation, diarrhea).

Very limited information is available on the adverse effects in cats. Dysphoria, mydriasis, and dose avoidance (unpalatability) have been reported.

Approximately 10% of humans receiving the drug develop pruritus. Injectable tramadol may cause respiratory and cardiac depression.

### Reproductive/Nursing Safety

In humans, the FDA categorizes tramadol as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) At dosages 3–15 times usual, tramadol was embryotoxic and fetotoxic in laboratory animals. Tramadol and its active metabolite enter maternal milk in very low levels, but the drug’s safety in neonates has not been established.

### Overdosage/Acute Toxicity

Acute oral overdoses may cause either CNS depressant signs or serotonin syndrome. Lethargy, mydriasis, ataxia and vomiting are most common, but stimulatory signs (tachycardia, tremors, vocalization) may also be seen.

There were 308 exposures to tramadol reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases 246 were dogs with 46 showing clinical signs, 60 were cats with 33 showing clinical signs, 1 case involved a bird that showed clinical signs and the remaining 1 case involved a lagomorph that showed no clinic signs. Common findings in dogs recorded in decreasing frequency included sedate, ataxia, agitation, somnolence, and seizures. Common findings in cats recorded in decreasing frequency included mydriasis, hypersalivation, tachycardia, agitation, lethargy, and ataxia.

Treatment is primarily supportive (maintaining respiration, treating seizures with benzodiazepines or barbiturates, etc.). Naloxone may NOT be useful in tramadol overdoses as it may only partially reverse some of the effects of the drug and may, in fact, increase the risk of seizures. Naloxone did not decrease the drug’s lethality in tramadol overdoses given to mice. Cyproheptadine and phenothiazines can be used to treat the stimulatory signs.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving tramadol and may be of significance in veterinary patients:

- **DIGOxin:** In humans, tramadol has been rarely linked to digoxin toxicity
- **MAO INHIBITORS (including amitraz and possibly, selegiline):** Potential for serotonin syndrome; use together should be avoided
- **ONDANSETRON:** In humans, use together may reduce the effectiveness of both drugs
- **QUINIDINE:** May increase tramadol concentrations and decrease M1 (active metabolite) concentrations
- **SAMe:** Theoretically, concurrent use of SAMe with tramadol could cause additive serotonergic effects
- **SEVOFLURANE:** Pretreatment with tramadol reduced MAC values by approximately 30% in dogs (Seddighi et al. 2009), and 40% in cats (Dirikolu et al. 2009).
- **SSRI ANTIDEPRESSANTS (fluoxetine, sertraline, paroxetine, etc.):** Can inhibit the metabolism of tramadol to its active metabolites thereby decreasing its efficacy and increasing the risk of toxicity (serotonin syndrome, seizures).
- **TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.):** Increased risk for seizures; amitriptyline may inhibit tramadol metabolism
- **WARFARIN:** In humans, increased PT and INR in patients taking tramadol has been reported (relatively rare)

### Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

### Doses

- **DOGS:**
  a) Current dosing recommendations for dogs are 5 mg/kg PO q6-8h and up to 10 mg/kg PO q6-8h in non-responsive dogs. The efficacy of these dosages has not been evaluated. It is important to remember that maximum analgesic effects may not occur immediately and may be delayed up to 14 days for chronic pain conditions such as cancer and degenerative joint disease. (KuKanich 2010)
  b) As an analgesic: Recent investigations and clinical use suggest a starting dose of 2–5 mg/kg four times daily. (Hellyer 2006)
  c) For chronic pain: 2.5 mg/kg PO 2-3 times a day is a reasonable for mild pain, although both dose and dosing interval may need to be adjusted for more severe pain. The pharmacokinetics in the dog are somewhat erratic, so the drug is best used as multimodal therapy with NSAIDs or other analgesic drugs. (Grubb 2010)

- **CATS:**
  a) Based upon the pharmacokinetics of tramadol and O-desmethyltramadol (ODT) in cats, a dose of 2 mg/kg twice daily is a reasonable starting dose. (Booth 2010)
  b) Current dosing recommendations for cats is 1–2 mg/kg PO q12h. The efficacy of these dosages has not been evaluated. It is important to remember that maximum analgesic effects may not occur immediately and may be delayed up to 14 days for chronic pain conditions such as cancer and degenerative joint disease. (KuKanich 2010)
  c) For chronic pain: 1–4 mg/kg PO 2–3 times a day is a reasonable for mild pain, although both dose and dosing interval may need to be adjusted for more severe pain. (Grubb 2010)

- **HORSES:**
  a) In a study of 10 horses with chronic laminitis pain: tramadol at 5 mg/kg PO twice daily for seven days, alone or with ketamine at 0.6 mg/kg/hr IV during six hours each day for the first 3 days of treatment, pain relief was enhanced. (Guedes et al. 2009)

- **ZOO, EXOTIC, WILDLIFE SPECIES:**
  For use of tramadol in zoo, exotic and wildlife medicine refer to specific references, including:
  b) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

### Monitoring

- **Clinical efficacy**
- **Adverse effects**

### Client Information

- **May be given with or without food**
In a retrospective study of 56 dogs (Gruen & Sherman 2008), evaluating trazodone as an adjunctive treatment for anxiety disorders in dogs, it was found to be well tolerated over a wide dose range and enhanced behavioral calming. The authors concluded that further controlled studies are needed to more fully evaluate the pharmacokinetics, safety profile, and efficacy of this drug in dogs.

Antidepressant that may be useful for adjunctive treatment of behavioral disorders (esp. anxiety- or phobia-related) in dogs

Little research or clinical experience available regarding veterinary use

Relatively inexpensive

**Uses/Indications**

Trazodone may be useful in treating behavioral disorders in small animals, particularly as an adjunctive treatment in those patients that do not adequately respond to conventional therapies.

In a retrospective study of 56 dogs (Gruen & Sherman 2008), evaluating trazodone as an adjunctive treatment for anxiety disorders in dogs, it was found to be well tolerated over a wide dose range and enhanced behavioral calming. The authors concluded that further controlled studies are needed to more fully evaluate the pharmacokinetics, safety profile, and efficacy of this drug in dogs.

In humans, trazodone is used for treating depression, aggressive behavior, alcohol or cocaine withdrawal, migraine prevention, and insomnia. It has fewer anticholinergic effects than the tricyclic antidepressants and is among the antidepressants with the lowest seizure risk.

**Pharmacology/Actions**

Trazodone is classified as a serotonin 2A antagonist/reuptake inhibitor (SARI) that primarily potentiates serotonin activity in the CNS. In laboratory animals, trazodone selectively inhibits serotonin uptake by brain synaptosomes and potentiates the behavioral changes induced by the serotonin precursor, 5-hydroxytryptophan. In dogs, trazodone exerts qualitatively different and less pronounced cardiac conduction effects than do the SSRIs (Virga 2010).

**Pharmacokinetics**

No information was located regarding the pharmacokinetics of trazodone in dogs. In humans, oral bioavailability of trazodone (immediate-release tablets) is about 65%; presence of food increases absorption (AUC is increased), but decreases Cmax (peak plasma level) and delays Tmax (time of peak level). It is approximately 90–95% bound to plasma proteins. Volume of distribution ranges from 0.47–0.84 L/kg. Metabolism is extensive among the antidepressants with the lowest seizure risk.

**Contraindications/Precautions/Warnings**

Trazodone is contraindicated in patients hypersensitive to it or those receiving MAO inhibitors (including amitraz and possibly, selegiline). It should be used with caution in patients with severe cardiac disease or hepatic or renal impairment.

**Adverse Effects**

The adverse effect profile for trazodone in dogs is not well documented. Potential adverse effects include sedation, lethargy, ataxia, cardiac conduction disturbances, increased anxiety, and aggression.

**Chemistry/Synonyms**

A mu-receptor opiate agonist, tramadol HCl occurs as a white crystalline powder that is freely soluble in water or alcohol, and very slightly soluble in acetone. Tramadol is not derived from opium nor is it a semi-synthetic opioid, but is entirely synthetically produced.

Tramadol HCl may also be known as: CG-315; CG-315E; tramadol hydrochloridum; U-26225A; many trade names are available.
Trazodone Oral Tablets: 50 mg, 100 mg, 150 mg, & 300 mg; generic; (Rx)

**Dosage Forms/Regulatory Status**

Store between 20-25°C (68-77°F); excursions are permitted to 15-30°C (59-86°F). Keep in an airtight container and protect from light.

**Storage/Stability**

Trazodone is a triazolopyridine antidepressant agent. It occurs as a white to off-white crystalline powder and is sparingly soluble in water, alcohol, or chloroform.

**Client Information**

In humans, the most common adverse effects include blurred vision; confusion, dizziness, dry mouth, orthostatic hypotension, sweating, lethargy or somnolence. QT prolongation can occur, but is much less common in humans with trazodone than with the tricyclic antidepressants. Priapism has been reported rarely in men taking trazodone.

**Reproductive/Nursing Safety**

Trazodone appears to be relatively safe to use during pregnancy. At very high dosages (15–50X) in rats and rabbits, some increase in fetal death/resorption rates and congenital abnormalities were noted. For humans, the FDA categorizes trazodone as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.) Trazodone alone is unlikely to cause serotonin syndrome at clinically used dosages, but when used with other serotonergic drugs, it is possible. The most common clinical signs seen with serotonin syndrome in dogs include (in descending order): vomiting, diarrhea, seizures, hyperthermia, hyperesthesia, depression, mydriasis, vocalization, death, blindness, hypersalivation, dyspnea, ataxia/paresis, disorientation, hyperreflexia, and coma (Wismer 2006).

In humans, the most common adverse effects include blurred vision; confusion, dizziness, dry mouth, orthostatic hypotension, sweating, lethargy or somnolence. QT prolongation can occur, but is much less common in humans with trazodone than with the tricyclic antidepressants. Priapism has been reported rarely in men taking trazodone.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving trazodone and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS**: Trazodone may increase reductions in blood pressure and cause hypotension
- **ASPIRIN**: Increase risk for GI bleeding; monitor
- **AZOLE ANTIFUNGALS (e.g., ketoconazole, itraconazole)**: May increase trazodone blood levels
- **CNS DEPRESSANTS**: Use with trazodone may cause additive CNS depressant effects
- **DIGOXIN**: Trazodone may increase digoxin levels
- **MACROLIDE ANTIBIOTICS (e.g., erythromycin, clarithromycin)**: May increase trazodone blood levels
- **METOCLOPRAMIDE**: Increased risk for serotonin syndrome
- **NSAIDS**: Increased risk for GI bleeding; monitor
- **PHENOTHIAZINES**: May increase trazodone blood levels; cause additive CNS effects
- **SSRI ANTIDEPRESSANTS (e.g., fluoxetine)**: Increased risk for serotonin syndrome. Trazodone is commonly used together with SSRI’s, but be alert for signs associated with serotonin syndrome (see adverse effects above).

**Laboratory Considerations**

- None noted

**Doses**

**DOGS:**

As an adjunctive treatment of anxiety-related disorders:

- a) From a retrospective study of 56 dogs. To allow dogs to become tolerant to the drug and avoid potential gastrointestinal adverse effects, trazodone was begun at an initial dose that was half of the target dose and administered for 3 days. Then the target dose was established as the lowest effective dose needed for behavioral calming. Additional dose increments were made empirically over time.

<table>

</table>

In the study, the following minimum, maximum and mean daily dosages and dosing frequencies were used:

- Daily medication only: 1.9 mg/kg/day–16.2 mg/kg/day (mean = 7.3 mg/kg/day)
- As needed only: 2.2 mg/kg/day–14 mg/kg/day (mean = 7.7 mg/kg/day)

- Daily medication and as needed: 1.7 mg/kg/day–19.5 mg/kg/day (mean = 7.25 mg/kg/day) (Gruen & Sherman 2008)
  - b) 1 mg/kg PO q12h for 7 days, then up to 3 mg/kg PO q12h. (Frank 2010)
  - c) 1–4.8 mg/kg PO twice daily; titrate to effect in 1 mg increments every 7 days). (Virga 2010)
  - d) In addition to the daily serotonin enhancing medication, trazodone can be used as an adjunctive drug to increase clinical control of anxiety related conditions. It is given about an hour prior to the onset of anxiety and with a typical starting dose between 2–5 mg/kg and adjusting upwards as necessary to get control (maximum dose 14 mg/kg/day). (Neilson 2010)

**Monitoring**

- Clinical efficacy and adverse effects

**Client Information**

- Preferably give with food
- Clients should understand that trazodone has not been used extensively in dogs and to report any unforeseen adverse effects to the veterinarian

**Chemistry/Synonyms**

Trazodone is a triazolopyridine antidepressant agent. It occurs as a white to off-white crystalline powder and is sparingly soluble in water, alcohol, or chloroform.

Trazodone may also be known as AF-1161, trazodon, trazodon, or “sleepy.” A common trade name is Desyrel®.

**Storage/Stability**

Store between 20-25°C (68-77°F); excursions are permitted to 15-30°C (59-86°F). Keep in an airtight container and protect from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

Trazodone Oral Tablets: 50 mg, 100 mg, 150 mg, & 300 mg: generic; (Rx)
The following drug interactions have either been reported or are theoretical in humans or animals receiving triamcinolone and may be of significance in veterinary patients:

**Prescriber Highlights**

- Oral, parenteral, topical & inhaled glucocorticoid that is 4–10X (some say up to 40X) more potent than hydrocortisone; no appreciable mineralocorticoid activity
- Contraindications (relatively): Systemic fungal infections, manufacturer lists: “in viral infections, ... animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, & Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, & active tuberculosis necessitates carefully controlled use.”
- If using systemically for therapy, goal is to use as much as is required & as little as possible for as short an amount of time as possible
- Primary adverse effects are “Cushingoid” in nature with sustained use
- Many potential drug & lab interactions

**Uses/Indications**
The systemic veterinary labeled product (Vetalog® Injection) is labeled as “indicated for the treatment of inflammation and related disorders in dogs, cats, and horses. It is also indicated for use in dogs and cats for the management and treatment of acute arthritis, allergic and dermatologic disorders.”

In horses, intra-articular (IA) injection of triamcinolone acetonide (TA), particularly in high motion joints is often recommended to improve clinical lameness and reduce articular protein, inflammatory cell infiltration, intimal hyperplasia and subintimal fibrosis, and synovial levels of hyaluronan and glycosaminoglycan can be increased. Combining TA with a local anesthetic (e.g., mepivacaine) has been shown not to alter the potency or duration of action of TA and may be useful to both confirm the joint causing lameness and to reduce synovitis (Kay et al. 2008). There is some evidence supporting the IA use of TA with hyaluronic acid. In clinically normal horses, IA triamcinolone acetonide diffused directly from the distal interphalangeal joint with or without hyaluronic acid and, after additional studies, may prove to be useful in treating navicular syndrome (Boyce et al. 2010).

Intralesional injection of triamcinolone into eosophageal structures has been done in dogs and cats prior to dilution (Richter 2009). Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

**Pharmacology/Actions**
Triamcinolone acetonide is considered an intermediate acting (metabolic activity of 24-48 hours when given orally) glucocorticoid that is approximately 4-10 times more potent than hydrocortisone. When injected IM, duration of action may persist for 4-6 (and sometimes up to 8) weeks.

Glucocorticoids have effects on virtually every cell type and system in mammals. For more information, refer to the Glucocorticoid Agents, General Information monograph.

**Contraindications/Precautions/Warnings**
Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thymocytopenia or hypersensitive to a particular compound. Sustained-release injectable glucocorticoids use is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy.

**Adverse Effects**
Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP) and polyuria (PU), may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipodermis, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially lead to “Cushingoid” effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

**Reproductive/Nursing Safety**
Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas and mammary development.

Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

**Overdosage/Acute Toxicity**
Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

**References**
For a list of references for this monograph, please refer to the Veterinary Information Network (VetInfo) website.
**Doses**

**HORSES:** (Note: ARCI UCGFS Class 4 Drug)

**For glucocorticoid effects:**

- **Cats:**
  a) 0.25–0.5 mg PO once daily for 7 days (Kirk 1989)
  b) For pododermatitis, feline plasmacytic pharyngitis: 2–4 mg (total dose) PO once a day or every other day 0.4–0.6 mg/kg PO once daily, then taper. For pemphigus complex: 0.2–0.4 mg/kg/day PO (Williamson 2003)
  c) For tablets: 0.11 mg/kg PO initially once a day, may increase to 0.22 mg/kg PO once daily if initial response is unsatisfactory. As soon as possible, but not later than 2 weeks, reduce dose gradually to 0.028–0.055 mg/kg/day. (Package insert; Vetalog® Tablets—Solvay)
  d) For injectable product: 0.11–0.22 mg/kg for inflammatory or allergic disorders, and 0.22 mg/kg for dermatological disorders. Effects generally persist for 7–15 days; if symptoms recur, may repeat or institute oral therapy.

- **Cattle:**
  For glucocorticoid effects:
  a) 0.02–0.04 mg/kg IM; 6–18 mg intra-articularly. (Howard 1986)

**Mice:** (Note: ARCI UCGFS Class 4 Drug)

- **For glucocorticoid effects:**
  a) 0.011–0.022 mg/kg PO twice daily; 0.011–0.022 mg/kg IM or SC; 0.02–0.04 mg/kg IM; 6–18 mg intra-articularly. (Howard 1986)
Monitoring
Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Chemistry/Synonyms
Triamcinolone acetonide, a synthetic glucocorticoid, occurs as slightly odorous, white to cream-colored, crystalline powder with a melting point between 290–294°C. It is practically insoluble in water, very soluble in dehydrated alcohol and slightly soluble in alcohol. The commercially available sterile suspensions have a pH range of 5–7.5.

Triamcinolone acetonide may also be known as: triamcinolone acetonidum; many trade names are available.

Storage/Stability
Triamcinolone acetonide products should be stored at room temperature (15–30°C); the injection should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:
Triamcinolone Acetate Tablets: 0.5 mg, 1.5 mg; Vetalog® (BIVI), generic; (Rx). FDA-approved for use in dogs and cats.
Triamcinolone acetonide Suspension for Injection: 2 mg/mL; 6 mg/mL; Vetalog® Parenteral (BIVI); (Rx). FDA-approved for use in dogs, cats, and horses not intended for food.
The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:
Triamcinolone Acetone Injection: 10 mg/mL suspension & 40 mg/mL suspension in 1 mL, 5 mL, and 10 mL vials; Kenalog-10 & -40 (Bristol-Myers Squibb); (Rx).
Triamcinolone Hexacetonide Injection: 5 mg/mL & 20 mg/mL suspension in 1 mL, 5 mL, and 10 mL vials; Aristospan Intrarticular® & Intra-articular® (Sandoz); (Rx)

Many topical preparations are available, alone and in combination with other agents. Oral mucosal paste & Inhaled products are also FDA-approved. All are Rx.

References

TRIAMTERENE
(trye-am-ter-een) Dynastem®
POTASSIUM-SPARING DIURETIC
Prescriber Highlights

- Potassium-sparing diuretic that may be considered as an alternative to spironolactone for treating CHF in dogs; limited clinical experience with this drug in dogs/cats
- Contraindications: Anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation
- Hyperkalemia possible; must monitor serum K+

Uses/Indications
Triamterene is a potassium-sparing diuretic that potentially could be used as an alternative to spironolactone for the adjunctive treatment of congestive heart failure in dogs, however, there is little experience associated with its use in dogs or cats.

Pharmacology/Actions
By exerting a direct effect on the distal renal tubule, triamterene inhibits the reabsorption of sodium in exchange for hydrogen and potassium ions. Unlike spironolactone, it does not competitively inhibit aldosterone.
Triamterene increases excretion of sodium, calcium, magnesium and bicarbonate; urinary pH may be slightly increased. Serum concentrations of potassium and chloride may be increased. When used alone, triamterene has little effect on blood pressure. Triamterene can reduce GFR slightly, probably by affecting renal blood flow. This effect is reversible when the medication is discontinued.

Pharmacokinetics
Pharmacokinetic data for dogs or cats was not located. In humans, triamterene is rapidly absorbed after oral administration and oral bioavailability is about 85%. Onset of diuresis occurs in 2–4 hours and diminishes after about 8 hours. Triamterene is metabolized in the liver to 6-p-hydroxytriamterine and its sulfate conjugate. These metabolites are eliminated in the bile/feces and urine; elimination half-life is about 2 hours.

Adverse Effects
Because triamterene has been infrequently used in veterinary medicine, an accurate adverse effect profile for small animals is not known, however, hyperkalemia is a definite possibility and monitoring of electrolytes and renal function are necessary. In humans, hyperkalemia rarely occurs in patients with normal urine output and potassium intake. Less common adverse effects reported in humans include headache/dizziness, GI effects, byonotremia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking triamterene.

Monitoring
Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal’s age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose

TRIAMTERENE
(trye-am-ter-een) Dynastem®
POTASSIUM-SPARING DIURETIC
Prescriber Highlights

- Potassium-sparing diuretic that may be considered as an alternative to spironolactone for treating CHF in dogs; limited clinical experience with this drug in dogs/cats
- Contraindications: Anuria, severe or progressive renal disease, severe hepatic disease, hypersensitivity to triamterene, preexisting hyperkalemia, concurrent therapy with another potassium-sparing agent (spironolactone, amiloride) or potassium supplementation
- Hyperkalemia possible; must monitor serum K+

Uses/Indications
Triamterene is a potassium-sparing diuretic that potentially could be used as an alternative to spironolactone for the adjunctive treatment of congestive heart failure in dogs, however, there is little experience associated with its use in dogs or cats.

Pharmacology/ Actions
By exerting a direct effect on the distal renal tubule, triamterene inhibits the reabsorption of sodium in exchange for hydrogen and potassium ions. Unlike spironolactone, it does not competitively inhibit aldosterone.
Triamterene increases excretion of sodium, calcium, magnesium and bicarbonate; urinary pH may be slightly increased. Serum concentrations of potassium and chloride may be increased. When used alone, triamterene has little effect on blood pressure. Triamterene can reduce GFR slightly, probably by affecting renal blood flow. This effect is reversible when the medication is discontinued.

Pharmacokinetics
Pharmacokinetic data for dogs or cats was not located. In humans, triamterene is rapidly absorbed after oral administration and oral bioavailability is about 85%. Onset of diuresis occurs in 2–4 hours and diminishes after about 8 hours. Triamterene is metabolized in the liver to 6-p-hydroxytriamterine and its sulfate conjugate. These metabolites are eliminated in the bile/feces and urine; elimination half-life is about 2 hours.

Adverse Effects
Because triamterene has been infrequently used in veterinary medicine, an accurate adverse effect profile for small animals is not known, however, hyperkalemia is a definite possibility and monitoring of electrolytes and renal function are necessary. In humans, hyperkalemia rarely occurs in patients with normal urine output and potassium intake. Less common adverse effects reported in humans include headache/dizziness, GI effects, byonotremia, and an increased sensitivity to sunlight. Rarely, hypersensitivity reactions have occurred in human patients taking triamterene.
Triamterene. Other rare adverse effects include triamterene-nephrolithiasis, agranulocytosis, thrombocytopenia, or megaloblastosis.

Reproductive/Nursing Safety

Studies to determine triamterene’s effects on fertility have not been performed.

Studies in pregnant rats given triamterene at 6–20X (human dose) did not show adverse effects to the fetuses. Triamterene crosses the placental barrier. For humans, triamterene is either in FDA category B or category C, depending on the reference. Category C for use during pregnancy states: Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans. If considering use of this product in a pregnant animal, weigh the potential benefits of treatment versus the risks.

Triamterene is distributed into milk. Although unlikely to pose much risk to nursing animals, safety during nursing cannot be assured.

Overdosage/Acute Toxicity

The oral LD50 for triamterene in mice is 380 mg/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. GI effects or hypotension are also possible. Consider gut emptying protocols for very large or quantity unknown ingestions. Acute overdoses should generally be managed by observation, with fluid, electrolyte (especially serum potassium) and acid-base monitoring. Supportive treatment should be initiated if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving triamterene and may be of significance in veterinary patients:

- ACE INHIBITORS (e.g., enalapril, benazepril): Increased risks for hyperkalemia
- ANTIDIABETIC AGENTS (insulin, oral hypoglycemic agents): Triamterene may increase blood glucose
- ANTHYPERTENSIVE AGENTS: Possible potentiation of hypotensive effects
- DIURETICS, POTASSIUM-SPARING (spironolactone, amiloride): Increase risk of hyperkalemia; use of these drugs with triamterene in humans is contraindicated
- LITHIUM: Triamterene may reduce lithium clearance
- NSAIDS: Triamterene with NSAIDs (esp. indomethacin) may increase the risks of nephrotoxicity
- POTASSIUM SUPPLEMENTS or HIGH POTASSIUM FOODS: Increased risk for hyperkalemia

Laboratory Considerations

Quinidine: Triamterene may interfere with fluorescent assay of quinidine

Doses

DOGS:

a) For adjunctive treatment of recurrent heart failure associated with chronic mitral valve insufficiency: 1–2 mg/kg PO q12h. Documentation of use is limited; spironolactone is drug of choice. (Haggstrom et al. 2005)
b) As a diuretic for adjunctive treatment of CHF: 2–4 mg/kg/day PO (Ware 2003)

Monitoring

- Serum electrolytes (especially potassium), BUN, creatinine
- Hydration status
- Blood pressure, if indicated
- Signs of edema; patient weight, if indicated

Client Information

- Give this medication with food to help prevent stomach upset
- Urine may develop a bluish hue, this is normal
- Because this medication has not been used very much in dogs or cats; report any unusual effects to the veterinarian

Chemistry/Synonyms

Triamterene is structurally related to folic acid and occurs as a yellow, odorless, crystalline powder. It is practically insoluble in water and very slightly soluble in alcohol. At 50°C, it is slightly soluble in water. In acidified solutions, triamterene gives off a blue fluorescence.

Triamterene. Other rare adverse effects include triamterene-nephrolithiasis, agranulocytosis, thrombocytopenia, or megaloblastosis.

Overdosage/Acute Toxicity

The oral LD50 for triamterene in mice is 380 mg/kg. Fluid and electrolyte imbalance is the most likely risk associated with an overdose. GI effects or hypotension are also possible. Consider gut emptying protocols for very large or quantity unknown ingestions. Triamterene may also be known as NSC-77625, KF-8542, FI-6143, triamteren, trimaterenum, triamtereen, or Dyrenium®. International trade names include Dyte®0, Dyazide®, Maxzide-25®, and Trierten®. There are many international trade names for combination products with hydrochlorothiazide.

Storage/Stability

Triamterene capsules should be stored between 15–30°C (59–86°F) in tight, light-resistant containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

HUMAN-LABELED PRODUCTS:

Triamterene Capsules: 50 mg & 100 mg; Dyrenium® (SmithKline Beecham); (Rx)

In humans, triamterene is often prescribed as a fixed-dose combination with hydrochlorothiazide. Products include:

- Triamterene 37.5 mg/Hydrochlorothiazide 25 mg Tablets and Capsules; generic; Dyazide®, Maxzide-25®; generic; (Rx)
- Triamterene 50 mg/Hydrochlorothiazide 25 mg Capsules; generic; (Rx)
- Triamterene 75 mg/Hydrochlorothiazide 50 mg Tablets; Maxzide®; generic; (Rx)

References

Oral copper chelating agent for copper hepatopathy

- Probably fewer adverse effects than penicillamine, but acute renal failure possible
- Very limited experience with this drug
- More expensive than penicillamine; may need to be compounded into smaller dosages
- Give on an empty stomach

**Uses/Indications**
Trientine may be useful for the treatment of copper-associated hepatopathy in dogs, particularly when dogs cannot tolerate the adverse effects (e.g., vomiting) associated with penicillamine.

**Pharmacology/Actions**
Trientine is an effective chelator of copper and increases its elimination via urinary excretion. It apparently has a greater affinity for copper in plasma than penicillamine, but penicillamine has a greater affinity for tissue copper.

**Pharmacokinetics**
No data was located.

**Contraindications/Precautions/Warnings**
Trientine is contraindicated in patients hypersensitive to it. It is not indicated for cystinuria, rheumatoid arthritis, or biliary cirrhosis.

**Adverse Effects**
Albeit with limited veterinary experience, trientine has had relatively minimal adverse effects in dogs treated for copper hepatotoxicity, but acute renal failure has been reported. Human patients have developed iron deficiency anemia after taking trientine long-term. There is a chance for topical dermatitis developing if trientine gets on skin; wash off immediately. The drug should be given in a capsule (may need to be compounded) and not sprinkled on food.

**Reproductive/Nursing Safety**
Trientine is a potential teratogen. It was teratogenic in rats given doses similar to those for humans and should only be used in pregnancy when the benefits to the mother outweigh the risks to offspring. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

It is not known whether this drug is excreted in breast milk. Exercise caution when administering to nursing patients.

**Overdosage/Acute Toxicity**
Little information is available; a case of a human ingesting 30 grams of trientine without significant morbidity has been reported.

**Drug Interactions**
The following drug interactions have either been reported or are theoretical in humans or animals receiving trientine and may be of significance in veterinary patients:

- **IRON**: Iron and trientine inhibit the absorption of one another; if iron therapy is needed, give doses at least 2 hours apart from one another
- **ZINC**: Because trientine may also chelate zinc or other minerals, separate doses as above

**Doses**

**DOGS**:
- As a chelator for copper hepatotoxicity:
  - a) 10–15 mg/kg PO twice daily; 1–2 hours before a meal (Twedt 1999)
  - b) 10–15 mg/kg PO q12h; give one hour before meals (Johnson 2000)
  - c) 15–30 mg/kg PO twice daily (q12h). Give prior to meals (Richter 2002)

**Chemistry/Synonyms**
An oral copper chelator, trientine HCl occurs as a white to pale yellow crystalline powder. It is hygroscopic and freely soluble in water.

**Storage/Stability**
Store trientine capsules in the refrigerator (2–8°C) in tightly closed containers.

**References**

Laboratory Considerations

KETOCONAZOLE:
The following drug interactions have either been reported or are theoretical in humans or animals receiving trilostane and may be of significance in veterinary patients:

- ACE INHIBITORS (e.g., benazepril, enalapril): Could increase risk for hyperkalemia
- KETOCONAZOLE: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- MITOTANE: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- POTASSIUM-SPARING DIURETICS (e.g., spironolactone): Could increase risk for hyperkalemia
- POTASSIUM-SUPPLEMENTS; HIGH POTASSIUM FOODS: Could increase risk for hyperkalemia

Reproductive/Nursing Safety

Because trilostane can significantly reduce the synthesis of progesterone in vivo, it should not be used in pregnancy. Trilostane reportedly (not confirmed) is classified by the FDA as a category X drug (Contraindicated in pregnancy).

Information on trilostane levels in maternal milk were not located; use with caution in lactating animals.

Overdosage/Acute Toxicity

Specific information on trilostane acute toxicity was not located. One source states that trilostane overdoses would be unlikely to threaten life and no clinical signs would be expected. However, blood pressure, hydration status, and electrolyte balance should be monitored. If the animal is stressed, consider giving exogenous corticosteroids short-term. Because the drug's effects are relatively short lived, monitoring of patients without complications should only be required for a few days post ingestion.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving trilostane and may be of significance in veterinary patients:

- ACE INHIBITORS (e.g., benazepril, enalapril): Could increase risk for hyperkalemia
- KETOCONAZOLE: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- MITOTANE: May potentiate the effects of trilostane and lead to hypoadrenocorticism
- POTASSIUM-SPARING DIURETICS (e.g., spironolactone): Could increase risk for hyperkalemia
- POTASSIUM-SUPPLEMENTS; HIGH POTASSIUM FOODS: Could increase risk for hyperkalemia

Doses

DOGS:

For treatment of canine hyperadrenocorticism (HAC):

a) The starting dose for the treatment of hyperadrenocorticism in dogs is 2.2–6.7 mg/kg PO once a day with food based on body weight and capsule size. The package insert has a dosing table (Table 1) to help determine the appropriate size and number of capsules to administer.

After approximately 10-14 days at this dose, re-examine the dog and conduct a 4-6 hour post-dosing ACTH stimulation test. If physical examination is acceptable adjust dose according to Table 2 (found in the package insert). Individual dose adjustments and close monitoring are essential. Re-examine and conduct an ACTH stimulation test 10-14 days after every dose alteration. Care must be taken during dose increases to monitor the dog’s clinical signs and serum electrolyte concentrations. Once daily administration is recommended. However, if clinical signs are not controlled for the full day, twice daily dosing may be needed. To switch from a once daily dose to a twice daily dose, increase the total daily dose by ½ to ¾ and divide the total amount into two doses given 12 hours apart. (Label Information; Vetoryl® — Dechra)

b) For treatment of canine hyperadrenocorticism (HAC) whether due to adrenal tumor or PHD: Initial therapy at 2–10 mg/kg PO once daily. Adjust dosage per monitoring parameters below. Doses of up to 50 mg/kg/day divided twice daily have been given without untoward side effects. Give with food. Some dogs require twice daily administration.

ACTH stimulation test done at 10–14 days, 30 days and 90 days after starting therapy. ACTH stimulation tests should be performed 4–6 hours post-trilostane dose. Interpret ACTH test in light of physical exam. If ACTH Stim results are <20 nmol/L (0.72 micrograms/dL), then the drug is discontinued for 48–72 hours and then re-started at a lower dosage. If ACTH Stim results are >200 nmol/L (7.2 micrograms/dL), then the dose is increased. If the ACTH Stim results are between these two values and the dog is clinically well controlled, then no change. If between these two results and the patient appears not to be clinically well-controlled, then the drug may need to be given twice daily. Once the dog is stable, repeat ACTH Stim test every 3–6 months. (Neiger 2004)

c) Author’s (Feldman) experience of trilostane is not more effective or safer than mitotane and that trilostane is less predictable (under dose, over dose, resolution of signs, or the need for dosing more than once per day) than mitotane.

If using trilostane current recommendation is: Initiate at 1 mg/kg PO once daily and continue for about one week until a veterinary recheck can occur. Have owners collect a small urine sample from their dog...
is combined with trimeprazine (Temaril-P®). Temaril-P® is reportedly still an FDA-approved human drug, but was withdrawn from the market in the USA in 1994.

References
Scott-Moncrieff, J.C. (2010). Treatment of feline hyperadrenocorticism: 7 mg/kg/day divided and given twice daily. Doses of up to 60 mg per cat per day have been used in a small number of cats with PDH. (Greco 2007)

HORSES:
a) For treatment of equine Cushing’s syndrome: 0.4–1 mg/kg (total dose 120–240 mg) PO once daily. (McGowan & Neiger 2003)

Monitoring
■ Clinical effects
■ Adverse effects
■ Serum electrolytes
■ Urisanalysis including specific gravity, glucose and urine cortisol/creatinine ratio (UCCR)
■ ACTH stimulation tests (see doses for recommendations). For long-term monitoring, the manufacturer recommends: Once an optimum dose has been reached, re-examine the dog at 30 days, 90 days and every 3 months thereafter. At a minimum, this monitoring should include a thorough history and physical examination, ACTH stimulation test (conducted 4-6 hours after trilostane administration), and serum biochemical tests (with particular attention to electrolytes, renal and hepatic function). A post-ACTH stimulation test resulting in a cortisol of <1.45 micrograms/dL (<40 nMol/L), with or without electrolyte abnormalities, may precede the development of clinical signs of hypoadrenocorticism. Good control is indicated by favorable clinical signs as well as post-ACTH serum cortisol of 1.45-9.1 micrograms/dL (40-250 nMol/L). If the ACTH stimulation test is <1.45 micrograms/dL (<40 nMol/L) and/or if electrolyte imbalances characteristic of hypoadrenocorticism (hyperkalemia and hypernatremia) are found, trilostane should be temporarily discontinued until reversion of clinical signs consistent with hyperadrenocorticism and test results return to normal (1.45-9.1 micrograms/dL or 40-250 nMol/L). Trilostane may then be re-introduced at a lower dose.

Client Information
■ Keep out of reach of children and pets
■ Trilostane capsules do not require any special safety handling precautions. The manufacturer states: Wash hands after use. Do not empty capsule contents and do not attempt to divide the capsules. Do not handle the capsules if pregnant or if trying to conceive. Clients should report any adverse effects to the veterinarian
■ Give the drug with food, unless otherwise directed by veterinarian
■ Clients should understand that trilostane is a treatment for the condition and not a cure

Chemistry/Synonyms
A synthetic steroid analog, trilostane has a molecular weight of 329.4 and its chemical name is 4-alpha, 5-alpha-Epoxy-17-beta-hydroxy-3-oxoandrostane-2-alpha-carbonitrile. It reportedly is relatively insoluble in water.

Trilostane may also be known as: WIN 24540, Vetoryl®, Despariban®, Modrastane® or Modrenal®.

Storage/Stability
Commercially available trilostane capsules should be stored at room temperature in tight, light-resistant containers.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None in the USA.
Trilostane Oral Capsules: 10 mg, 30 mg, & 60 mg packaged in aluminum foil blister cards of 10 capsules; Vetoryl® (Dechra); (Rx).

HUMAN-LABELED PRODUCTS:
Modrastane® is reportedly still an FDA-approved human drug, but was withdrawn from the market in the USA in 1994.

TRIMEPRAZINE TARTRATE WITH PREDNISOLONE
(trye-mpr-za-rez) Temaril-P®
PHENOTHIAZINE ANTIHISTAMINE & CORTICOSTEROID

Prescriber Highlights

❖ Combination phenothiazine antihistamine & corticosteroid used for pruritus & potentially as an antitussive
❖ Relatively Contraindicated: Systemic fungal infections, hypovolemia, or shock & in patients with tetanus or strychnine intoxication. Caution: Hepatic dysfunction, cardiac disease, active bacterial or viral infections, peptic ulcer, acute psychoses, corneal ulcer, Cushingoid syndrome, diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, general debilitation, very young animals
❖ Primary adverse effects: Sedation, may cause significant hypotension, cardiac rate abnormalities, hypo- or hyper- thermia, “Cushingoid” effects with sustained use
❖ Many potential drug & lab interactions

Uses/Indications
Trimeprazine with prednisolone is used for the treatment of pruritic conditions, especially if induced by allergic conditions. Many dermatologists believe, and there is reasonable evidence to support, that when prednisolone is combined with trimeprazine (Temaril-P®)
Pharmacology/Actions
Trimeprazine has antihistaminic, sedative, antitussive, and antipruritic qualities. The veterinary FDA-approved product also has prednisolone in its formulation that provides additional antiinflammatory effects.

Pharmacokinetics
The pharmacokinetics of trimeprazine have not been studied.

Contraindications/Precautions/Warnings
The contraindications and precautions of this product follow those of the other phenothiazines and antihistaminic agents. For more information, it is suggested to review the acepromazine and chlorpheniramine monographs.

Adverse Effects
For trimeprazine, possible adverse reactions include: sedation, depression, hypotension and extrapyramidal reactions (rigidity, tremors, weakness, restlessness, etc.).

Additional adverse effects, if using the product containing steroids include: elevated liver enzymes, weight loss, polyuria/polydipsia, vomiting, and diarrhea. If used chronically, therapy must be withdrawn gradually and Cushing’s syndrome may develop.

The manufacturer of the veterinary combination product (Temaril®-P) includes the following adverse effects in its package insert: sodium retention and potassium loss, negative nitrogen balance, suppressed adrenocortical function, delayed wound healing, osteoporosis, possible increased susceptibility to and/or exacerbation of bacterial infections, sedation, protruding nictitating membrane, blood dyscrasias. In addition, intensification and prolongation of the action of sedatives, analgesics or anesthetics can be noted and potentiation of organophosphate toxicity and of procaine HCl activity.

Reproductive/Nursing Safety
The manufacturer of the veterinary combination product (Temaril®-P) warns that corticosteroids can induce the first stages of parturition if administered during the last trimester of pregnancy.

Overdosage/Acute Toxicity
Acute overdosage should be handled as per the acepromazine monograph found at the beginning of the book.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving promethazine (a related phenothiazine antihistamine) or prednisolone and may be of significance in veterinary patients:

ACE INHIBITORS: Phenothiazines may increase effects
AMPHOTERICIN B: When administered concomitantly with glucocorticoids may cause hypokalemia
ANTACIDS: May cause reduced GI absorption of oral phenothiazines
ANTIDIARRHEAL MIXTURES (e.g., Kaolin/pectin, bismuth subsalicylate mixtures): May cause reduced GI absorption of oral phenothiazines
ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.): In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
ASPIRIN (salicylates): Glucocorticoids may reduce salicylate blood levels
CISAPRIDE: Increased risk for cardiac arrhythmias when used with phenothiazines
CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.): May cause additive CNS depression if used with phenothiazines
CYCLOPHOSPHAMIDE: Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
CYCLOSPORINE: Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
DIGOXIN: Secondary to hypokalemia, increased risk for arrhythmias
DIURETICS, POTASSIUM-DEPLETING (furosemide, thiazides): When administered concomitantly with glucocorticoids may cause hypokalemia
EPHEDRINE: May increase metabolism
ESTROGENS: The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
INSULIN: Requirements may increase in patients receiving glucocorticoids
KETOCONAZOLE: May decrease metabolism
MITOTANE: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
NSAIDS: Administration of other ulcerogenic drugs with glucocorticoids may increase risk
PAROXETINE: May increase phenothiazine plasma levels
PHENOBARBITAL: May increase the metabolism of glucocorticoids
PHENYTOIN: May increase the metabolism of glucocorticoids
RIFAMPIN: May increase the metabolism of glucocorticoids
VACCINES: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations
- Glucocorticoids may increase serum cholesterol and urine glucose levels.
- Glucocorticoids may decrease serum potassium.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce T_3_ & T_4_ values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I^131 by the thyroid may be decreased by glucocorticoids.
- Reactions to skin tests may be suppressed by glucocorticoids or trimeprazine.
- False-negative results of the nitroblue tetrazolium test for systemic bacterial infections may be induced by glucocorticoids.

Doses
DOGS:
- a) For antipruritic and antitussive therapy: Weight up to 10 lb = ½ tab PO twice daily; 11–20 lb = 1 tablet twice daily; 21–40 lb = 2 tablets twice daily; over 40 lb = 3 tablets twice daily. After 4 days reduce dose to ½ of initial dose or to an amount just sufficient to maintain remission of symptoms; adjust as necessary. (Package Insert: Temaril®-P—Pfizer)
- b) For treatment of pruritus: 1 tablet per 10 kg of body weight once daily for 3–5 days, then every other day. Giving with an EFA (essential fatty acid) may reduce the dose and frequency, if not the need for, glucocorticoids. (White 2003)
- c) For atopic dermatitis: 1 tablet of Temaril®-P per 5 kg body weight q12h for one week, then once daily for one week, then q48h (every other day). (Hillier 2006)

Monitoring
- Efficacy
- Degree of sedation, and anticholinergic effects
Client Information
- Follow veterinarians dosage recommendations carefully
- Dog’s appetite and water consumption may increase
- If side effects are worrisome, contact veterinarian

Chemistry/Synonyms
A phenothiazine antihistamine related to promethazine, trimeprazine tartrate occurs as an odorless, white, to off-white crystalline powder with a melting range of 160–164°C. Approximately 0.5 gm is soluble in 1 mL water, and 0.05 gram is soluble in 1 mL of alcohol.
Trimeprazine Tartrate may also be known as: trimeprazine tartrate, alimemazine tartrate, Chemists Own Petalix®, Nedeltran®, Panectyl®, Rephetol®, Temaril®, Theralene®, Therapeutica®, Valbergurr®, or Variargil®.

Storage/Stability
Store trimeprazine products at room temperature (15–30°C); protect tablets from light.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
No single agent trimeprazine products are FDA-approved for veterinary medicine.
Trimeprazine Tartrate 5 mg; Prednisolone 2 mg Tablets; Temaril-P® Tablets (Pfizer); (Rx). FDA-approved for use in dogs. Trade name in Canada is Vanectyl-P®.
The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

References

TRIPELENNAMINE HCL
(tri-pel-ehn-a-meen) Re-Covr®
ANTHISTAMINE
Prescriber Highlights
- Injectable antihistamine
- Contraindications: Do not give IV to horses
- Adverse Effects: CNS stimulation (if given IV to horses), sedation, depression, ataxia, GI effects (oral use)

Uses/Indications
Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects. Tripelennamine has been used as a CNS stimulant in “Downer cows” when administered slow IV.

Pharmacology/Actions
Antihistamines (H1-receptor antagonists) competitively inhibit histamine at H1 receptor sites. They do not inactivate or prevent the release of histamine, but can prevent histamine’s action on the cell. Besides their antihistaminic activity, these agents also have varying degrees of anticholinergic and CNS activity (sedation). Tripelennamine is considered to have moderate sedative activity and minimal anticholinergic activity when compared to other antihistamines.

Pharmacokinetics
The pharmacokinetics of tripelennamine have apparently not been thoroughly studied in domestic animals or humans. One study performed in horses and camels (Wasfi et al. 2000), showed that after IV administration similar pharmacokinetic profiles were obtained for both species. Terminal elimination half-lives were around 2+ hours; volumes of distribution steady-state approximately 1.5–3 L/kg; protein binding was 80% and total body clearance approximately 1 L/hour/kg.

Contraindications/Precautions/Warnings
Do not administer Tripelennamine IV in horses (see Adverse Effects).

Adverse Effects
CNS stimulation (hypereactivity, nervousness, and muscle tremors) lasting up to 20 minutes, has been noted in horses after receiving tripelennamine intravenously. Other effects seen (in all species) include CNS depression, incoordination, and GI disturbances.

Overdosage/Acute Toxicity
Overdosage of tripelennamine reportedly can cause CNS excitation, seizures and ataxia. Treat symptomatically and supportively if clinical signs are severe. Phenytoin (IV) is recommended in the treatment of seizures caused by antihistamine overdose in humans; barbiturates and diazepam are generally avoided.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving tripelennamine and may be of significance in veterinary patients:
- CNS DEPRESSANTS, OTHER: Increased sedation can occur if chlorpheniramine is combined with other CNS depressant drugs
- HEPARIN, WARFARIN: Antihistamines may partially counteract the anti-coagulation effects of heparin or warfarin.

Laboratory Considerations
- Antihistamines can decrease the wheal and flare response to antigen skin testing. In humans, it is suggested that antihistamines be discontinued at least 4 days prior to testing.

Doses
It is recommended to warm the solution to near body temperature before injecting; give IM injections into large muscle areas. Note: Oral dosage forms may no longer be obtainable.
DOGS:
a) 1mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)

CATS:
a) 1 mg/kg PO q12h; 1 mg/kg IM (Kirk 1986)

CATTLE:
a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IV (for more immediate effect) or IM q6–12h as needed (Package Insert; Re-Covr®—Solvay)
b) As adjunctive treatment in “Downer Cow Syndrome” as a CNS stimulant: 0.5 mg/kg slow IV in conjunction with parenteral mineral treatment (Caple 1986)
c) 1 mg/kg IV or IM (Howard 1986)

HORSES:
a) 1.1 mg/kg (2.5 mL per 100 lbs body weight) IM q6–12h as needed (Package Insert; Re-Covr®—Solvay)
b) 1 mg/kg IM (Robinson 1987)

SWINE:
a) 1 mg/kg IV or IM (Howard 1986)

Monitoring
Clinical efficacy
Adverse effects
Chemistry/Synonyms
An ethylenediamine-derivative antihistamine, tripelennamine HCl occurs as a white, crystalline powder that will slowly darken upon exposure to light. It has a melting range of 188–192°C and pKas of 3.9 and 9.0. One gram is soluble in 1 mL of water or 6 mL of alcohol.

Tripelennamine HCl may also be known as: tripelennaminium chloride, Azaron®, Etono®, Fenistil®, PBZ®, Pelamine®, Pyribenzamine®, Re-Covr® or Vaginex®.

Storage/Stability
Store the injection at room temperature and protect from light; avoid freezing or excessive heat.

Dosage Forms/Regulatory Status
VETERINARY-LABELLED PRODUCTS:
Tripelennamine HCl for Injection: 20 mg/mL in 20 mL, 100 mL, and 250 mL vials; Re-Covr® (Fort Dodge) Note: This product is still listed as FDA-approved, but may not be available commercially; generic (various manufacturers and trade names); (Rx). Tripelennamine HCl injection is FDA-approved for use in cattle and horses. Treated cattle must not be slaughtered for food purposes for 4 days following the last treatment. Milk must not be used for food for 24 hours (2 milkings) after treatment. No specific tolerance for residues has been published.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELLED PRODUCTS:
None

TRYPAN BLUE
(trip-ann-bloe)
ANTI-BABESIAL AGENT; OPHTHO SURGERY DYE

Prescriber Highlights

▪ Uncommonly used alternative treatment for babesia (R. canis) in dogs that can rapidly alleviate clinical signs, but does not eliminate parasite
▪ Must follow-up treatment with other antibabesial drugs (e.g., diminazene, imidocarb)
▪ Must be given IV
▪ Will stain all body tissues and secretions for several weeks
▪ Likely teratogen when used systemically

Uses/Indications
Trypan blue was among the first agents used to treat Babesia. It may be useful as an adjunctive treatment for dogs with mild, to moderate signs of infection with babesiosis (R. canis). Some have recommended its use in dogs with severe infections as it does not possess imidocarb’s anticholinergic effects or the CNS toxic effects of some of the other diamidine drugs (e.g., diminazene, pentamidine). Trypan blue suppresses parasitemia and can alleviate clinical signs, but it does not eliminate the infection and results can be variable. Other treatments (e.g., imidocarb, diminazene) must be used within a month of trypan blue to be curative (Greene & Ewing 2006; Taboada & Lobetti 2006). In a study comparing the effects of trypan blue and diminazene on hematocrit and parasitemia in dogs with clinically mild to moderate, uncomplicated babesiosis, there were no significant differences between diminazene and trypan blue on hematocrit or parasite clearance (Jacobson et al. 1996).

Trypan blue is also used as a dye in eye surgery to stain the anterior capsule of the lens and the epiretinal membranes.

Pharmacology/Actions
Trypan blue blocks the C3b receptor on both the erythrocyte membrane and the Babesia organism and likely prevents the parasite from entering the erythrocyte.

Pharmacokinetics
No information was located.

Contraindications/Precautions/Warnings
As trypan blue is a known teratogen it should be used during pregnancy in dogs only when the benefits to the dam outweigh the potential effects on puppies.

Adverse Effects
Trypan blue is well tolerated in dogs. The bluish-color change of secretions, urine, eyes and mucous membranes is most often the only adverse effect seen. This effect can persist for several weeks after treatment.

Reproductive/Nursing Safety
Trypan blue is teratogenic when used systemically in rats, mice, rabbits, hamsters, dogs, guinea pigs, and pigs. Systemically administered trypan blue to rats was teratogenic at 50 mg/kg (single dose) and 25 mg/kg/day (multiple doses). The FDA categorizes trypan blue used as a ophthalmologic dye as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Trypan blue can distribute into milk and cause it to have a bluish-tint. Safety in nursing offspring has not been established.

Overdosage/Acute Toxicity
No information located; figure dosages carefully.

Drug Interactions
None noted

Laboratory Considerations
Trypan blue can tint plasma to a bluish color it may affect photometric-based test results or affect erythrocyte monitoring.

Doses

**DOGS:**
- For *B. canis*:
  - a) 10 mg/kg IV (only) once. (Schoeman 2008)
  - b) 10 mg/kg IV as a 1% solution once. (Taboada & Lobetti 2006)

Monitoring
Efficacy against babesia organism’s effects on patient (bluish color change in plasma may make blood smear evaluation more difficult and affect erythrocyte counts and hematocrit determination)

Client Information
This medication may cause a bluish color change in the dog’s mucous membranes, eyes, urine, or secretions. This should diminish in a few weeks, but secretions may stain fabrics.

Trypan blue does not completely eradicate the organism and additional treatments are required using other drugs

Chemistry/Synonyms
Trypan blue is an azo-naphthalene dye derived from toluidine. Trypan blue can also be known as azidione blue 3B, benzamine blue 3B, Niagara blue, Congo blue, diamine blue, CI Direct Blue 14, or trypanum caeruleum. Trade names include VisionBlue® and MembranBlue®.

Storage/Stability
Trypan blue powder or solutions should be stored at 15-25°C (59-77°F). Protect from direct sunlight.

Compatibility/Compounding Considerations
A 1% solution (10 mg/mL) is usually given intravenously. Trypan blue for injection that is compounded from powder should be administered through an in-line filter during intravenous administration.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA

**HUMAN-LABELED PRODUCTS:**
Trypan blue powder is available and it is also available as an ophthalmic stain in 0.06% and 0.15% solutions; VisionBlue®, MembraneBlue® (Dutch Ophthalmic); (Rx)

References
**Pharmacology/Actions**

While tulathromycin is a macrocyclic antibiotic such as erythromycin or azithromycin, it is structurally unique in that it has three amine groups (tribasic), while erythromycin and azithromycin have one (monobasic) and two (dibasic) groups, respectively. The tribasic group of compounds are called triamilide macrolides.

It is believed that tulathromycin’s tribasic structure allows it to better penetrate gram-negative pathogenic bacteria and its low affinity for bacterial efflux pumps may allow the drug to remain and accumulate within the bacteria.

The mechanism of action of tulathromycin is similar to other macrolides in that it inhibits protein synthesis by penetrating the cell wall and binding to the 50S ribosomal subunits in susceptible bacteria. It is considered a bacteriostatic antibiotic, but it possesses some bactericidal activity as well, particularly for *Mannheimia haemolytica* and *Pasteurella multocida*.

Tulathromycin’s efficacy is probably enhanced by its ability to accumulate and be released by host phagocytic cells. Neither time-dependent nor concentration-dependent models may accurately predict or describe the drug’s efficacy. Some modern macrolides (e.g., azithromycin) efficacy may be more predictable by assessing the total drug exposure to the pathogen; the AUC/MIC ratio may be helpful.

**Chemistry/Synonyms**

The commercially available injection contains 100 mg/mL of tulathromycin in an equilibrated mixture of the two isomeric forms of tulathromycin in a 9:1 ratio. The injectable vehicle consists of 50% propylene glycol, monothioglycerol (5 mg/mL); citric and hydrochloric acids are added to adjust pH. It has a relatively low viscosity.

**Pharmacokinetics**

In feeder calves given 2.5 mg/kg SC (in the neck), tulathromycin is rapidly and nearly completely absorbed (bioavailability >90%). Peak plasma concentrations generally occur within 15 minutes after dosing. Volume of distribution is very large (approximately 11 L/kg) and total systemic clearance is approximately 170 mL/hr/kg. This extensive volume of distribution is largely responsible for the long elimination half-life of this compound. In plasma, elimination half life is approximately 2.75 days, but in lung tissue it is about 8.75 days. Tulathromycin is eliminated from the body primarily unchanged via biliary excretion.

Following intramuscular administration to feeder pigs at a dosage of 2.5 mg/kg, tulathromycin is readily and rapidly absorbed (bioavailability 88%) with peak levels occurring in about 15 minutes. Tulathromycin rapidly distributes into body tissues, and the volume of distribution is 13–15 L/kg. Plasma half-life is approximately 60–90 hours, but lung tissue half life is about 5.9 days. Tulathromycin is eliminated from the body primarily unchanged via the feces and urine.

**Contraindications/Precautions/Warnings**

Tulathromycin is contraindicated in animals with a prior hypersensitivity reaction to the drug.

Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment. Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established for this product in pre-ruminating calves. Do not use in calves to be processed for veal.

Swine intended for human consumption must not be slaughtered within 5 days from the last treatment.

**Drug Interactions**

No drug interactions are noted in the manufacturer’s label and none could be found in other references for tulathromycin.

**Laboratory Considerations**

No concerns were noted.

**Doses**

**CATTLE:**

For labeled indications:

- a) Inject subcutaneously as a single-dose in the neck at a dosage of 2.5 mg/kg (1.1 mL/100 lb) body weight (BW). Do not inject more than 10 mL per injection site. (Label directions; Draxxin®—Pfizer)

**SWINE:**

For labeled indications:

- a) Inject intramuscularly as a single-dose in the neck at a dosage of 2.5 mg/kg (0.25 mL/22 lb) BW. Do not inject more than 2.5 mL per injection site. (Label directions; Draxxin®—Pfizer)

**HORSES:**

- a) For foals with *R. equi*; Anecdotally, 2.5 mg/kg IM every 5–7 days has been used successfully in milder clinical cases. (Divers 2009)

**Monitoring**

**Clinical efficacy**

**Client Information**

- Follow dosing guidelines exactly; adhere to withdrawal times
- Not for female dairy cattle (20 months or older) or veal calves
- Cattle are dosed subcutaneously in the neck, not more than 10 mL per injection site
- Swine are dosed intramuscularly in the neck, not more than 2.5 mL per injection site

**Chemistry/Synonyms**

Tulathromycin is a semi-synthetic macrolide antibiotic of the subclass triamilide. It occurs as white to off-white crystalline powder that is readily soluble in water at pH<8. At a pH of 7.4 (physiological pH), tulathromycin (a weak base) is approximately 30 times more soluble in hydrophilic than hydrophobic media.

The commercially available injection contains 100 mg/mL of tulathromycin in an equilibrated mixture of the two isomeric forms of tulathromycin in a 9:1 ratio. The injectable vehicle consists of 50% propylene glycol, monothioglycerol (5 mg/mL); citric and hydrochloric acids are added to adjust pH. It has a relatively low viscosity.

Tulathromycin may also be known as tulathromycine, tulathromycinum, CP-472295 (component A), CP-547272 (component B), or Draxxin®.

**Storage/Stability**

Tulathromycin injection should be stored at, or below 25°C (77°F). The product is stable at room temperature for up to 36 months.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Tulathromycin Injection 100 mg/mL in 50, 100, 250, & 500 mL vials; Draxxin® (Pfizer); FDA-approved for use in cattle and swine. Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment.

**Monitoring**

**Clinical efficacy**

**Client Information**

- Follow dosing guidelines exactly; adhere to withdrawal times
- Not for female dairy cattle (20 months or older) or veal calves
- Cattle are dosed subcutaneously in the neck, not more than 10 mL per injection site
- Swine are dosed intramuscularly in the neck, not more than 2.5 mL per injection site

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

Tulathromycin Injection 100 mg/mL in 50, 100, 250, & 500 mL vials; Draxxin® (Pfizer); FDA-approved for use in cattle and swine. Cattle intended for human consumption must not be slaughtered within 18 days from the last treatment.
Information on potential interactions.

Drug interactions with tylosin have not been well documented. It has been suggested that tylosin may increase AST (SGOT), ALT (SGPT) and can be altered by concomitant macrolide administration.

**Pharmacokinetics**

Tylosin tartrate is well absorbed from the GI tract, primarily from the intestine. The phosphate salt is less well absorbed after oral administration. Tylosin base injected SC or IM is reportedly rapidly absorbed.

Tylosin is thought to have the same mechanism of action as erythromycin (binds to 50S ribosome and inhibits protein synthesis) and exhibits a similar spectrum of activity. It is a bacteriostatic antibiotic. Tylosin may also have immunomodulatory effects on cell-mediated immunity. In dogs, tylosin increases concentrations of enterococci (Enterococcus fecalis) in the jejunum. Enterococci are thought to have probiotic effects.

For more specific information on organisms where tylosin is usually active, refer to the erythromycin monograph; cross-resistance with erythromycin occurs.

**Adverse Effects**

Most likely adverse effects with tylosin are pain and local reactions at intramuscular injection sites, and mild GI upset (anorexia, and diarrhea). Tylosin may cause severe diarrheas if administered orally to ruminants or by any route to horses.

Adverse effects may be altered by concomitant macrolide administration.

**Contraindications/Precautions/Warnings**

Tylosin is contraindicated in patients hypersensitive to it or other macrolide antibiotics. Tylosin is also used clinically in cattle and swine for infections caused by susceptible organisms.

Although the injectable form of tylosin is FDA-approved for use in dogs and cats, it is rarely used parenterally in those species. Oral tylosin is sometimes recommended for the treatment of chronic colitis in small animals (see Doses). A double-blinded prospective study, comparing tylosin to placebo in dogs with a history of chronic diarrhea that was thought to be responsive to tylosin in the past, showed that 85% dogs receiving tylosin had perceived normal fecal consistency versus 29% of those receiving placebo (Kilpienn et al. 2009). Tylosin has been used and been used anecdotally in cats as an immunomodulating agent for treating FIP. In dogs, tylosin has been used orally to treat tear staining (epiphora).

Tylosin is also used clinically in cattle and swine for infections caused by susceptible organisms.

**Contraindications/Precautions/Warnings**

Tylosin is contraindicated in patients hypersensitive to it or other macrolide antibiotics (e.g., erythromycin). Most clinicians feel that tylosin is contraindicated in horses, as severe and sometimes fatal diarrheas may result from its use in that species.

**Adverse Effects**

Most likely adverse effects with tylosin are pain and local reactions at intramuscular injection sites, and mild GI upset (anorexia and diarrhea). Tylosin may induce severe diarrheas if administered orally to ruminants or by any route to horses. In swine, adverse effects reported include edema of rectal mucosa and mild anal protrusion with pruritus, erythema, and diarrhea.

**Reproductive/Nursing Safety**

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: B (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

**Overdosage/Acute Toxicity**

Tylosin is relatively safe in most overdose situations. The LD50 in pigs is greater than 5 grams/kg orally, and approximately 1 gram/kg IM. Dogs are reported to tolerate oral doses of 800 mg/kg. Long-term (2 year) oral administration of up to 400 mg/kg produced no organ toxicity in dogs. Shock and death have been reported in baby pigs overdosed with tylosin, however.

**Drug Interactions**

Drug interactions with tylosin have not been well documented. It has been suggested that tylosin may increase digoxin blood levels with resultant toxicity. It is suggested to refer to the erythromycin monograph for more information on potential interactions.

**Laboratory Considerations**

- Macrolide antibiotics may cause falsely elevated values of AST (SGOT), and ALT (SGPT) when using colorimetric assays.
- Fluorometric determinations of urinary catecholamines can be altered by concomitant macrolide administration.

**Doses**

**Dogs:**

When using Tylan® Soluble (100 grams per bottle) powder: Using volumetric containers to measure powders is not necessarily accurate, but 1 level teaspoonful (5 mL) of powder contains approximately 2.5–2.7 grams of tylosin; ¼ of a teaspoonful contains approximately 325 mg tylosin.

- a) For small intestinal bacterial overgrowth: 10–20 mg/kg PO q12h; recommended for chronic cases, may require therapy for as long as 6 weeks. (Ludlow & Davenport 2000)
- b) For adjunctive treatment of IBD: 10 mg/kg PO three times daily. Therapeutic trial for 21 days to evaluate efficacy. (Simpson 2003)
- c) For clostridial colitis: 10–40 mg/kg PO twice daily. Practically (using the wettable powder): 1/10th of teaspoon 2–3 times daily for dogs (<7 kg); 1/4th of a teaspoon 2–3 times a day for medium dogs (7–15 kg); and 1/4 teaspoon 2–3 times a day for larger dogs (>15 kg). Mix with food to hide unpleasant taste or put into capsules. Animals with chronic clostridial colitis can often be controlled with one treatment every 2–3 days. (Willard 2006)
- d) For IBD and antibiotic responsive diarrhea: 20–40 mg/kg PO q12h (Marks 2007)
**Dosage Forms/Regulatory Status**

Stability information for this procedure has not been performed.

**Client Information**

Follow veterinarians dosage recommendations carefully.

**Adverse effects**

When administered orally to small animals, tylosin is usually very well tolerated, but contact veterinarian if adverse effects are seen.

**Chemistry/Synonyms**

A macrolide antibiotic related structurally to erythromycin, tylosin is produced from Streptomyces fradiae. It occurs as an almost white to buff-colored powder with a pKa of 7.1. It is slightly soluble in water and soluble in alcohol. Tylosin is considered highly lipid soluble. The tartrate salt is soluble in water. The injectable form of the drug (as the base) is in a 50% propylene glycol solution.

Tylosin may also be known as Desmycoxin, tilosina, tylosin, tilosini, tylosinum, tyloxyra or Tylosı.®

**Storage/Stability**

Unless otherwise instructed by the manufacturer, injectable tylosin should be stored in well-closed containers at room temperature. Tylosin, like erythromycin, is unstable in acidic (pH <4) media. It is not recommended to mix the parenteral injection with other drugs.

**Compatibility/Compounding Considerations**

Because converting volume measurements into weights is not very accurate for powders, it is recommended to actually weigh powders when using them for pharmaceutical purposes. However, if this is not possible, one (1) level teaspoon (5 mL) of commercially-available tylosin tartrate (Tylosı.® Soluble) contains approximately 2.5–2.7 grams of tylosin; ⅛th of a teaspoonful contains approximately 325 mg tylosin.

Tylosin tartrate powder added to food can be very unpalatable for dogs or cats. Placing the proper dose in a gelatin capsule and dosing may be preferable to mixing in food. Another suggestion for dogs or cats that absolutely won’t eat food that has tylosin in it is to: Melt approximately ¼ teaspoon of butter and place in one of the compartments in a mini-ice tray. Add the proper dose of tylosin powder, mix well and freeze. (Note: Stability information for this procedure has not been performed).

**Monitoring**

- Clinical efficacy
- Adverse effects

**Regresses:**

For susceptible infections:

- a) 10 mg/kg PO once to twice daily (Williams 2000)

**Rabbits, Rodents, small mammals:**

a) Rabbits: 10 mg/kg PO, SC, IM q12–24h (Ivey & Morrisey 2000)

b) Gerbils, Hamsters, Rats: 10 mg/kg SC q24h (Adamcak & Otten 2000)

**Cattle:**

For susceptible infections:

a) 17.6 mg/kg IM once daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 5 days. Do not inject more than 10 mL per site. Use the 50 mg/mL formulation in calves weighing less than 200 pounds. (Package insert; Tylosin® Injection—TechAmerica)

b) For bronchopneumonia and fibrinous pneumonia in cattle associated with penicillin G-refractory C. pyogenes infections or other bacteria sensitive to tylosin and resistant to sulfas, penicillin G and tetracyclines: using Tylosin 200 mg/mL; 44 mg/kg IM q24h. Recommend a 21-day slaughter withdrawal at this dosage. (Hjarpe 1986)

c) 5–10 mg/kg IM or slow IV once daily; not to exceed 5 days (Huber 1988)

d) Tylosin base injectable: 10 mg/kg IM initially, then 6 mg/kg IM q8h (q8–12h in calves) (Baggot 1983)

**Swine:**

For susceptible infections:

a) 8.8 mg/kg IM twice daily. Continue treatment for 24 hours after symptoms have stopped, not to exceed 3 days. Do not inject more than 5 mL per site. (Package insert; Tylosin® Injection—TechAmerica)

b) 5–10 mg/kg until 24 hours after remission of disease signs; not to exceed 3 days therapy (Huber 1988)

c) Tylosin base injectable: 12.5 mg/kg IM q12h (Baggot 1983)

**Sheep & Goats:**

For susceptible infections:

a) 10 mg/kg, treatment not to exceed 5 days (Huber 1988)

**Birds:**

For susceptible infections:

a) For initial therapy in caged birds for upper respiratory infections (especially if mycoplasma suspected). Using 200 mg/mL: 40 mg/kg IM. Used in combination with aminoglycosides. (McDonald 1989)

b) For initial therapy of upper respiratory infections and air sacculitis. Using 50 mg/mL or 200 mg/mL injectable: 10–40 mg/kg IM twice daily or three times daily (Clubb 1986)

c) 30 mg/kg IM q12h (Hoeffer 1995)

**Reptiles:**

For susceptible infections:

a) For tortoises: 5 mg/kg IM once daily for at least 10 days. Used primarily for chronic respiratory infections or when Mycoplasma is suspected (Gauvin 1993)

b) All species: 5 mg/kg IM once daily (Jacobson 1999)

**Compatibility/Compounding Considerations**

Because converting volume measurements into weights is not very accurate for powders, it is recommended to actually weigh powders when using them for pharmaceutical purposes. However, if this is not possible, one (1) level teaspoon (5 mL) of commercially-available tylosin tartrate (Tylosı.® Soluble) contains approximately 2.5–2.7 grams of tylosin; ⅛th of a teaspoonful contains approximately 325 mg tylosin.

Tylosin tartrate powder added to food can be very unpalatable for dogs or cats. Placing the proper dose in a gelatin capsule and dosing may be preferable to mixing in food. Another suggestion for dogs or cats that absolutely won’t eat food that has tylosin in it is to: Melt approximately ¼ teaspoon of butter and place in one of the compartments in a mini-ice tray. Add the proper dose of tylosin powder, mix well and freeze. (Note: Stability information for this procedure has not been performed).

**Dosage Forms/Regulatory Status**

Stability information for this procedure has not been performed. (Kilpienn et al. 2009)
The following drug interactions have either been reported or are theoretical in humans or animals receiving ursodiol and may be of significance in veterinary patients:

- May bind to ursodiol, thereby reducing its efficacy
- May bind to ursodiol, thereby reducing its efficacy

Ursodiol is well absorbed from the small intestine after oral administration. In humans, up to 90% of dose is absorbed. After absorption, it enters the portal circulation. In the liver, it is extracted and combined (conjugated) with either taurine or glycine and secreted into the bile. Only very small quantities enter the systemic circulation and very little is detected in the urine. After each entero-hepatic cycle, some quantity of conjugated and free biliary ursodiol is reabsorbed and returned to the liver for metabolism or excretion.

Uses/Indications

In small animals, ursodiol may be useful as an adjunctive therapy for the medical management of cholesterol-containing gallstones and/or in patients with chronic liver disease, particularly where cholestasis (bile toxicity) plays an important role. Ursodiol’s benefit in treating canine or feline hepatobiliary disease is unknown at the time of writing (studies are ongoing), but it may be of help in slowing the progression of inflammatory hepatic disorders, particularly autoimmune hepatitis and acute hepatotoxicity.

Pharmacology/Actions

After oral administration, ursodiol suppresses hepatic synthesis and secretion of cholesterol. Ursodiol also decreases intestinal absorption of cholesterol. By reducing cholesterol saturation in the bile, it is thought that ursodiol allows solubilization of cholesterol-containing gallstones. Ursodiol also increases bile flow and in patients with chronic liver disease, it apparently reduces the hepatocyte toxic effects of bile salts by decreasing their detergent action, and may protect hepatic cells from toxic bile acids (e.g., lithocholate, deoxycholate, and chenodeoxycholate).

Pharmacokinetics

Ursodiol is well absorbed from the small intestine after oral administration. In humans, up to 90% of dose is absorbed. After absorption, it enters the portal circulation. In the liver, it is extracted and combined (conjugated) with either taurine or glycine and secreted into the bile. Only very small quantities enter the systemic circulation and very little is detected in the urine. After each entero-hepatic cycle, some quantity of conjugated and free drug undergoes bacterial degradation; eventually most of the drug is eliminated in the feces after being oxidized or reduced to less soluble compounds. Ursodiol detected in the systemic circulation is highly bound to plasma proteins.

Contraindications/Precautions/Warnings

Ursodiol is contraindicated in rabbits and other hindgut fermenters as it is converted into lithocholic acid (toxic). Patients sensitive to other bile acid products may also be sensitive to ursodiol. The benefits of using ursodiol should be weighed against its risks in patients with complications associated with gallstones (e.g., biliary obstruction, biliary fistulas, cholecystitis, pancreatitis, cholangitis). While ursodiol may be useful in treating patients with chronic liver disease, some patients may experience further impairment of bile acid metabolism.

Adverse Effects

While ursodiol use in animals has been limited, it appears to be well tolerated in dogs and cats. Although hepatotoxicity has not been associated with ursodiol therapy, some human patients have an inability to sulfate lithocholic acid (a naturally occurring bile acid and also a metabolite of ursodiol). Lithocholic acid is a known hepatotoxin; veterinary significance is unclear. Diarrhea and other GI effects have rarely been noted in humans.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category B for use during pregnancy. (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) It is not known whether ursodiol is excreted in breast milk.

Overdosage/Acute Toxicity

Overdosage of ursodiol would most likely cause diarrhea. Treatment, if required, could include supportive therapy; oral administration of an aluminum-containing antacid (e.g., aluminum hydroxide suspension); gastric emptying (if large overdose) with concurrent administration of activated charcoal or cholestyramine suspension.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ursodiol and may be of significance in veterinary patients:

- ALUMINUM-CONTAINING ANTACIDS: May bind to ursodiol, thereby reducing its efficacy
- CHOLESTYRAMINE RESIN: May bind to ursodiol, thereby reducing its efficacy
- TAURINE: Although not documented, concern has been raised that chronic administration of ursodiol in cats may lead to taurine deficiency.
**Pharmacology/Actions**

Serum levels do not accurately reflect clinical efficacy. Clearly, additional studies are needed to determine the clinical role, if any, for this drug.

**Micrograms/mL** may be too high in dogs. The drug (free form) actually may concentrate in the CSF, and anticonvulsant effects may persist even after valproate levels are non-detectable in CSF, lending to the idea that it is of benefit when added to phenobarbital in patients not adequately controlled with that drug alone. Additionally, it is less protein bound in dogs than in humans, so the human serum therapeutic range of the drug (40–100 μg/mL) may be too high in dogs. Cats may still eat their food even if drug is sprinkled on top. (Tams 2000)

**Uses/Indications**

Because of its cost, apparent unfavorable pharmacokinetic profile, and potential hepatotoxicity, valproic acid must be considered at best, a third or fourth line drug in the treatment of seizures in the dog. Some clinicians feel it is of benefit when added to phenobarbital in patients not adequately controlled with that drug alone. Additionally, it is less protein bound in dogs than in humans, so the human serum therapeutic range of the drug (40–100 micrograms/mL) may be too high in dogs. The drug (free form) actually may concentrate in the CSF, and anticonvulsant effects may persist even after valproate levels are non-detectable in CSF, lending to the idea that serum levels do not accurately reflect clinical efficacy. Clearly, additional studies are needed to determine the clinical role, if any, for this drug.
Pharmacology/Actions
The mechanism of the anticonvulsant activity of valproic acid is not understood. Animal studies have demonstrated that valproic acid inhibits GABA transferase and succinic aldehyde dehydrogenase causing increased CNS levels of GABA. Additionally, one study has demonstrated that valproic acid inhibits neuronal activity by increasing potassium conductance.

Pharmacokinetics
Sodium valproate is rapidly converted to valproic acid in the acidic environment of the stomach where it is rapidly absorbed from the GI tract. The bioavailability reported in dogs following oral administration is approximately 80%; peak levels occur in approximately 1 hour. Food may delay absorption, but does not alter the extent of it. Divalproex in its enteric-coated form has an approximately 1-hour delay in its oral absorption. Patients who exhibit GI (nausea, vomiting) adverse effects may benefit from this dosage form.

Valproic acid is rapidly distributed throughout the extracellular water spaces and plasma. It is approximately 80–95% plasma protein bound in humans, and 78–80% plasma protein bound in dogs. CSF levels are approximately 10% those found in plasma; it readily crosses the placenta. Valproic acid is metabolized in the liver and is conjugated with glucuronide. These metabolic conjugates are excreted in the urine; only very small amounts of unchanged drug are excreted in the urine. The elimination half-life in humans ranges from 5–20 hours, in dogs from 1.5–2.8 hours.

Contraindications/Precautions/Warnings
Valproic acid is contraindicated in patients with significant hepatic disease or dysfunction, or exhibiting previous hypersensitivity to the drug. It should be used with caution in patients with thrombocytopenia or altered platelet aggregate function.

Adverse Effects
Because of the limited experience with this agent, the following adverse effects may not be complete nor valid for dogs: Gastrointestinal effects consisting of nausea, vomiting, anorexia, and diarrhea are the most common adverse effects seen in people and also appear, in dogs. GI effects may be diminished by administration with food. Hepatotoxicity is the most serious potential adverse (human) reaction reported and must be considered for canine patients also. Dose related increases in liver enzymes may be seen and, rarely, hepatic failure and death may occur. In humans, incidences of hepatotoxicity are greater in very young (<2 yr. old) patients, those on other anticonvulsants, or with multiple congenital abnormalities.

Other potential adverse effects include: CNS (sedation, ataxia, behavioral changes, etc.), dermatologic (alopecia, rash, etc.), hematologic (thrombocytopenia, reduced platelet aggregation, leukopenias, anemias, etc.), pancreatitis, and edema.

Overdosage/Acute Toxicity
There were 14 exposures to valproic acid/valproate reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 11 were dogs with 1 showing clinical signs and the remaining 3 reported cases were cats that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included sedation.

Severe overdoses can cause profound CNS depression, ataxia, motor restlessness, hallucinations, and death. One human patient recovered after a serum level of 2000 micrograms/mL (20 times over therapeutic) was measured. Treatment consists of supportive measures and maintenance of adequate urine output is considered mandatory. Because the drug is rapidly absorbed, emesis or gastric lavage may be of limited value. Because of its delayed absorptive characteristics, the divalproex form may be removed by lavage or emesis if ingestion occurred recently. Naloxone is reported to be of benefit in reversing some of the CNS effects of valproic acid, but may also reverse the anticonvulsant properties of the drug.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving valproic acid and may be of significance in veterinary patients:

- **ANTICOAGULANTS:** Valproic acid may have effects on platelet aggregation; use with caution with other drugs that affect coagulation status
- **ASPIRIN:** Salicylates may displace valproic acid from plasma protein sites, thus increasing valproic acid levels
- **CLONAZEPAM:** The sedative effects of clonazepam may be enhanced by valproic acid and the anticonvulsant efficacy of both may be diminished
- **CNS DEPRESSANTS, OTHER:** VPA may enhance the CNS depressant effects of other CNS active drugs.
- **PHENOBARBITAL, PRIMIDONE:** Valproic acid may increase serum levels of phenobarbital and primidone

Laboratory Considerations

- A keto-metabolite of valproic acid is excreted into the urine and may yield false positive urine ketone tests.
- Altered thyroid function tests have been reported in humans with unknown clinical significance.

Does
Note: Because of its very short half-life in dogs, most neurologists do not recommend using VPA in dogs.

**DOGS:**

- a) Add on therapy with phenobarbital or bromide: 60 mg/kg PO q8h (Thomas 2000)

Monitoring

- Anticonvulsant efficacy
- If used chronically, routine CBC’s and liver enzymes at least every 6 months

Client Information

- Compliance with therapy must be stressed to clients for successful epilepsy treatment. Encourage administering daily doses at same time each day, preferably with food.
- Veterinarian should be contacted if animal develops significant adverse reactions (including clinical signs of anemia and/or liver disease) or if seizure control is unacceptable.

Chemistry/Synonyms

Structurally unrelated to other anticonvulsant agents; valproic acid, valproate sodium, divalproex sodium are derivatives of carboxylic acid. Valproic acid occurs as a colorless to pale yellow clear liquid. It is slightly viscous; has a characteristic odor, a pKa of 4.8, is slightly soluble in water and freely soluble in alcohol. It is also known as Dipropylacetic acid, DPA, 2-propylpentanoic acid, and 2-propylvaleric acid.

Valproate sodium occurs as a white, crystalline, saline tasting, very hygroscopic powder. It is very soluble in water or alcohol. The commercially available oral solution has a pH of 7–8. Divalproex sodium is a stable compound in a 1:1 molar ratio of valproic acid and valproate sodium. It occurs as a white powder with a characteristic odor. It is insoluble in water and very soluble in alcohol. Valproate sodium may also be known as: Abbott-44906, natrii valproas; many trade names are available.

Valproic acid may also be known as: Abbott-44090, acidum valproicum; many trade names are available.

Storage/Stability

Valproic acid capsules should be stored at room temperature (15–30°C) and in tight containers; avoid freezing. Valproate sodium oral solution should be stored at room temperature and in tight containers; avoid freezing. Divalproex sodium enteric-coated tablets should be stored at room temperature in light, tight resistant containers.
**HUMAN-LABELLED PRODUCTS:**

Valproic Acid Oral Capsules: 250 mg; **Depakene®** (Abbott); generic; (Rx)

Valproate Sodium Syrup: 250 mg/5 mL in 473 mL; **Depakene®** (Abbott); generic; (Rx)

Divalproex Sodium Delayed/Extended Release Tablets/Capsules: 125 mg, 250 mg, 500 mg; **Depakote® & Depakote ER®** (Abbott); **Stavzor®** (Noven); generic; (Rx)

Divalproex Sodium Oral Capsules (Sprinkle): 125 mg; **Depakote®** (Abbott); generic; (Rx)

Valproate Sodium Injection Concentrate: 100 mg/mL in 5 mL single-dose vials (may be preservative free); **Depacon®** (Abbott); generic; (Rx)

**References**

### VANADIUM

**VANADYL SULFATE**

(van-ah-dee-um; van-ah-dil)

*Vanadyl Fuel®*

**TRACE METAL**

**Prescriber Highlights**

- Trace metal “nutraceutical” that may be useful as an adjunctive treatment for diabetes mellitus in cats
- Efficacy questionable, but probably safe

**Uses/Indications**

Vanadium supplementation may be useful in the adjunctive treatment of diabetes mellitus, particularly in cats. There is controversy whether or not this treatment is beneficial.

**Pharmacology/Actions**

In humans with non-insulin dependent diabetes mellitus (NIDDM), vanadium can reduce fasting blood glucose and glycosylated hemoglobin levels, reduces hepatic glucose release, and increases peripheral glucose disposal and uptake into skeletal muscle mediated by insulin. Vanadium does not influence blood glucose levels in normal patients. While the exact mechanism of action of vanadium is unknown, it apparently inhibits protein tyrosine phosphatase (PTP). PTP is important in signal transduction and allows vanadium to act via both insulin-dependent and insulin-independent pathways.

**Pharmacokinetics**

Little information on the pharmacokinetics of vanadium was located. Only about 5% is absorbed from foodstuffs. *In vivo* it is converted to the vanadyl cation and forms complexes with ferritin and transferrin. Highest vanadium concentrations are found in the liver, bone and kidney. Vanadium is eliminated via renal routes. Effects on glucose in NIDDM humans may persist for weeks after discontinuation of therapy.

**Contraindications/Precautions/Warnings**

Vanadium supplements could potentially exacerbate renal insufficiency; use with caution in these patients.

**Adverse Effects**

Gastrointestinal effects have been reported in some cats receiving vanadium supplements; anorexia and vomiting is most commonly reported. It has been reported that cats initially unable to tolerate vanadium, can have therapy re-instituted without ill effect. Vanadium in high dosages may have renal toxic effects.

**Reproductive/Nursing Safety**

It is unknown if supplemental vanadium is safe in pregnancy.

Vanadium is unlikely to have negative effects in nursing kittens.

**Overdosage/Acute Toxicity**

Vanadyl sulfate may be mildly toxic. The oral LD50 in rats is 450 mg/kg. Consider gut removal protocols if an acute overdose occurs. Contact an animal poison control center for further guidance. Chronic overdoses may cause kidney damage.

**Drug Interactions**

- No specific interactions of note were located. When used with other agents for diabetes management, effects may be additive.

**Laboratory Considerations**

- No specific laboratory interactions or considerations were noted

**Doses**

**Note:** Because vanadium is given as a salt, do not confuse dosages for vanadium with vanadyl sulfate. Vanadyl sulfate reportedly contains 31% elemental vanadium, but labeled amounts of vanadium vary considerably.

**CATS:**

a) Using **Super Vanadyl Fuel®** (Twin Labs; also contains chromium): ½ capsule PO once daily with food. (Dowling 2000)

b) For adjunctive use in treating feline type 2 diabetes: Vanadium (Note: salt not specified, assume elemental vanadium) 0.2 mg/kg PO once daily in food or water. (Greco 2002)

c) For diabetes mellitus: Vanadyl sulfate 1 mg/kg PO once daily or vanadium 0.2 mg/kg PO once daily. (Wynn 2002)

d) For early NIDDM using **Vanadyl Fuel®** (Twin Labs; also contains chromium): One capsule PO once daily (q24h) (Melendez & Lorenz 2002)

**Monitoring**

As there is no reliable way to measure vanadium in the body, a clinical trial is the only way to determine whether vanadium is effective in helping to control blood glucose. Standard methods for monitoring efficacy of diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels).

**Client Information**

- Clients should give the medication only as prescribed and not change brands without their veterinarian’s guidance
- Give with food

**Chemistry/Synonyms**

A trace element, vanadium (V, atomic number 23) is usually given in the form of the inorganic salt, vanadyl sulfate. Vanadyl sulfate occurs as blue crystals and is very soluble in water. Vanadyl sulfate reportedly contains 31% elemental vanadium.
Drug Interactions

Intravenous overdoses of vancomycin may cause an increased risk of adverse effects, particularly ototoxicity and nephrotoxicity. Supportive care is advised. Hemodialysis does not appear to remove the drug in

Adverse Effects

When given parenterally, nephrotoxicity and ototoxicity are the most serious potential adverse effects of vancomycin. Unlike aminoglycosides, these effects are believed to be uncommon. In humans, dermatologic reactions and hypersensitivity can occur; it is unknown if these effects are issues for veterinary patients. Reversible neutropenia has been reported in humans, particularly when dosage is high and prolonged.

Contraindications/Precautions/Warnings

Vancomycin should only be used to treat infections that are documented resistant to other antibiotics and susceptible to vancomycin, usually methicillin-resistant

Suspensions are available from a wide variety of sources. Common products include 7.5 mg, and 10 mg tablets or 15 mg capsules. One proprietary product that has been used in cats is Super Vanadyl Fuel® (Twin Labs). This is a combination product that contains per capsule (among many other ingredients): 150 micrograms chromium (from chromium nicotinate and picolinate) and 1.25 mg of elemental vanadium (from BMOV [bi-maltolato oxovanadium] and vanadyl sulfate). Bioequivalence between products cannot be assumed.

References

VANCOMYCIN HCL
(van-koe-my-sin) Vancocin®
GLYCOPOLYPEPTIDE ANTIBIOTIC

Prescriber Highlights

- Glycopeptide antibiotic reserved for IV use for multi-drug resistant Staph or Enterococcus infections; can also be used PO to treat Clostridium difficile diarrhea
- Oral vancomycin is not absorbed systemically and is only useful for treating GI C. difficile overgrowth
- When used systemically, must be given IV; severe pain & tissue injury occurs with SC or IM injection
- May be synergistic with aminoglycoside therapy, but increased risk of nephrotoxicity, ototoxicity & neutropenia also possible
- If decreased renal dysfunction, adjust dosage

Uses/Indications

Vancomycin should only be used to treat infections that are documented resistant to other antibiotics and susceptible to vancomycin, usually methicillin-resistant Staphylococcus spp. (MRSA) or multidrug-resistant Enterococcus spp. It potentially is useful for oral treatment of pseudomembranous colitis caused by Clostridium difficile.

Pharmacology/Actions

Vancomycin inhibits cell-wall synthesis and bacterial cell-membrane permeability. It also affects bacterial RNA synthesis. It is only effective against gram-positive bacteria, including many strains of staphylococci, staphylococci, and enterococci. Vancomycin is generally a bactericidal antibiotic, but is bacteriostatic against enterococci. Vancomycin also has activity against Clostridium difficile, Listeria monocytogenes, Corynebacterium, and Actinomyces spp.. Vancomycin and aminoglycosides can have synergistic action against susceptible bacteria. Pus and cellular debris may bind to vancomycin and reduce its efficacy.

Resistance to vancomycin by certain strains of enterococci and staphylococci is an increasing concern in human medicine and potentially, for veterinary patients.

Pharmacokinetics

When given orally, vancomycin is not appreciably absorbed. After intravenous administration, vancomycin is widely distributed. Therapeutic levels can be found in pleural, ascitic, pericardial, and synovial fluids. At usual serum levels, it does not readily distribute into the CSF.

Contraindications/Precautions/Warnings

Vancomycin is an important antibiotic for treating multi-drug resistant infections in humans. It should not be used in veterinary patients when other antibiotics can be used to successfully treat the infection; some believe that the drug should never be used in veterinary patients. Patients with decreased renal function that require vancomycin should have dosages reduced or dosing interval increased. Serum levels should be monitored.

Adverse Effects

When given parenterally, nephrotoxicity and ototoxicity are the most serious potential adverse effects of vancomycin. Unlike aminoglycosides, these effects are believed to be uncommon. In humans, dermatologic reactions and hypersensitivity can occur; it is unknown if these effects are issues for veterinary patients. Reversible neutropenia has been reported in humans, particularly when dosage is high and prolonged.

Do not administer IV rapidly or as a bolus; thrombophlebitis, severe hypotension or cardiac arrest (rare) have been reported. Vancomycin must be given over at least 30 minutes as a dilute solution.

Do not give IM, SC, or IP. Severe tissue damage and pain may occur.

Oral therapy may cause GI effects (nausea, inappetence).

Reproductive/Nursing Safety

When used orally, vancomycin is relatively safe to use during pregnancy (FDA category B). When used IV, it is not known whether vancomycin can cause fetal harm. A limited study performed in humans did not detect fetal harm, but the numbers studied were small. In humans, the FDA categorizes IV vancomycin as a category C drug for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans.) Because in veterinary patients, vancomycin should only be used for serious infections, the potential benefits of therapy will probably outweigh the risks in most circumstances.

Vancomycin is excreted into milk. Because the drug is not appreciably absorbed, it is unlikely to pose significant harm to nursing animals, although diarrhea could occur.

Overdosage/Acute Toxicity

Patients with colitis associated with Clostridium difficile taking an oral overdose, could potentially absorb enough drug to cause adverse effects. The IV LD50 for vancomycin in mice and rats is 400 mg/kg and 319 mg/kg, respectively. Intravenous overdoses of vancomycin may cause an increased risk of adverse effects, particularly ototoxicity and nephrotoxicity. Supportive care is advised. Hemodialysis does not appear to remove the drug in significant amounts.

Drug Interactions

References

Vancomycin HCl occurs as an odorless, tan to brown free-flowing powder. It is freely soluble in water. A 5% aqueous solution has a pH of 2.5–4.5.

**Storage/Stability**

Vancomycin should be stored at room temperature in tight containers that are protected from light. Once reconstituted (see directions in package insert or in the Doses section), the injectable or oral solutions are stable for 14 days if refrigerated. If diluted further with D5W or sodium chloride 0.9% for parenteral administration, solutions are stable for 24 hours at room temperature and 2 months if refrigerated.

Vancomycin must be prepared immediately before administration to patient, further dilute reconstituted solutions with (at least 100 mL for 500 mg; 200 mL for 1 gram vial) a compatible diluent (e.g., D5W, lactated Ringer’s, 0.9% NaCl).

**Monitoring**

When used parenterally:
- Renal function, baseline and periodic
- Vancomycin levels, maintain trough level above 5 micrograms/mL (some say troughs between 10–15 micrograms/mL)
- Periodic CBC if therapy is prolonged

**Client Information**

- Parenteral vancomycin is used in an inpatient setting
- Oral vancomycin may be used for outpatient therapy; clients should be counseled to give as prescribed
- May give oral dosage forms with a small amount of food

**Chemistry/Synonyms**

A glycopeptide antibiotic, vancomycin HCl may increase the risk of aminoglycoside-related ototoxicity or nephrotoxicity. Because this combination of drugs may be medically required (there is evidence of synergy against staphylococci and enterococci), only enhanced monitoring is suggested.

**Nephrotoxic Drugs, Other** (e.g., amphotericin B, cisplatin): Use with caution with other nephrotoxic drugs

**Laboratory Considerations**

- No specific concerns were noted

**Doses**

To prepare parenteral solution using vancomycin 500 mg or 1 gram powder for injection: Reconstitute the 500 mg for injection vial by adding 10 mL of sterile water for injection. Add 20 mL to the 1 gram vial. Before administering to patient, further dilute reconstituted solutions with (at least 100 mL for 500 mg; 200 mL for 1 gram vial) a compatible diluent (e.g., D5W, lactated Ringer’s, 0.9% NaCl).

**DOGS:**

For susceptible infections:

**Note:** Oral vancomycin is not appreciably absorbed and is only effective for susceptible enteric infections.

a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003)
c) For oral use to treat C. difficile enterocolitis: 10–20 mg/kg PO q6h for 5–7 days; For IV use to treat skin, urinary, soft tissue infections: 10–20 mg/kg IV q12h for 7–10 days; For IV use to treat systemic infections, bacteremia: 15 mg/kg IV q6h for 10 days. (Greene et al. 2006)

**CATS:**

- For susceptible infections:
  a) For confirmed bacteremia/septicemia for enterococci or staphylococci resistant to other commonly used antibiotics: 15 mg/kg IV over 30–60 minutes q6–8h. (Ford 2005)
  b) 15 mg/kg IV over 30–60 minutes q6h. For successful therapy of serious infections, an aminoglycoside such as gentamicin or amikacin should also be administered. (Papich 2003)

**Compatibility/Compounding Considerations**

Vancomycin is compatible with DSW, 0.9% NaCl, and lactated Ringer’s injection.

**Dosages Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Vancomycin HCl Oral Capsules: 125 mg & 250 mg; Vancocin® (ViroPharma); (Rx)
- Vancomycin HCl Powder for Injection Solution: 500 mg, 750 mg, 1 gram, 5 grams, & 10 grams (some preservative free) in single-dose vials, 100 mL pharmacy bulk packagers and premixed 100 mL & 200 mL Galaxy containers; generic; (Rx)

**References**

**Preiser Highlights**

- **Hormone used primarily as a diagnostic agent & sometimes for treatment of diabetes insipidus; it may be useful for the adjunctive treatment of shock syndromes and cardio-pulmonary cerebral resuscitation (CPRC)**
- **Contraindications:** Chronic nephritis until nitrogen retention is resolved to reasonable levels, or patients hypersensitive to it; Caution: Vascular disease, seizure disorders, heart failure, or asthma
- **Adverse Effects:** Local irritation at the injection site (including sterile abscesses), skin reactions, abdominal pain, hematuria, &, rarely, a hypersensitivity (urticarial) reaction
- **Overdosage can lead to water intoxication**
Doses

The following drugs may inhibit the antidiuretic activity of vasopressin:

- **ALCOHOL**
- **DEMECLOCYCLINE**
- **EPINEPHRINE (large doses)**
- **HEPARIN**
- **NOREPINEPHRINE (large doses)**

The following drugs may potentiate the antidiuretic effects of vasopressin:

- **ANTIDEPRESSANTS, TRICYCLIC**
- **CARBAMAZEPINE**
- **CHLORPROPAMIDE**
- **CLOFIBRATE**
- **FLUCONCORTISONE**
- **PHENFORMIN**
- **UREA**

**Uses/Indications**

Vasopressin is used in veterinary medicine as a diagnostic agent and in the treatment of diabetes insipidus in small animals. In recent years, there has been significant interest in using vasopressin for treating shock syndromes and for cardiopulmonary cerebral (CPCR) in humans and animals. In ventricular asystole or pulseless electrical activity, vasopressin has some advantages over epinephrine. Vasopressin can act as a vasoconstricting agent even when acidosis is present and may cause less vasoconstriction of coronary and renal vasculature, thereby increasing myocardial perfusion and does not have the arrhythmogenic or chronotropic effects that are associated with epinephrine. Ongoing research is being conducted.

In human medicine, vasopressin has been used to treat acute GI hemorrhage and to stimulate GI peristalsis. Vasopressin CRI is also being used for treatment of hypotensive septic patients unresponsive to conventional vasopressor. Prior to radiographic procedures, it has been used to dispel interfering gas shadows or help concentrate contrast media.

**Pharmacology**

Vasopressin or antidiuretic hormone (ADH) acts through at least 5 different receptors (three subtypes, V1, V2, V3, the oxytocin receptor, and the puterinergic P2 receptor). It promotes the renal reabsorption of solute-free water in the distal convoluted tubules and collecting duct. ADH increases cyclic adenosine monophosphate (cAMP) at the tubule which increases water permeability at the luminal surface resulting in increased urine osmolality and decreased urine flow. Without vasopressin, urine flow can be increased up to 90% greater than normal.

At doses above those necessary for antidiuretic activity, vasopressin can cause smooth muscle contraction. Capillaries and small arterioles are most affected, with resultant decreased blood flow to several systems. Hepatic flow may actually be increased, however.

Vasopressin can cause contraction of smooth muscle of the bladder and gall bladder and increase intestinal peristalsis, particularly of the colon. Vasopressin may decrease gastric secretions and increase GI sphincter pressure; gastric acid concentration remains unchanged.

Vasopressin possesses minimal oxytocic effects, but at large doses may stimulate uterine contraction. Vasopressin also causes the release of corticotropin, growth hormone, and follicle-stimulating hormone (FSH).

**Pharmacokinetics**

Vasopressin is destroyed in the GI prior to being absorbed and therefore must be administered either intranasally or parenterally. After IM or SC administration in dogs, aqueous vasopressin has antidiuretic activity for 2–8 hours.

Vasopressin is distributed throughout the extracellular fluid. The hormone apparently is not bound to plasma proteins.

Vasopressin is rapidly destroyed in the liver and kidneys. The plasma half-life has been reported to be only 10–20 minutes in humans.

**Contraindications/Precautions/Warnings**

In humans, vasopressin is contraindicated in patients hypersensitive to it or with chronic nephritis until nitrogen retention is resolved to reasonable levels. Because of its effects on other systems, particularly at high doses, vasopressin should be used with caution in patients with vascular disease, seizure disorders, heart failure, or asthma.

**Adverse Effects**

Adverse effects that can be seen include local irritation at the injection site (including sterile abscesses), skin reactions, platelet aggregation, bilirubinemia, abdominal pain, hematuria, and, rarely, a hypersensitivity (urticarial) reaction. Overdosage can lead to water intoxication (see below).

**Reproductive/Nursing Safety**

Although the drug has minimal effects on uterine contractions at usual doses, it should be used with caution in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

**Overdosage/Acute Toxicity**

Early clinical signs of overdose-induced water intoxication can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures, and eventually death. Treatment for mild intoxication is stopping vasopressin therapy and restricting water access until resolved. Severe intoxication may require the use of osmotic diuretics (mannitol, urea, or dextrose) with or without furosemide.

**Drug Interactions**

Note: Because vasopressin tannate in oil is no longer commercially available; most clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.

For adjunctive treatment of shock/CPCR:

- Exogenous vasopressin test: After WDT, empty bladder and start IV catheter and slowly reintroduce water. Give aqueous vasopressin in D5W IV at a dose of 2.5 mU/kg over one hour. To make one liter of a 5 mU/ml solution add 5 Units of vasopressin to one liter of D5W. Empty bladder and collect urine at 30 minutes, 60 minutes, and 90 minutes. If urine specific gravity >1.1015 = ADH-responsive DI; if <1.015 = either nephrogenic DI or medullary washout effect. (Nichols & Miller 1989)

**Doses**

**DOGS:**

As a diagnostic agent after the water deprivation test (WDT): monitor carefully. The WDT is considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin. Refer to a current small animal internal medicine text for further information.

- Exogenous vasopressin test: After WDT, empty bladder and start IV catheter and slowly reintroduce water. Give aqueous vasopressin in D5W IV at a dose of 2.5 mU/kg over one hour. To make one liter of a 5 mU/ml solution add 5 Units of vasopressin to one liter of D5W. Empty bladder and collect urine at 30 minutes, 60 minutes, and 90 minutes. If urine specific gravity >1.1015 = ADH-responsive DI; if <1.015 = either nephrogenic DI or medullary washout effect. (Nichols & Miller 1989)

**Cats:**

As a diagnostic agent after the water deprivation test (WDT): The WDT is generally considered contraindicated in animals that are dehydrated or have known renal disease and is used to characterize whether DI is central or nephrogenic in origin.
a) In patients with vasodilatory shock that is unresponsive to fluid resuscitation and catecholamine (dobutamine, dopamine, and norepinephrine) administration: 0.01–0.04 Units/minute IV.

For CPR with pulseless electrical activity or ventricular asystole, vasopressin may be beneficial for myocardial and cerebral blood flow: 0.2–0.8 Units/kg, IV once. (Note: This reference has a stepwise guidance flowchart for treating vasodilatory shock and CPR with pulseless electrical activity or ventricular asystole that veterinary practices are encouraged to have on hand—Plumb) (Scroggin & Quandt 2009)

For treatment of central diabetes insipidus: [Note: Because vasopressin tannate in oil is no longer commercially available; most clinicians are using desmopressin (DDAVP) for treating central DI. Refer to that monograph for more information.]

Monitoring
- Urine output/frequency
- Water consumption
- Urine specific gravity &/or osmolality

Chemistry/Synonyms
A hypothalamic hormone stored in the posterior pituitary, vasopressin is a 9-amino acid polypeptide with a disulfide bond. In most mammals (including dogs and humans), the natural hormone is arginine vasopressin, while in swine the arginine is replaced with lysine. Lysine vasopressin has only about ½ the antidiuretic activity of arginine vasopressin. The commercially available vasopressin products may be a combination of arginine or lysine vasopressin derived from natural sources or synthetically prepared. The products are standardized by their pressor activity in rats [USP posterior Pituitary (pressor) Units]; their antidiuretic activity can be variable. Commercially available vasopressin has little, if any, oxytocic activity at usual doses.

Vasopressin injection occurs as a clear, colorless or practically colorless liquid with a faint, characteristic odor. Vasopressin is soluble in water.

Vasopressin may also be known as: ADH, antidiuretic hormone, 8-arginine vasopressin, beta-hypophamine, Neo-Lidocat® or Pitressin®.

Storage/Stability
Vasopressin (aqueous) injection should be stored at room temperature; avoid freezing.

Compatibility/Compounding Considerations
If the aqueous injection is to be administered as an intravenous or intra-arterial infusion, it may be diluted in either DSW or normal saline. For infusion use in humans, it is usually diluted to a concentration of 0.1–1 Unit/mL.

Dosage Forms/Regulatory Status
VETERINARY-LABELLED PRODUCTS: None

HUMAN-LABELLED PRODUCTS:

Vasopressin Injection: 20 pressor Units/mL in 0.5 mL, 1 mL & 10 mL vials; Pitressin® Synthetic (JHP Pharm); generic; (Rx)

Vasopressin Tannate Sterile Suspension in oil is no longer commercially available.

References

VECURONIUM BROMIDE
(vek-yew-roe-noo-um) Norcuron®
NONDEPOLARIZING NEUROMUSCULAR BLOCKER

Prescriber Highlights

- Nondepolarizing neuromuscular blocking agent
- Caution: Severe renal dysfunction, hepatic, or biliary disease; extreme caution: myasthenia gravis
- Adverse Effects: None, other than pharmacologic actions
- No analgesia or anesthetic effects

Uses/Indications
Vecuronium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation. It causes very minimal cardiac effects and generally does not cause the release of histamine. Vecuronium has been used topically to cause mydriasis in birds.

Pharmacology/Actions
Vecuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor endplate, thereby inhibiting the effects of acetylcholine. The potency of vecuronium when compared to pancuronium (on a weight basis) has been described as being equipotent to up to 3 times as potent.

Pharmacokinetics
The onset of neuromuscular blockade after IV injection is dependent upon the dose administered. In dogs administered 0.1 mg/kg IV, full neuromuscular block occurs within 2 minutes and the duration of action at this dose is approximately 25 minutes (also receiving halothane anesthesia). Vecuronium has a shorter duration of action than pancuronium (approx. ½ to ½ as long), but is very similar to that of atracurium.

A study done in rats showed that vecuronium was absorbed after intratracheal administration with an onset of action that was slower than intravenous administration, but faster than intramuscular. Intratracheal administration resulted in a longer duration of action then intravenous dosing (Sunaga et al. 2006).

Vecuronium is partially metabolized; it and its metabolites are excreted into the bile and urine. Prolonged recovery times may result in patients with significant renal or hepatic disease.

Contraindications/Precautions/Warnings
Vecuronium is contraindicated in patients hypersensitive to it. It should be used with caution in patients with severe renal dysfunction. Lower doses may be necessary in patients with hepatic or biliary disease. Vecuronium has no analgesic or sedative/anesthetic actions. In patients with myasthenia gravis, neuromuscular blocking agents should be used with extreme caution, if at all. One case of successful use in a dog with myasthenia gravis has been reported.
Adverse Effects
In humans and one limited dog study, adverse effects other than what would be seen pharmacologically (skeletal muscle weakness to profound, prolonged musculoskeletal paralysis) have not been reported.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Overdosage/Acute Toxicity
No cases of vecuronium overdosage have yet been reported (human or veterinary). Should an inadvertent overdose occur, treat conservatively (mechanical ventilation, O2, fluids, etc.). Reversal of blockade might be accomplished by administering an anticholinesterase agent (edrophonium, physostigmine, or neostigmine) with an anticholinergic (atropine or glycopyrrolate). A suggested dose for neostigmine is 0.06 mg/kg IV after atropine 0.02 mg/kg IV.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving vecuronium and may be of significance in veterinary patients:

- **Non-depolarizing muscle relaxant drugs, other:** May have a synergistic effect if used with vecuronium
- **Succinylcholine:** May speed the onset of action and enhance the neuromuscular blocking actions of vecuronium; do not give vecuronium until succinylcholine effects have subsided
- **Aminoglycosides**
- **Anesthetics (Halothane, Isoflurane, Sevoflurane)**
- **Clindamycin, Lincomycin**
- **Dantrolene**
- **Magnesium salts**
- **Piperacillin, Mezlocillin**
- **Quinidine**
- **Tetracyclines**
- **Verapamil**

Dosages

- **DOGS:**
  - a) 0.1 mg/kg IV initially (after meperidine and/or acepromazine pre-op 30 minutes before); may give subsequent incremental doses of 0.04 mg/kg IV. Duration of action after initial dose averages 25 minutes. (Jones & Seymour 1985)
  - b) 10–20 micrograms/kg IV (Morgan 2003)
  - c) If using CRI propofol-fentanyl anesthesia: CRI maintenance infusion rate of vecuronium at 0.2 mg/kg/hr.
    - If using CRI fentanyl-isoflurane or fentanyl-sevoflurane anesthesia: CRI maintenance infusion rate of vecuronium at 0.1 mg/kg/hr. (Nagahama et al. 2006)

- **CATS:**
  - a) 20–40 micrograms/kg (0.02–0.04 mg/kg) IV (Morgan 2003)

Monitoring

- **Level of neuromuscular relaxation**

Client Information

- This drug should only be used by professionals familiar with its use

Chemistry/Synonyms

Structurally similar to pancuronium, vecuronium bromide is a synthetic, nondepolarizing neuromuscular blocking agent. It contains the steroid (androstane) nucleus, but is devoid of steroid activity. It occurs as white to off-white crystals or crystalline powder. In aqueous solution, it has a pKa of 8.97, and the commercial injection has a pH of 4 after reconstitution. 9 mg are soluble in 1 mL of water; 23 mg are soluble in 1 mL of alcohol.

Vecuronium Bromide may also be known as: Org-NC-45, Curlem®, Norcuron®, Rivecuron®, Vecurat®, or Vecuron®.

Storage/Stability

The commercially available powder for injection should be stored at room temperature and protected from light. After reconstitution with sterile water for injection, vecuronium is stable for 24 hours at 2–8°C or at room temperature (less than 30°C) if stored in the original container. As it contains no preservative, unused portions should be discarded after reconstitution. The drug is stable for 48 hours at room temperature or refrigerated when stored in plastic or glass syringes, but the manufacturer recommends that it be used within 24 hours.

Compatibility/Compounding Considerations

Vecuronium bromide has been shown to be physically compatible with D5W, normal saline, D5 in normal saline, and lactated Ringer’s.

It should not be mixed with alkaline solutions (e.g., thiobarbiturates).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Vecuronium Bromide Powder for Injection: 10 mg & 20 mg; in 10 mL & 20 mL vials, with and without diluent; Norcuron® (Organon); generic; (Rx)

References
The following drug interactions have either been reported or are theoretical in humans or animals receiving verapamil and may be of significance in veterinary patients:

**Drug Interactions**

Patients that develop a rapid ventricular rate after verapamil due to antegrade conduction in flutter/fibrillation with WPW syndrome, have been treated with D.C. cardioversion, lidocaine, or procainamide.

**Pressor agents**

Intravenous calcium salts (1 mL of 10% solution per 10 kgs of body weight) have been suggested to treat the negative inotropic clinical signs, but may not adequately treat clinical signs of heart block. Use of fluids and pressor agents (e.g., dopamine, norepinephrine, etc.) may be utilized to treat hypotensive clinical signs. The AV block and/or bradycardia can be treated with isoproterenol, norepinephrine, atropine, or cardiac pacing.

**Overdosage/Acute Toxicity**

Verapamil is potentially a neurotoxic substrate of P-glycoprotein; use with caution in those herding breeds (e.g., Collies) that may have the gene mutation that causes a nonfunctional protein.

**Contraindications/Precautions/Warnings**

Verapamil should be used with caution in patients with heart failure, hypertrophic cardiomyopathy, and hepatic or renal impairment. Toxicity may be potentiated in patients with hepatic dysfunction. It should be used very cautiously in patients with atrial fibrillation and Wolff-Parkinson-White (WPW) syndrome as fatal arrhythmias may result. Verapamil crosses the placenta and milk levels may approach those in the plasma. Verapamil's volume of distribution is between 4.5-7 L/kg in humans and has been reported to be approximately 4.5 L/kg in dogs. In humans, approximately 90% of the drug in the serum is bound to plasma proteins. Use of this combination in patients with wide complex ventricular tachycardia (QRS >0.11 seconds) can cause rapid hemodynamic deterioration and ventricular fibrillation.

Verapamil is contraindicated in the first trimester of pregnancy because it has been shown to have adverse effects on the fetus. Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.

**Reproductive/Nursing Safety**

Verapamil crosses the placenta and can be detected in umbilical vein blood at delivery. In humans, the FDA categorizes this drug as category C for use during pregnancy (Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.)

Verapamil is excreted in milk. Consider discontinuing nursing if the dam requires verapamil therapy.

**Adverse Effects**

The following adverse reactions may occur: hypotension, bradycardia, tachycardia, exacerbation of CHF, peripheral edema, AV block, pulmonary edema, nausea, constipation, dizziness, headache or fatigue.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving verapamil and may be of significance in veterinary patients:

**ACE INHIBITORS**: May cause additive hypotensive effects

**ALPHA-ADRENERGIC BLOCKERS** (e.g., prazosin): May cause additive hypotensive effects

**BETA-ADRENERGIC BLOCKERS** (e.g., propranolol): May cause additive negative cardiac inotrope and chronotrope effects

**DOXORUBICIN**: Verapamil may increase concentrations

**COPP CHEMOTHERAPY** (cyclophosphamide, vincristine, procarbazine, prednisone): May decrease oral absorption of verapamil

**CYCLOSPORINE**: Verapamil may increase levels

**DANTROLENE**: Cardiovascular collapse reported in animals when used with verapamil

**DIGOXIN**: Verapamil may increase the blood levels of digoxin; monitoring of digoxin levels recommended

**DISOPYRAMIDE**: May cause additive effects; impair left ventricular function; use together within 24-48 hours not recommended

**DIURETICS**: May cause additive hypotensive effects

**ERYTHROMYCIN, CLARITHROMYCIN**: May increase verapamil levels

**FLECAINIDE**: Possible additive effects; use in together with verapamil is to be avoided in humans

**NEUROMUSCULAR BLOCKERS**: Neuromuscular blocking effects of nondepolarizing muscle relaxants may be enhanced by verapamil

**PHENOBARBITAL**: May reduce verapamil levels

**QUINIDINE**: Additive alpha-adrenergic blocking activity; increased hypotensive effect; verapamil can block quinidine’s AV conductive effects and increase quinidine levels

**RIFAMPIN**: May reduce verapamil levels

**THEOPHYLLINE**: Verapamil may increase serum levels of theophylline and lead to toxicity
**VINCristine**: Calcium channel blockers may increase intracellular vincristine by inhibiting the drug’s outflow from the cell

**Laboratory Considerations**

- Verapamil may elevate blood glucose in dogs and confuse blood glucose determinations

**Doses**

**DOGS:**

- a) Initial dose of 0.05 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–2 mg/kg PO q8h (Ware 2000)
- b) For treatment of hypertension: 1–5 mg/kg PO q8h (Browd 2002)
- c) For emergency treatment for hemodynamically unstable and sustained (continuous) supraventricular tachycardia: As an alternative to diltiazem, verapamil can be given IV in a series of 0.05 mg/kg boluses IV (slowly) up to a total dose of 0.15 mg/kg. (Smith 2009)
- d) 1–5 mg/kg PO three times daily; 0.05–0.25 mg/kg IV slowly (Kramer 2003)
- e) For the acute termination of supraventricular tachycardia: Initial dose of 0.05 mg/kg should be administered over 1–2 minutes while ECG is monitored; if not effective, may repeat in 5–10 minutes. If arrhythmia still not terminated, may give one last dose of 0.05 mg/kg (total = 0.15 mg/kg). Effect may persist for 30 minutes or less. For longer control, may give as a CRI at 2–10 micrograms/kg/minute. (Kittleson 2006)

**CATS:**

- a) Initial dose of 0.025 mg/kg IV slowly, can repeat every 5 minutes up to a total dose of 0.15–0.2 mg/kg; Oral Dose: 0.5–1 mg/kg PO q8h (Ware 2000)

**HORSES:** (NOTE: ARCI UCFS CLASS 4 DRUG)

- a) To control ventricular rate in atrial fibrillation: 0.025–0.05 mg/kg IV q 30 minutes; give less than 0.2 mg/kg total dose (Reimer 2002)

**SMALL MAMMALS:**

- a) Hamsters: 0.25–0.5 mg (total dose per hamster) SC;
  - Rabbits: 8–16 mg/kg PO + 0.5–2 mg/kg SC once daily (q24h). (Heatley 2009)

**Monitoring**

- ECG
- Clinical signs of toxicity (see Adverse Effects);
- Blood pressure, during acute IV therapy
- Serum concentration, if efficacy or toxicity warrant (100–300 ng/mL is considered therapeutic)

**Client Information**

- To be effective, the animal must receive all doses as prescribed
- If animal becomes lethargic or becomes exercise intolerant, begins wheezing, has shortness of breath or cough, or develops a change in behavior or attitude, notify veterinarian.

**Chemistry/Synonyms**

A calcium channel blocking agent, verapamil HCl occurs as a bitter-tasting, nearly white, crystalline powder. It is soluble in water and the injectable product has a pH of 4–6.5.

**Compatibility/Compounding Considerations**

Verapamil HCl for injection is physically compatible when mixed with all commonly used intravenous solutions. However, a crystalline precipitate may form if verapamil is added to an infusion line with 0.45% sodium chloride with sodium bicarbonate running. Verapamil is reported to be physically compatible with the following drugs: amikacin sulfate, aminophylline, ampicillin sodium, ascorbic acid, atropine sulfate, bretlytoxytate, calcium chloride/glucanate, cefazolin sodium, cephalaxin sodium, cefotaxime sodium, ceftazidime, chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dexamethasone sodium phosphate, diazepam, digoxin, dobutamine HCl (slight discoloration due to dobutamine oxidation), dopamine HCl, epinephrine HCl, furosemide, gentamicin sulfate, heparin sodium, hydrocortisone sodium succinate, metoclopramide HCl, morphine sulfate, nitroglycerin, phentolamine mesylate, phenytoin sodium, potassium chloride/phosphate, procainamide HCl, propranolol HCl, protamine sulphate, quindine gluconate, sodium bicarbonate, sodium nitroprusside, tobramycin sulfate, vasopressin, and Vitamin B complex with C.

The following drugs have been reported to be physically incompatible with verapamil: albumin injection, amphotericin B, hydralazine HCl, and trimethoprim/sulfamethoxazole. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS: None**

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Verapamil HCl Tablets: 20 mg, 40 mg & 120 mg; Calan® (Pfizer); generic; (Rx)

Verapamil HCl Sustained/Extended-Release Tablets/Capsules: 100 mg, 120 mg, 180 mg, 200 mg, 240 mg, 300 mg & 360 mg; Calan® SR & Covera-HS® (Pfizer); Isoptin® SR (FSC Laboratories); Verelan® & Verelan® PM (Schwarz Pharma); generic; (Rx)

Verapamil HCl for Injection: 2.5 mg/mL in 2 mL & 4 mL vials, amps and syringes, 2 mL fill in single-use 2 mL Carpuject & Carpuject Interlink syringes; generic; (Rx)

**References**

**VINBLASTINE SULFATE**

**(vin-blas-ten) Velban®**

**ANTINEOPLASTIC**

**Prescriber Highlights**

- A Vinca alkaloid antineoplastic used for a variety of tumors in dogs (& sometimes cats)
- Contraindications: Preexisting leukopenia or granulocytopenia (unless a result of the disease being treated) or active bacterial infection; reduce dose if hepatic disease
Vinblastine may be employed in the treatment of lymphomas, carcinomas, mastocytomas, and splenic tumors in small animals. It is more effective than vincristine in the treatment of canine mast cell tumors.

**Pharmacology/Actions**
Vinblastine apparently binds to microtubular proteins (tubulin) in the mitotic spindle, thereby preventing cell division during metaphase. It also interferes with amino acid metabolism by inhibiting glutamic acid utilization and preventing purine synthesis, citric acid cycle, and urea formation.

**Adverse Effects**
Vinblastine can cause gastroenterocolitis (nausea/vomiting), which generally lasts less than 24-hours. It can be myelosuppressive at usual dosages (nadir at 4–9 days after treatment; recovery at 7–14 days). Vinblastine is considered more myelosuppressive than is vincristine.

Vinblastine may not possess the degree of peripheral neurotoxic effects seen with vincristine, but at high doses, these effects may be seen. Additionally, vinblastine may cause constipation, alopecia, stomatitis, ileus, inappropriate ADH secretion, jaw and muscle pain, and loss of deep tendon reflexes.

Cats can develop neurotoxicity causing constipation or paralytic ileus and aggravating anorexia; they may develop reversible axon swelling and paranodal demyelination.

Extravasation of vinblastine may cause significant tissue irritation and cellulitis. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw the drug from the vial. Should clinical signs of extravasation be noted, discontinue infusion immediately at that site and apply moderate heat to the area to help disperse the drug. Injections of hyaluronidase have also been suggested to help diffuse the drug.

**Contraindications/Precautions/Warnings**
Vinblastine is contraindicated in patients with preexisting leukopenia or granulocytopenia (unless a result of the disease being treated), or active bacterial infection.

Doses of vinblastine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dL.

Because vinblastine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies) that may have the gene mutation (MDR1; ABCB1) that causes a nonfunctional protein. Bone marrow suppression (decreased blood cell counts, particularly neutrophils) and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the ABCB1 mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25-30% and carefully monitoring these patients (WSU-VetClinPharmLab 2009).

As vinblastine may be a skin irritant, gloves and protective clothing should be worn when preparing or administering the drug. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

**Exercise Precautions**
Vinblastine may significantly increase both blood and urine concentrations of uric acid.

**Notes**
Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages are provided for general guidance only. Consultation with a veterinary oncologist and referral to current veterinary oncology references is recommended.

**Usages/Indications**

- **Gastroenterocolitis**
- **Myelosuppression**
- **Alopecia**
- **Stomatitis**
- **Ileus**
- **Inappropriate ADH Secretion**
- **Jaw & Muscle Pain**
- **Loss of Deep Tendon Reflexes**
Vincristine is administered IV as it is unpredictably absorbed from the GI tract. After injection it is rapidly distributed to tissues. In humans, approximately 75% is bound to tissue proteins and the drug does not appreciably prevent purine synthesis, citric acid cycle and urea formation. Tumor resistance to one Vinca alkaloid does not imply resistance to another.

Uses/Indications

A Vinca alkaloid antineoplastic used for a variety of tumors in dogs & cats (primarily lymphoid & hematopoietic neoplasms); also used for the treatment of immune-mediated thrombocytopenia

Caution: Hepatic disease, leukopenia, infection, or preexisting neuromuscular disease; reduce dose if hepatic disease

Adverse Effects: Much less myelosuppressive than vinblastine, but may cause more peripheral neurotoxic effects; neuropathic clinical signs can include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation; Can develop neurotoxicity causing constipation or paralytic ileus & aggravating anorexia; can also develop reversible axon swelling & paranodal demyelination

Potentially teratogenic

Avoid extravasation; wear gloves & protective clothing when preparing or administering

Drug Interactions

Avoid extravasation; wear gloves & protective clothing when preparing or administering

References

Vincristine is administered IV as it is unpredictably absorbed from the GI tract. After injection it is rapidly distributed to tissues. In humans, approximately 75% is bound to tissue proteins and the drug does not appreciably enter the CNS.

Vincristine is extensively metabolized, presumably by the liver and primarily excreted in the bile/feces; lesser amounts are eliminated in the urine. The elimination half-life in dogs is reportedly biphasic with an alpha half-life of 13 minutes and a beta half-life of 75 minutes.

Contraindications/Precautions/Warnings
Vincristine should be used with caution in patients with hepatic disease, leukopenia, infection, or preexisting neuromuscular disease.

Doses of vincristine should be reduced in patients with hepatic disease. A 50% reduction in dose should be considered if serum bilirubin levels are greater than 2 mg/dL.

Because vincristine is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies) that may have the gene mutation that causes a nonfunctional protein. Bone marrow suppression (decreased blood cell counts, particularly neutrophils) and GI toxicity (anorexia, vomiting, diarrhea) are more likely to occur at normal doses in dogs with the ABCB1 mutation. To reduce the likelihood of severe toxicity in these dogs (mutant/normal or mutant/mutant), the Veterinary Clinical Pharmacology Laboratory at Washington State University recommends reducing the dose by 25-30% and carefully monitoring these patients (WSU-VeClinPharmLab 2009).

As vincristine may be a skin irritant, gloves and protective clothing should be washed thoroughly when preparing to administer the medication. If skin/mucous membrane exposure occurs, thoroughly wash area with soap and water.

Adverse Effects
Although structurally related to and having a similar mechanism of action as vinblastine, vincristine has a different adverse reaction profile. Vincristine is much less myelosuppressive (mild leukopenia) at usual doses than is vinblastine, but may cause more peripheral neurotoxic effects. Neuropathic clinical signs may include proprioceptive deficits, spinal hyporeflexia, or paralytic ileus with resulting constipation. In humans, vincristine commonly causes mild sensory impairment and peripheral paresthesias. These may also occur in animals, but are not usually noted due to difficulty in detection. Cats, however, can develop neurotoxicity that can be associated with constipation or paralytic ileus thereby aggravating anorexia. They can develop reversible axon swelling and paranodal demyelination.

Additionally, in small animals, vincristine may cause impaired platelet aggregation, increased liver enzymes, inappropriate ADH secretion, jaw pain, alopecia, stomatitis, or seizures.

A case report of cat developing pulmonary edema attributed to vincristine administration has been published (Polton & Elwood 2008).

Extravasation injuries associated with perivascular injection of vincristine can range from irritation to necrosis and tissue sloughing. Because of the vesicant action of this drug, it is recommended to use a different needle for injecting the drug than the one used to withdraw it from the vial. Recommendations for therapy for extravasation include discontinuing the infusion immediately at that site and applying moderate heat to the area to help disperse the drug. Injections of hyaluronidase have been suggested to help diffuse the drug. Others have suggested applying ice to the area to limit the drug’s diffusion and minimize the area affected. Topical dimethyl sulfoxide (DMSO) has also been recommended by some to treat the area involved.

Reproductive/Nursing Safety
Little is known about the effects of vincristine on developing fetuses, but it is believed that the drug possesses some teratogenic and embryotoxic properties. It may also cause aspermia in males. In humans, the FDA categorizes this drug as category D for use during pregnancy (There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (These drugs may have potential risks or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.) It is not known whether this drug is excreted in milk. Because of the potential for serious adverse reactions in nursing offspring, consider using milk replacer if dams are being given this drug.

Overdosage/Acute Toxicity
In dogs, it is reported that the maximally tolerated dose of vincristine is 0.06 mg/kg every 7 days for 6 weeks. Animals receiving this dose showed signs of slight anemia, leukopenia, increased liver enzymes, and neuronal shrinkage in the peripheral and central nervous systems.

In cats, the lethal dose of vincristine is reportedly 0.1 mg/kg. Cats receiving toxic doses showed clinical signs of weight loss, seizures, leukopenia, and general debilitation. A case report of cat receiving a 10X overdose (5 mg/m²) has been published (Hughes et al. 2009). Despite intensive treatment including using calcium folinate, the cat died 72 hours after the overdose.

In humans, cardiovascular and hematologic monitoring are performed after an overdose. Treatment can include anticonvulsants, and prevention of ileus. Additionally, an attempt is made to prevent the effects associated with the syndrome of inappropriate antidiuretic hormone (SIADH) with fluid restriction and loop diuretics to maintain serum osmolality. There have been some reports of leucovorin calcium being used to treat vincristine overdoses in humans, but efficacy of this treatment has not yet been confirmed.

Drug Interactions
The following drug interactions have either been reported or are theoretical in humans or animals receiving vincristine and may be of significance in veterinary patients:

ASPARGINASE: Additive neurotoxicity may occur; is apparently less common when asparaginase is administered after vincristine

MITOMYCIN: In humans who have previously or simultaneously received mitomycin-C with Vinca alkaloids, severe bronchospasm has occurred

Caution is advised if using other drugs that can inhibit P-glycoprotein particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”), unless tested “normal”. Drugs and drug classes involved include:

AMIODARONE
AZOLE ANTIFUNGALS (e.g., ketoconazole)
CARVEDILOL
CYCLOSPORINE
DILTIAZEM
ERYTHROMYCIN; CLARITHROMYCIN
QUINIDINE
SPIRONOLACTONE
TAMOXIFEN
VERAPAMIL

Laboratory Considerations
• Vincristine may significantly increase both blood and urine concentrations of uric acid

Doses
Note: Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle et al. 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2003)] are strongly recommended.

DOGS:
For neoplastic diseases (usually used in combination protocols with other drugs; consultation with a veterinary oncologist is encouraged before use; see above): Vincristine is usually dosed in dogs at 0.5–0.75 mg/m² (NOT mg/kg) IV and administered every 1–2 weeks. When used for transmissible venereal tumor, vincristine is used as sole therapy usually at 0.5 mg/m² (maximum dose 1 mg) IV once weekly for 4-6 weeks of therapy.

For adjunctive treatment of immune-mediated thrombocytopenia:

a) 0.5 mg/m² IV if platelet count <10,000,000 cells/mcL or bleeding; consider bone marrow aspiration to document presence of megakaryocytes. (Saxon 2008)

b) If refractory to prednisone (3–5 days), give vincristine at 0.5–0.7 mg/m² IV bolus or as an infusion over 4–6 hours. (Trepanier 1999)

c) 0.02 mg/kg IV once; generally single use (Cohn 2004)

CATS:
For neoplastic diseases; (consultation with a veterinary oncologist is encouraged before use; see above): Vincristine is usually dosed in cats at 0.5–0.75 mg/m² (NOT mg/kg) IV and administered every 1-3 weeks.

HORSES:
For neoplastic diseases; (consultation with a veterinary oncologist is encouraged before use; see above): Vincristine is usually dosed in horses at 0.5–0.75 mg/m² (NOT mg/kg) IV and administered every 1-3 weeks.
a) Usual doses used in horses are: 0.5 mg/m² (usually 2.5–3 mg total dose per horse) IV weekly. For generalized lymphoma the CAP protocol was used at the time of publication by one of the authors: cytarabine (cytosine arabinoside) at an average dose of 1–1.2 grams (total dose), SC or IM once every 1–2 weeks; cyclophosphamide at a dose of 1 gram (total dose) IV every 2 weeks (alternating with cytarabine); and prednisolone at a dose of 1 mg/kg PO every other day. Vincristine at 2.5 mg (total dose) IV is added on the weeks when the cytarabine is administered if there is no response. These are starting doses; the total doses can be increased by 20–30% without expecting complications. With remission, the starting doses are maintained for 2–3 months and then the horse is switched onto a maintenance protocol. The first cycle of maintenance therapy increases the treatment interval for each drug by one week (except prednisolone which is kept at the same frequency but with a reducing dose). If horse is still in remission after 2–3 months of the first cycle, the second cycle is begun by adding a further week to the treatment intervals of each drug. (Mair & Couto 2006)

Monitoring

- Efficacy (tumor burden reduction or platelet count)
- Toxicity (peripheral neuropathic clinical signs; complete blood counts with platelets; liver function tests prior to therapy and repeated as necessary; serum uric acid)

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Clients should contact the veterinarian if the patient exhibits any signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising, severe constipation, or severe peripheral neuropathic signs
- Avoid contact with treated patient’s urine, saliva or feces after treatment. Vincristine or metabolites have been detected in dogs’ urine up to 7 days after treatment.

Chemistry/Synonyms

Commonly referred to as a Vinca alkaloid, vincristine sulfate is isolated from the plant _Catharanthus roseus_ ( _Vinca rosea_ Linn) and occurs as a white or slightly yellow, hygroscopic, amorphous or crystalline powder that is freely soluble in water and slightly soluble in alcohol. The commercially available injection has a pH of 3.5–5.5. Vincristine sulfate has pKas of 5 and 7.4

Vincristine Sulfate may also be known as: leurocristine sulfate, VCR, LCR compound 37231, leurocristine sulphate, NSC-67574, 22-oxovincaleukoblastine sulphate, sulfato de vincristina, vincristini sulfas and Oncovil®; many other trade names are available.

Storage/Stability

Vincristine sulfate injection should be protected and stored in the refrigerator (2–8°C).

Compatibility/Compounding Considerations

Vincristine sulfate is reportedly physically compatible with the following intravenous solutions and drugs: D5W, bleomycin sulfate, cytarabine, fluorouracil, and methotrexate sodium. In syringes or at Y-sites with: bleomycin sulfate, cisplatin, cyclophosphamide, doxorubicin HCl, droperidol, fluorouracil, heparin sodium, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, and vinblastine sulfate.

Vincristine sulfate is reportedly physically incompatible with furosemide. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

Vincristine Sulfate Injection: 1 mg/mL in 1 mL, 2 mL & 5 mL vials and flip-top vials; Vincasar® PFS (Sicor); generic; (Rx)

References

Other top dress equine products containing Vitamin E and Selenium include: Vitamin E and Selenium Powder (Farnam, Horse Health), approved for oral use in horses.

**Vitamin E/Selenium Oral**

- **Vitamin E Injection**: 300 mg/mL in 250 mL vials;
- **Vitamin E (Alone) Injection**

**VETERINARY-LABELED PRODUCTS:**

**Dosage Forms/Regulatory Status**

Vitamin E/Selenium for injection should be stored at temperatures less than 25°C (77°F).

**Chemistry/Synonyms**

Vitamin E is a lipid soluble vitamin that can be found in either liquid or solid forms. The liquid forms occur as clear, yellow to brownish red, viscous oils that are insoluble in water, soluble in alcohol and miscible with vegetable oils. Solid forms occur as white to tan-white granular powders that disperse in water to form cloudy suspensions. Vitamin E may also be known as alpha tocopherol.

Large overdoses of vitamin E can cause coagulopathies.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving vitamin E/selenium and may be of significance in veterinary patients:

- **IRON**: Large doses of vitamin E may delay the hematologic response to iron therapy in patients with iron deficiency anemia.
- **MINERAL OIL**: May reduce the absorption of orally administered vitamin E
- **VITAMIN A**: Absorption, utilization and storage may be enhanced by vitamin E
- **WARFARIN**: Vitamin E may increase the effects of warfarin

**Doses (Vitamin E alone):**

For doses of vitamin E/selenium products see the Dosage Form section

**DOGS:**

- For treatment of discoid lupus erythematosus, canine demodicosis or acanthosis nigricans:
  a) 200–400 Units PO three times daily; variable efficacy, but relatively innocuous at these dosages (White 2000)
  For adjunctive treatment of cholestatic hepatopathies; necro-inflammatory hepatopathies:
  a) 10–15 Units/kg per day PO as alpha-tocopherol acetate. (Webster & Cooper 2009)
  For adjunctive treatment of copper-associated hepatopathy:
  a) 400–600 Units PO per day (Johnson, S. 2000)
  For treatment of tocopherol deficiency associated with exocrine pancreatic disease:
  a) 100–400 Units PO once daily for one month then every 1–2 weeks as needed (Williams 2000)

**CATS:**

- For treatment of tocopherol deficiency associated with exocrine pancreatic disease:
  a) 30 Units PO once daily for one month then every 1–2 weeks as needed (Williams 2000)
  For adjunctive treatment of hepatic lipodosis:
  a) 10 Units/kg once PO once daily. (Scherk & Center 2005)

**HORSES:**

- For adjunctive treatment of ionophore (monensin) toxicity:
  a) 4–12 Units/kg PO once daily (Mogg 1999)
  For adjunctive therapy for EPM:
  a) 8000–9000 Units PO per day (Dowling 1999)
  For adjunctive therapy for metabolic syndrome:
  a) 10,000 Units PO once daily (Johnson, P. 2003)
  For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):
  a) Foals: 4,000 Units PO once daily; Mares: 10,000 Units PO once daily (Slivovis 2003)

**Monitoring**

- **Clinical efficacy**
- **Blood selenium levels (when using the combination product). Normal values for selenium have been reported as: >1.14 micromol/L in calves, >0.63 micromol/L in cattle, >1.26 micromol/L in sheep, and >0.6 micromol/L in pigs. Values indicating deficiency are: <0.40 micromol/L in cattle, <0.60 micromol/L in sheep, and <0.20 micromol/L in pigs. Intermediate values may result in suboptimal production**
- **Optionally, glutathione peroxidase activity may be monitored**

**Chemistry/Synonyms**

Vitamin E is a lipid soluble vitamin that can be found in either liquid or solid forms. The liquid forms occur as clear, yellow to brownish red, viscous oils that are insoluble in water, soluble in alcohol and miscible with vegetable oils. Solid forms occur as white to tan-white granular powders that disperse in water to form cloudy suspensions. Vitamin E may also be known as alpha tocopherol.

Selenium in commercially available veterinary injections is found as sodium selenite. Each mg of sodium selenite contains approximately 460 micrograms (46%) of selenium.

**Pharmacokinetics**

Absorption, utilization and storage may be enhanced by vitamin E

Vitamin E may increase the effects of warfarin

Large doses of vitamin E may delay the hematologic response to iron therapy in patients with iron deficiency anemia.

**VETERINARY-LABELED PRODUCTS:**

- **Vitamin E Injections:**

  For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):
  a) Foals: 4,000 Units PO once daily; Mares: 10,000 Units PO once daily (Slivovis 2003)

**Vitamin E/Selenium Crumbles**

- **Equ-Se5E® (one teaspoonful contains 1 mg selenium and 220 Units vitamin E) and Equ-Selenium Crumbles® (one teaspoonful contains 1 mg selenium and approximately 1100 Units vitamin E); (Vet-a-Mix); (OTC or Rx) FDA-approved for oral use in horses.

**Vitamin E and Selenium Powder** (Farnam, Horse Health), approved for oral use in horses.

**Vitamin E and Selenium Crumbles® (Horse Health)**

**Vitamin A:**

- For adjunctive treatment of perinatal asphyxia syndrome (hypoxic ischemic encephalopathy):
  a) Foals: 4,000 Units PO once daily; Mares: 10,000 Units PO once daily (Slivovis 2003)

**Warfarin:**

- For adjunctive treatment of hepatic lipidosis:
  a) 10 Units/kg once PO once daily. (Scherk & Center 2005)

**Storage/Stability**

Vitamin E/Selenium for injection should be stored at temperatures less than 25°C (77°F).

**Dosage Forms/Regulatory Status**

**Vitamin E (Alone) Injection**

Vitamin E Injection: 300 mg/mL in 250 mL vials; Emulsivo® E-300 (Vedco); Vital E®-300 (Schering-Plough); (OTC or Rx)

**Vitamin E/Selenium Oral**

**Emulsivit® (Vet-A-Mix)** (one teaspoonful contains 1 mg selenium and 220 Units vitamin E) and **Equ-Se5E®** (one teaspoonful contains 1 mg selenium and approximately 1100 Units vitamin E); (Vet-a-Mix); (OTC) FDA-approved for oral use in horses.

Other top dress equine products containing Vitamin E and Selenium include: Vitamin E and Selenium Powder (Farnam, Horse Health), **Vitamin E and Selenium Crumbles® (Horse Health)**

**Other top dress equine products containing Vitamin E and Selenium include:**

- **Vitamin E and Selenium Powder** (Farnam, Horse Health)
- **Vitamin E and Selenium Crumbles® (Horse Health)**

**Contraindications/Precautions/Warnings**

Vitamin E/Selenium products should only be used in the species for which they are FDA-approved. Because selenium can be extremely toxic, the promiscuous use of these products cannot be condoned.
Voriconazole is a synthetic derivative of flavocazole, has broad-spectrum antifungal activity against a variety of organisms, including Candida, Aspergillus, Trichosporon, Histoplasma, Cryptococcus, Blastomyces, and Fusarium species. Like the other azole/triazole antifungals it inhibits cytochrome P-450-dependent 14-alpha-sterol demethylase that is required for ergosterol biosynthesis in fungal cell walls. Unlike fluconazole, voriconazole also inhibits 24-methylene dehydrosterol demethylation in molds such as Aspergillus giving it more activity against these fungi.

**Uses/Indications**
Voriconazole may be a useful treatment for a variety of fungal infections in veterinary patients, particularly against Blastomyces, Cryptococcus, and Aspergillus. It has high oral bioavailability in a variety of species and can cross into the CNS. Currently available human dosage forms are extremely expensive, however, and little clinical experience has occurred using voriconazole in veterinary patients. There is considerable interest in using voriconazole for treating aspergillosis in pet birds as their relative small size may allow the drug to be affordable; additional research must be performed before dosing regimens are available.

**Pharmacology/Actions**
Voriconazole is a broad-spectrum oral/parenteral triazole antifungal. It is very little clinical experience thus far in veterinary medicine; extremely expensive.

**VORICONAZOLE**
(2R,4S,5R)-4-[4-(4-Chlorophenyl)-1,2-4,5-tetrahydro-3,5-dihydroimidazol-2-yl]-3-piperidinyl-1-hydroxybenzimidazole oxalate (HCl) Lables:ивидекс® (Schering); (Rx): Each ml contains: selenium 0.25 mg (as sodium selenite) and Vitamin E 68 Units in 30 mL vials FDA-approved for use in dogs. Dose: Dogs: Initial, 1ml per 20 lbs of body weight minimum (0.25 mL); maximum (5 mL SC), or IM in divided doses in 2 or more sites. Repeat dose at 3 days intervals until satisfactory results again. If no response in 14 days reevaluate. Maintenance dose: 1 ml per 40 lbs body weight (minimum 0.25 mL) repeat at 3–7 day intervals (or longer) to maintain.

**HUMAN-LABELED PRODUCTS:**
Vitamin E Tablets: 100 Units, 200 Units, 400 Units, 500 Units & 800 Units; generic (various; OTC)

**References**
The Veterinary Clinics of North America: Equine Practice, 15:3

Voriconazole tablets should be stored at 15–30°C. The unreconstituted powder for oral suspension should be stored in the refrigerator (2–8°C); it has a shelf-life of approximately 18 months. Once reconstituted, it should be stored in tightly closed containers at room temperature (15–30°C); do not refrigerate or freeze. After reconstitution, the suspension is stable for 14 days. The suspension should be shaken well for 10 seconds prior to each administered dose.

**Chemistry/Synonyms**

A triazole antifungal, voriconazole occurs as a white to light colored powder with a molecular weight of 349.3. Aqueous solubility is 0.7 mg/mL.

**Doses**

**DOGS:**
- For coccidioidomycosis: 4 mg/kg PO q12h. (Graupmann-Kuzma et al. 2008)
- For avian aspergillosis: 12.5 mg/kg PO twice daily for 60-90 days or by nebulization as a 1 mg/mL solution for 60 minutes once daily. (Black 2008)
- Studies were necessary to determine safety and efficacy of long-term treatment (Guzman 2008)

**CATS:**
- From a published case report in 3 cats: Two of the cats were treated with oral voriconazole for orbital aspergillosis initially at 10 mg/kg PO once daily. Both responded to treatment, but significant systemic reactions were noted. Authors concluded that based on their experience, voriconazole should be used with caution as adverse side effects may be common. (Smith & Hoffman 2010)

**HORSES:**
- Based upon pharmacokinetic studies, doses of 3 mg/kg PO q24h should be sufficient to treat aspergillosis, but higher doses (4–5 mg/kg) are probably necessary to treat infections with *Fusarium* spp. However, clinical experience is lacking, and the drug is currently too expensive for practical use. (Davis 2008)

**BIRDS:**
- Based upon this pharmacokinetic study in Hispaniolan Amazon parrots the authors concluded that the drug could be safely administered to this species at a dose of 18 mg/kg PO q8h for 11 days, but that further studies were necessary to determine safety and efficacy of long-term treatment (Guzman et al. 2010).
- For avian aspergillosis: 12.5 mg/kg PO twice daily for 60-90 days or by nebulization as a 1 mg/mL solution for 60 minutes once daily. (Black 2008)

**Monitoring**

- Efficacy
- Liver function tests, serum electrolytes

**Client Information**

- Inform clients of the investigational nature of using this drug in veterinary species and the associated expense
- Give at least one hour before or one hour after feeding
- Because experience with this medication has been limited, report any possible adverse effects to the veterinarian immediately, including itching/rash, yellowing of whites of the eyes, reduced appetite, difficulty walking, vision problems, etc.

**Chemistry/Synonyms**

A triazole antifungal, voriconazole occurs as a white to light colored powder with a molecular weight of 349.3. Aqueous solubility is 0.7 mg/mL.

Voriconazole may also be known as UK-109496, voriconazol, voraconazolum, or Vfend®.

**Storage/Stability**

Voriconazole tablets should be stored at 15–30°C. The unreconstituted powder for oral suspension should be stored in the refrigerator (2–8°C); it has a shelf-life of approximately 18 months. Once reconstituted, it should be stored in tightly closed containers at room temperature (15–30°C); do not refrigerate or freeze. After reconstitution, the suspension is stable for 14 days. The suspension should be shaken well for 10 seconds prior to each administered dose.
Use with caution in nursing patients.

Reproductive/Nursing Safety

The principal adverse effect of warfarin use is dose-related hemorrhage, which may manifest with clinical signs of anemia, thrombocytopenia, weakness, hematomas and ecchymoses, epistaxis, hematemesis, hematuria, malignant hypertension, hepatic insufficiency, pericardial effusion, pregnancy, and visceral carcinomas.

Contraindications/Precautions/Warnings

Warfarin is contraindicated in patients with preexistent hemorrhagic tendencies or diseases, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, surgery of large, open surfaces, active bleeding from the GI, respiratory, or GU tract; aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, & visceral carcinomas.

Adverse Effects: Dose-related hemorrhage

Teratogenic; contraindicated in pregnancy

Must actively monitor coagulation status

Many potentially significant drug interactions

Uses/Indications

In veterinary medicine, warfarin is used primarily for the oral, long-term treatment (or prevention of recurrence) of thrombotic conditions, primarily in cats, dogs, or horses. Use of warfarin in veterinary species is somewhat controversial and due to unproven benefit in reducing mortality, increased expense associated with monitoring, and potential for serious effects (bleeding), many do not recommend its use.

Pharmacology/Actions

Warfarin acts indirectly as an anticoagulant (it has no direct anticoagulant effect) by interfering with the action of vitamin K1 in the synthesis of the coagulation factors II, VII, IX, and X. Sufficient amounts of vitamin K1 can override this effect. Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. The S enantiomer is a significantly more potent vitamin K antagonist than the R enantiomer in species studied.

Pharmacokinetics

Warfarin is administered as a racemic mixture of S (+) and R (-) warfarin. Warfarin is rapidly and completely absorbed in humans after oral administration. In cats, warfarin is also rapidly absorbed after oral administration. After absorption, warfarin is highly bound to plasma proteins in humans, with approximately 99% of the drug bound. In cats, more than 96% of the drug is protein bound. It is reported that there are wide species variations with regard to protein binding; horses have a higher free (unbound) fraction of the drug than do rats, sheep or swine. Only free (unbound) warfarin is active. While other coumarin and indanedione anticoagulants are distributed in milk, warfarin does not enter milk in humans.

Warfarin is principally metabolized in the liver to inactive metabolites that are excreted in urine and bile (and then reabsorbed and excreted in the urine). The plasma half-life of warfarin may be several hours to several days, depending on the patient (and species?). In cats, the terminal half-life of the S enantiomer is approximately 23–28 hours and the R enantiomer approximately 11–18 hours.

Contraindications/Precautions/Warnings

Warfarin is contraindicated in patients with preexistent hemorrhagic tendencies or diseases, those undergoing or contemplating eye or CNS surgery, major regional lumbar block anesthesia, or surgery of large, open surfaces. It should not be used in patients with active bleeding from the GI, respiratory, or GU tract. Other contraindications include: aneurysm, acute nephritis, cerebrovascular hemorrhage, blood dyscrasias, uncontrolled or malignant hypertension, hepatic insufficiency, pericardial effusion, pregnancy, and visceral carcinomas.

Adverse Effects

The principal adverse effect of warfarin use is dose-related hemorrhage, which may manifest with clinical signs of anemia, thrombocytopenia, weakness, hematomas and ecchymoses, epistaxis, hematemeses, hematuria, melena, heematochezia, hemarthrosis, hemotheroras, intracranial and/or pericardial hemorrhage, and death.

Reproductive/Nursing Safety

Warfarin is embryotoxic, can cause congenital malformations and considered contraindicated during pregnancy. If anticoagulant therapy is required during pregnancy, most clinicians recommend using low-dose heparin. In humans, the FDA categorizes this drug as category X for use during pregnancy (Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1988), this drug is categorized as in class D (Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.) Based on very limited published data, warfarin has not been detected in the breast milk of humans treated, but there are reports of some breast-fed infants whose mothers were treated having prolonged prothrombin times. Use with caution in nursing patients.
Overdosage/Acute Toxicity

Acute overdosages of warfarin may result in life-threatening hemorrhage. In dogs and cats, single doses of 5–50 mg/kg have been associated with toxicity. It must be remembered that a lag time of 2–5 days may occur before signs of toxicity occur, and animals must be monitored and treated accordingly.

Cumulative toxic doses of warfarin have been reported as 1–5 mg/kg for 5–15 days in dogs and 1 mg/kg for 7 days in cats.

If overdosage is detected early, prevent absorption from the gut using standard protocols. If clinical signs are noted, they should be treated with blood products and vitamin K1 (phytonadione). Refer to the phytonadione monograph for more information.

Drug Interactions

Drug interactions with warfarin are perhaps the most important in human medicine. The following drug interactions have either been reported or are theoretical in humans or animals receiving warfarin and may be of significance in veterinary patients:

A multitude of drugs have been documented or theorized to interact with warfarin. The following drugs or drug classes may increase the anticoagulant response of warfarin (not necessarily complete):

- ACETAMINOPHEN
- ALLOPURINOL
- AMIODARONE
- ANABOLIC STEROIDS
- AZITHROMYCIN
- CIMETIDINE
- CISAPRIDE
- CO-TRIMOXAZOLE (trimethoprim/sulfa)
- DANAZOL
- DIAZoxide
- ERYTHROMYCIN
- ETHACRYNIC ACID
- FLUOROQUINOLONES
- FLUOXETINE
- HEPARIN
- METRONIDAZOLE
- NSAIDS
- PENTOXIFYLLINE
- PROPYLEThOURACIL
- QUINIDINE
- SALICYLATES
- SERTRALINE
- SULFONAMIDES
- THYROID MEDICATIONS
- ZAFIRLUKAST

The following drugs or drug classes may decrease the anticoagulant response of warfarin (not necessarily complete):

- BARBITURATES (phenobarbital, etc.)
- CORTICOSTEROIDS
- ESTROGENS
- GRISEOFULVIN
- MERCAPTOPURINE
- RIFAMPIN
- SPIRONOLACTONE
- SUCRALFATE
- VITAMIN K

Should concurrent use of any of the above drugs with warfarin be necessary, enhanced monitoring is required. Refer to other references on drug interactions for more specific information.

Laboratory Considerations

Warfarin may cause falsely decreased theophylline values if using the Schack and Waxler ultraviolet method of assay.

Doses

**DOGS:**

For adjunctive therapy of thromboemboli:

a) For adjunctive maintenance therapy for venous thrombosis with or without pulmonary thromboembolism (PTE): warfarin may be considered at a dose of 0.22 mg/kg PO q12h initially and then adjusted to achieve a PT prolongation of 1.25 to 1.5 times the pretreatment value. (Lumsford & Mackin 2007)

b) 0.22 mg/kg PO q12h; target dosage to prolong PT by 1.25–1.5 times the pretreatment value. (Brooks 2000)

c) For prophylactic use in patients with glomerular disease and severe proteinuria: Initially, 0.22 mg/kg, PO once daily. Monitor PT and adjust dose so that PT is maintained at 1.5 times normal. (Grauer & DiBartola 2000)

**CATS:**

For adjunctive therapy of thromboembolism:

a) For adjunctive maintenance therapy for venous thrombosis with or without pulmonary thromboembolism (PTE): warfarin may be considered at a dose of 0.5 mg (total dose per cat) PO once daily and then adjusted to achieve a PT prolongation of 1.25 to 1.5 times the pretreatment value.

For maintenance therapy for feline arterial thromboembolism: Aspirin (ultra-low dose 5 mg) is often preferred over warfarin as it is difficult to dose accurately (active enantiomers not evenly distributed in tablets and they must be finely crushed and carefully compounded for precise dosing), and frequent and costly monitoring is required. Pharmacokinetic and pharmacodynamic studies in cats have demonstrated that a warfarin dose of 0.06 to 0.09 mg/kg/day is appropriate. Heparinization is recommended during the first 5 to 7 days that warfarin is administered. (Lumsford & Mackin 2007)

b) For long-term thromboprophylaxis: Initially warfarin at 0.06–0.09 mg/kg per day PO. Due to unequal drug distribution, tablets should be crushed and mixed well. PT, adjusted to international normalized ratio
XYLAXINE HCL
((2%-to-axon) Rompun®)
ALPHA2-ADRENERGIC AGONIST
Prescriber highlights

- Alpha2-adrenergic agonist used for its sedative & analgesic in a variety of species; sometimes used as an emetic in cats
- Contraindications: Animals receiving epinephrine or having active ventricular arrhythmias. Extreme caution: preexisting cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Should generally not be used in the last trimester of pregnancy, particularly in cattle. Do not give to ruminants that are debilitated, dehydrated, or with urinary tract obstruction. Horses may kick after a stimulatory event (usually auditory); use caution. Avoid intra-arterial injection; may cause severe seizures & collapse. Caution in patients treated for intestinal impactions. Use cautiously in horses during the vasodilatatory phase of lamination.

- Adverse Effects: Cats: emesis, muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, & increased urination.

- Adverse Effects: Dogs: Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, emesis, bloat from aerophagia which may require decompression.

- Adverse Effects: Horses: Muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, sweating, increased intracranial pressure, or decreased mucociliary clearance.

- Adverse Effects: Cattle: Salivation, ruminal atony, bloating, regurgitation, hyperthermia, diarrhea, bradycardia, premature parturition, & ataxia.

- Yohimbine, atipamezole, & tolazoline may be used alone or in combination to reverse effects or speed recovery times.
Dosages between species can be very different; be certain of product concentration when drawing up into syringe, especially if treating ruminants.

Drug Interactions

Uses/Indications

Xylazine is FDA-approved for use in dogs, cats, horses, deer, and elk. It is indicated in dogs, cats, and horses to produce a state of sedation with a shorter period of analgesia, and as a preanesthetic before local or general anesthesia.

Xylazine use in small animals is somewhat controversial and because it can cause arrhythmias, reduce cardiac output, and increase risk for general anesthesia-related death, it is usually reserved for "healthy animals."

Because of the emetic action of xylazine in cats, it is occasionally used to induce vomiting after ingesting toxins.

Pharmacology/Actions

A potent α₂-adrenergic agonist, xylazine is classified as a sedative/analgescic with muscle relaxant properties. Although xylazine possesses several of the same pharmacologic actions as morphine, it does not cause CNS excitation in cats, horses or cattle, but causes sedation and CNS depression. In horses, the visceral analgesia produced has been demonstrated to be superior to that produced by meperidine, butorphanol or pentazocine.

Xylazine can also have α₂-agonist activity and is less selective for α₂-receptors than methoxamine, dexmedetomidine or remifentanil.

Xylazine causes skeletal muscle relaxation through central mediated pathways. Emesis is often seen in cats, and occasionally in dogs receiving xylazine. While thought to be centrally mediated, neither dopaminergic blockers (e.g., thioperamide) nor alpha-blockers (yohimbine, tolazoline) block the emetic effect. Xylazine does not cause emesis in horses, cattle, sheep or goats. Xylazine depresses thermoregulatory mechanisms and either hypothermia or hyperthermia is a possibility depending on ambient air temperatures.

Effects on the cardiovascular system include an initial increase in total peripheral resistance with increased blood pressure followed by a longer period of lowered blood pressures (below baseline). A bradycardic effect can be seen with some animals developing a second-degree heart block or other arrhythmias. An overall decrease in cardiac output of up to 30% may be seen. Xylazine has been demonstrated to enhance the arrhythmogenic effects of epinephrine in dogs with or without concurrent halothane.

Xylazine’s effects on respiratory function are usually clinically insignificant, but at high dosages it can cause respiratory depression with decreased tidal volumes and respiratory rates, and an overall decreased minute volume. Brachycephalic dogs and horses with upper airway disease may develop dyspnea.

Xylazine can increase blood glucose secondary to decreased serum levels of insulin; in non-diabetic animals, there appears to be little clinical significance associated with this effect.

In horses, sedatory signs include a lowering of the head with relaxed facial muscles and drooping of the lower lip. The retractor muscle is relaxed in male horses, but unlike acepromazine, no reports of permanent penile paralysis have been reported. Although, the animal may appear to be thoroughly sedated, auditory stimuli may provoke arousal with kicking and avoidance responses.

With regard to the sensitivity of species to xylazine, define differences are seen. Ruminants are extremely sensitive to xylazine, but with horses, dogs, or cats. Ruminants generally require approximately 1/10th the dosage that is required for horses to exhibit the same effect. In cattle (and occasionally cats and horses), polyuria is seen following xylazine administration, probably because of decreased production of vasopressin (anti-diuretic hormone, ADH). Bradycardia and hypersalivation are also seen in cattle and diminished by pretreating with atropine. Because swine require 20–30 times the ruminant dose, it is not routinely used.

Pharmacokinetics

Absorption is rapid following IM injection, but bioavailabilities are incomplete and variable. Bioavailabilities of 40–48% in horses, 17–73% in sheep, and 52–90% in dogs have been reported after IM administration.

In horses, the onset of action following IV dosage occurs within 1–2 minutes with a maximum effect 3–10 minutes after injection. The duration of effect is dose dependent but may last for approximately 1.5 hours. The serum half-life after a single dose of xylazine is approximately 50 minutes in the horse; recovery times generally take from 2–3 hours.

In dogs and cats, the onset of action following an IM or SC dose is approximately 10–15 minutes, and 3–5 minutes following an IV dose. The analgesic effects may persist for only 15–30 minutes, but the sedative actions may last for 1–2 hours depending on the dose given. The serum half-life of xylazine in dogs has been reported as averaging 30 minutes. Complete recovery after dosing may take 2–4 hours in dogs and cats.

Xylazine is not detected in milk of lactating dairy cattle at 5 and 21 hours post-dose, but the FDA has not approved its use in dairy cattle and no meat or milk withdrawal times have been specified.

Contraindications/Precautions/Warnings

Xylazine is contraindicated in animals receiving epinephrine or having active ventricular arrhythmias. It should be used with extreme caution in animals with preexisting cardiac dysfunction, hypotension or shock, respiratory dysfunction, severe hepatic or renal insufficiency, preexisting seizure disorders, or if severely debilitated. Because it may induce premature parturition, it should generally not be used in the last trimester of pregnancy, particularly in cattle.

Be certain of product concentration when drawing up into syringe, especially if treating ruminants. Do not give to ruminants that are dehydrated, debilitated, or with urinary tract obstruction. It is not FDA-approved for any species to be consumed for food purposes.

Horses have been known to kick after a stimulatory event (usually auditory); use caution. The addition of opioids (e.g., butorphanol) may help temper this effect, but may cause increased risks for hypotension or ileus development. Avoid intravascular injection; may cause severe seizures and collapse. The manufacturers warn against using xylazine in conjunction with other tranquilizers. Because this drug may inhibit gastrointestinal motility, use with caution in patients treated for intestinal impactions. Use cautiously in horses during the vasoconstrictive development phase of laminitis as xylazine has been shown to reduce digital flow of blood for about 8 hours after administration.

Adverse Effects

Emesis is generally seen within 3–5 minutes after xylazine administration in cats and horses. To prevent aspiration, do not induce further anesthesia until this time has lapsed. Other adverse effects listed in the package insert (Gemini®, Butler) for dogs and cats include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and increased urination in cats.

Xylazine can reduce tear production in cats and cause diuresis in dogs.

Dogs may develop bloat from aerophagia that may require decompression. Because of gaseous distention of the stomach, xylazine’s use before radiography can make test interpretation difficult.

Adverse effects listed in the package insert (AnaSed®, Lloyd) for horses include: muscle tremors, bradycardia with partial A-V block, reduced respiratory rate, movement in response to sharp auditory stimuli, and sweating (rarely profuse). Additionally, horses receiving xylazine may develop transient hypertension, or decreased mucociliary clearance rates.

Adverse reactions reported in cattle include: salivation, ruminal atony, bloating and regurgitation, hypothermia, diarrhea, and bradycardia. Hypersalivation and bradycardia may be alleviated by pretreating with atropine. Large animals may become ataxic following dosing and caution should be observed.

Reproductive/Nursing Safety

Limited information was located on the safety of xylazine in pregnancy; apparently, there are no reports of teratogenicity in animals. Xylazine may induce premature parturition in cattle.

Xylazine does not appear to be excreted in detectable quantities in cows’ milk.

Overdosage/Acute Toxicity

In the event of an accidental overdosage, cardiac arrhythmias, hypotension, and profound CNS depression may occur. Seizures have also been reported after overdoses. There has been much interest in using vasopressin (anti-diuretic hormone, ADH). Bradycardia and hypersalivation are also seen in cattle and diminished by pretreating with atropine. Because swine require 20–30 times the ruminant dose, it is not routinely used.

To treat the respiratory depressant effects of xylazine toxicity, mechanical respiratory support with respiratory stimulants (e.g., doxapram) have been recommended for use.

Drug Interactions

The manufacturers warn against using xylazine in conjunction with other tranquillizers.

ACEPROMAZINE: The combination use of acepromazine with xylazine is generally considered safe, but there is potential for additive hypotensive effects and this combination should be used cautiously in animals susceptible to hemodynamic complications.

CHLORAMPHENICOL: Prolonged sedation and gastrointestinal stasis possible (Davis 2007)

CNS DEPRESSANT AGENTS, OTHER (barbiturates, narcotics, anesthetics, phentolamines, etc.): May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.

EPIEPIPHINE: The use of epinephrine with or without the concurrent use of halothane with xylazine may induce the development of ventricular arrhythmias.

RESERPINE: A case of a horse developing colic-like clinical signs after reserpine and xylazine has been reported. Until more is known about this potential interaction, use of these two agents together should be avoided.

Doses

**DOGS:**

**CNS DEPRESSANT AGENTS, OTHER (barbiturates, narcotics, anesthetics, phentolamines, etc.):** May cause additive CNS depression if used with xylazine. Dosages of these agents may need to be reduced.

**EPIEPIPHINE: The use of epinephrine with or without the concurrent use of halothane with xylazine may induce the development of ventricular arrhythmias.**
CAMELIDS:

- BIRDS:
- FERRETS:
- RABBITS, RODENTS, SMALL MAMMALS:
- CATS: Ketamine 3.7 mg/kg; xylazine 0.37 mg/kg; telazol 3.7 mg/kg. Add butorphanol (0.02–0.04 mg/kg IM). Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analesia and increase recumbency time by about 5–10 minutes. D) As a short-acting, potent analgesic for mild, to moderate colic that will control pain but allow an estimate of the severity of the colic episode: 0.3–0.5 mg/kg IV; may be combined with butorphanol (0.01 mg/kg) and doxazosin 0.001 mg/kg IV. If the signs of colic are so violent as to prevent safe IV administration, an increased dose of xylazine (1.1 mg/kg) or detomidine (0.02 mg/kg) may be administered IM. The general rule is to double the IV dose. Expect a longer duration of effect with the IM route. (Bilsagler 2008)
- For field anesthesia: Sedate with ketamine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures). If adequate sedation does not occur, either: 1) Redose xylazine: up to half the original dose, 2) Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analesia and increase recumbency time by about 5–10 minutes. 3) Diazepam (0.03 mg/kg IV), Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes. 4) Guafenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)
- As part of a balanced anesthesia protocol: 0.5–1 mg/kg IV given over ½–1 minute. (MAC sparing effect approximately 20–34%). (Driessen 2008)

SHEEP & GOATS:

- Note: Use xylazine with extreme caution in these species. Use only the 20 mg/mL solution.

- For procedural pain (e.g., castrations) when recumbency (up to 30 minutes) is desired: Alpacas: butorphanol 0.046 mg/kg; xylazine 0.46 mg/kg; ketamine 4.6 mg/kg. Llamas: butorphanol 0.037 mg/kg; xylazine 0.37 mg/kg; ketamine 3.7 mg/kg. All drugs are combined in one syringe and given IM. May administer 50% of original dose of ketamine and xylazine during anesthesia to prolong effect up to 15 minutes. If doing mass castrations on 3 or more animals, can make up bottle of the “cocktail.” Add 10 mg (1 mL) of butorphanol and 100 mg (1 mL) xylazine to a 1 gram (10 mL) vial of ketamine. This mixture is dosed at 1 mL/40 lbs. (18 kg) for alpacas, and 1 mL/50 lbs. (22 kg) for llamas. Handle quietly and allow plenty of time before starting procedure. Expect 20 minutes of surgical time; patient should stand 45 minutes after induction before starting procedure.

CAMELIDS:

Expect 20 minutes of surgical time; patient should stand 45 minutes after induction before starting procedure.
**Pharmacology/Actions**

For use of xylazine in zoo, exotic and wildlife medicine refer to specific references, including:

c) Restrain and Handling of Wild and Domestic Animals. Fowler, M (ed.), Iowa State University Press, 1995

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse

**Monitoring**

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Hydration status if polyuria present

**Client Information**

Xylazine should only be used by individuals familiar with its use

**Chemistry/Synonyms**

Xylazine HCl is an alpha₂-adrenergic agonist structurally related to clonidine. The pH of the commercially prepared injections is approximately 5.5. Dosages and bottle concentrations are expressed in terms of the base.

Xylazine HCl may also be known as Bay-Va-1470, Rompun®, AnaSed®, Sedazine®, X-Ject®, or Xyla-Ject®.

**Storage/Stability**

Do not store above 30°C (86°F).

**Compatibility/Compounding Considerations**

Xylazine is reportedly physically compatible in the same syringe with several compounds, including: acepromazine, butorphanol, chloral hydrate, and meperidine.

A study (Taylor et al. 2009) evaluating the stability, sterility, pH, particulate formation and efficacy in laboratory rodents of compounded ketamine, acepromazine and xylazine (“KAX”) supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored at room temperature in the dark.

**Dosage/VEMS/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

Xylazine Injection: 20 mg/mL in 20 mL vials or 100 mg/mL in 50 mL vials: Rompun® (Bayer), AnaSed®, Cervicize® (300 mg/mL; for deer and elk) (Lloyd); Sedazine® (BIVI); Chanazine® (Teva); generic; (Rx); FDA-approved for use (depending on strength and product) in dogs, cats, horses, deer, and elk.

While xylazine is not FDA-approved for use in cattle in the USA, it is reportedly been assigned withdrawal times of 3 days for meat and 48 hours for milk. FARAD has reportedly suggested a withdrawal of 7 days for meat and 72 hours for milk for extra-label use.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

**References**

**YOHIMBINE HCL**

(yo-him-been) Yohimbel®

ALPHA2-ADRENERGIC ANTAGONIST

**Prescriber Highlights**

- Alpha₂-adrenergic antagonist used to reverse xylazine, other alpha₂ agonists & potentially amitraz; may be used prophylactically before amitraz dips
- Caution: Renal disease, seizure disorders
- Adverse Effects: Transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, & hyperemic mucous membranes; more likely in small animals and horses
- Drug interactions

**Uses/Indications**

Yohimbine is indicated to reverse the effects of xylazine in dogs, but it is being used clinically for other alpha₂ agonists and in several other species as well.

Yohimbine may be efficacious in reversing some of the toxic effects associated with other agents (e.g., amitraz) and can be used prophylactically before amitraz dips.

**Pharmacology/Actions**

Yohimbine is an alpha₂-adrenergic antagonist that can antagonize the effects of xylazine. Alone, yohimbine increases heart rate, blood pressure, causes CNS stimulation and antidiuresis, and has hyperinsulinemic effects.
Doses
Little information is available, use with caution with Drug Interactions.

Dogs receiving 0.55 mg/kg (5 times recommended dose) exhibited clinical signs of transient seizures and muscle tremors. Overdosage/Acute Toxicity
Safe use of yohimbine in pregnant animals has not been established. No information on safety during lactation was located.

Reproductive/Nursing Safety
horses.

Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animals and horses.

Contraindications/Precautions/Warnings
Yohimbine is contraindicated in patients hypersensitive to it. In humans, yohimbine is contraindicated in patients with renal disease.

Adverse Effects
Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animals and horses.

Pharmacokinetics
The pharmacokinetics of this drug have been reported in steers, dogs, and horses (Jernigan et al. 1988). The apparent volume of distribution (steady-state) is approximately 5 L/kg in steers, 2–5 L/kg in horses, and 4.5 L/kg in dogs. The total body clearance is approximately 70 mL/min/kg in steers, 35 mL/min/kg in horses, and 30 mL/min/kg in dogs. The half-life of the drug is approximately 0.5–1 hours in steers, 0.5–1.5 hours in horses, and 1.5–2 hours in dogs.

Yohimbine is believed to penetrate the CNS quite readily and, when used to reverse the effects of xylazine, onset of action generally occurs within 3 minutes. The metabolic fate of the drug is not known.

Contraindications/Precautions/Warnings
Yohimbine is contraindicated in patients hypersensitive to it. In humans, yohimbine is contraindicated in patients with renal disease. Yohimbine should be used cautiously in patients with seizure disorders. When used to reverse the effects xylazine, normal pain perception may result.

Adverse Effects
Yohimbine may cause transient apprehension or CNS excitement, muscle tremors, salivation, increased respiratory rates, and hyperemic mucous membranes. Adverse effects appear to be more probable in small animals and horses.

Reproductive/Nursing Safety
Safe use of yohimbine in pregnant animals has not been established. No information on safety during lactation was located.

Overdosage/Acute Toxicity
Dogs receiving 0.55 mg/kg (5 times recommended dose) exhibited clinical signs of transient seizures and muscle tremors. Overdoses of yohimbine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, all 5 were dogs with 2 showing clinical signs. Reported findings in dogs included diarrhea, disorientation, hyperactivity, panting, tachycardia, and hypersalivation.

For more information on clinical effects and treatment for yohimbine toxicity see: (Volmer et al. 1994)

Drug Interactions
Little information is available, use with caution with other alpha₂-adrenergic antagonists or other drugs that can cause CNS stimulation.

TRICYCLIC ANTIDEPRESSANTS: In humans, yohimbine is not recommended for use with antidepressants or other mood-altering agents; hypertension has been reported with tricyclics.

Doses

DOGS:
For alpha₂ agonist reversal:

a) For xylazine: 0.11 mg/kg IV slowly (Package insert; Yohin®—Lloyd
b) For xylazine: 0.1 mg/kg IV (Gross & Tranquilli 1989)
c) For medetomidine: 0.11 mg/kg IV. (Park et al. 2009)
For reversal or prevention of amitraz effects:

a) To reverse centrally mediated bradycardia and hypotension associated with amitraz ingestion: 0.1 mg/kg IV; repeat as necessary (Manning 2000)
b) In cases of toxicity or to prevent a dog from having an acute episode of toxicity associated with demodicosis treatment: Yohimbine at 0.11 mg/kg IV or 0.25 mg/kg IM with atipamezole (50 micrograms/kg IM).
(Torres 2007)
c) For treatment or prevention of side effects associated with amitraz dips: 0.1 mg/kg IV; may give prior to, or after bathing to prevent effects. (Hillier 2006)
As an anxiolytic:

a) 0.25–0.5 mg/kg SC or IM q12h. (Washabau & Elie 1995), (Encarnacion et al. 2009), (Neiger 2007)

RABBITS, RODENTS, SMALL MAMMALS:
To reverse the effects of xylazine and to partially antagonize the effects of ketamine and acepromazine:

a) Rabbits: 0.2 mg/kg IV as needed
b) Mice/Rats: 0.2 mg/kg IP as needed (Huerkamp 1995)

BIRDS:
As a reversal agent for alpha2-adrenergic agonists (e.g., xylazine):

a) 0.1 mg/kg IV (Clyde & Paul-Murphy 2000)

CATTLE:
For xylazine reversal:

a) 0.125 mg/kg IV (Gross & Tranquilli 1989)
b) Yohimbine (or tolazoline) may be used to reverse the effects of xylazine to facilitate a quicker recovery at the end of a procedure and minimize the risks of gastrointestinal complications. IM administration of the reversal agent is preferred in all but emergency situations as it decreases the risk of CNS excitement or cardiovascular complications. The amount of reversal agent used depends on the dose and time elapsed after administering xylazine. Reversal of xylazine should not be attempted until sufficient time has elapsed to allow any ketamine or Telazol® used to resolve (30–45 min. post IM and 15–30 min. post-IV administration) to reduce the chances of a rough recovery. When dosed properly the effects of reversal should start to become evident about 10 minutes following IM administration. Emergency doses of yohimbine at 0.1 mg/kg can be administered IV, but the shorter duration of action when given IV can result in the return of the effects of IM administered xylazine. (Anderson & Abrahamsen 2008)

HORSES: (Note: ARCI UCGFS Class 2 Drug)
For xylazine reversal:

a) 0.075 mg/kg IV (Gross & Tranquilli 1989)

LAMAS:
For xylazine reversal:

a) 0.25 mg/kg IV or IM (Fowler 1989)

ZOON, EXOTIC, WILDLIFE SPECIES:
For use of yohimbine in zoo, exotic and wildlife medicine refer to specific references, including:

c) Restraint and Handling of Wild and Domestic Animals. Fowler, M (ed.), Iowa State University Press, 1995
e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: http://goo.gl/BHRih or http://goo.gl/9UJse
Overdosage/Acute Toxicity

Zafirlukast is contraindicated in patients hypersensitive to it.

Contraindications/Precautions/Warnings
Zafirlukast is contraindicated in patients hypersensitive to it. Zafirlukast is not indicated for, and is ineffective for treating bronchospasm associated with acute asthma attacks.

Adverse Effects
Veterinary experience is very limited, but some dogs reportedly have vomited after oral dosing. In humans, the adverse effect profile seems to be minimal; headache was noted most often, but incidence is not much different than placebo.

Reproductive/Nursing Safety
In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) Zafirlukast is excreted in milk, but it is probably safe to administer to nursing veterinary patients.

Overdosage/Acute Toxicity

In humans, the FDA categorizes this drug as category B for use during pregnancy (Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Yohimbine injection should be stored at room temperature (15–30°C) and protected from light and heat.

Storage/Stability

Yohimbine may also be known as: aphrodyne hydrochloride, chlorhydrate de quebrachine, corynine hydrochloride, Aphrodyne®, Dayto Himbin®, Pluriviron mono®, Prowess Plain®, Virigen®, Yobine®, Yocor®, Yocoral®, Yohimeyn®, Yohibol®, Yohybol®, or Zamba®.

Uses/Indications

While zafirlukast potentially could be useful for treating a variety of conditions (e.g., feline asthma, atopic dermatitis, inflammatory bowel disease) where leukotrienes are thought to contribute to morbidity, to date, efficacy has been shown to be disappointing, limited, or not fully studied. A study using zafirlukast to evaluate effects on pruritus (owner subjective evaluation) in dogs with atopic dermatitis, showed that only 11% of treated dogs had at least 50% reductions in pruritus (Senter et al. 2002).

Pharmacology/Actions

Zafirlukast selectively and competitively inhibits leukotriene receptors, specifically receptors for leukotriene D4 and E4 (LTD4 and LTE4). Additionally, it competes for receptors with some components of slow-reacting substance of anaphylaxis (SRS-A). These substances have all been implicated in the inflammatory and bronchoconstrictive aspects of bronchial asthma.

Pharmacokinetics

No specific veterinary data was located. In humans, zafirlukast is rapidly absorbed after oral administration. Food may impair the absorption of the drug, therefore, give on an empty stomach. Peak plasma levels occur about 4 hours after dosing. Zafirlukast is highly bound to plasma proteins (>99%). The drug is extensively metabolized; less than 10% of a dose is excreted in the urine, the rest in the feces. Half lives in humans average about 10 hours.

References

In dogs, doses of up to 500 mg/kg were tolerated without mortality.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving zafirlukast and may be of significance in veterinary patients:

- **ASPIRIN**: May significantly increase zafirlukast plasma levels
- **ERYTHROMYCIN**: May decrease the bioavailability of zafirlukast
- **THEOPHYLLINE**: May decrease plasma levels of zafirlukast
- **WARFARIN**: Zafirlukast may significantly increase the prothrombin time of patients taking warfarin.

Laboratory Considerations

- None noted

Doses

- **DOGS**: For adjunctive treatment of atopic dermatitis:
  
a) 20 mg (total dose) PO twice daily; only moderate success (Foil 2003)
  
b) In the study dogs received: 5 mg PO q12h, if the dog weighed less than 11.4 kg (25 lb); 10 mg PO q12h, if 11.4–22.3 kg (25–49 lb); 20 mg PO q12h, if 22.7–34.1 kg (50–75 lb); and 30 mg PO q12h, if greater than 34.1 kg (75 lb). Given on an empty stomach, 1 hour before, or 2 hours after meals. (Senter et al. 2002)

- **CATS**: For adjunctive treatment of feline bronchial “asthma.”
  
a) 1–2 mg/kg PO once to twice daily (Noone 1999)
  
b) 0.5–1 mg/kg q12–24h. (Scherk 2010)
  
c) 5 mg (total dose) per cat PO q12h. (Lappin 2008)

  For adjunctive treatment of mild inflammatory bowel disease:

  a) 0.15–0.2 mg/kg PO once daily. Author has used a combination of zafirlukast (3 months), famotidine (4 weeks), and sucralfate (2 weeks) (along with a low-allergen diet) to successfully treat a case. (Boothe 2009)

Monitoring

- **Clinical efficacy**

Client Information

- Preferably give on an empty stomach.

- Give this medication even if animal appears well; do not use to treat acute asthma clinical signs.

- Because experience in veterinary medicine is limited, report any untoward effects to the veterinarian.

Chemistry/Synonyms

A leukotriene-receptor antagonist, zafirlukast occurs as a white to pale yellow, fine amorphous powder. It is practically insoluble in water.

Zafirlukast may also be known as: ICI-204219, Accolate®, Accoleit®, Aeronix®, Azimax®, Olmoran®, Resma®, Vanticon®, Zafarismal®, Zafirst®, or Zuvair®.

Storage/Stability

Zafirlukast tablets should be stored at room temperature and protected from light and moisture. The manufacturer states that the tablets should be dispensed only in the original, unopened container.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Zafirlukast Tablets (film-coated): 10 mg & 20 mg; Accolate® (AstraZeneca); (Rx)

References

**ZIDOVUDINE (AZT)**

(zid-o-vew-den) Retrovir®

**ANTIRETROVIRAL**

**Prescriber Highlights**

- Antiretroviral agent that may be useful for adjunctive treatment of FeLV or FIV in cats
- Use with caution if renal, hepatic, or bone marrow dysfunction present
- Anemia (non-regenerative) most common adverse effect in cats

**Uses/Indications**

In veterinary medicine, zidovudine may be useful for treating feline immunodeficiency virus (FIV) or feline leukemia virus (FeLV). While zidovudine can reduce the viral load in infected cats and improve clinical signs, it may not alter the natural course of the disease to a great extent.

**Pharmacology/Actions**
Zidovudine is considered an antiretroviral agent. While its exact mechanism of action is not fully understood, zidovudine is converted in vivo to an active metabolite (triphosphate) that interferes with viral RNA-directed DNA polymerase (reverse transcriptase). This causes a virustatic effect in retroviruses.

Zidovudine has some activity against gram-negative bacteria and can be cytotoxic as well.

**Pharmacokinetics**

Zidovudine is well absorbed after oral administration. In cats, oral bioavailability is approximately 95%. When administered with food, peak levels may be decreased, but total area under the curve may not be affected; peak levels occur about one hour post-dosing in cats. The drug is widely distributed, including into the CSF. It is only marginally bound to plasma proteins. Zidovudine is rapidly metabolized and excreted in the urine. Half-life in cats is about 1.5 hours.

**Contraindications/Precautions/Warnings**

Zidovudine is considered contraindicated in patients who have developed life threatening hypersensitivity reactions to it in the past.

Use zidovudine with caution in patients with bone marrow, renal or hepatic dysfunction. The European Advisory Board on Cat Diseases (ABCD) guidelines on prevention and management of feline immunodeficiency state that: Cats with bone marrow suppression should not be treated (with zidovudine; see monitoring guidelines, below). Dosage adjustment may be necessary in cats with renal or hepatic dysfunction.

**Adverse Effects**

In cats, reductions in RBC’s, PCV and hemoglobin are the most common adverse effects reported. Anemia may be non-regenerative and is most commonly seen with the higher end of the dosage range (10–15 mg/kg). Diarrhea and weakness have also been reported. While there are many adverse effects reported in humans, granulocytopenia and GI effects appear to be the most likely to occur.

**Overdosage/Acute Toxicity**

Human adults and children have survived oral overdoses of up to 50 grams without permanent sequelae. Vomiting and transient hematologic effects are the most consistent adverse effects reported with overdoses.

**Drug Interactions**

The following drug interactions have either been reported or are theoretical in humans or animals receiving zidovudine and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (ketoconazole, etc.): May increase zidovudine levels**
- **ATOVAQUONE: May increase zidovudine levels**
- **DOXORUBICIN: May antagonize each other’s effects; avoid use together**
- **INTERFERON ALFA: Increased risk for hematologic and hepato-toxicity**
- **PROBENECID: May increase zidovudine levels**
- **MYELO-/CYTOTOXIC DRUGS (e.g., chloramphenicol, doxorubicin, flucytosine, vincristine, vinblastine): Administered with zidovudine may increase the risk of hematologic toxicity**
- **RIFAMPIN: May decrease blood levels (AUC) of zidovudine**

**Laboratory Considerations**

- None were noted.

**Doses**

- **CATS:**
  - For adjunctive therapy of FeLV and FIV:
    - a) 5–10 mg/kg q12h PO or SC. The higher dose should be used carefully as side effects can develop. For SC injection, the lyophilized product should be diluted in isotonic sodium chloride solution to prevent local irritation. For PO dosing, syrup or gelatin capsules (dosage/weight calculated individually for each cat) can be given. See the ABCB monitoring guidelines below. (Hosie et al. 2009)
    - b) 5–10 mg PO or SC q12h. The higher dose should be carefully used in FeLV-infected cats because side effects, particularly non-regenerative anemia, can develop. (Levy et al. 2008)
    - c) For FELV: 5 mg/kg PO or SC q12h. If giving SC dilute in sterile normal saline to prevent local irritation. Check CBC weekly the first month as anemia (non-regenerative) can be seen. If values are stable; may monitor monthly. Some cats develop mild decreases in hematocrit that resolves even if treatment is continued. (Hartmann 2007)
    - d) For FIV encephalopathy: 20 mg/kg PO q12h (Taylor 2003)

**Monitoring**

- The European Advisory Board on Cat Diseases (ABCD) guidelines on prevention and management of feline immunodeficiency (Hosie et al. 2009) recommends: During treatment, a CBC should be performed weekly for the first month, because non-regenerative anemia is common, especially at higher doses. If the values are stable, monthly checks are sufficient. If hematocrit drops below 20%, treatment should be discontinued, and anemia then usually resolves within a few days.
- CD4/CD8 rates, if possible
- Clinical efficacy

**Client Information**

- Must be considered “experimental” therapy for cats
- Must be administered as prescribed for efficacy
- Regular blood tests required

**Chemistry/Synonyms**

A thymidine analog, zidovudine is synthetically produced and occurs as a white to beige-colored, odorless, crystalline solid. Approximately 20 mg are soluble in one mL of water.

Zidovudine may also be known as: ZDV, azidothymidine, 3'-azido-2',3'-dideoxythymidine, azidothymidine, AZT, BW-A509U, BW-509U, compound-S, zidovudinum or Retrovir®; many other trade names are available.

**Storage/Stability**

Zidovudine oral tablets or capsules should be stored at room temperature. Protect from heat, light and moisture. The oral solution should be stored at room temperature. Zidovudine injection (for IV infusion) should be stored at room temperature and protected from light.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

- Zidovudine Oral Tablets: 300 mg; Retrovir® (GlaxoSmithKline); generic; (Rx)
- Zidovudine Oral Capsules: 100 mg; Retrovir® (GlaxoSmithKline); generic; (Rx)
- Zidovudine Oral Syrup: 50 mg/5 mL in 240 mL.; Retrovir® (GlaxoSmithKline); generic; (Rx)
The following drug interactions have either been reported or are theoretical in humans or animals receiving zinc and may be of significance in veterinary patients:

**Drug Interactions**

- Dark or bright green diarrhea, foul-smelling feces, paresis, seizures, and sudden death (Puschner & Poppenga 2009). Treatment involves removing the source of zinc, chelation therapy (edetate calcium disodium or dilution with milk or water, and chelation therapy using edetate calcium disodium (Calcium EDTA). Refer to that monograph for possible doses and usage information.

- Signs associated with overdoses of zinc in mammals include hemolytic anemia, hypotension, jaundice, vomiting, and pulmonary edema. Suggestions for treatment of overdoses of oral zinc include removing the source, adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.

**Overdosage/Acute Toxicity**

- Zinc supplementation should be carefully considered before administering to patients with copper deficiency.

- When administered orally, large doses of zinc can inhibit the absorption of copper.

**Pharmacology/Actions**

- Zinc is a necessary nutritional supplement; it is required by over 200 metalloenzymes for proper function. Enzyme systems that require zinc include alkaline phosphatase, alcohol dehydrogenase, carbonic anhydrase, and RNA polymerase. Zinc is also necessary to maintain structural integrity of cell membranes and nucleic acids. Zinc dependent physiological processes include sexual maturation and reproduction, cell growth and division, vision, night vision, wound healing, immune response, and taste acuity.

- Zinc acetate or methionine may be less irritating to the stomach. Mixing the contents of the capsule with a small amount of tuna or hamburger may minimize vomiting.

- When administered orally, large doses of zinc can inhibit the absorption of copper.

**Reproductive/Nursing Safety**

- Zinc supplementation should be carefully considered before administering to patients with copper deficiency.

- When dosing, do not confuse the concentrations of zinc salts with elemental zinc.

**Contraindications/Precautions/Warnings**

- Large doses may cause GI disturbances or hematologic abnormalities (usually hemolysis), particularly if a coexistent copper deficiency exists. Zinc acetate or methionine may be less irritating to the stomach. Mixing the contents of the capsule with a small amount of tuna or hamburger may minimize vomiting.

**Adverse Effects**

- Large doses may cause GI disturbances. Hematologic abnormalities (usually hemolysis) may occur with large doses or serum levels greater than 1000 micrograms/dL (1 mg/dL), particularly if a coexistent copper deficiency exists. Zinc acetate or methionine may be less irritating to the stomach. Mixing the contents of the capsule with a small amount of tuna or hamburger may minimize vomiting.

**Uses/Indications**

- Zinc sulfate is used systemically as a nutritional supplement in a variety of species. Oral zinc acetate has been shown to reduce copper toxicity in susceptible dog breeds (Bedlington Terriers, West Highland White Terriers) with hepatic copper toxicosis. Zinc therapy may also be of benefit in the treatment of hepatic fibrosis in the dog. Zinc sulfate is used topically as an astringent and as a weak antiseptic for dermatologic and ophthalmic conditions.

**Dosages**

- **Dogs:** For adjunctive treatment and prophylaxis of hepatic copper toxicosis:
  - Initially, give a loading dose of 100 mg elemental zinc (zinc acetate used in this study) twice daily (separate doses by at least 8 hours) for about 3 months; then reduce dose to 50 mg (elemental zinc) twice daily. If animal vomits, give doses with a small piece of meat. Do not give within one hour of a meal. Monitoring of zinc levels every 2–3 months initially is recommended. Target zinc levels are 200–500 micrograms/dL. Do not allow levels to increase higher than 1000 micrograms/dL. May require 3–6 months of therapy before significant efficacy is noted. (Brewer et al. 1992)

**References**

Zinc sulfate is also available in topical ophthalmic preparations.

Zinc Acetate Capsules: 25 mg & 50 mg as zinc acetate; None as single-ingredient products for systemic use; several vitamin/mineral supplements contain zinc, however.

VETERINARY-LABELED PRODUCTS:

Dosage Forms/Regulatory Status

Store zinc acetate crystals in tight containers. Unless otherwise recommended by the manufacturer, store zinc sulfate products in tight containers at room temperature.

Client Information

Although it is best to give oral zinc acetate on an empty stomach, if vomiting occurs mix with hamburger or tuna fish to decrease this side effect. There is poor correlation between serum zinc levels and zinc-deficient states in dogs, and zinc levels may have more value in detection of potentially toxic intake or corroboration of a clinical diagnosis of toxicity or deficiency (Cummings & Kovacic 2009).

CATS:

For adjunctive therapy of severe hepatic lipidosis:

a) 7–10 mg/kg PO once daily, in B-Complex mixture if possible (Center 1994)

As an appetite stimulant:

b) 5–10 mg/kg

c) 10 mg/kg

Monitoring; Client Information

See information in individual doses above

There is poor correlation between serum zinc levels and zinc-deficient states in dogs, and zinc levels may have more value in detection of potentially toxic intake or corroboration of a clinical diagnosis of toxicity or deficiency (Cummings & Kovacic 2009).

Chemistry/Synonyms

Zinc acetate occurs as white crystals or granules. It has a faint acetic odor and effloresces slightly. One gram is soluble in 2.5 mL of water or 30 mL of alcohol. Zinc acetate contains 30% elemental zinc (100 mg zinc acetate = 30 mg elemental zinc).

Zinc sulfate occurs as a colorless granular powder, small needles, or transparent prisms. It is odorless but has an astringent metallic taste. 1.67 grams are soluble in one mL of water. Zinc sulfate is insoluble in alcohol and contains 25% zinc by weight (100 mg zinc sulfate = 23 mg elemental zinc).

Zinc gluconate occurs as white or practically white powder or granules. It is soluble in water; very slightly soluble in alcohol. Zinc gluconate contains 14.3% zinc (100 mg zinc gluconate = 14.3 mg elemental zinc).

Zinc methionine contains 18–21% elemental zinc. For every 5 mg of zinc methionine there is approximately 1 mg of elemental zinc.

Zinc acetate may also be known as: E650, or zinc acetates dihydrous. Zinc sulfate may also be known as: zinc sulphate; zinci sulfas, zincum sulfuricum; many trade names are available.

Storage/Stability

Store zinc acetate crystals in tight containers. Unless otherwise recommended by the manufacturer, store zinc sulfate products in tight containers at room temperature.

Dosage Forms/Regulatory Status

None as single-ingredient products for systemic use; several vitamin/mineral supplements contain zinc, however.

HUMAN-LABELED PRODUCTS:

Zinc Acetate is available from chemical supply houses.

Zinc Acetate Capsules: 25 mg and 50 mg as zinc acetate; Galzin® (Gate Pharmaceuticals®); (Rx)

Zinc Injection: 1 mg/ml (as sulfate; as 4.39 mg heptahydrate or 2.46 mg anhydrous) in 10 mL & 30 mL vials; 5 mg/mL (as 21.95 mg sulfate) in 5 mL & 10 mL vials; 1 mg/mL (as 2.09 mg chloride) in 10 mL vials; ZincaPol® (Smith & Nephew SoloPak®); generic; (Rx)

Zinc Gluconate Tablets: 10 mg (1.4 mg zinc), 15 mg (2 mg zinc) & 50 mg (7 mg zinc); generic; (OTC)

Zinc sulfate is also available in topical ophthalmic preparations.

References

Zolazepam—see: Zolazepam HCl (Tiletamine HCl/Zolazepam HCl)
Antiseizure medication that may be useful as an “add-on” drug for refractory epilepsy. May be considered for initial treatment as monotherapy in dogs.

- Half-life of 15 hours makes twice daily dosing possible in dogs; 33 hour half-life in cats may allow once daily dosing.
- Adverse effect profile not fully elucidated for dogs; sedation, ataxia, & inappetence have been reported
- Known teratogen in dogs
- Contraindicated in patients hypersensitive to sulfonamides
- Generics now available

Uses/Indications
Zonisamide may be useful as an “add-on” drug for refractory epilepsy in dogs. It has been suggested that it could be useful as monotherapy as the initial drug choice for dogs, particularly when the client wishes to avoid adverse effects associated with phenobarbital or bromides (Thomas 2010).

Pharmacology/Actions
The exact mechanism of action for zonisamide is not known. It may produce its antiseizure activity by blocking sodium channels and reducing transient inward currents, thereby stabilizing neuronal membranes and suppressing neuronal hypersynchronization. It does not appear to potentiate GABA. Zonisamide has weak carbonic anhydrase inhibitory activity.

Pharmacokinetics
In dogs, zonisamide is well absorbed (bioavailability about 70%) after oral administration and has low protein binding. Zonisamide has been demonstrated to be absorbed rectally in dogs. The elimination half-life in dogs is about 15 hours. Most of the drug is excreted via the kidneys into the urine, but about 20% is metabolized, primarily in the liver. Unlike in humans, zonisamide exhibits linear pharmacokinetics (dose to plasma trough concentrations) in dogs (at doses between 5–30 mg/kg PO twice daily) (Fukunaga et al. 2010).

Zonisamide has a long half-life in cats of approximately 33 hours (Hasegawa et al. 2008).

Contraindications/Precautions/Warnings
Zonisamide is contraindicated in patients hypersensitive to it or to any of the sulfonamide drugs.

Adverse Effects
Because there has been limited use of this drug in veterinary patients the adverse effect profile is not fully known. Adverse effects that have been reported in dogs include sedation (usually transient), ataxia, and inappetence. Because it is a sulfonamide, there is concern (yet no reports as of writing) that zonisamide may cause KCS or other sulfonamide-related adverse effects in dogs or cats.

In a combined pharmacokinetic and toxicity study in cats, half of cats receiving 20 mg/kg per day developed adverse effects that included inappetence, diarrhea, vomiting, ataxia and somnolence (Hasegawa et al. 2008). Tolerance to therapy is possible.

In humans, the most common adverse effects associated with zonisamide include anorexia, nausea, dizziness, somnolence, agitation and headache. Rarely, serious dermatologic reactions (Stevens-Johnson syndrome, TEN), blood dyscrasias, oligohydrosis, and hyperthermia have been reported in humans.

Overdosage/Acute Toxicity
The LD50 of zonisamide in dogs is reportedly 1 gram/kg. In human overdoses, effects reported include coma, bradycardia, hypotension, and respiratory depression. Treatment recommendations include GI evacuation, if ingestion was recent, and supportive therapy. Because of the drug’s long half-life, support may be required for several days.

Drug Interactions
Because zonisamide is not an enzyme inducer or inhibitor, there should be no significant interactions with many commonly used drugs. For those drugs that are metabolized by the cytochrome P450 system, such as phenobarbital, it is possible that zonisamide could increase the metabolism of these drugs through induction of microsomal enzymes. In cats, zonisamide may affect the metabolism of bromides, and this could influence its own metabolism. In a study of the effect of cimetidine on the pharmacokinetics of zonisamide, there were no significant interactions (Martin-Jimenez 2010).

Efficacy
- DOGS: a) 5–10 mg/kg PO q12h. The high end of the dose range is needed when used in combination with phenobarbital, probably as a result of phenobarbital-induced microsomal enzyme induction. (Munana 2010) b) As monotherapy: Initially at 5 mg/kg PO twice daily (q12h). When used in combination with phenobarbital: 10 mg/kg PO q12h. (Thomas 2010), (Martin-Jimenez 2010) c) As initial monotherapy: 3–5 mg/kg PO q12h. As an add-on agent: 10 mg/kg PO q12h. (Mariani 2010) d) Initial dose: 5–10 mg/kg PO q12h; gradual adaptation in dosing is recommended. Reduce phenobarbital doses by 25% at the time of starting zonisamide. (Podell 2006)
- CATS: a) There are anecdotal reports of the use of zonisamide in cats, with oral doses of 5 mg/kg every 12-24 hours most commonly utilized. (Munana 2010) b) Because of its long half-life, doses of 5–10 mg/kg PO once daily are likely to be appropriate in cats, although additional studies are needed to determine this. The authors report using the drug in 2 cats that were refractory to phenobarbital therapy; one developed anorexia and the drug had to be discontinued, but the other responded well. (Bailey & Dewey 2009) c) 10–20 mg/kg PO once daily. (Martin-Jimenez 2010)

Monitoring
- Efficacy
- Monitoring zonisamide blood levels may be useful in veterinary patients, but this has not been confirmed nor have veterinary therapeutic blood concentrations been identified. Therapeutic levels for humans are thought to be: 10–40 micrograms/mL.
- Adverse effects

Client Information
- In dogs, phenobarbital may increase the clearance of zonisamide as repeated phenobarbital dosing decreased the bioavailability, peak concentrations, half-life, and area under the curve of zonisamide, but it did not affect the time to peak level or the volume of distribution of zonisamide. This effect persisted up to 10 weeks after phenobarbital discontinuation (Orito et al. 2008). See the dose section for suggestions on altering zonisamide doses for dogs on phenobarbital.

Laboratory Considerations
- No specific laboratory interactions or considerations were noted
- While plasma concentrations of zonisamide are not routinely monitored in human patients, in dogs, the therapeutic range has been suggested to be from 10–40 micrograms/mL.

Prescriber Highlights
- Generics now available
- Contraindicated in patients hypersensitive to sulfonamides
- Known teratogen in dogs
- Adverse effect profile not fully elucidated for dogs; sedation, ataxia, & inappetence have been reported
- Half-life of 15 hours makes twice daily dosing possible in dogs; 33 hour half-life in cats may allow once daily dosing.
- Antiseizure medication that may be useful as an “add-on” drug for refractory epilepsy. May be considered for initial treatment as monotherapy in dogs.
Chemistry/Synonyms
A sulfonamide unrelated to other antiseize drugs, zonisamide occurs as a white powder with a pKa of 10.2. It is moderately soluble in water (0.8 mg/mL).

Zonisamide may also be known as: AD-810, CI-912, Excegran®, or Zonegran®.

Storage/Stability
Zonisamide capsules should be stored at 25°C (76°F); excursions permitted to 15–30°C (59–86°F). Store in a dry place and protected from light.

Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
Zonisamide Capsules: 25 mg, 50 mg & 100 mg; Zonegran® (Esai); generic; (Rx)

References

Zonisamide is a sulfonylurea that is a sodium channel blocker. It is a non-competitive antagonist of the α2-adrenergic receptor and has a high affinity for the α1c-adrenergic receptor. It is used to treat seizures in dogs and cats.

Diagnostic Agents

**Note:** A logical sequence of diagnostic tests must be used to perform ocular examination based on the special needs of each diagnostic agent and test. For example, evaluation of the tear film is performed with the Schirmer Tear Test and must be done before the eye is manipulated or any drug agents are instilled in order to provide a true picture of tear production. Likewise, cultures of the external ocular structures must be done prior to administration of any drugs that may alter bacterial culture. The use of mydriatics is essential to examination of the interior elements of the eye, but must not be given prior to measuring intraocular pressure as these agents will likely affect aqueous humor outflow. Intraocular pressure determination requires topical anesthetic, but must quickly be recorded prior to excessive manipulation of the eye or before the patient becomes anxious and uncooperative.

**FLUORESCEIN SODIUM**

(FLO-re-seen)

Indications/Pharmacology

Fluorescein sodium is a yellow water-soluble dye that fluoresces under a Wood’s Lamp, but is plainly visible after binding to corneal stroma through an ophthalmic examination light source. It is used most commonly to delineate full thickness loss of corneal epithelium indicating the presence of a corneal ulceration. In this instance, it will stain the corneal stroma. The epithelium is not stained because its outer lipid cell membrane repels the dye.

Fluorescein sodium is used to determine patency of the nasolacrimal outflow system. The normal wait time is 2–5 minutes in dogs and up to 10 minutes in cats. A positive test indicates patency of the nasolacrimal outflow system. A negative test is not indicative of disease, as the test is negative in a large percentage of normal animals. Fluorescein stain, then, can be added to irrigating solution to flush the nasolacrimal system, making detection the irritation solution at the nose more obvious during flushing of the system.
Suggested Dosages/Precautions/Adverse Effects

Fluorescein stain is applied by dropping a drop of irrigating solution onto the sterile strip and then allowing the drop to fall on the eye. The strip should not contact the cornea or it will cause false positive stain retention at the site of contact with the epithelial cells. Fluorescein impregnated paper strips are preferred to fluorescein solution to insure sterility. After a few seconds, the excess fluorescein is irrigated from the eye, staining areas of full thickness epithelial loss.

For procedures requiring topical anesthesia as well as a disclosing agent, benoxinate is added to fluorescein solutions in a ratio of 0.25% fluorescein to 0.4% benoxinate. These solutions are useful for removal of foreign bodies or sutures, but are not commonly used in veterinary medicine.

Conjunctival or corneal epithelial cells for fluorescent antibody testing should be collected prior to application of fluorescein stain, which can cause a false positive test for several days after application of the stain.

Fluorescein may rarely cause hypersensitivity reactions. Temporary staining of fur and skin may result. Do not use during intraocular surgery.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Sterile strips of paper impregnated with fluorescein sodium are the most commonly used form in veterinary medicine. Solutions (2%) of fluorescein are available, however they are not popular following one study indicating that Pseudomonas is readily grown in such solutions. Injectable products are also available (for ophthalmic angiography), but are not routinely used in veterinary medicine.

Fluorescein Sodium Strips: 0.6 mg, Fal-Glo® (Barnes Hind); 1 mg, Fluor-I-Strip®-A.T. (W-A); 9 mg, Fluor-I-Strip® (W-A); (all Rx); 1 mg Bio-Glo®, 100 ct or 300 ct (Wilson Ophthalmic); AK Flor 10% Injection (Akorn) 5 mL ampules

Fluorescein Sodium: Benoxinate: Fluores® (Akorn) 0.25:0.4% Drops in 5 mL, Fluor® (Hub) 0.25:0.4% Drops in 5 mL, Flurate® (Bausch and Lomb) 0.25:0.4% Drops in 5 mL.

LISAMINE GREEN

(lis-ah-meen)

Indications/Pharmacology

Lissamine green is used for diagnosis of corneal damage and to quantify tear production. These strips work by staining the cornea blue upon instillation, resulting in a “speckling” of the cornea. This speckling marks any corneal ulcerations as well as dry patches from any mucous-deficient or damaged corneal cells. A white or blue light may be used on the slit lamp during detection. Lissamine green possesses a therapeutic advantage in that it does not sting the eye like Rose Bengal; however, as interpretation of lissamine green results requires broader experience than that of Rose Bengal and fluorescein, fluorescein staining is considered a more reliable indicator of corneal damage.

Suggested Dosages/Precautions/Adverse Effects

Lissamine Green impregnated strips are placed in the conjunctival sac and staining is scored based on 6 areas of staining.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lissamine Green Ophthalmic Strips (Imperial Chemical Industries—available through distributors such as Wilson Ophthalmic) 1.5 mg, 100 individually wrapped strips per box.

PHENOL RED THREAD

(fee-nol)

Indications/Pharmacology

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantitatively with either the Schirmer Tear Test or the Phenol Red Thread Test. The Phenol Red Thread (PRT) test is a new, fast and equally accurate method to test tear production as compared to the Schirmer Tear Test. The PRT test has a 75mm long yellow-colored thread that is impregnated with phenol red, a pH sensitive indicator.

Suggested Dosages/Precautions/Adverse Effects

The 3mm indentation at the end of the thread is inserted into the inferior conjunctival sac for 15 seconds. As tears travel up the thread, the alkaline pH of the tears turns the thread red. The PRT requires only 15 seconds for diagnostic results as opposed to 1 minute for the Schirmer Tear Test in dogs. Normal tear production via PRT in cats at 15 seconds is 18.4 to 27.7 mm/15 seconds and, in dogs, 29.7 to 38.6 mm/15 seconds.

Dosage Forms/Regulatory Status

Phenol Red Thread Test: Zone QuickDiagnostic Threads®, 100 per box, (Menicon—available through distributors such as Wilson Ophthalmic)

ROSE BENGAL

(rose-ben-gal)

Indications/Pharmacology

Rose bengal is a vital stain and stains dead epithelial cells and mucus. Full thickness loss of the corneal epithelium is not necessary (only dead cells need be present) to obtain rose bengal stain uptake. It does not stain epithelial defects and does not pass into intercellular spaces.

Rose bengal stain is most commonly employed in the detection of the presence of viral keratitis in the cat. Because feline herpes virus tends to infect one cell, moving then to an adjacent cell (causing the so called dendritic tracts in the cornea) without full thickness loss of corneal epithelium initially, rose bengal is an ideal diagnostic agent for this infection. Rose Bengal can also be used to detect damaged corneal epithelium on the dorsal cornea in early cases of keratoconjunctivitis sicca. Rose bengal stain is virucidal although no information is available relative to its use as a therapeutic agent.

Suggested Dosages/Precautions/Adverse Effects
Damage to the corneal epithelium if a significant quantity of solution enters the eye through the incision.

Tetracaine is more irritating than proparacaine but is sometimes used in veterinary medicine. It is indicated to produce local anesthesia of short duration for ophthalmic procedures including measurement of intraocular pressure.

Proparacaine primarily anesthetizes the cornea; with limited penetration into conjunctiva. Anesthesia is of short duration (5–10 minutes). Proparacaine is a rapid acting topical anesthetic useful for a variety of ophthalmic procedures including tonometry (intraocular pressure measurement), relief of corneal pain to facilitate examination, biopsy/sample collection, and to distinguish between corneal and uveal pain.

Rose Bengal is applied as a solution (1–2 drops in conjunctival sac before examination) or from an impregnated strip (saturate tip of strip with sterile irrigating solution; touch bulbar conjunctiva or lower fornix with moistened strip; cause patient to blink several times to distribute the stain). Rose bengal is apparently toxic to the cornea and conjunctiva and should be thoroughly flushed from the eye after use to prevent irritation. Hypersensitivity reactions are possible. May stain clothing.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
- Proparacaine HCl Solution: 0.5% in 15 mL bottles (Solvay); (Rx) (Spectrum); (Rx)
- Rose Bengal Strips: 1.3 mg per strip; Rosetin® (Akorn); generic (Barnes-Hind); (Rx)

**HUMAN-LABELED PRODUCTS:**
- Schirmer Tear Test Strips: 300 individually wrapped strips, (Schering Plough/Intervet)
- Clemence Clarke® Schirmer Tear Test Strips: 50 pair/box, Schirmer Tear Test Strips® (Akcon)

**Indications/Pharmacology**

Measurement of tear production is an important diagnostic test when deficiency of the lacrimal system is suspected. Tear production is evaluated qualitatively by assessment of the corneal surface for moistness and luster. Tear production is measured quantitatively by the Schirmer Tear Test or the Phenol Red Thread Test. The Schirmer Tear Test measures the aqueous aspect of tears and is the most commonly used test for measuring tear production.

**Suggested Dosages/Precautions/Adverse Effects**

Because of the risk of false readings, the following should be avoided prior to conducting a Schirmer Tear Test: excessive manipulation of the eyelids, topical anesthesia, and topical or systemic drugs (e.g., tranquilizers and atropine). The round end of the test paper is bent while still in the envelope and positioned to avoid contamination. The bent end should be positioned in the lacrimal lake at the junction of the lateral and middle thirds of the lower eyelid. Most animals will close the eye during the test but this does not affect results. The Schirmer Tear Test should be left in position for one minute as results are not linear and cannot be extrapolated from shorter test times. Schirmer tear test values are as follows for the following species: Dogs: 21.9 ± 4.0 mm wetting per minute, Rabbits: 5.3 ± 2.9 mm wetting per minute, Cats: 20.2 ± 4.5 mm wetting per minute.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
- Proparacaine HCl Solution: 0.5% in 15 mL dropper bottles (Spectrum); (Rx)

**HUMAN-LABELED PRODUCTS:**
- Schirmer Tear Test Strips: 300 individually wrapped strips, (Schering Plough/Intervet)
- Clemence Clarke® Schirmer Tear Test Strips: 50 pair/box, Schirmer Tear Test Strips® (Akcon)

**Ocular Anesthetics**

Local anesthetic effect is dependent upon chemical structure and concentration. Local anesthetic agents structurally consist of a hydrophobic aromatic ring (benzoic acid derivatives), a linkage site between the aromatic ring and an intermediate chain, and a hydrophilic amine. The hydrophobic portion is essential for activity, as it is the portion that enables diffusion through the lipid membrane of nerves increasing hydrophobicity increases access of the anesthetic to its site of action and decreases its metabolism, thereby increasing potency and duration. Greater hydrophobicity is also associated with increased toxicity. The hydrophilic amine portion may exist in an uncharged, poorly water-soluble form, or as the positively charged ammonium ion.

Topical anesthetics adversely affect the epithelial surface and delay wound healing. Adverse effects range from superficial punctuate keratitis, decreased tearing, and decreased blinking, to corneal edema, pain, and diffuse necrotizing keratitis. Long-term administration inhibits cell migration and mitosis leading to retarded wound healing and infection. For this reason, topical anesthetics are never administered therapeutically.

Contraindications to topical anesthetics include liver disease (decreased clearance), concurrent anticholinergic therapy (prevents metabolism of esters), perforating ocular injury, and for collection of ocular surface cultures (due to inhibition of microbial growth).

**Indications/Pharmacology**

Proparacaine is a rapid acting topical anesthetic useful for a variety of ophthalmic procedures including tonometry (intraocular pressure measurement), relief of corneal pain to facilitate examination, biopsy/sample collection, and to distinguish between corneal and uveal pain. Proparacaine primarily anesthetizes the cornea; with limited penetration into conjunctiva. Anesthesia is of short duration (5–10 minutes).

**Suggested Dosages/Precautions/Adverse Effects**

Usual dose is 1–2 drops prior to examination or procedure. For prolonged procedures only requiring local anesthesia; may repeat 1 drop doses every 5–10 minutes for 5–7 doses.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**
- Proparacaine HCl Solution: 0.5% in 15 mL bottles; Ophthaine® (Solvay); (Rx) (Allergan), Alcaine® (Akcon), Ophthaine® (Squibb), AK-Taine® (Akorn), Generic; (Rx). Protect from light. Some products should be refrigerated; check label.

**HUMAN-LABELED PRODUCTS:**
-Proparacaine HCl Solution: 0.5% in 2 & 15 mL bottles; Ophthaine® (Allergan), Alcaine® (Akcon), Ophthaine® (Squibb), AK-Taine® (Akorn), Generic; (Rx). Protect from light. Some products should be refrigerated; check label.

**Indications/Pharmacology**

Tetracaine is more irritating than proparacaine but is sometimes used in veterinary medicine. It is indicated to produce local anesthesia of short duration for ophthalmic procedures including measurement of intraocular pressure (tonometry), removal of foreign bodies and sutures, and conjunctival and corneal scraping in diagnosis and gonioscopy. Tetracaine is also indicated to produce local anesthesia prior to surgical procedures in humans such as cataract extraction and pterygium excision, usually as an adjunct to locally injected anesthetics. Ophthalmic solutions used for intraocular procedures should be preservative-free. Preservatives may cause
Indications/Pharmacology
Benoxinate is only available in combination with vital dyes, either sodium fluorescein 0.25% or disodium fluorescein 0.35% (a high-molecular-weight fluorescein that does not stain hydrogel contact lenses, allowing contacts to be worn sooner following administration, without concern of staining). It has a similar onset, intensity, and duration of action to that of tetracaine 0.5% and proparacaine 0.5%. Benoxinate has not been evaluated in veterinary ophthalmology.

Dosage Forms/Regulatory Status

Human-Labeled Products:
Benoxinate: Fluores® (Akorn) 0.25:0.4% Drops in 5 mL, Fluorost® (Hub) 0.25:0.4% Drops in 5 mL, Flurate® (Bausch and Lomb) 0.25:0.4% Drops in 5 mL.

Ocular Hypotensive Agents, Topical
Note: It is important to review the basic pathophysiology of glaucoma in order to understand drug therapy of this disease. Aqueous humor production results from ciliary body secretion and ultrafiltration of plasma. Carbonic anhydrase is a vital enzyme in the production of aqueous humor. Outflow of aqueous humor flows from the posterior chamber into the anterior chamber and exits at the iridocorneal angle, or exits through the iris, ciliary body, choroids, and sclera. The balance of generation and outflow of aqueous humor maintains the intraocular pressure at between 15 and 25 mmHg. By definition, glaucoma is an increase in intraocular pressure with resulting visual deficits. Delayed, inadequate or inappropriate therapy can result in severe pain and irreversible blindness as well as a cosmetically unappealing eye. Generally, once acute congestive primary glaucoma (generally breed-related and hereditary) is noted in one eye in the dog, it is treated as an emergency using a topical prostaglandin such as latanoprost. Surgery may be considered for lasting control of intraocular pressure. The following topical drugs are used “in general” as a preventative measure to prevent the occurrence of primary glaucoma in the unaffected eye in canine patients. Topical ocular antiglaucomatous medications are sometimes employed for pressure control with secondary glaucomas also. Because primary glaucoma in dogs is a progressive disorder, many patients are initially treated with single agents but combinations of drugs are often ultimately necessary to maintain pressure control.

Primary glaucoma in the feline species is increasingly being recognized in several forms. Although breed-related glaucoma in Siamese and Persian cat breeds has been noted, many veterinary ophthalmologists feel that domestic shorthaired cats are most likely affected. One form involving misdirected flow of aqueous humor into the vitreous, secondarily resulting in a forward displacement of the lens-iris diaphragm, has been described in the literature. The forward displacement of the iris has resulted in an average intraocular pressure of 30 mmHg in most patients. Topical medications have been successful in preventing progressive vision loss in most of these cats. Other forms of feline glaucomas that are presumably genetic are being noted sporadically in clinical practice and most of these cases, in complete contrast with primary glaucoma in the canine, are managed successfully with medications. Pharmacologic agents utilized for medical treatment of glaucoma are noted below categorized by therapeutic class but not by therapeutic priority.

Parasympathomimetics (Miotics)
The parasympathomimetic nervous system utilizes acetylcholine as the pre- and post-synaptic neurotransmitter. Parasympathomimetic drugs act either directly by mimicking acetylcholine, or indirectly by preventing its breakdown by acetylcholinesterase. Parasympathomimetics are useful ocular therapeutic agents by virtue of inducing contraction of the intraocular smooth muscle (miosis), which reduces intraocular pressure.

CARBACHOL
(kar-bah-coli)

Indications/Pharmacology
Carbachol is a direct-acting parasympathomimetic but also has some indirect action through inhibition of acetylcholinesterase. It cannot penetrate intact epithelium and when used topically (rarely), its use must be accompanied with a surfactant (benzalkonium chloride) to enhance penetration. Carbachol has been used to induce miosis in treatment of glaucoma, but more commonly, is used by veterinary ophthalmologists as an intracameral 0.01% injection at the conclusion of phacoemulsification surgery (cataract removal) to protect against postoperative increases in intraocular pressure (Crasta et al. 2010; Stuhr et al. 1998).

Suggested Dosages/Precautions/Adverse Effects
Carbachol 0.75% has been used topically, although rarely, to reduce intraocular pressures in dogs at a dose of 1 drop every 4-8 hours. Carbachol is administered intraoperatively at a dose of 0.5 mL of a 0.01% solution. Carbachol shares the potential for the same adverse effects of all other miotic agents, and in humans has been noted to cause severe headaches and accommodative muscle spasms. Corneal clouding, persistent bullous keratopathy, retinal detachment and postoperative iritis have been reported in humans following intracameral injection of carbachol following cataract extraction.

Dosage Forms/Regulatory Status

Veterinary-Labeled Products: None

Human-Labeled Products:
Carbachol 0.01% Injection, for intraocular use only, 10 x 1 mL ampules, Carbastat® (Novartis), Miostar® Intraocular (Alcon); (Rx)
Carbachol Ophthalmic Solution: 0.75%, 1.5%, 2.25%, and 3%, in 15 mL plastic dropper bottles; Isopto Carbachol® (Alcon), Carboptic® (Optopics); (Rx)

**DEMECARIUM BROMIDE**

(Dem-e-meh-ker-ox-im)

**Indications/Pharmacology**

Demecarium is a potent, long-acting carbamylcholine inhibitor that may reduce intraocular pressure for up to 48 hours in canines. Demecarium reversibly inhibits anticholinesterase thereby causing miosis. Demecarium is generally used in preventive management of the contralateral eye in canine patients after the diagnosis of an acute congestive crisis of primary glaucoma in the other eye. It is not used in secondary glaucoma. Demecarium has the advantage of once or twice daily dosing.

**Suggested Dosages/Precautions/Adverse Effects**

One drop once or twice daily. Demecarium is contraindicated during pregnancy. Because of additive effects, demecarium should be used with caution with other cholinesterase inhibitors (e.g., carbamate/organophosphate antiparasiticides), or succinylcholine. Demecarium can cause systemic effects (vomiting, diarrhea, increased salivation, bronchiolar spasm, and pulmonary edema). Pilocarpine should be avoided in dogs with glaucoma secondary to uveitis as well as in dogs with lens luxation or subluxation due to potential for papillary block.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Formerly available as: Demecarium 0.125% or 0.25% in 5 mL dropper bottles; Humorsoll® (Merck); (Rx). Do not freeze and protect from heat. Demecarium must be obtained from an appropriately qualified compounding pharmacy.

---

**ECHOTHIOPHATE IODIDE**

(Echo-thye-oh-dide)

**Indications/Pharmacology**

Echothiophate iodide for ophthalmic solution is a long-acting, irreversible cholinesterase inhibitor for topical use that enhances the effect of endogenously liberated acetylcholine in irises, ciliary muscle, and other parasympathetically innervated structures of the eye. It thereby causes miosis, increase in facility of outflow of aqueous humor, fall in intraocular pressure, and potentiation of accommodation. Echothiophate iodide for ophthalmic solution will depress both plasma and erythrocyte cholinesterase levels in most patients after a few weeks of eye drop therapy.

**Suggested Doses/Precautions/Adverse Effects**

One drop twice daily. Echothiophate is contraindicated in the presence of active uveal inflammation, and in most cases of angle-closure glaucoma, due to the possibility of increasing angle block. Temporary or permanent discontinuation of the drug may be required if cardiac irregularities, urinary incontinence, diarrhea, muscle weakness, nausea, abdominal cramps, fatigue, weakness or respiratory difficulties occur. Echothiophate should be avoided in patients with asthma, gastric ulcers, bradyarrhythmia, hypotension, epilepsy or other disorders that may respond adversely to vagotonic effects. Carbamate and organophosphate pesticides should not be used on patients receiving echothiophate.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Formerly available as: Demecarium 0.125% or 0.25% in 5 mL dropper bottles; Humorsoll® (Merck); (Rx). Do not freeze and protect from heat. Demecarium must be obtained from an appropriately qualified compounding pharmacy.

Sympathomimetics (Alpha2-Agonists)

Alpha-agonists reduce intraocular pressure by activation of presynaptic alpha-receptors, inhibiting release of norepinephrine, blocking adrenergic stimulation of the ciliary body and decreasing production of aqueous humor. Chronic use of these agents also results in increased uveoscleral outflow.

Apraclonidine

Apraclonidine is an alpha2 adrenergic agonist used to reduce aqueous humor formation. Apraclonidine is a relatively selective, alpha-adrenergic agonist and does not have significant membrane stabilizing (local anesthetic) activity. The primary ocular side effects noted following use of apraclonidine include conjunctival blanching, eyelid elevation, and mydriasis. While its systemic side effects are relatively mild compared to those of the beta-blockers, apraclonidine can cause dry eye or dry mouth, as well as mild elevations in resting heart rate, blood pressure, and respiration. Chronic use of apraclonidine can lead to decrease in therapeutic response. The onset of action is within 3–5 hours of a single dose. It is apparently less effective than brimonidine in dogs and is very potent, causing vomiting and diarrhea in dogs and cats (Miller & Rhea 1996). Severe side effects such as bradycardia, salivation and vomiting preclude use of apraclonidine in cats. Apraclonidine will reduce aqueous production, but it must be combined with other agents for adequate control. Neither the beta-blockers nor alpha-agonists are as effective as the carbonic anhydrase inhibitors in decreasing aqueous production.

Brimonidine

Brimonidine is an alpha2 adrenergic agonist used to reduce aqueous humor formation. Brimonidine is a relatively selective, alpha-adrenergic agonist and does not have significant membrane stabilizing (local anesthetic) activity. The primary ocular side effects noted following use of apraclonidine include conjunctival blanching, eyelid elevation, and mydriasis. While its systemic side effects are relatively mild compared to those of the beta-blockers, apraclonidine can cause dry eye or dry mouth, as well as mild elevations in resting heart rate, blood pressure, and respiration. Chronic use of apraclonidine can lead to decrease in therapeutic response. The onset of action is within 3–5 hours of a single dose. It is apparently less effective than brimonidine in dogs and is very potent, causing vomiting and diarrhea in dogs and cats (Miller & Rhea 1996). Severe side effects such as bradycardia, salivation and vomiting preclude use of apraclonidine in cats. Apraclonidine will reduce aqueous production, but it must be combined with other agents for adequate control. Neither the beta-blockers nor alpha-agonists are as effective as the carbonic anhydrase inhibitors in decreasing aqueous production.

Suggested Dosage/Precautions/Adverse Effects

1% solution applied as 1 drop 2–3 times daily. Apraclonidine should be used with caution in the face of hepatic and renal function impairment (since a structurally related medication, clonidine, is partly metabolized in the liver and undergoes a significant increase in half life in humans with renal impairment). Apraclonidine should not be used in cats due to severe adverse effects including vomiting, diarrhea, bradycardia and salivation. Ironically, in humans the 0.5% concentration is more likely to cause cardiovascular adverse effects than the 1% solution. In humans the following side effects have been noted: For 0.5% ophthalmic apraclonidine: Allergic reaction, abnormal coordination, arrhythmia, asthma, blepharitis, blepharoconjunctivitis, conjunctivitis, blurred vision or change in vision, chest pain, contact dermatitis, corneal erosion, corneal infiltrate, foreign body sensation, keratitis, keratopathy, depression, dizziness, dryness, edema of eye, eyelid, or conjunctiva, eye discharge, facial edema, lid retraction, paresthesia, or peripheral edema. For 1% ophthalmic apraclonidine: allergic reaction, arrhythmia, or ocular inflammation or injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None
HUMAN-LABELLED PRODUCTS:
Brimonidine 0.2%/Timolol maleate: 0.5% in 5 mL & 10 mL; Brimonidine 0.15% solution: 5 mL, 10 mL, & 15 mL;
HUMAN-LABELED PRODUCTS:
VETERINARY-LABEL PRODUCTS:
Apraclonidine 0.5% Solution: 5 mL & 10 mL; 1% Iopidine® (Alcon); (Rx). Supplied as follows: 0.1 mL in plastic ophthalmic dispensers, packaged two per pouch. These dispensers are enclosed in a foil overwrap as an added barrier to evaporation.

References

Indications/Pharmacology

Brimonidine tartrate is an alpha-adrenergic receptor agonist with a greater affinity for alpha2 receptors than apraclonidine. Brimonidine has a longer duration of action than apraclonidine as it binds to melanin, which acts as a reservoir to slowly release brimonidine. When used as a monotherapy, it is recommended that brimonidine be administered every 8 hours. Every 12-hour administration is acceptable when brimonidine is used in combination with timolol, latanoprost or dorzolamide. Brimonidine may also provide a protective effect to the retina and optic nerve (Karakucuk et al. 2009). However, this effect has not been clinically explored nor utilized in animals. Fluorophotometric studies in animals and humans suggest that brimonidine tartrate has a dual mechanism of action by reducing aqueous humor production and by increasing uveoscleral outflow. After ocular administration of either a 0.1% or 0.2% solution, plasma concentrations peaked within 0.5 to 2.5 hours and declined with a systemic half-life of approximately 2 hours. In humans, systemic metabolism of brimonidine is extensive. It is metabolized primarily by the liver. Urinary excretion is the major route of elimination of the drug and its metabolites. Approximately 87% of an orally administered radioactive dose was eliminated within 120 hours, with 74% found in the urine.

Suggested Dosages/Precautions/Adverse Effects

The usual dosage is 1 drop in the affected eye twice daily. Adverse events in humans include: allergic conjunctivitis, conjunctival hyperemia, and eye pruritus, burning sensation, conjunctival folliculosis, hypertension, oral reaction, arrhythmia, or ocular inflammation or injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELLED PRODUCTS: None
HUMAN-LABELLED PRODUCTS:
Brimonidine 0.2%/Timolol maleate: 0.5% in 5 mL & 10 mL; Alphagan P® (Allergan); (Rx). Store under refrigeration. Once reconstituted, may be stored at room temperature for up to 4 weeks.

Betaxolol HCl 0.5% and 0.25% Solution: 2.5, 5, 10, & 15 mL bottles; HUMAN-LABELED PRODUCTS:
VETERINARY-LABELED PRODUCTS:
Dosage Forms/Regulatory Status
the selective beta1-blocking properties of this particular drug would tend to minimize these risks for patients with pulmonary disease. 8 months respectively). While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure, although like timolol maleate, betaxolol HCl is supplied in a 0.5% and 0.25% solution. Because in animal patients, minimal pressure reduction is noted with concentrations below 0.5% with timolol maleate, many veterinary Suggested Dosages/Precautions/Adverse Effects
One drop 2-3 times daily in the unaffected eye. Epinephrine may cause ocular discomfort upon instillation. When injected intracameraly, it may be injected as a 1:10,000 dilution or added to ophthalmic irrigating solutions at a 1:100,000,000 dilution. It used intracameraly, epinephrine solutions should be preservative-free and bisulfate-free to avoid endothelial toxicity.

Beta-Adrenergic Antagonists
This class of ocular hypotensive drugs currently consists of both non-selective and beta-selective agents. At the time of writing, it is not known how blockade of the ciliary body epithelium beta-receptors reduces intraocular pressure. Several mechanisms have been postulated including: beta-blockade of norepinephrine-induced tonic sympathetic stimulation, decreased activation of cAMP in the ciliary body leading to decreased aqueous humor production, inhibition of Na+K+ATPase activity, or action through a vasoactive mechanism. Because beta-blockers significantly affect function of the cardiovascular and pulmonary systems, patients with heart block, bradycardia, heart failure, asthma, chronic bronchitis or other cardiopulmonary conditions are poor candidates for use of topi cal beta-blockers to reduce intraocular pressure. Topical use of beta-blockers also can affect membrane stabilizing ability and induce local anesthesia. While this property is of no clinical value, adverse effects such as punctuate keratitis and epitheliopathies have been reported with chronic use in humans.

BETAXOLOL
(beta-taks-ok-lo-lol)

Indications/Pharmacology
Betaxolol HCI is a specific beta1-adrenergic blocking agent that theoretically reduces the potential for beta2-induced adverse pulmonary effects; however, its cardiac effects are the same as non-selective beta-antagonists. Either levobunolol HCl or betaxolol HCl would be the first choice beta-blocking agent in a feline patient with glaucoma and asthma, although a topical carbonic anhydrates inhibitor should be considered before a beta-blocking agent in this situation. Betaxolol and the other beta-blockers should be used with caution in patients with cardiac disease. Betaxolol also inhibits glutamine-induced increases in intracellular calcium thereby providing a potential protective effect against ischemic insult to the retina (Bartlett et al. 2008).

Suggested Dosages/Precautions/Adverse Effects
Like timolol maleate, betaxolol HCI is supplied in a 0.5% and 0.25% solution. Because in animal patients, minimal pressure reduction is noted with concentrations below 0.5% with timolol maleate, many veterinary ophthalmologists only consider use of the 0.5% betaxolol HCI product. One drop of the 0.5% betaxolol HCI solution is instilled twice daily alone or in combination with other glaucoma medications. A study (Miller et al. 2000) utilizing 0.5% betaxolol as prophylaxis in the normal eye of dogs with unilateral glaucoma demonstrated a delay in onset of glaucoma in the normal eye relative to dogs who received no prophylaxis (31 months versus 8 months respectively). While problems have rarely been noted in veterinary medicine, ophthalmic beta-blockers should be used with caution in patients with bronchoconstrictive disease or congestive heart failure, although the selective beta-blocking properties of this particular drug would tend to minimize these risks for patients with pulmonary disease.

BETAXOLOL
(beta-taks-ok-lo-lol)

BETAXOLOL
(beta-taks-ok-lo-lol)
Timolol maleate is used primarily to prevent the development of primary glaucoma in the contralateral eye of a dog that has developed primary glaucoma in one eye. It only reduces intraocular pressure 3–10 mmHg and, therefore is of minimal usefulness in patients requiring treatment of primary acute congestive glaucoma. Timolol may cause slight miosis in dogs and cats. It is rarely used alone, but is combined with dorzolamide solution forming solution, applied once daily for seven days, reduced IOP in normotensive dogs by a mean of 5.3 mmHg (Takiyama et al. 2001). The 0.5% gel-forming solution has increased lipophilicity, resulting in greater anterior chamber relative to plasma concentrations (and therefore potentially fewer systemic side effects). Evaluation of 0.25 and 0.5% timolol in normotensive and glaucomatous eyes of Beagles with open-angle glaucoma, caused a reduction of 4-5 mmHg in glaucomatous eyes only (Gum et al. 1991). The 0.5% gel-forming solution, applied once daily for seven days, reduced IOP in normotensive dogs by a mean of 5.3 mmHg (Takiyama et al. 2006). Timolol has also been evaluated in horses utilizing a 0.5% solution alone or in combination with 2% dorzolamide and both studies indicate that every 12 hour dosing is preferred utilizing either regimen to effectively reduce intraocular pressure (van der Woerd et al. 2000; Willis et al. 2001).

Timolol maleate is mainly used to prevent the development of primary glaucoma in the contralateral eye of a dog that has developed primary glaucoma in one eye. Its use is limited to reducing intraocular pressure by 3–10 mmHg, which is minimal compared to other treatments. It is rarely used alone and is usually combined with dorzolamide. The 0.5% gel-forming solution is preferred as it provides increased lipophilicity, leading to higher anterior chamber concentrations compared to systemic ones, potentially reducing systemic side effects.
Ophthalmic prostaglandin analogues are chemically modified versions of PGF2-alpha, an endogenous inflammatory mediator, that have ocular hypotensive effects. Chemical modification of these agents improves lipid solubility, allowing them to penetrate the cornea and aqueous humor. Dorzolamide and brinzolamide are two examples of such agents.

### References
- Timolol Maleate 0.5% and Dorzolamide 2% Solution: 5 & 10 mL
- Dorzolamide HCl 2% Solution: 5, 10 & 15 mL;

### Human-Labeled Products:
- Brinzolamide HCL 1% solution: 2.5, 5, 10 & 15 mL containers; Azopt® (Alcon); (Rx)

### Brinzolamide HCL

**Indications/Pharmacology**
Brinzolamide is chemically similar to dorzolamide and reduces aqueous humor production by altering H+/Na+ active transport mechanisms associated with aqueous humor production in the ciliary epithelial cells. It can be used as a substitute for dorzolamide and some patients that exhibit excessive topical irritation following application of dorzolamide drops, tolerate brinzolamide better or vice versa. Cats seem to be particularly sensitive to irritation from topical dorzolamide and often brinzolamide can be used in these patients.

### Suggested Dosages/Precautions/Adverse Effects
One drop three times daily is the standard treatment frequency, adjusted based on clinical response. Like dorzolamide, may also cause stinging upon application.

### Brinzolamide HCL

**Dosage Forms/Regulatory Status**

**Veterinary-Labeled Products:** None

**Human-Labeled Products:**
- Brinzolamide HCl 1% solution: 2.5, 5, 10 & 15 mL containers; Azopt® (Alcon); (Rx)

### Dorzolamide HCL

**Indications/Pharmacology**
Dorzolamide was the first topical carbonic anhydrase inhibitor marketed. Its chemical structure allows it to be both lipophilic and hydrophilic, thereby enabling penetration of the cornea and sclera. It is often used in the contralateral eye of a dog with primary glaucoma to prevent development of bilateral disease. It is also an excellent agent to consider for most secondary glaucomas in dogs and cats because it has no effect on pupil size. Like the related oral carbonic anhydrase inhibitors (dichlorphenamide or Daranide®, methazolamide or Neptazane®), dorzolamide decreases aqueous humor production by the ciliary body epithelium by altering pH and affecting the H+Na+ active transport exchange mechanism. Oral carbonic anhydrase inhibitors cause numerous systemic side effects such as metabolic acidosis and panting, diarrhea, vomiting, anorexia and others, all of which can be avoided with topical carbonic anhydrase inhibitors. Investigations of dorzolamide have been conducted to establish efficacy in dogs and cats (McLean et al. 2008; Rainbow & Dzielyce 2003). Studies in horses indicate that dorzolamide is an effective monotherapy however, twice daily dosing is required (Willis et al. 2001).

### Suggested Dosages/Precautions/Adverse Effects
One drop two to three times daily is the standard treatment frequency, adjusted based on clinical response. Dorzolamide may cause stinging (related to the low pH of the solution) upon topical application, particularly in cats. Superficial punctuate keratitis or local hypersensitivity may occur. Approximately 5–10% of humans will experience irritation with use of topical dorzolamide. Systemic effects are not usually associated with topical administration.

**Travoprost 0.004% Solution; 2.5 mL, 5 mL bottles,**

**Indications/Pharmacology**

Latanoprost was the first drug marketed in this class; it is labeled for once daily use in humans. Clinical studies show reduced effectiveness when once daily treatment is exceeded in humans. Although latanoprost is initially dosed once daily in the evening for canine glaucoma, a study (Gelatt & MacKay 2001) was performed evaluating once versus twice daily administration of latanoprost in dogs that demonstrated that twice daily administration of latanoprost produced greater and more significant control of intraocular pressure. The canine uveal tract apparently metabolizes latanoprost at a rate higher than in humans as IOP reduction is profound, but it persists only for 12–15 hours in most dogs. Latanoprost will provide the greatest amount of pressure reduction in canine primary glaucoma cases compared with any other single oral or topical agent and efficacy is even greater when combined with carbonic anhydride inhibitors. Latanoprost has not been found to be useful in the management of glaucoma in cats (Studer et al. 2000). Equine glaucoma is usually secondary to uveitis and latanoprost treatment for glaucoma in horses is not considered effective and is associated with a high incidence of side effects, including ocular discomfort. (Davidson et al. 2002; van der Woerdt et al. 2000). Suggested Dosages/Precautions/Adverse Effects

One drop of latanoprost is applied in the PM initially, but with progression of the glaucoma, twice daily treatment schedules will provide additional reduction in intraocular pressure. Latanoprost may cause topical irritation. Conjunctival hyperemia is commonly noted in patients using this medication. A direct stimulation of iris melanocytes results in excess melanin production in the iris of people using this medication, causing an irreversible dark brown color change to the iris, and reversible hyperpigmentation of the eyelid. Hypertrichosis, conjunctival hyperemia, allergy, cystoid macular edema, anterior uveitis, and punctuate corneal erosions have also been reported. Profound miosis is noted with the use of latanoprost in dogs. It is not recommended for use in cats and horses due to adverse effects.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

*Latanoprost 0.005% Solution: 2.5 mL; Xalatan® (Pharmacia & Upjohn); (Rx). Store under refrigeration until use; may be stored at room temperature for 6 weeks after opened.*

**References**

**Bimatoprost 0.03% Solution 2.5 mL, 5 mL, 7.5 mL bottles;**

**Indications/Pharmacology**

While bimatoprost is grouped in the prostaglandin-analog class, it is considered a synthetic prostamide. It is derived from anandamide, a fatty acid precursor. Prostamides interact only weakly with prostaglandin receptors, and the mechanism of action in reducing intraocular pressure remains unknown. Bimatoprost is available in solutions containing minimal concentrations of benzalkonium chloride and causes less ocular discomfort than latanoprost or travoprost. Bimatoprost also is initially administered once daily in the evening, but an evaluation in dogs (Gelatt & MacKay 2002) demonstrated that twice daily dosing provided for less fluctuation in intraocular pressure. Since latanoprost does not seem to be effective for most forms of feline glaucoma, it is unlikely bimatoprost will prove effective in these cases either.

**Suggested Dosages/Precautions/Adverse Effects**

Bimatoprost is dosed 1–2 drops once daily in the evening and increased to twice daily as glaucoma progresses. Bimatoprost shares the same adverse effects profile as latanoprost.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

*Bimatoprost 0.03% Solution 2.5 mL, 5 mL, 7.5 mL bottles; Lumigan® (Allergan); (Rx), Latisse® (Allergan); (Rx)*

**References**

**Travoprost 0.004% Solution; 2.5 mL, 5 mL bottles,**

**Indications/Pharmacology**

Travoprost is a PGF2-alpha analog that is available preserved with benzalkonium chloride as well as in a benzalkonium chloride-free product that avoids the toxic epithelial effects commonly noted with this preservative in humans. As with latanoprost, travoprost is dosed once daily in the evening and produces mean intraocular pressure reductions of 7-8 mmHg. It shares the same adverse effect profile as latanoprost. Since latanoprost does not seem to be effective for most forms of feline glaucoma, it is not likely travoprost will prove effective in these cases either.

**Suggested Dosages/Precautions/Adverse Effects**

Travoprost is dosed 1-2 drops in the evening and increased to twice daily dosing with progression of glaucoma.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

*Travoprost 0.004% Solution; 2.5 mL, 5 mL bottles, Travatan® (Alcon); (Rx)*

References

Indications/Pharmacology
Unoprostone is a prostaglandin analog that is no longer commercially available in the United States. It is converted by ocular esterases to the active free acid form of isopropyl unoprostone instead of PGF2-alpha like other ocular prostaglandin produgs. Evaluations of unoprostone in dogs (Ofri et al. 2000) demonstrated that once daily evening dosing or twice daily dosing produced the best intraocular pressure control as well as the fewest adverse effects. Like latanoprost, unoprostone did not demonstrate any effects in lowering intraocular pressure in cats (Bartoe et al. 2005).

Suggested Dosages/Precautions/Adverse Effects
Unoprostone is dosed 1–2 drops in the evening and increased to twice daily dosing with progression of glaucoma.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
None currently available in the United States, but may be obtained through importation or through the services of appropriately qualified pharmacy.

References

Osmotic Agents For Treatment of Glaucoma
Osmotic agents increase the osmotic pressure of plasma and create a concentration gradient that will draw fluid out of the intraocular environment. Effective osmotic agents should be non-toxic, small in molecular weight, and have poor intraocular penetration (else intraocular pressure may increase). These agents are systemically administered with concurrent water deprivation (4–6 hrs) and are indicated only for acute episodes of glaucoma, not maintenance. For further information, see systemic monographs for Mannitol, Glycerin, and Isosorbide.

Mydriatic-Cycloplegic-Vasoconstrictors

CYCLOPENTOLATE
(cyclo-pen-tol-ate)

Indications/Pharmacology
Cyclopentolate is an anticholinergic agent that induces relaxation of the sphincter of the iris and the ciliary muscles. When applied topically to the eyes, it causes a rapid, intense cycloplegic and mydriatic effect that is maximal in 15–60 minutes; recovery usually occurs within 24 hours. The cycloplegic and mydriatic effects are slower in onset and longer in duration in animal patients who have darkly pigmented irises. Cyclopentolate is used mainly to produce mydriasis and cycloplegia for diagnostic purposes.

Suggested Dosages/Precautions/Adverse Effects
1 drop instilled in the eye(s), followed by a second drop 5 minutes later, if necessary. Drops should be administered 40–50 minutes prior to diagnostic procedure. Cyclopentolate increases intraocular pressure and should not be used in animals with glaucoma. Slight stinging is noted with the higher (1%) concentration of the drug.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Cyclopentolate Solution 0.5%, 1%, & 2%; in 2, 5 & 15 mL bottles: AK-Pentolate® (Akorn); Cyclogyl® (Alcon); generic; (Rx)

PHENYLEPHRINE HCL
(fen-e-fer-line)

Indications/Pharmacology
Phenylephrine is a direct-acting alpha agonist vasooconstrictor that is most commonly used in veterinary medicine as an adjunct preoperative medication to induce mydriasis prior to phacoemulsification for cataract removal. Phenylephrine is also used prior to minor surface (e.g., conjunctival) procedures to limit bleeding. Phenylephrine can be used to confirm the diagnosis of Horner’s syndrome. Dilution of 2.5% phenylephrine solution with saline (1:10) produces a 0.25% solution. Normal eyes will not demonstrate mydriasis in response to this low concentration of phenylephrine. Third order Horner’s syndrome of greater than two weeks duration is associated with receptor up regulation and therefore a response to 0.25% phenylephrine is noted. In this way, the diagnosis of Horner’s is confirmed and a suggestion as to whether or not the condition is 2nd or 3rd order in nature.

In dogs, maximum mydriasis persists for about 2 hours and effects may last for up to 18 hours. Phenylephrine has significant alpha-adrenergic effects (vasoconstriction and pupillary dilation) and minimal effects on beta-receptors. When used alone, phenylephrine is reportedly not efficacious in the cat unless used with other mydriatics.

Suggested Dosages/Precautions/Adverse Effects
For diagnosis and characterization of Horner’s syndrome: Apply 0.25% solution (see above) in both eyes. If there is a response in the miotic eye, it is 3rd order. If no response in 20–30 minutes, apply 2.5% solution; if there is a response in both eyes it confirms Horner’s and probably is 2nd order.

For treatment of Horner’s syndrome: Treatment is indicated only if patient experiences visual difficulty because third eyelid is elevated over pupil; then given on an as needed basis with an average duration of effect of 3–6 hours.

Prior to cataract or intraocular surgery: 2.5% or 10% given every 15 minutes for two hours. Smaller animals (e.g., cats and dogs weighing <5kg) are more susceptible to life-threatening systemic effects on blood pressure and cardiac rhythm and preoperative use of phenylephrine in these animals is generally not recommended. In larger animals, repeated dosing is also associated with cardiovascular adverse effects. Phenylephrine is ineffective as a sole mydriatic in cats or horses and it should be combined with atropine to achieve adequate mydriasis.

Local discomfort may occur after instillation and chronic use may lead to inflammation. In some species (cats, rabbits, humans), transient stromal clouding may occur if used when corneal epithelium is damaged.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS:
Indications/Pharmacology
Atropine is a potent mydriatic-cycloplegic utilized for therapeutic (not diagnostic) purposes. When used topically on the eye, atropine acts by blocking the cholinergic receptors of the sphincter muscle of the iris and the ciliary body to cause mydriasis (pupillary dilation) and accommodation paralysis (cycloplegia). Atropine is significantly ionized at physiological pH and it has limited corneal penetration. Atropine controls pain secondary to corneal and uveal disease; to maximally dilate the pupil prior to intracocular surgery; to dilate the pupil and prevent pupillary block in glaucoma and uveitis. In the dog, atropine causes maximal mydriasis in about 1 hour and it may persist for up to 120 hours. Cats also show a delayed onset of action and mydriasis may persist for up to 144 hours (dose dependent). Atropine is particularly long acting in horses and may last days to weeks.

Atropine may be used in combination with 10% phenylephrine to achieve mydriasis and cycloplegia in cases of anterior uveitis. Atropine may also be used in uveitis to break up synechiae.

Suggested Dosages/Precautions/Adverse Effects
Ointments or drops are routinely used in dogs. One percent is commonly used, but 2% solutions may be required in severe cases of uveitis. Ointments are generally used in cats to prevent hypersalivation associated with the bitter taste of this medication. Dosage frequencies are variable depending on the condition and its severity. Commonly, atropine is given as one drop 2–3 times a day or every other day until pupillary dilation is achieved and once daily thereafter to maintain this response.

Atropine may precipitate acute, congestive primary glaucoma in dogs predisposed to primary glaucoma; do not use in primary glaucoma. Repeated topical application prior to surgery can result in systemic atropine toxicity (mania, hyperthermia, etc.). Salivation may result in dogs as well as cats (see above) secondary to the bitter taste. Atropine may also decrease tear production in small animals.

Reportedly, very frequent treatment with atropine may induce colic in horses secondary to systemic absorption and atropine’s vagal parasympathetic effects. However, clinically this effect is only rarely noted.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS:
Atropine Sulfate Ophthalmic Solution: 0.5%, 1%, and 2% in unit dose droppers, 2, 5, & 15 mL bottles; various trade names & generic; (Rx)

HUMAN-LABELED PRODUCTS:
Atropine Sulfate Ophthalmic Ointment: 10 mg/gm (1%) in 3.5 gm tubes; Atrophate® (Schering-Plough); (Rx)

Tropicamide may cause salivation, particularly in cats. It may also sting when applied. Tropicamide may precipitate acute congestive glaucoma in predisposed patients. Tropicamide has been reported to decrease Schirmer Tear Test values for several hours following application in cats and horses.

Dosage Forms/Regulatory Status
Veterinary-LaBELED Products: None

HUMAN-LABELED PRODUCTS:
Tropicamide Solution 0.5% and 1%: 2 mL & 15 mL bottles; Mydriacyl® (Alcon), Opticyl® (Optopics), Tropicacyl® (Akorn), generic; (Rx)

Anti-inflammatory/Analgesic Ophthalmic Agents
Mast Cell Stabilizers, Antihistamines, Decongestants

CROMOLYN SODIUM
(droe-mo-lin)

Indications/Pharmacology
Cromolyn sodium is a mast cell stabilizing agent that blocks release of histamine and slow-reacting substance of anaphylaxis from mast cells following antigen recognition. Similar to lodoxamine tromethamine, cromolyn sodium has no intrinsic vasoconstrictor, antihistaminic, cyclooxygenase inhibition or other anti-inflammatory properties. Mast cell stabilizing agents are most useful in animal patients suffering from allergic conjunctivitis.

Suggested Dosages/Precautions/Adverse Effects
For relief of seasonal allergy, one drop 2–6 times daily. A stinging sensation is noted in a low percentage of people using this medication.
**Indications/Pharmacology**

Bromfenac is a nonsteroidal anti-inflammatory drug (NSAID) by virtue of its ability to block prostaglandin synthesis by inhibiting cyclooxygenase 1 and 2. Bromfenac is indicated for treatment of postoperative inflammation in patients who have undergone cataract extraction.

**Suggested Doses/Precautions/Adverse Effects**

One drop twice daily.

Bromfenac is contraindicated in patients with known hypersensitivity to any ingredient in the formulation. Bromfenac ophthalmic solution contains sodium sulfite, a sulfite known to cause allergic reactions especially in asthmatics. Caution should be exercised when utilizing bromfenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity. There have been reports that topically applied NSAIDs may cause increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroidal agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or ocularly applied NSAIDs may cause increased belled of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing.

**References**

Ketorolac Tromethamine Solution 0.5%: 3, 5, & 10 mL;

**Dosage Forms/Regulatory Status**

**HUMAN-LABELED PRODUCTS:** None

**VETERINARY-LABELED PRODUCTS:** Xibrom® (ISTA) (Rx). Store at room temperature.

**Indications/Pharmacology**

Ketorolac tromethamine is a pyrrolol-pyrrole nonsteroidal anti-inflammatory agent that inhibits prostaglandin formation. Ketorolac tromethamine is marketed for use before cataract extraction in human patients (to prevent miosis during surgery) and for control of post surgical inflammation, especially following cataract surgery. Ketorolac is also effective in treating postoperative cystoid macular edema and ocular surface inflammation. It is also used in diabetic patients, especially smaller patients, adversely affected by systemic uptake of topically applied corticosteroids. Nonsteroidal agents like ketorolac tromethamine can be combined with topical corticosteroids for better control of uveitis in animals when the condition is severe.

**Suggested Dosages/Precautions/Adverse Effects**

Before surgery: One drop 4 times at 20-minute intervals. One drop four times daily following cataract surgery or for the treatment of uveitis. Caution should be used when applying any anti-inflammatory agent on the cornea in the face of corneal stromal infection because of the positive role inflammation plays in the immune response to microbial invasion of tissue. A stinging sensation is noted in 15% of people using this medication.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Diclofenac Sodium 0.1% Solution: 2.5 & 5 mL; Voltaren® (Novartis); (Rx)

**Indications/Pharmacology**

Diclofenac sodium is a phenylacetic acid that inhibits cyclooxygenase, inhibiting prostaglandin synthesis. Diclofenac sodium topical solution reduces inflammation following cataract extraction in people and counteracts photophobia in humans having refractive corneal surgery. In veterinary medicine, diclofenac sodium is used for treatment of uveitis following surgery on the eye or other causes of uveitis especially when corneal infection is suspected or in diabetic patients whose insulin regulation could be altered by the systemic uptake of topical corticosteroids. Diclofenac can be combined with topical corticosteroids for better control of uveitis in animals when the condition is severe.

**Suggested Dosages/Precautions/Adverse Effects**

Prior to surgery: One drop 4 times at 20-minute intervals. Because flurbiprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with infected corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shuttled into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of flurbiprofen prior to cataract surgery has resulted from these studies.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Flurbiprofen Sodium 0.03% Solution: 2.5 mL, 5 mL & 10 mL btls; Ocufert® (Allergan); generic; (Rx)

**Indications/Pharmacology**

Flurbiprofen is a non-steroidal anti-inflammatory agent that probably acts by inhibiting the cyclo-oxygenase enzyme system, thereby reducing the biosynthesis of prostaglandins. Prostaglandins may mediate certain kinds of ocular inflammation. They may disrupt the blood-aqueous humor barrier, cause vasodilation, increase intraocular pressure and lenskocytosis, and increase vascular permeability. Prostaglandins may also cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Flurbiprofen can inhibit this intraocular miosis and it may be useful in the management of uveal inflammation (usually in addition to topical steroids).

**Suggested Dosages/Precautions/Adverse Effects**

Prior to surgery: One drop 4 times at 20-minute intervals. Caution should be used when applying any anti-inflammatory agent on the cornea in the face of corneal stromal infection because of the positive role inflammation plays in the immune response to microbial invasion of tissue. A stinging sensation is noted in 15% of people using this medication.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Bromfenac 0.09% solution: 7.5 mL & 10 mL;

**Indications/Pharmacology**

Bromfenac is a topical nonsteroidal anti-inflammatory agent that inhibits cyclooxygenase. Bromfenac is indicated for the treatment of postoperative ocular inflammation following cataract surgery and for the treatment of signs and symptoms of ocular inflammation associated with ocular allergy in adult patients. It may also be used in the medical management of ocular inflammation associated with a variety of ocular conditions, including but not limited to anterior uveitis, posterior uveitis, iritis, keratitis, and conjunctivitis. It is also used in diabetic patients, especially smaller patients, adversely affected by systemic uptake of topically applied corticosteroids. Nonsteroidal agents like ketorolac tromethamine can be combined with topical steroids in patients with severe uveal inflammation.

**Suggested Dosages/Precautions/Adverse Effects**

Prior to surgery: One drop 4 times at 20-minute intervals. The manufacturer indicates that ketorolac tromethamine does not enhance the spread of preexisting corneal fungal, viral or bacterial infections in animal models. Ketorolac tromethamine does not induce postoperative pressure elevation beyond which that frequently follows cataract extraction in people and animals.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** Ketorolac Tromethamine Solution 0.5%: 3, 5, & 10 mL; Acular® (Allergan); (Rx)
Indications/Pharmacology
Nepafenac is a nonsteroidal anti-inflammatory and analgesic prodrug. After topical ocular dosing, nepafenac penetrates the cornea where it is converted by ocular tissue hydrolases to amfenac, a nonsteroidal anti-inflammatory drug. Amfenac is thought to inhibit the action of prostaglandin H synthase (cyclooxygenase), an enzyme required for prostaglandin production. Nepafenac is indicated for the treatment of pain and inflammation associated with cataract surgery.

Suggested Dosages/Precautions/Adverse Effects
One drop three times daily. Shake well before use.

Nepafenac is contraindicated in patients who have demonstrated hypersensitivity to any of the ingredients in the formulation or to other NSAIDs. Caution should be exercised when utilizing nepafenac in patients who have previously exhibited sensitivity to other NSAID drugs as there is potential for cross-sensitivity.

There have been reports that ophthalmically applied NSAIDs may cause increased bleeding of ocular tissues (including hyphema) in conjunction with ocular surgery due to interference with platelet aggregation. All topical NSAIDs may slow or delay healing. Concomitant use with topical steroid agents may increase the potential for delayed healing. Use of topical NSAIDs may result in keratitis due to epithelial breakdown, corneal thinning, corneal erosion, corneal ulceration or corneal perforation. Use of nepafenac should be discontinued immediately in patients exhibiting evidence of corneal epithelial breakdown. Post marketing experience with topical NSAIDs suggests that use more than 24 hours prior to surgery or use beyond 14 days after surgery may increase patient risk for the occurrence of corneal adverse events. Nepafenac should be used with caution in patients with known bleeding tendencies or who are receiving other medications, which may prolong bleeding time. In controlled clinical studies, the most frequently reported ophthalm adverse events following cataract surgery were capsular opacity, decreased visual acuity, foreign body sensation, increased intraocular pressure, and sticky sensation. These events occurred in approximately 5–10% of patients. Other ophthalm adverse events occurring at an incidence of approximately 1–5% included conjunctival edema, corneal edema, dry eye, lid margin crusting, ocular discomfort, ocular hyperemia, ocular pain, ocular pruritus, photophobia, tearing and vitreous detachment. Some of these events may be the consequence of the cataract surgical procedure. Non-ocular adverse events reported at an incidence of 1–4% included headache, hypertension, nausea/vomiting, and sinusitis. Nepafenac ophthalmic suspension may be administered in conjunction with other topical ophthalmic medications such as beta-blockers, carbonic anhydrase inhibitors, alpha-agonists, cycloplegics, and mydriatics.

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Nepafenac Ophthalmic Suspension: 0.1% in 3 mL; Nevanac® (Alcon); (Rx). Shake well and store at room temperature.

SUPROFEN

(su-pr-o-fen)

Indications/Pharmacology
Suprofen is a non-steroidal anti-inflammatory agent similar to flurbiprofen. Suprofen and flurbiprofen are phenylalkanoic acids that inhibit the cyclo-oxygenase enzymes responsible for conversion of arachidonic acid from cell membranes into various prostaglandins. These prostaglandins mediate certain aspects of ocular inflammation including disruption of the blood-aqueous barrier, uveal vasodilation, increases in intraocular pressure, and leakage of white blood cells and protein from uveal vessels into the aqueous humor. Prostaglandins cause iris sphincter constriction (miosis) independent of cholinergic mechanisms. Suprofen can inhibit this intracocular miosis and may be useful in the management of increased intraocular inflammation (usually in addition to topical steroids).

Suggested Dosages/Precautions/Adverse Effects
Prior to surgery: One drop 4 times at 20-minute intervals.

Because suprofen may be as immunosuppressive as topical corticosteroids, it should not be used in patients with bacterial corneal ulcers. By blocking prostaglandin synthesis, arachidonic acid metabolites may be shunted into leukotriene pathways and this effect may result in a transient increase in intraocular pressure commonly noted after intraocular surgery. Postoperative pressure spikes following cataract surgery have been the subject of much study in recent years and a general trend away from the use of suprofen or flurbiprofen prior to cataract surgery has resulted from these studies.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:
Suprofen Sodium 1% Solution in 2.5 mL bds; Profena® (Alcon); (Rx). Shake well and store at room temperature.

Steroidal Anti-inflammatory Agents
Topical corticosteroids are used to treat diseases of the eye involving the conjunctiva, sclera, cornea, and anterior chamber. Efficacy of corticosteroids applied topically to the eye is dependent on many patient-related and drug-related factors. Patient factors include frequency and route of administration as well as conditions influencing penetration such as corneal ulceration or ocular inflammation. Topically delivered corticosteroids are best able to penetrate the cornea if they are both hydrophilic and lipophilic. The solubility can be improved by utilizing salts that are more lipophilic in nature (e.g. acetates), hydrophilic in nature (e.g. sodium phosphate or hydrochloride) or biphasic (e.g. alcohol derivatives). Hydrophilic ocular preparations are usually supplied as solutions while lipophilic agents are usually supplied as ointments or suspensions. In order to increase efficacy of topicaly administered corticosteroids, frequency of administration is increased instead of drug concentration (e.g., prednisolone acetate 1% suspension is equally efficacious as 1.5% and 3% suspensions when used at the same frequency.) Penetration of topically applied corticosteroids into the eyelids is poor as is penetration to the posterior segment of the eye. Corticosteroid-responsive conditions affecting these areas are usually managed with systemically administered agents (with or without adjunctive topically applied medications).

Ocular side effects of ophthalmic corticosteroids can be numerous, including the development of cataracts, increased IOP, infection, decreased would healing, mydriasis, and calcific keratopathy. While these side effects may be frequent in humans, some are less common in animals. With the exceptions of mydriasis and calcific keratopathy, these side effects may occur in association with systemically administered corticosteroids as well. Systemic side effects of topical ophthalmic corticosteroids include glucocorticoid-induced hepatopathy, suppression of endogenous glucocorticoid production, or local ocular. It is important to note that such side effects occur more readily with systemic administration of corticosteroids, but occur in a dose and duration-dependent manner following topical ophthalmic administration.

Conjunctivitis in animals is often treated symptomatically, particularly during the first occurrence of the condition for any particular patient. Antibiotic agents with hydrocortisone or dexamethasone, or antibiotic agents alone initially, are used for conjunctivitis in the dog and the horse. Allergic and eosinophilic conjunctivitis are rare diagnoses in the cat. Topically applied corticosteroids should not be used to treat conjunctivitis in cats. Herpes virus is the most common feline conjunctival pathogen and topically applied steroids can induce prolonged disease, steroid dependency and corneal complications including ulcerative keratitis and/or corneal sequestrum formation.

Inflammatory conditions of the canine sclera and episclera include episcleritis, scleritis, nodular granulomatous episclerokeratitis, Collie granuloma and others. Potency and penetration of corticosteroid agents is important in the management of these conditions. Dexamethasone sodium phosphate ointment is often employed and the relatively reduced penetration of the fibrous ocular tunics of this medication compared with that of 1% prednisolone acetate ophthalmic suspension is made up for by increased contact time of the ointment form of this drug and by the increased potency of dexamethasone (30X cortisone) relative to prednisolone (4-5X cortisol). Dexamethasone products alone (without antibiotics) are becoming increasingly scarce in the marketplace and because of this, dexamethasone is often used in combination with an antibiotic for availability reasons only. Four times daily treatment is often the initial frequency with tapering paralleled to clinical response. Topical treatment is often used following subconjunctival injection of corticosteroid agents into or adjacent to the lesion (if focal). Systemic steroid treatment is usually not necessary.

Non-inflammatory conditions of the cornea include animals of chronic superficial keratitis (pannus) of the German Shepherd and other breeds, eosinophilic keratitis of the cat and certain, often poorly understood, keratopathies of the equine, including Onchocerca related keratitis. German Shepherd pannus may be better managed using cyclosporine ophthalmic solution or ointment with or without concurrent topical steroids as needed. Suprofen sodium phosphate ointment is often used in conjunction with other topical ophthalmic medications such as beta-blockers, carbonic anhydrase inhibitors, alpha-agonists, cycloplegics, and mydriatics.
Indications/Pharmacology
Prednisolone is an intermediate-acting synthetic corticosteroid available as acetate or phosphate salts. The acetate derivative has superior anti-inflammatory activity in comparison to the phosphate derivative, and it is considered the most effective drug for anterior uveits. Prednisolone acetate ophthalmic suspension is generally used for anterior uveits because of superior penetration into the anterior segment of the eye in comparison with dexamethasone products. The frequency of treatment depends on the severity of the condition. Severe anterior uveits can be treated with subconjunctival corticosteroids given in combination with hourly topical corticosteroids with reevaluation performed again 24 hours after beginning treatment. Moderate to mild uveits and that found following surgery of the anterior segment are often treated initially at the QID level with tapering based on clinical response. Anterior uveits in animals can often be associated with an underlying systemic infectious or neoplastic condition in animals. Clinicians are advised to evaluate the patient for generalized infectious or neoplastic conditions prior to or concurrent with a course of corticosteroid anti-inflammatory therapy, particularly if the condition dictates systemic treatment with these agents in combination with subconjunctival and topical treatment. Uveits has also been successfully treated utilizing subconjunctival injections of triamcinolone acetonide. As commercially available triamcinolone injections are preserved with benzyl alcohol, veterinary ophthalmologists centrifuge triamcinolone injections and remove the alcohol-containing supernatant vehicle. An equal volume of non-preserved sodium chloride injection is then utilized to reconstitute the remaining triamcinolone to provide for an acceptable subconjunctival injection. Uveits in the equine species is often treated with either 1% prednisolone acetate ophthalmic suspension or with 0.1% dexamethasone ointment. Many clinicians prefer to use the ointment because of increased contact time and potency and the logistics of frequent treatment of this species. 1% prednisolone acetate can be passed through a subpalpebral lavage catheter very frequently to treat equine patients with anterior uveits when necessary.

Indications/Pharmacology
Prednisolone is a long-acting corticosteroid with anti-inflammatory properties. It is available as a generic product under different trade names.

Doseage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Prednisolone Acetate Drops: 0.125% Suspension: Pred Mild® (Allergan); 0.125% Suspension: Econopred® (Alcon); 1% Suspension: Econopred Plus® (Alcon); Pred Forte® (Allergan), generic; (Rx)
- Prednisolone Sodium Phosphate Drops: 0.125 & 1% Solution; (various); (Rx)
- Prednisolone (0.25%) and Atropine (1%) Drops in 5 mL btls; Mydriate® (Allergan), generic; (Rx)

**BETAMETHASONE**

Indications/Pharmacology
Betamethasone is a long-acting corticosteroid that is available in various forms and is used for various conditions.

Doseage Forms/Regulatory Status
**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

Note: Compounding pharmacists can still provide the combination of gentamicin and betamethasone, but this preparation should never be utilized if corneal abrasion or ulceration are suspected, and should not be used to treat herpes keratitis in cats.
**Indications/Pharmacology**

Flurometholone is actually an analog of progesterone instead of cortisol, available in alcohol or acetate salt formulations. Flurometholone alcohol formulations have less anti-inflammatory effect than prednisolone acetate, but acetate salts have activity comparable to prednisolone acetate suspensions. Higher concentrations of flurometholone (0.25%) have been noted to raise intraocular pressure (Sendrowski et al. 2008).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

- Flurometholone 0.1% ointment, 3.5 gram tube: FML S.O.P.® (Allergan); (Rx)
- Flurometholone 0.25% alcohol suspension, 5 mL, 10 mL bottles, FML Forte® (Allergan); (Rx)
- Flurometholone acetate 0.1% suspension, 5 mL, 10 mL, 15 mL bottles, FML® (Allergan); Flarex® (Alcon), generic; (Rx)

**References**

---

**LOTEPREDNOL**

(lo-teh-pred-nol)

**Indications/Pharmacology**

Loteprednol etabonate is synthesized from an inactive metabolite of the parent drug (i.e. a "soft drug") that is briefly activated to the active metabolite in vivo, exerts its pharmacological effects, and then is transformed back to the inactive metabolite. Loteprednol antiinflammatory effect is comparable to other topical corticosteroids and it has a lower risk of raising intraocular pressure.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

- Loteprednol 0.5% suspension: 2.5 mL, 5 mL, 10 mL, 15 mL bottles; Lotemax® (Bausch & Lomb); (Rx)
- Loteprednol 0.2% suspension: 5 mL, 10 mL; Alrex® (Bausch & Lomb); (Rx)

---

**RIMELOXOLONE**

(rem-eh-lox-a-lone)

**Indications/Pharmacology**

Rimeloxolone is a topical corticosteroid agent that has comparable anti-inflammatory activity to prednisolone acetate. It is used for treatment of uveitis and is administered in aggressive pulse doses to patients with mild to moderate inflammation.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:**

- Rimeloxolone 1% suspension, 5 mL and 10 mL bottles; Vexol® (Alcon); (Rx)

**Ophthalmic Analgesics**

---

**MORPHINE SULFATE**

(mor-foe-n)

**Indications/Pharmacology**

A recent study showed that topical use of 1% morphine sulfate solution in dogs with corneal ulcers provided analgesia and did not interfere with normal wound healing. Both mu and delta opioid receptors were identified in normal corneas of dogs, although the mu receptors were present only in small numbers. Dogs treated with morphine sulfate 1% topical solution had significantly less blepharospasm and lower esthesiometer readings than did control dogs. Morphine sulfate is a Schedule II controlled substance.

**Suggested Dosages/Precautions/Adverse Effects**

1 drop of 1% morphine sulfate solution in the affected eye(s) three times daily. Preserved solutions of morphine should not be used.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELLED PRODUCTS:** None

A 1% morphine sulfate ophthalmic solution may be compounded by utilizing the preservative-free morphine 2.5% injectable solution diluted with sterile saline observing appropriate aseptic technique.
Antimicrobial Ophthalmic Therapy

Indications/Pharmacology

A review of the literature reveals that solutions of topical nalbuphine were used clinically to provide analgesia and reduce ophthalmic pain in humans as early as 1983. Nalbuphine hydrochloride is a potent analgesic. Its analgesic potency is essentially equivalent to that of morphine on a milligram basis. Receptor studies show that nalbuphine hydrochloride binds to mu, kappa, and delta receptors, but not to sigma receptors. Nalbuphine hydrochloride is primarily a kappa agonist/partial mu antagonist analgesic. Nalbuphine hydrochloride is not commercially available for ophthalmic use, but may be obtained through appropriately qualified compounding pharmacies.

Suggested Dosages/Precautions/Adverse Effects

One drop two to six times daily as needed for corneal pain. Do not use in conjunction with topical morphine as nalbuphine will reverse the effects of morphine at the mu receptor.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

The 10 mg/mL (1%) nalbuphine injection may be applied as an ophthalmic solution. A 1% nalbuphine ophthalmic solution may also be compounded by utilizing nalbuphine 20 mg/mL injectable solution diluted with 1:1 sterile saline observing appropriate aseptic technique.

Gentamicin Sulfate

(gehn-tam-i-sin sulf-ate)

Indications/Pharmacology

Gentamicin may be administered topically or subconjunctivally and is primarily used for keratitis caused by Pseudomonas aeruginosa. The commercially available 0.3% solution is generally too dilute to achieve topical concentrations required for treatment of Pseudomonas keratitis. Fortified solutions of amikacin sulfate may be compounded in concentrations of 8 mg/mL.

Suggested Dosages/Precautions/Adverse Effects

Administration must be separated by a time lapse if concurrently administered. Subconjunctival injection does raise ocular concentrations of amikacin; however, parenteral administration does not demonstrate benefit in treating ocular infections. Of the aminoglycosides, amikacin demonstrates the least potential for microbial resistance or adverse reactions. For therapeutic use, the causative agent should be determined and an appropriate antimicrobial applied again monitoring for development of resistance or adverse effects.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Mycelex® (Upjohn) (Rx). Approved for use in dogs.
- Neosporin Ophthalmic Solution (Upjohn) (Rx). Approved for dogs and cats.
- Optiprime® (Syntex); (Rx). Approved for use in dogs.
- Tricoptic-P0 (Pfizer); Vetropolycin® (Dechra); generic; (Rx). Approved for dogs and cats.
- None

HUMAN-LABELED PRODUCTS:

- Bacitracin zinc 400 units/Neomycin 3.5 mg/Polyoxymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; Mycelex® (Upjohn) (Rx); Neosporin® Ophthalmic Solution: Optiprime® (Syntex); (Rx). Approved for use in dogs.
- None

Antibiotics, Single & Combination Products

Antimicrobials are critical to the management of ocular disease, however several considerations determine appropriate use. For prophylactic use, drugs effective against pathogens likely at the site should be selected as well as potential for microbial resistance or adverse reactions. For therapeutic use, the causative agent should be determined and an appropriate antimicrobial applied again monitoring for development of resistance or adverse effects.

AMIKACIN SULFATE

(am-i-ka-sin sulf-ate)

Indications/Pharmacology

Although amikacin is not commercially available as a topical preparation, it has been compounded for use in corneal infections caused by gram-negative bacilli that have become resistant to gentamicin or tobramycin. Subconjunctival injection does raise ocular concentrations of amikacin; however, parenteral administration does not demonstrate benefit in treating ocular infections. Of the aminoglycosides, amikacin demonstrates the least retinal toxicity, making it useful in treating endophthalmitis.

Suggested Dosages/Precautions/Adverse Effects

Amikacin may be compounded to a concentration of 8mg/ml as a sterile, fortified ophthalmic antibiotic solution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Fortified solutions of amikacin sulfate may be compounded in concentrations of 8 mg/mL.

NEOMYCIN SULFATE

(nee-o-my-sin sulf-ate)

Indications/Pharmacology

Neomycin is commonly included in triple antibiotic formulations. It has minimal corneal penetration in the presence of intact corneal epithelium, but is useful for treatment of superficial corneal ulceration or surface ocular infections.

Suggested Dosages/Precautions/Adverse Effects

Neomycin may cause contact sensitivity and it is contraindicated in patients with a history of such.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Bacitracin zinc 400 units/Neomycin 3.5 mg/Polyoxymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; Mycelex® (Upjohn) (Rx); Neosporin® Ophthalmic Solution: Optiprime® (Syntex); (Rx). Approved for use in dogs.
- Neomycin 3.5 mg/Polyoxymyxin B Sulfate 10,000 Units per mL Ophthalmic Solution: Optiprime® (Syntex); (Rx). Approved for use in dogs.
- None

HUMAN-LABELED PRODUCTS:

There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (e.g., gramicidin in place of bacitracin in topical solutions-Neosporin® Ophthalmic Solution). All of these products require a prescription.

NALBUPHINE

(nal-byoo-feen)

Indications/Pharmacology

A review of the literature reveals that solutions of topical nalbuphine were used clinically to provide analgesia and reduce ophthalmic pain in humans as early as 1983. Nalbuphine hydrochloride is a potent analgesic. Its analgesic potency is essentially equivalent to that of morphine on a milligram basis. Receptor studies show that nalbuphine hydrochloride binds to mu, kappa, and delta receptors, but not to sigma receptors. Nalbuphine hydrochloride is primarily a kappa agonist/partial mu antagonist analgesic. Nalbuphine hydrochloride may precipitate withdrawal in patients dependent on opioid drugs. Nalbuphine hydrochloride should be used with caution in patients who have been receiving mu opioid analgesics on a regular basis. Nalbuphine is not commercially available for ophthalmic use, but may be obtained through appropriately qualified compounding pharmacies.

**Fluoroquinolones, Ocular**

Fluoroquinolones (FQNs) are bactericidal through inhibition of bacterial DNA gyrase thereby disrupting bacterial DNA replication. Nalidixic acid is considered the first fluoroquinolone with a spectrum of activity limited to gram-negative organisms and weak activity against *Pseudomonas aeruginosa*. Second generation FQNs (lomefloxacin, norfloxacin, enoxacin, enrofloxacin, ciprofloxacin and ofloxacin) also demonstrate weak activity against *Pseudomonas aeruginosa*, and *Streptococcus* spp are also increasing in resistance to second generation FQN. Third generation FQNs (sparfloxacin, gemifloxacin and levofloxacin) are rarely used in ophthalmology. Fourth generation FQNs (gatifloxacin, moxifloxacin and besifloxacin) have a greater efficacy against gram-positive organisms compared to earlier generation FQNs, but are still relatively ineffective against *Pseudomonas* spp. Moxifloxacin has consistently demonstrated superior ocular penetration when compared to other FQNs (Solomon et al. 2005; Yagci et al. 2007).

**Suggested Dosages/Precautions/Adverse Effects**

Solution: One drop three to four times daily. Ointment: ½ inch strip three to four times daily.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:**

- Tobramycin Ophthalmic Ointment: 3 mg/gram in 3.5 gm tubes; Tobrex® (Alcon); (Rx)
- Tobramycin Ophthalmic Drops: 3 mg/mL in 5 mL btl; Tobrex® (Alcon); (Rx)

**Human-Labeled Products:**

- Ciprofloxacin: Dexamethasone 0.3%/0.1% drops in 7.5 mL btl; Ciprodex® (Alcon); (Rx)
- Ciprofloxacin: Dexamethasone 0.3%/0.1% drops in 7.5 mL btl; Genoptic® (Allergan); generic; (Rx)

**Tobramycin Sulfate**

- Tobramycin Ophthalmic Drops: 3 mg/mL in 5 mL btl; Tobrex® (Alcon); (Rx)
- Tobramycin Ophthalmic Ointment: 3 mg/gram in 3.5 gm tubes; Tobrex® (Alcon); (Rx)

**Indications/Pharmacology**

Tobramycin possesses a similar spectrum of activity to that of gentamicin. The commercially available solutions and ointments are sometimes not concentrated enough to achieve therapeutic effect and fortified concentrations of greater than 14.5 mg/mL are compounded for use. Ocular drug levels of tobramycin can be increased with use of subconjunctival injections, however, systemic use of tobramycin does not demonstrate benefit in ocular infections.

**References**

- Solomon, R., E.D. Donnenfeld, et al. (2005). Penetration of topically applied gatifloxacin 0.3%, moxifloxacin 0.5%, and ciprofloxacin 0.3% into the aqueous humor.
Indications/Pharmacology

Erythromycin has a spectrum against gram-positive organisms except for enterococci. Use of erythromycin in ophthalmology is targeted towards infections caused by *Mycoplasma* spp, *Chlamydia* spp, and *Borrelia burgdorferi*. Resistance to erythromycin is still limited enough that it remains a potentially useful therapeutic option for diseases caused by these organisms.

Suggested Dosages/Precautions/Adverse Effects

½ inch strip three to four times daily.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

- Erythromycin 0.5% ophthalmic ointment, 3.5 gram tube, generic (Rx)

Tetracyclines, Ocular

Tetracyclines exert an antimicrobial effect through inhibition of bacterial protein synthesis at the 30S ribosomal subunit. While tetracyclines have a broad spectrum of antimicrobial coverage, their clinical usefulness is limited by efflux mechanisms in bacteria that actively pump tetracyclines out of cells to create resistant strains. *Pseudomonas* spp are considered resistant to tetracyclines.

Tetracyclines are also useful as anti-inflammatory agents by virtue of their ability to inhibit matrix metalloproteinases (MMP). The role of MMP in destroying corneal collagen can be blocked by tetracyclines administered orally to patients with melting corneal ulcers. Oral administration of doxycycline at doses of 20 mg/kg PO twice daily have resulted in detectable levels of doxycycline in aqueous humor (Davis et al. 2006).

Indications/Pharmacology

The tetracyclines are most useful in cats for the treatment of Chlamydial and Mycoplasma conjunctivitis as well as nonspecific or symptomatic therapy for undiagnosed (causative organism not determined) conjunctivitis in cats.

Suggested Dosages/Precautions/Adverse Effects

For Chlamydial/Mycoplasma keratoconjunctivitis: Apply 4 times daily. Dramatic improvement should be noted in 3–4 days, but treatment should continue for 3–4 weeks for Chlamydia to break the reproductive cycle of this organism. Expect potential recurrence after discontinuation of topical treatment from organisms dormant in the nasal passage. As oral doxycycline has been documented to eliminate the carrier state of Chlamydia in cats, better treatment is oral doxycycline 25 mg PO twice daily for three weeks.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Oxytetracycline HCl 5 mg/Polymyxin B Sulfate 10,000 Units/gm: 3.5 gram tubes; *Terramycin® Ophthalmic Ointment* (Pfizer); (Rx)

HUMAN-LABELED PRODUCTS: None

TETRACYCLINE

(HI-t-ri-se-a-klleen)

Indications/Pharmacology

The tetracyclines are most useful in cats for the treatment of Chlamydial and Mycoplasma conjunctivitis as well as nonspecific or symptomatic therapy for undiagnosed (causative organism not determined) conjunctivitis in cats.

At the time of writing, there are no commercially available ophthalmic dosage forms of tetracycline.

Suggested Dosages/Precautions/Adverse Effects

For Chlamydial/Mycoplasma keratoconjunctivitis: Apply 4 times daily. Dramatic improvement should be noted in 3–4 days, but treatment should continue for 3–4 weeks for Chlamydia to break the reproductive cycle of this organism. Expect potential recurrence after discontinuation of topical treatment from organisms dormant in the nasal passage. As oral doxycycline has been documented to eliminate the carrier state of Chlamydia in cats, better treatment is oral doxycycline 25 mg PO twice daily for three weeks.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Formerly available as Tetracycline HCl Ophthalmic Suspension: 10 mg/mL in 4 mL btl's; *Achromycin®* (Storz/Lederle); (Rx)

Formerly available as Tetracycline HCl Ophthalmic Ointment: 10 mg/gm in 3.75 gram tubes; *Terramycin®* (Storz/Lederle); (Rx)

Miscellaneous Antibiotics, Ocular

BACITRACIN

(bah-si-trak-sin)

Indications/Pharmacology

Bacitracin inhibits bacterial cell wall synthesis through inhibition of a peptidoglycan precursor, and exhibits a spectrum of action primarily against gram-positive organisms. Bacitracin is unstable in solution, however, it is a common component of combination antibiotic ointments. It is usually combined with polymyxin B and neomycin due to their greater gram-negative activity. This broad spectrum of activity makes triple antibiotic products useful in prophylaxis and therapy for corneal and ocular surface infections. Bacitracin poorly penetrates the cornea and is of limited value in deep corneal or intraocular infections.

Suggested Dosages/Precautions/Adverse Effects

The primary adverse effect associated with bacitracin is local hypersensitivity.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

- Bacitracin zinc 400 units/Neomycin 3.5 mg/Polymyxin B Sulfate 10,000 Units per gram Ophthalmic Ointment: 3.5 gm tubes; *Myctracin®* (Upjohn) (Note: contains 500 mg bacitracin/gram); *Neobacimyx®* (Schering); *Trioptic-P®* (Pfizer); *Vetropolyxin®* (Dechra); generic; (Rx). Approved for dogs and cats.

HUMAN-LABELED PRODUCTS:

- There is a wide variety of human-labeled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polymyxin B. However, there are variations of this theme (e.g., gramicidin in place of bacitracin in topical solutions-*Neosporin® Ophthalmic Solution*). All these products require a prescription.

CHLORAMPHENICOL

(klor-am-feen-i-kol)
A broad spectrum antibiotic, chloramphenicol has the ability to cross the corneal barrier and enter the anterior chamber. However, very few infections occur in the anterior chamber and if bacteria are actually present, the blood ocular barrier is lost and systemically administered antibiotics can achieve therapeutic levels. Typically, Staph spp. and Strep spp. are susceptible to chloramphenicol while Pseudomonas spp. are resistant.

Because of the potential toxicity associated with chloramphenicol to humans, chloramphenicol’s use in veterinary opthalmology is becoming less widespread. It may be useful, however, in treating cats with suspected Mycoplasma or chlamydial conjunctivitis, and at the time of printing is one of the few commercially available ophthalmic antibiotics available in an ointment form.

**Indications/Pharmacology**

Polymyxin B is a cationic surfactant (detergent) that disrupts cell membrane integrity through interaction with cell phospholipids. The antimicrobial spectrum is against gram-negative organisms and it is therefore frequently combined with antimicrobials possessing gram-positive activity (e.g., bacitracin).

**Suggested Dosages/Precautions/Adverse Effects**

Local reactions can be noted in hypersensitive patients.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

**Polymyxin B Sulfate Ophthalmic Solution (pahl-e-myk-sin)**

For conjunctivitis and other superficial ocular infections due to susceptible microorganisms, and as an adjunctive in systemic sulfonamide therapy of trachoma, *Escherichia coli*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Streptococcus* (viridans group), *Haemophilus Muenzzer*, Klebsiella species and Enterobacter species. Topically applied sulfonamides do not provide adequate coverage against *Neisseria* species, *Serratia marcescens* and *Pseudomonas aeruginosa*. A significant percentage of staphylococcal isolates are completely resistant to sulfa drugs.

**Precautions/Adverse Effects**

For conjunctivitis and other superficial ocular infections: Instill one or two drops into the conjunctival sac(s) of the affected eye(s) every two to three hours initially. Dosages may be tapered by increasing the time interval between doses as the patient responds. The usual duration of treatment is seven to ten days. Owners with sulfa allergies should be cautioned to avoid all contact with this medication. Adverse effects seen in animals include gastrointestinal disturbances, allergic skin reactions, renal damage and blood dyscrasias. In dogs, sulfonamides are known to cause keratoconjunctivitis sicca associated with direct toxic effect to the lacrimal acinar cells. This effect is caused by the nitrogen-containing pyridine and pyrimidine rings in sulfonamides and is dose-related. The estimated incidence is 15%-25% in dogs treated with sulfonamides and may occur long after treatment. Dogs demonstrating squinting or excess ocular mucous discharge should be evaluated for this adverse effect, which may be reversible if sulfonamides are discontinued in time.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

**Sulfacetamide (sul-fa-se-at-a-mide)**

**Indications/Pharmacology**

For the treatment of conjunctivitis and other superficial ocular infections due to susceptible microorganisms, and as an adjunctive in systemic sulfonamide therapy of trachoma, *Escherichia coli*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Streptococcus* (viridans group), *Haemophilus Muenzzer*, Klebsiella species and Enterobacter species. Topically applied sulfonamides do not provide adequate coverage against *Neisseria* species, *Serratia marcescens* and *Pseudomonas aeruginosa*. A significant percentage of staphylococcal isolates are completely resistant to sulfa drugs.

**Precautions/Adverse Effects**

For conjunctivitis and other superficial ocular infections: Instill one or two drops into the conjunctival sac(s) of the affected eye(s) every two to three hours initially. Dosages may be tapered by increasing the time interval between doses as the patient responds. The usual duration of treatment is seven to ten days. Owners with sulfa allergies should be cautioned to avoid all contact with this medication. Adverse effects seen in animals include gastrointestinal disturbances, allergic skin reactions, renal damage and blood dyscrasias. In dogs, sulfonamides are known to cause keratoconjunctivitis sicca associated with direct toxic effect to the lacrimal acinar cells. This effect is caused by the nitrogen-containing pyridine and pyrimidine rings in sulfonamides and is dose-related. The estimated incidence is 15%-25% in dogs treated with sulfonamides and may occur long after treatment. Dogs demonstrating squinting or excess ocular mucous discharge should be evaluated for this adverse effect, which may be reversible if sulfonamides are discontinued in time.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

**Sulfacetamide Ophthalmic Solution 10%**: 15 mL, btl; *Sulf-10®, AK-10®* (Akorn); *Bleph-10®* (Allergan); (Rx)

**Sulfacetamide Ophthalmic Ointment 10%**: *Bleph-10®* (Allergan); (Rx)

**VANCOMYCIN (van-co-mye-sin)**

**Indications/Pharmacology**

Vancomycin inhibits bacterial cell wall synthesis through inhibition of peptidoglycan development. Vancomycin has strong activity against gram-positive organisms, particularly *Staphylococcus* and *Streptococcus* species. Vancomycin is generally reserved for those gram-positive species that have been classified as methicillin-resistant. Vancomycin is used for topical administration in infections keratitis or bacterial endophthalmitis. An evaluation of vancomycin to treat methicillin-resistant *Staph* keratitis in rabbits, demonstrated that concentrations of 0.3%-1% vancomycin are effective (Eguchi et al. 2009). Injection of vancomycin nanoparticles into the anterior chamber of rabbits demonstrated good prophylactic activity against MRSA with minimal adverse effects (Kodijkan et al. 2010).

**Suggested Dosages/Precautions/Adverse Effects**

Systemic vancomycin therapy can be associated with ototoxicity, potentially leading to permanent deafness, and nephrotoxicity with resultant fatal uremia.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** Vancomycin topical solutions intended for ocular use may be prepared by appropriately qualified compounding pharmacists in concentrations from 0.3%-1%.

**References**

This combination products exhibit a broad-spectrum of activity and are considered the first choice for symptomatic treatment of conjunctivitis in dogs and for prophylactic treatment of small animals prior to or after eye surgery. These agents are also used prophylactically for corneal injuries/wounds.

**Suggested Dosages/Precautions/Adverse Effects**

- Neomycin has been reported to cause allergic reactions in dogs and cats, particularly after prolonged usage. As noted above, avoid neomycin treatment in cats unless absolutely necessary. Interestingly, anaphylactic reactions in cats have only been associated with neomycin products in ointment form in the absence of cortisone, but not with antibiotic-steroid combination preparations.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

- **Bacitracin zinc 400 Units/Neomycin 3.5 mg/Polyoxymyin B Sulfate 10,000 Units/gram Ophthalnic Ointment:** 3.5 gm tubes; **Mycelex®** (Upjohn); **Note:** contains 500 mg bacitracin/gm; **Bacitracin zinc 400 Units/Polymyxin B Sulfate 10,000 Units/gram Ophthalnic Ointment:** 3.5 gm tubes; **Trioptic®-PB** (Pfizer); **Vetropoly 7000®** (Dechra); generic; (Rx). FDA-approved for dogs and cats.

**HUMAN-LABELLED PRODUCTS:**

There is a wide variety of human-labelled ophthalmic combination products available. Most are a combination of bacitracin/neomycin/polyoxymyIN B. However, there are variations of this theme (e.g., gramicidin in place of bacitracin in topical solutions-Neosporin® Ophthalnic Solution). All these products require a prescription.

**ANTIBIOTIC AND CORTICOSTEROID COMBINATIONS**

**Indications/Pharmacology**

There are three basic categories of these products that are routinely used in veterinary medicine; antibiotic combinations with hydrocortisone, antibiotic combinations with dexamethasone, and individual antibiotics (e.g., gentamicin or chloramphenicol) with a steroid.

- Antibiotic combinations with hydrocortisone (ointment or solution) are used in dogs and horses for conjunctivitis as non-specific therapy after ruling out other causes for red painful eyes, including glaucoma and anterior uveitis. They are generally applied 4 times daily and then on a tapering schedule based on the response to therapy. The hydrocortisone is relatively weak as an anti-inflammatory agent and is not effective for intraocular inflammatory disease such as anterior uveitis. The relative penetration and potency of hydrocortisone in these preparations makes them relatively ineffective for immune mediated extraocular disease including scleritis, episcleritis and nodular granulomatous episclerokeratitis. Anterior uveitis is statistically more common in horses than simple conjunctivitis and the steroid in these agents would not be helpful in improving the clinical signs of immune mediated uveitis.

- Antibiotic combinations with dexamethasone are valuable for use in cases of severe canine or equine conjunctivitis, non ultracentrifugal keratitis and for immune-mediated scleral or corneal conditions such as chronic superficial keratitis (German shepherd panus), feline eosinophilic keratitis, scleritis, episcleritis and nodular granulomatous episclerokeratitis. For these conditions, the antibiotic agent is not necessary but dexamethasone-only products are not always available. These medications are also used in the equine species with equine uveitis because the ointment forms persist on the cornea longer than drops.

- Single agent antibiotic (gentamicin) and potent steroid (betamethasone) combination products (e.g., Gentocin®) are commonly used in veterinary medicine. However, there are few instances in veterinary ophthalmology in which a very potent corticosteroid agent and an aminoglycoside antibiotic is necessary in combination. Simple conjunctivitis in dogs and horses is adequately treated with antibiotic combinations with hydrocortisone. Avoid use of this agent in cats with conjunctivitis for the reasons noted below.

**Suggested Dosages/Precautions/Adverse Effects**

See individual product label information and the information noted above.

Avoid use of antibiotic/steroid combination agents in cats with conjunctivitis as the most common cause of conjunctivitis in the cat is primary or recurring infection with exposure to, or reactivation of, latent feline herpes virus. Recent research indicates that topical steroids increase the length of the typical course of feline herpes virus related conjunctivitis and/or keratitis and can induce corneal involvement in cases that might otherwise have remained confined to conjunctiva. Corneal sequestration has been noted to occur in cats with herpes virus conjunctivitis after treatment with topical steroids. Recommended treatment for feline herpes virus conjunctivitis is tetracycline ointment (QD) during active disease, as this drug is effective against Mycoplasma and Chlamydia (Note: concurrent systemic treatment with doxycycline will likely be necessary to clear Chlamydia organisms from the nasal and/or GI passages in cats as discussed above).

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELLED PRODUCTS:**

- **Trioptic Antibiotic Ointments with Hydrocortisone:**
  - Bacitracin zinc 400 units/Neomycin 3.5 mg/Polyoxymyin B Sulfate 10,000 Units & Hydrocortisone acetate 1% per gram in 3.5 gm tubes; **Neobacimyx®** (Schering); **Trioptic®** (Pfizer); **Vetropoly 7000®** (Dechra); generic; (Rx). Approved for dogs and cats.

- **Other Antibiotic/Steroid Ointments:**
  - Neomycin Sulfate 5 mg & Prednisolone 2 mg (0.2%) per gram in 3.5 gm tubes; **Optione®** (Evso); (Rx). Approved for use in dogs and cats.
  - Neomycin Sulfate 5 mg & Isoflupredone acetate 1 mg (0.1%) per gram in 3.5 & 5 gm tubes; **Neo-Pred® Sterile Ointment** (Upjohn); (Rx). Approved for use in horses, cattle, dogs and cats.
  - Chloramphenicol 1% and Prednisolone acetate 2.5 mg (0.25%) in 3.5 gm tubes; **Chlorasone®** (Evso); (Rx). Approved for use in dogs and cats.

**Drops:**

- Gentamicin Ophthalmic Drops 3 mg/mL & Betamethasone acetate 1 ml/mL in 5 mL vials; **Gentotic Daurasil®** (Schering); (Rx). Approved for use in dogs.

**HUMAN-LABELLED PRODUCTS:**

There is a wide variety of human-labelled ophthalmic antibiotic/steroid combination products available. Some of the more commonly used combinations include:

- **Ointments:**
  - Bacitracin/Neomycin/Polyoxymyin B and Hydrocortisone; **Coritspin®** (BW); (Rx)
  - Neomycin/Polyoxymyin B & Dexamethasone; **Maxitrol®** (Alcon); (Rx)
  - Neomycin and Dexamethasone; **NeoDecadron®** (Merck); (Rx)

- **Drops:**
  - Neomycin/Polyoxymyin B and Hydrocortisone; **Coritspin®** (BW, etc.); (Rx)
  - Neomycin/Polyoxymyin B & Dexamethasone; **Maxitrol®** (Alcon); (Rx)
  - Neomycin and Dexamethasone; **NeoDecadron®** (Merck); (Rx)

**Antifungals, Ocular**

Antifungal agents act primarily by inhibition of fungal cell wall and fall into four classes: polyenes, pyrimidines, azoles, or echinocandins. Polyenes (ampicillin, nystatin and natamycin) bind ergosterol in a dose-related effect causing fungal cell wall leakage and cell death. Fungal keratitis is a serious corneal disease, most commonly reported in the horse. The species selectivity of this disease is related to the environment of this animal, which is often contaminated with fungal elements. An increased incidence of fungal keratitis in people was directly related to the development of multiple topical steroid agents for treatment of eye diseases. In the horse, many cases of fungal keratitis are noted in association with prior treatment of conjunctival and/or corneal diseases with topical steroid agents. Aspergillus is the most common cause of fungal keratitis in the horse, although there is a great deal of variation in fungal isolates from the cornea depending upon geographical location. Studies in people and anecdotal reports from veterinarians suggest that fungal keratitis due to fusarium organisms are more resistant to therapy than those caused by aspergillus. Most studies in the equine suggest that about 50% of cases of fungal keratitis in the horse result in perforation of the corneal and enucleation of the eye. Medical and surgical therapy (keratectomy, corneal debridement, and conjunctival grafting) are used to treat such cases with the goals of therapy including arresting infection, mechanical removal of organisms from the cornea, and promoting healing of the corneal stroma.
AMPHOTERICIN B

Indications/Pharmacology
Amphotericin B is a broad spectrum antifungal drug derived from Streptomyces nodosus. Originally formulated as a colloidal suspension to overcome poor water solubility, amphotericin frequently caused significant systemic toxicity to kidneys, liver and blood. Amphotericin is now provided in a variety of dosage forms to reduce the risk for systemic toxicity including liposomal injection, lipid complex injection, and colloidal dispersion. No ocular topical dosage form of amphotericin is commercially available, however, the colloidal suspension has been used topically and subconjunctivally to treat cases of equine fungal keratitis. When reconstituting amphotericin, sterile water should be utilized as saline decreases the stability of amphotericin. Resulting dilutions should be refrigerated and protected from light. Amphotericin B is fungistatic or fungicidal depending on the concentration obtained in body fluids and the susceptibility of the fungus. Amphotericin B has been shown to be effective against the following fungi: Histoplasma capsulatum, Coccidioides immitis, Candida species, Blastomyces dermatitidis, Rhodotorula, Cryptococcus neoformans, Sporeobrix schenckii, Mucor macrod, and Aspergillus fumigatus. While Candida albicans is generally quite susceptible to amphotericin B, non-albicans species may be less susceptible. Pseudallescheria boydii and Fusarium spp. are often resistant to amphotericin B.

Suggested Dosages/Precautions/Adverse Effects
Instill 0.2 mL of a 0.15% solution in the eye or the palpebral lavage catheter every 2–6 hours, or 0.25 mL of a 0.5 mg/mL solution subconjunctivally every 48 hours. There are no commercially available amphotericin B ophthalmic products, but the non-liposomal injectable formulation can be reconstituted with sterile water to make sterile solutions suitable for topical or subconjunctival administration. Amphotericin B should not be reconstituted with sodium chloride containing solutions as this encourages degradation of the drug.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None
Sterile solutions for topical ophthalmic administration or subconjunctival injection may be prepared by reconstituting commercially available amphotericin B injection lyophilized powder and diluting to appropriate concentrations with sterile water for injection. Chemical stability is concentration dependent, but most resulting solutions may be stored for at least 7 days under refrigeration and protected from light.

NATAMYCIN

Indications/Pharmacology
Natamycin (pirimicin) is a semisynthetic polyene antibiotic and has an improved antimycotic spectrum compared to amphotericin B. It is well-tolerated and induces fewer ocular toxicities compared to amphotericin B. However, natamycin is poorly water-soluble and will not penetrate the intact corneal epithelium. Natamycin is the only antifungal agent approved for use on the eye and the only commercially available eye drug for treatment of fungal keratitis.

Suggested Dosages/Precautions/Adverse Effects
The product comes as a thick white suspension that complicates the use of subpalpebral lavage apparatus for frequent treatment of the cornea of the horse. This drug will obstruct catheter systems used for medication. It will cause dramatic swelling and pain in the upper eyelid if it leaks out of the tubing into the subcutaneous tissues of the eyelid. Corneal penetration is poor and the medication is very expensive. Fungal keratitis cases are treated aggressively with hourly or bi-hourly treatment the first 1–3 days and gradual reduction in treatment frequency with signs of clinical improvement. Cytology and repeated cultures of the cornea are used to indicate treatment effectiveness. Worsening of the corneal edema and cellular infiltration can be a sign of treatment response. This is thought to be due to antigenic release associated with killing of fungal organisms (like the pulmonary response noted in dogs with institution of antifungal therapy for blastomycosis, etc.). Four to six weeks of treatment is not uncommon for fungal keratitis cases.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None
Natamycin Ophthalmic Suspension 5%: 15 mL btls; Natacyn® (Alcon); (Rx)

MICONAZOLE

Indications/Pharmacology
Miconazole is a broad spectrum imidazole antifungal agent with some antibacterial activity. Miconazole will penetrate the intact corneal epithelium. Topical miconazole therapy has been a favorite first choice agent for treatment of fungal keratitis in the horse by veterinary ophthalmologists for several years. Miconazole may be delivered by subconjunctival route, but with some local irritation, and topical use is the most commonly employed treatment method.

Suggested Dosages/Precautions/Adverse Effects
Miconazole was formerly available as a 10 mg/mL injectable solution for IV use in humans. It can now only be obtained through s. It is a clear solution readily delivered through subpalpebral lavage apparatus systems. The medication is significantly less expensive compared with natamycin and its corneal penetration is more favorable, although still less than optimal. Treatment is generally delivered hourly or bi-hourly during the first several days of treatment. Once clinical improvement is noted and cytology specimens and repeated cultures indicate eradication of fungal organisms, the treatment frequency is gradually reduced. Most fungal keratitis cases are treated 4–6 weeks.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None suitable for the eye.

All commercially available miconazole topical preparations contain alcohols or other agents that cause corneal damage. It is imperative that a 1% miconazole solution be compounded without alcohols for use on the cornea.

POVIDONE IODINE

Indications/Pharmacology
Dilute solutions of povidone iodine (1%–5%) have been utilized for chemical debridement of loose epithelium in canine indolent ulcers. 5% povidone iodine has also been used as an antifungal for fungal keratitis, but must be lavaged from the eye within 5 minutes to prevent damage to corneal epithelium. Generally, povidone iodine is only used once daily and then rinsed off when used in the eye as an anti-fungal. There has also been a renewed interest in utilizing povidone iodine in treating feline herpes keratitis. Solutions of commercially available 10% povidone iodine are diluted in physiologic saline to concentrations of 0.5–1% and applied 1 drop twice to four times daily for treatment of chronic feline herpes keratitis and may also be used prophylactically for feline herpes-virus (FHV) cats with a history of recurring ulcer.

Suggested Dosages/Precautions/Adverse Effects
Solutions of 1% are applied twice to four times daily for treatment and prophylaxis of feline herpes-virus (FHV) keratitis and for chemical debridement of epithelium for canine indolent ulcers. Solutions of concentration greater than 1% should be lavaged from the eye after no more than 5 minutes to prevent corneal epithelial damage.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None
VORICONAZOLE
(i-tra-co-naz-ole)

Indications/Pharmacology
Voriconazole is derived from fluconazole and is considerably more efficacious than amphoterionic B for filamentous organisms. Following oral (4 mg/kg) or IV (1 mg/kg) doses to horses, voriconazole demonstrated excellent absorption, bioavailability and tolerance (Davis et al. 2006). Although there are currently no approved ocular formulations of voriconazole, compounded solutions of 1% voriconazole have been shown to achieve acceptable ocular concentrations in the aqueous humor (Clode et al. 2006).

Voriconazole has been used clinically for the treatment of equine fungal keratitis. Voriconazole is a triazole antifungal agent. The primary mode of action of voriconazole is the inhibition of fungal cytochrome P-450-mediated 14 alpha-lanosterol demethylation, an essential step in fungal ergosterol biosynthesis. The accumulation of 14 alpha-methyl sterols correlates with the subsequent loss of ergosterol in the fungal cell wall and may be responsible for the antifungal activity of voriconazole. Voriconazole has been shown to be more selective for fungal cytochrome P-450 enzymes than for various mammalian cytochrome P-450 enzyme systems. Voriconazole has demonstrated in vitro activity against Aspergillus (A. fumigatus, A. flavus, A. niger and A. terreus), Candida (C. albicans, C. glabrata, C. krusei, C. parapsilosis), Scedosporium apiospermum and Fusarium spp., including Fusarium solani. Voriconazole drug resistance development has not been adequately studied in vitro against Candida, Aspergillus, Scedosporium and Fusarium species. The frequency of drug resistance development for the various fungi for which this drug is indicated is not known. Fungal isolates exhibiting reduced susceptibility to fluconazole or itraconazole may also show reduced susceptibility to voriconazole, suggesting cross-resistance can occur among these azoles. The relevance of cross-resistance and clinical outcome has not been fully characterized. Clinical cases whereazole cross-resistance is demonstrated may require alternative antifungal therapy. There are no approved ophthalmic formulations of voriconazole, however, a suitable solution for ophthalmic administration can be prepared by utilizing the approved voriconazole injectable product.

Suggested Dosages/Precautions/Adverse Effects
0.2 mL in the eye or palpebral lavage catheter every 2–4 hours. Voriconazole is contraindicated in patients with known hypersensitivity to voriconazole or its excipients. There is no information regarding cross-sensitivity between voriconazole and other azole antifungal agents. Caution should be used when prescribing voriconazole to patients with hypersensitivity to other azoles. Voriconazole treatment-related visual disturbances are common in humans. In therapeutic trials, approximately 21% of patients experienced abnormal vision, color vision change and/or photophobia. The visual disturbances were generally mild and rarely resulted in discontinuation. Visual disturbances may be associated with higher plasma concentrations and/or doses. Since topical administration of voriconazole has not been evaluated in humans, it is not known if this adverse event is related and other systemic fungal infections in dogs and people. Itraconazole specifically targets oxidative enzymes of fungal organisms thereby increasing efficacy while lowering toxicity. Itraconazole prepared as a 1% ointment in 30% dimethylsulfloxide (DMSO) is well tolerated in horses with keratomycosis with reported good results. Itraconazole is relatively insoluble in water and must be diluted in DMSO to achieve solution. Itraconazole suspensions in a vehicle of 30% DMSO and 70% artificial tears have also been used successfully to treat fungal keratitis in horses. It is important to note that the DMSO may be topically irritating to many horses. The fungal species most commonly isolated from cases of equine keratomycosis and their particular sensitivity to specific antifungal agents varies greatly by geography in the United States. In vitro sensitivity testing can be done at select laboratories on fungal isolates from the equine eye but this information generally takes several weeks to become available. Because of these considerations, the selection of a particular antifungal drug for an individual case is largely based on local clinical experience and impressions.

DOSAGE FORMS/REGULATORY STATUS
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None

VORICONAZOLE
(ve-rid-on-a-nol)

Indications/Pharmacology
Itraconazole is a broad spectrum synthetic antifungal agent effective against a wide range of filamentous fungi, dimorphic fungi, and yeasts. It is the most popular systemic antifungal agent for treatment of blastomycosis related and other systemic fungal infections in dogs and people. Itraconazole specifically targets oxidative enzymes of fungal organisms thereby increasing efficacy while lowering toxicity. Itraconazole prepared as a 1% ointment in 30% dimethylsulfloxide (DMSO) is well tolerated in horses with keratomycosis with reported good results. Itraconazole is relatively insoluble in water and must be diluted in DMSO to achieve solution. Itraconazole suspensions in a vehicle of 30% DMSO and 70% artificial tears have also been used successfully to treat fungal keratitis in horses. It is important to note that the DMSO may be topically irritating to many horses. The fungal species most commonly isolated from cases of equine keratomycosis and their particular sensitivity to specific antifungal agents varies greatly by geography in the United States. In vitro sensitivity testing can be done at select laboratories on fungal isolates from the equine eye but this information generally takes several weeks to become available. Because of these considerations, the selection of a particular antifungal drug for an individual case is largely based on local clinical experience and impressions.

Suggested Dosages/Precautions/Adverse Effects
Compounded itraconazole/DMSO preparation is applied to the cornea frequently in horses with confirmed keratomycosis. Initially, treatment every 2–3 hours is not uncommon; tapering of the treatment based on clinical response. Individuals treating horses need to use routine precautions (gloves) while handling this medication to minimize any skin uptake enhanced by the DMSO solvent.

DOSAGE FORMS/REGULATORY STATUS
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None

SILVER SULFADIAZINE
(sil-ver-sulf-a-dye-a-zeen)

Indications/Pharmacology
Silver sulfadiazine cream is a broad spectrum agent that covers bacteria (gram-positive and -negative) and fungal agents. It has been used extensively in people suffering from skin burns. It is nontoxic to the skin, conjunctiva and cornea and has been used in the last several years for cases of fungal keratitis. Particularly good results have been noted in cases of superficial keratitis prior to development of advanced disease. Clinical response is better when used early in the course of the disease. Treatment with silver sulfadiazine is considered non-conventional in people. It is gaining in popularity in the treatment of equine fungal keratitis by veterinary ophthalmologists. For medic-legal reasons, in very expensive horses in which litigation may be an issue, treatment with more conventional therapy (natamycin) may be indicated first, or consideration can be given to signed consent regarding treatment with silver sulfadiazine. The initial response to this drug has been promising, however.

The medication is inexpensive and is available from any pharmacy, but it is not labeled for use in eyes. The label (package insert) specifically states "not to be used in eyes” so liability for use in eyes rests solely with the prescribing veterinarian and some pharmacists may be unwilling to dispense this medication for ophtalmic use. Argyriusmus has been reported in patients receiving topical silver sulfadiazine on a chronic basis.
Antivirals, Ocular

Antiviral drugs are used most commonly in clinical practice for the treatment of feline ocular herpes virus infections. Simple acute conjunctivitis is best managed with symptomatic antibiotic therapy alone (i.e., tetracycline treatment or systemic doxycycline treatment). The development of concurrent corneal disease, however, indicates that consideration should be given to the use of antiviral drugs. Persistent cases of conjunctivitis in the cat due to feline herpes virus infection may also benefit from treatment with topical antiviral drugs. Although in vitro studies indicate that trifluridine is the most effective agent against feline herpes virus, idoxuridine is a less irritating, more economical alternative. In general, all antivirals are virustatic (not cidal) and require application every 2 hours for the first 24 hours followed by 5–6 times daily treatment thereafter. While this appendix focuses mostly on topical ophthalmic therapies, it is important to note that studies support use of 1-lysine at 500 mg orally twice daily in cats to prevent or reduce the severity of feline herpes virus ocular infections through disruption of viral replication.

TRIFLURIDINE (TRIFLUOROTHYMIDINE)

(trye-flour-oh-thye-mi-deen)

Indications/Pharmacology

Trifluridine (trifluorothymidine; Viriropin®) is a pyrimidine nucleoside analog. It is structurally related to 2-deoxythymidine, the natural precursor of DNA synthesis and exerts its effects via inhibition of thymidylate synthetase. An in vitro study in which several strains of feline herpes virus were collected from the United States and were used to infect kidney epithelial cells showed that trifluridine was more effective at lower concentrations compared with several other agents. For this reason, trifluridine was the first choice drug employed in the treatment of feline herpes virus ocular disease for many years. Because of the topical toxicity associated with use of trifluridine in cats, its popularity has diminished greatly. In many milder cases, the irritation associated with topical trifluridine is more intense than the inflammation induced by viral infection. Antiviral agents have also been used in the treatment of superficial punctate keratitis in the horse, thought to be associated with equine herpes virus-2 (EHV-2) infection of the cornea.

Suggested Dosages/Precautions/Adverse Effects

Trifluridine must be applied very frequently. Many veterinary ophthalmologists recommend treatment every 2 hours (waking hours) during the first 2 days of therapy to establish effective corneal drug levels. After this time, treatment 4–6 times daily is indicated. Because trifluridine is virostatic and not virucidal, treatment 1 week beyond the resolution of clinical signs is recommended, to prevent a rebound effect associated with poor surface immunity in combination with residual active viral agents. However, a maximum supply of 3 weeks medication should initially be dispensed as trifluridine is a corneal toxin and can retard corneal epithelial healing. Additionally, if cats do not respond favorably to trifluridine therapy within three weeks, they are not likely to respond with longer durations of therapy. If no improvement is noted in three weeks, trifluridine (or any antiviral) should be discontinued for a rest period and then a different antiviral initiated.

Anecdotally, improvement with antiviral agents is noted in about 50% of cats in which the treatment is employed. In some cats, the ocular disease persists despite treatment with antiviral agents. It is not certain if these are truly cases of feline herpes virus infection or other disease. Except in acute cases with respiratory and ocular involvement, the confirmation of feline herpes virus infection is exceedingly difficult in private practice, primarily due to the logistics of performing specific viral isolation tests. Chronic conjunctivitis in the cat seems to be the most resistant to treatment with antiviral agents. Conjunctival and lid margin irritation are commonly reported with trifluridine use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Trifluridine Ophthalmic Solution: 1% in 7.5 mL bts; Viriropin® (Monarch); (Rx)

IDOXURIDINE

(eye-do-peer-i-deen)

Indications/Pharmacology

Idoxuridine (IDU) is chemically similar to thymidine and its substitution into viral DNA causes misreading of the viral genetic code thereby inhibiting viral replication. Because IDU is a non-specific inhibitor of DNA synthesis, it affects any cellular function requiring thymidine and is not suitable for systemic use. Even with topical therapy, corneal toxicity can occur. Like trifluridine, IDU is considered virostatic rather than virucidal. IDU was found to be second to trifluridine in efficacy in vitro against common strains of feline herpes virus growing in kidney epithelial cells. IDU is extremely well tolerated in cats and this feature alone makes it the most popular antiviral currently available for use in cats with presumed or established feline herpes virus infection. Although trifluridine was shown to be more effective in vitro, the topical irritation it induces in cats frequently negates any beneficial effect that might be noted clinically. Stinging upon application is a rare feature with IDU/artificial tear preparations.

Suggested Dosages/Precautions/Adverse Effects

IDU, like trifluridine, penetrates poorly into the cornea (except in instances of ulceration) and conjunctiva and therefore must initially be applied frequently. Most treatment protocols involve application every two to three hours during waking hours the first two days of acute infection, followed by four to five times daily treatment continued a week beyond resolution of clinical signs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None. Formerly approved as Stoxil® and Herplex®; must be obtained from appropriately qualified compounding pharmacies as a 0.1% ophthalmic solution or a 0.5% ophthalmic ointment.

INTERFERON ALPHA

(in-ter-feer-on al-fa)

Indications/Pharmacology

Interferon alpha-2B is thought to stimulate local immunity against viral infection and has been advocated as an adjunct therapy for treatment of feline herpes viral keratitis. Few peer-reviewed, placebo controlled, prospective clinical trials evaluating interferon administration to FHV cats exist at the time of writing, and until further studies are conducted, the dosage, frequency and efficacy of interferon in FHV cannot be stated. Furthermore, the stability of interferon for long term administration has not been scientifically evaluated. The gastric degradation of interferon by peptidases precludes likely systemic absorption of this drug; however, absorption across the oropharyngeal mucosa may occur and low concentrations of interferon may be amplified via a cascade effect (Weigent et al. 1984).

Suggested Dosages/Precautions/Adverse Effects

It has been used both systemically (30 Units PO q24h) and/or topically (30–50 Units/mL in artificial tears in both eyes 3–5 times daily) for refractory cases of feline herpes keratitis although these doses, routes and frequencies have not been scientifically evaluated.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None. The human interferon alpha-2B injection (Intron-A®—Schering) is diluted to a final concentration of 30–50 Units/mL in saline or artificial tears and administered orally or topically respectively.

References

**Indications/Pharmacology**

These antiviral drugs represent the acyclic nucleoside analogs and require three phosphorylation steps for activation: catalyzation by thymidine kinase, followed by phosphorylation by host enzymes. Because the Feline Herpes virus (FHV) thymidine kinase enzyme is less active than the human Herpes simplex virus (HSV) enzyme, these agents are not as effective against FHV as they are against HSV.

A 0.5% acyclovir ophthalmic ointment administered 5 times daily demonstrated a mean time of 10 days to resolution of clinical signs (Williams et al. 2005). Ophthalmic ganciclovir is available as a 0.15% topical gel for human use, but at the time of writing has not been studied in cats. Systemic anti-retroviral agents have been tried in cats with persistent herpes keratitis, but myelosuppression and nephrotoxicity following systemic use is a serious risk with acyclovir and valacyclovir. Acyclovir should only be used by itself as a last resort and CBC should be monitored weekly in cats receiving this drug. Valacyclovir apparently has no effect on feline herpes replication and should never be used in cats due to fatal myeloid dysplasia. The pharmacokinetics of systemic famciclovir in cats are extremely complex and this drug should be used with caution in this species.

However, a study of famciclovir administered at 90 mg/kg orally three times daily in experimentally infected FHV cats demonstrated significantly reduced clinical signs, serum globulin concentrations, histologic evidence of conjunctivitis, viral shedding, and serum FHV titers with no evidence of adverse clinical, hematologic or biochemical effects (Thomasy et al. 2010). As other agents in this drug class are myelosuppressive, extreme caution is recommended regarding famciclovir therapy in cats. Topically administered cidovir 0.5% solutions have recently been shown to reduce the severity and duration of FHV-1 infections. The in vitro efficacy of commonly available antiviral agents for FHV-1 has been studied and is as follows: trifluridine > ganciclovir = idoxuridine = cidovir = penciclovir = vidarabine > acyclovir >> foscarnet.

**Suggested Doses/Precautions/Adverse Effects**

Acyclovir 0.5% ointment applied 5-6 times daily. Cidofovir 0.5% topical solution, 1 drop in each eye twice daily. Until further data is available, systemic use of these agents is not recommended in cats. Topical use of these agents should be conducted with caution in cats as they are likely to grom off medication and experience systemic adverse effects.

**Dosage Forms/Regulatory Status**

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS: None

Sterile solutions of cidovir suitable for ophthalmic administration may be prepared by diluting the commercially available injection to a final concentration of 5 mg/mL, using 1% carboxymethylcellulose solutions (Fontenelle et al. 2008). Acyclovir 0.5% ophthalmic ointment may be obtained from appropriately qualified compounding pharmacies.

Artificial Tear Products/Ocular Lubricants

**ARTIFICIAL TEARS/OCULAR LUBRICANTS**

**Indications/Pharmacology**

Various solutions and ointments have been designed to replace (in quality or quantity) the precorneal tear film with the goal of restoring ocular comfort and corneal protection. Artificial tear solutions are aqueous, isotonic, pH buffered viscous solutions with appropriate surface tension that serve as a lubricant for dry eyes and associated eye irritation due to dry eye syndromes. They are often useful adjuncts in keratoconjunctivitis sicca in dogs early in cyclosporine therapy. Most are water-based preparations that may also include polymers (methylcellulose, polyvinyl alcohol, povidone, dextran and propylene glycol) and other agents (gelatin, glyc erin, polyethylene glycol, pluronic gel and polysorbate 80) to increase viscosity, lubrication and retention time. Toxicity and pH are achieved through use of sodium chloride, potassium chloride and boric acid. Preservatives may be present or absent, however, preservatives may add to disease through toxicity to the corneal epithelium.

Ocular lubricant ointments are white petrolatum-based products that serve to lubricate and protect eyes. They are particularly useful during anesthetic procedures where animals’ eyes may remain open and during which time tear production is dramatically reduced.

Tacrolimus is a macrolide antibiotic that exerts its effects in KCS through mechanisms similar to that of cyclosporine, however exact mechanisms of action in causing tear production are still being determined.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

None appropriate for the eye. At the time of publication, Fujisawa, Inc. has granted exclusive rights to Sucampo, Inc. to study, develop, and market an ophthalmic tacrolimus formulation for use in KCS. 

**Suggested Dosages/Precautions/Adverse Effects**

Tacrolimus should be administered as a 1% ophthalmic solution twice daily.
Viscoelastic Substances

Viscoelastic substances are vital to ocular surgery, minimizing loss of fluid from the anterior chamber while maintaining intraocular space during surgical procedures. The purity and integrity of viscoelastics ensure tissue preservation during and after surgery. Viscoelastics generally fall into two categories: cohesives, that tend to stick together, and dispersives, that are more likely to diffuse out into the anterior chamber. Cohesives in general' tend to stick together and are less likely to diffuse out into the anterior chamber. Dispersives on the other hand are more likely to diffuse out into the anterior chamber. They are generally used to maintain the anterior chamber during surgery and to prevent the formation of a flat chamber. Viscoelastics are also vital to tear replacement.

HYALURONIC ACID

Indications/Pharmacology

Hyaluronic acid is a natural complex sugar of the glycosaminoglycan family and is a long-chain polymer containing repeating disaccharide units of Na-glucuronate-N-acetylglucosamine. Hyaluronic acid is indicated for use in posterior segment surgery, to prevent the formation of a flat chamber. Hyaluronic acid is also used to provide a viscoelastic shield to the cornea and to prevent the formation of a flat chamber. In posterior segment surgery, hyaluronic acid serves as a surgical aid to gently separate, maneuver and hold the IOL. Additionally, hyaluronic acid is used to provide a viscoelastic shield to the cornea and to prevent the formation of a flat chamber. In posterior segment surgery, hyaluronic acid serves as a surgical aid to gently separate, maneuver and hold the IOL.

Suggested Dosages/Precautions/Adverse Effects

A sufficient amount of hyaluronic acid (generally 10% concentration) is slowly and carefully introduced (using a cannula or needle into the anterior chamber. Injection of hyaluronic acid can be performed either before or after delivery of the lens. Injection prior to lens delivery will, however, have the additional advantage of protecting the corneal endothelium from possible damage arising from the removal of the cataractous lens. Hyaluronic acid may also be used to coat surgical instruments and the IOL prior to insertion. Additional hyaluronic acid can be injected during surgery to replace any hyaluronic acid lost during surgical manipulation. Topical solutions of hyaluronic acid are also used to provide a viscoelastic shield to the cornea and to prevent the formation of a flat chamber.
Cytotoxic Ophthalmic Agents

CISPLATIN BEADS

Indications/Pharmacology
Cisplatin 1.6 mg biodegradable beads are used for intralesional chemotherapy in various cutaneous neoplasia including squamous cell carcinoma and sarcomas in equine patients. A recent retrospective case series study demonstrated that implantation of cisplatin beads into cutaneous neoplasia was an effective method of treatment for these tumors. Implantation of commercially available beads is less time consuming and safer than intralesional injection of cytotoxic agents suspended in fixed oils.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: Matrix III Cisplatin Beads: 1.6 mg per 3 mm bead; 3 beads per packet; (Royer Biomedical, Inc.), (Rx) At the time of writing was being considered for approval by FDA.
HUMAN-LABELED PRODUCTS: None

5-FLUOROURACIL

Indications/Pharmacology/Suggested Dosage
5-fluorouracil is a potent cytotoxic chemotherapeutic agent used for the topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

1% solution applied to the affected eye three times daily. Note: Ingestion of 5-fluorouracil products by dogs has resulted in significant toxicity and a high rate of mortality. All 5-fluorouracil products should be kept well out of the reach of dogs.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None.

MITOMYCIN-C

Indications/Pharmacology
Mitomycin C is a potent cytotoxic chemotherapeutic agent used for topical therapy of equine limbal and eyelid squamous cell carcinoma. It is also used as an antimetabolite to limit fibrosis over the body of gonioimplant devices used to artificially shunt aqueous humor out of the eye in glaucoma as well as improve long-term filtering performance of the implant.

Suggested Doses/Precautions
0.4% solution applied initially followed by 0.04% solution applied topically three times daily for 21 days in a cycle of 7 days on followed by 7 days off. Caregivers should be counseled in proper handling of cytotoxic drugs and contact with biological waste from treated patients.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None

Must be compounded from the injectable product by an appropriately qualified compounding pharmacist in a biological safety cabinet approved for preparation of cytotoxic agents.

Sympathomimetics

HYDROXYAMPHETAMINE

Indications/Pharmacology
Hydroxyamphetamine is an indirectly acting alpha-agonist that is used to diagnose Cranial Nerve III denervation syndromes such as Horner’s Syndrome. Hydroxyamphetamine stimulates release of norepinephrine from postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denervated neurons.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately qualified compounding pharmacist.

COCAINE

Indications/Pharmacology
Cocaine is an indirectly acting sympathomimetic which is used to diagnose Cranial Nerve III denervation syndromes such as Horner’s Syndrome. Cocaine prevents reuptake of norepinephrine into postganglionic neurons and therefore amplifies pupil dilation response in hypersensitive, denervated neurons. Adrenergic agonist activity of cocaine prevents norepinephrine reuptake allowing maintenance of sympathetic stimulation, so it does not localize lesions but confirms diagnosis of sympathetic denervation syndromes.

Dosage Forms/Regulatory Status
VETERINARY-LABELED PRODUCTS: None
HUMAN-LABELED PRODUCTS: None

Must be compounded by an appropriately qualified compounding pharmacist.

Anticollagenase Agents

ACETYLCYSTEINE

Indications/Pharmacology
Acetylcysteine is a mucolytic agent that is also used to stop the melting effect of collagenases and proteases on the cornea. Acetylcysteine is useful in halting melting through inhibition of metalloproteinases, but is not felt to
Acetylcysteine is a mucolytic agent that is also used to stop the melting effect of collagenases and proteases on the cornea. Acetylcysteine is useful in halting melting through inhibition of metalloproteinases, but is not felt to be useful for melting caused by infectious agents.

**Suggested Dosages/Precautions/Adverse Effects**

Acetylcysteine 5% solution is dosed 1 drop in the affected eye every 1–2 hours for the first 24 hours and then 3–4 times daily for the next 7–10 days. Acetylcysteine solutions are diluted with artificial tears to a final concentration of 5% prior to administration as commercial solutions of 10% and 20% are typically irritating. Acetylcysteine possesses a foul, sulfur-like smell and owners should be informed that this foul odor does not indicate drug deterioration. Acetylcysteine is unstable at room temperature and solutions should be refrigerated.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- None; **Mucomyst®** 10% and 20% solution for inhalation may be used to compound a 5% solution in artificial tears.

**EDETATE DISODIUM**
(ad-a-day)

**Indications/Pharmacology**

Edetate Disodium (Sodium EDTA) is a chelating agent that is also used to stop the melting effect of collagenases and proteases on the cornea. EDTA is useful in halting melting through inhibition of matrix metalloproteinases, but is not felt to be useful for melting caused by infectious agents. As the effect of EDTA on metalloproteinases is reversible, it must be administered several times daily to be effective.

**Suggested Dosages/Precautions/Adverse Effects**

0.05%–1% solution applied as 1 drop in the affected eye several times daily.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

EDTA solutions must be compounded by an appropriately qualified compounding pharmacist.

**Fibrinolytics/Antifibrinolytic Agents, Ocular**

Fibrin clot formation results from activation of the clotting cascade in an effort to control hemorrhage. Intraocular fibrin formation can result in complications (synechia formation, pupillary seclusion, occlusion of gomio/implants, formation of traction bands) that compromise ocular integrity and vision, so lysis of the clot before these complications occur is essential. Agents developed for fibrinolysis in humans include urokinase, streptokinase and tissue plasminogen activator (tPA). At the time of writing, tPA is the only fibrinolytic commercially available for intraocular use.

Antifibrinolytic agents can be useful to inhibit the breakdown of fibrin clots when control of intraocular bleeding is desired. These agents are used particularly as antidotes following overdosage of fibrinolytics.

**Fibrinolytic Agents**

**TISSUE PLASMINOGEN ACTIVATOR (tPA)**
(tiss-u-plas-mo-gen-a-jen-ak-tivar-on)

**Indications/Pharmacology**

Recombinant human tPA is a fibrinolytic agent that is injected by the intracameral route to achieve lysis of intraocular clots. Intracameral injection of tPA in humans following cataract removal in doses of 10 micrograms dissolved fibrin clots, reduced posterior synechiae, and did not result in any re-bleeding (Heiligenhaus et al. 1998). Topical application of tPA to dogs does not result in therapeutic aqueous humor concentrations (Gerding et al. 1994). Intracameral injection of 25 micrograms of tPA caused fibrinolysis without corneal toxicity in dogs and cats, while doses of 50 micrograms have lead to corneal endothelial toxicity (Gerding et al. 1992; Hrach et al. 2000).

**Suggested Dosages/Precautions/Adverse Effects**

Tissue Plasminogen Activator, reconstituted to 250 micrograms/mL is injected intracamerally at 0.1 mL per dose. Adverse effects include repeat bleeding and profound hypotonia and corneal epithelium toxicity at doses equal to or greater than 50 micrograms.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Tissue Plasminogen Activator Lyophilized Powder for Injection: 2 mg, 50 mg, 100 mg, **Activase®** (Genentech); (Rx)

**References**

**Antifibrinolytic Agents**

**AMINOCAPROIC ACID**
(a-mee-a-cap-roh-ik as-id)

**Indications/Pharmacology**

Aminocaproic acid may be administered systemically or topically. Systemic administration significantly decreases intraocular re-bleeding episodes, but side effects can be severe and include nausea, dizziness, hypotension, and thrombosis of retinal vessels. Topical administration achieves therapeutic concentrations in aqueous humor in rabbits and humans, but clinical antifibrinolytic efficacy by this route is variable. Aminocaproic acid has also been used in patients with persistent corneal ulceration in order to maintain Fibronectin in the wound promoting re-epithelialization (Regnier et al. 2005).

**Suggested Dosages/Precautions/Adverse Effects**

If administered topically, aminocaproic acid is compounded in a concentration of 30% in 2% carboxypolymethylene gel.

**Dosage Forms/Regulatory Status**

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**
- Aminocaproic acid 30% solution in 2% carboxypolymethylene gel may be compounded by an appropriately qualified compounding pharmacist.

**References**

Examples of agents that are commonly used by veterinarians but are no longer commercially available currently include oxytetracycline ophthalmic ointment, idoxuridine ophthalmic solution and ointment, miconazole solution, vidarabine ophthalmic solution, trifluridine ophthalmic solution, tetracycline ophthalmic solution, rose bengal solution, and chloramphenicol ophthalmic ointment. Even if commercially available, products may be of inappropriate concentration to achieve a therapeutic effect in a given patient (e.g., cyclopentolate A) or may have agents and excipients that have adverse effects in animal patients (e.g., neomycin sulfate in cats). In other cases, no product is commercially available and must be compounded from other non-ophthalmic drugs or from bulk chemicals (e.g., acetylcysteine ophthalmic solution and disodium edetate ophthalmic solution). For these reasons, pharmacists are frequently called upon to compound products to be used in the animal eye. These products may be administered topically in the form of solutions, suspensions, or ointments, by periocular or intracanalicular injection, by drug-implanted collagen shields, or by drug-impregnated disposable contact lens delivery systems. The quality and sterility of these products is critical. To ensure adequate stability, uniformity, and sterility, both the American Society of Health-Systems Pharmacists and the United States Pharmacopeial (USP) Convention have published guidelines for pharmacy-prepared ophthalmic products. These guidelines address the following areas of concern.

Validation of Formulation:
Before compounding any product for ophthalmic use, the pharmacist should obtain documentation that substantiates the stability, safety, and benefit of the requested formulation. Pharmacists may call the manufacturer of the drug, refer to primary literature, call regional eye centers, or call professional compounding organizations to obtain such information. If no such documentation is available, the pharmacist must employ professional judgment in determining a suitable formulation for ophthalmic administration. Factors to consider when making this judgment include: sterility, toxicity, pH and buffering, toxicity of the drug, need for preservatives, solubility, stability in the chosen vehicle, viscosity, packaging, and any precautions necessary to keep drug residues from occurring in any food-producing animals.

Documentation:
A written procedure for each ophthalmic product compounded should be recorded and kept in a readily retrievable place. This master formulation sheet should indicate the name of the product, the dosage form, the specifications and source of each ingredient used, the weights and measures of each ingredient used, the equipment required, a complete description of each step in the compounding process with special notations of aseptic techniques utilized and which method of terminal sterilization is appropriate, beyond-use dating, storage requirements, specific packaging requirements, sample label and auxiliary labeling, quality control testing performed, and references for formula. Production records for each batch should include the date of compounding, lot or batch number assigned, the manufacturer and lot number and expiration date of each ingredient used, a sign-off provision for compounder and checker, the amount compounded, and the projected beyond-use date for the batch compounded.

Sterility:
Ophthalmic dosage forms must be compounded in aseptic conditions. Sterile Compounding Guidelines should be consulted in the United States Pharmacopeia General Chapter <797>. Sterility is the most important consideration for ophthalmic products. Contaminated ophthalmic products can result in eye infections leading to blindness or even loss of the eye, especially if pathogens such as Pseudomonas are present. Eye infections from contamination can also lead to systemic infections requiring hospitalization and may even result in death. All ophthalmics should be compounded in a laminar flow hood that has undergone annual checkups and certification of acceptable performance. It is also important to note that the laminar flow hood does not guarantee sterility. The compounding pharmacist must also use impeccable aseptic technique when handling products intended for use in the eye. All products must be rendered sterile after formulation in the laminar flow hood. Sterilization of the final product is most easily achieved through filtration through 0.2μm filters, which also remove particulate matter. This method is obviously only suitable for ophthalmic solutions. Ophthalmic suspensions and ointments must be sterilized by other means to avoid filtering out active drug. Other methods of sterilization available to the pharmacist include dry heat, autoclaving, and ethylene oxide gas sterilization. Gamma radiation is also commercially available for bulk sterilization, but is very expensive. Preservatives may also be added to prevent bacterial growth, especially if the container is intended for multiple use. The preservative selected must be compatible with the active drug and excipients as well as non-toxic to the eye or to the patient. A description of commonly used ophthalmic preservatives and maximal concentrations is provided in Table 1.

*As recommended by FDA Advisory Review Panel on OTC Ophthalmic Drug Products

Clarity:
Drugs prepared as ophthalmic solutions should be free from foreign particles. This can be accomplished through filtration with a 0.45μm filter needle attached to a sterile syringe, or through the use of clarifying agents such as polysorbate 20 (maximum of 1%) and polysorbate 80 (maximum of 1%). Drugs prepared as ophthalmic suspensions, obviously cannot be filtered, but must be of a particle size that does not irritate or scratch the cornea. A micronized form of the drug is required. The use of an ointment mill is highly recommended to decrease particle size for ophthalmic ointments.

Tonicity:
Ophthalmic products do not need to be isotonic if the contact time with the cornea is only for a few minutes. The eye can tolerate a range of 200–600 mOsm/L for short periods of time. For ointments, irrigations and products that will remain in contact with the eye longer than a few minutes, isotonic products should be used. Hypotonic agents may cause corneal edema and hypertonic agents may dehydrate the cornea and cause pain. Tear fluid and normal saline have identical osmotic pressures making 0.9% sodium chloride an excellent vehicle for ophthalmic products. For products that are hypotonic, sodium chloride equivalents can be used to determine how much sodium chloride to render the product isotonic.

Buffering and pH:
Ophthalmic preparations are generally buffered in a range from 4.5–11.5. Buffering is necessary to provide maximal stability of the drug or for comfort and safety of the patient. Alkaloids such as atropine and pilocarpine are usually buffered. If the activity and stability of the drug are not pH dependent, and the pH of the product is not irritating, then buffers may be omitted from the formulation. Commonly used buffers for ophthalmic preparations include Phosphates, borate buffers, citrate buffers, and acetate buffers. Formulations for these solutions and ratios required to achieve a desired pH are referenced in the International Journal of Pharmaceutical Compounding, Vol. 2, No. 3 May/June 1998.

Viscosity Enhancers:
Because tears and blinking reflexes reduce the total amount of drug available for penetration, an increase in residence time in the eye will increase drug absorption. Increasing the viscosity of the drug is the most common way to prolong contact time. Methylcellulose is the most commonly used agent and is generally formulated at a concentration of 0.25%. Hydroxypropylmethylcellulose is used in concentrations of 0.5–1%. Polyvinyl alcohol has also been used in concentrations of 0.5–1% w/v. Agents used to increase the viscosity of ophthalmic products are shown in Table 2.

Table 2. Agents used to increase viscosity of ophthalmic solutions and suspensions.

</tbody>
</table>

Quality Control:
Finished products should be thoroughly inspected visually for clarity and uniformity of suspension. The pH of the final product should always be checked and the value recorded on the master formula record for that batch. Most compounded products should have a pH of 5–7 unless otherwise indicated for stability or penetration of ocular tissue. Practitioners compounding large volumes of ophthalmic products should periodically perform testing to ensure sterility. Various agencies provide this service. The nearest college of pharmacy can be consulted for a list of providers of this service.
Beyond Use Dating:
The USP/NF standards for preparation of ophthalmic medications indicate that, unless otherwise documented, the beyond-use date for water containing formulations is 14 days. For non-aqueous liquids, the recommendation is not more than 25% of the time remaining until the expiration date of the starting product or six months, whichever is earlier. For all other products, the expiration dating should be the duration of therapy or 30 days whichever is shorter. These beyond-use recommendations can be extended in the face of supporting, valid, scientifically conducted stability information.

Contraindications:
Vaccines and other products that are applied topically, but are absorbed systemically and used primarily for their systemic effects are found in the general monograph section. For veterinary products, refer to the complete label for additional information.

Questions to Ponder Prior to Compounding Ophthalmic Products:

1. Where is the target of therapy? (eyelids, corneal surface, cornea, anterior segment, posterior segment)

2. What is the character of the drug?

   - Lipophilic/Hydrophilic?

   - What is the molecular weight?

   - What is the inherent toxicity of the drug to the eye (gentamicin)? To the caregiver (chloramphenicol); to the patient (neomycin sulfate in cats)?

   - Is there data to support what concentration is necessary for corneal penetration?

   - Is the drug soluble in a vehicle that is not toxic to the eye?

   - If not soluble, will the particle size of the suspension or the ointment scratch the corneal or conjunctiva?

   - What is the pH of the final product? Is this in an acceptable range to avoid irritation (4.5–11.5)?

   - What is the tonicity of the final product? Is this the same as the tonicity of the cornea?

   - How long will the product be in contact with the cornea if not isotonic?

   - Will the viscosity need to be enhanced in order to prolong contact with the eye? Which agent is compatible?

   - What is the inherent toxicity of the drug to the eye (gentamicin)? To the caregiver (chloramphenicol); to the patient (neomycin sulfate in cats)?

   - Will the product require preservation if long term multiple use? Which preservative is compatible?

Dermatological Agents, Topical

The following section lists many of the active ingredients and corresponding preparations used topically for their local action in veterinary medicine. It includes both veterinary-labeled dermatological products and some potentially useful human-labeled products. Active ingredients are listed by therapeutic class. The drug sponsor, availability and formulation of these products tend to change rapidly in the marketplace so this listing should be used as a basic guide.

Products that are applied topically, but are absorbed systemically and used primarily for their systemic effects are found in the general monograph section. For veterinary products, refer to the complete label for additional information.

Portions of this section are adapted from: Koch, Torres, & Plumb. (2011). *Canine and Feline Dermatology Drug Handbook.* IN PRESS. Wiley-Blackwell. This reference provides additional detail on these, and other compounds and products.

Note: While many of these products do not legally require a prescription (OTC), they are often marketed as “Sold only through licensed veterinarians” or “Sold by professionals only.”
ALUMINUM ACETATE SOLUTION (BعROW’S SOLUTION OR MODIFIED BUROW’S SOLUTION)
(al-um-i-num ass-ih-tate)

For otic use, refer to the Otics section

Indications/Actions
An astringent antipruritic agent, aluminum acetate solution (BعROW’s solution, modified BعROW’s solution) can be useful for adjunctive treatment of minor skin irritations such as insect bites, and localized inflamed and exudative skin conditions, including acute moist dermatitis, fold dermatitis (intertrigo) and contact dermatitis. It can also be used for the treatment of otitis externa (see Otics section). In addition to BعROW’s solution’s astringent and antipruritic actions, it also has acidifying effects and it mildly antiseptic. The exact mechanisms of action for these effects are not fully understood.

Suggested Dosages/Use
Topical use of BعROW’s solution (alone) is usually as a wet compress, dressing or soak. Application for 15–30 minutes is generally recommended and the affected area is air-dried between applications. Use can be as often as necessary, but every 4–6 hours is often employed. The veterinary-labeled products containing hydrocortisone may be directly applied. As BعROW’s solution products come in various dosage forms (powder or tablets for dissolving, liquid); refer to package directions for proper dilutions. Dilutions of 1:40, 1:20, or 1:10 are commonly used.

Precautions/Adverse Effects
Do not use plastic or any occlusive dressing material to prevent evaporation. Use room temperature water for dissolving and application. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

BعROW’s solution may cause dry skin or skin irritation on some patients.

COLLOIDAL OATMEAL
(ko-loyd-ahl oat-meal)

Indications/Actions
Colloidal oatmeal is used topically as an antiinflammatory and antipruritic, but an exact mechanism for this effect is not known. It is thought that as the concentration of oatmeal increases, both its drying and antipruritic effects increase; it has been suggested that it may inhibit prostaglandin synthesis.

Suggested Dosages/Use
Spray can be used 2–3 times per day as needed for itching or pain. Shampoo or conditioner is usually used once a day to once a week. Shampoo should be in contact with skin for at least 10 minutes and then rinsed well. Refer to each product’s label for further details.

Precautions/Adverse Effects
Other than the potential for increased drying of already dry skin, colloidal oatmeal is very safe. In humans, there are some reports of contact dermatitis associated with its use.

Veterinary-Labeled Colloidal Oatmeal Products

Note: Products listed are those containing only colloidal oatmeal as the principle active ingredient. For other products that contain colloidal oatmeal, see Diphenhydramine, Pramoxine, Hydrocortisone, Permethrin, or Pyrethrins listings.
Human-Labeled Colloidal Oatmeal Products

Note: There are several human products available containing colloidal oatmeal, including creams, lotions and products to be added to the bath. Common trade names include: Aveeno®, Geri SS®, and Acitibath®.

**ESSENTIAL FATTY ACIDS, TOPICAL**

For systemic use of essential fatty acids, refer to the Fatty Acids, Essential monograph found in the main section.

**Indications/Actions**

Essential fatty acids are indicated primarily for pruritic and inflammatory conditions such as atopic dermatitis and sebaceous adenitis, and keratinization disorders such as seborrhea. They may also be used to improve coat quality and ameliorate dry skin. Some of these products may contain other active ingredients, including other natural oils, which may have other adjunctive indications.

The exact mechanism of action of essential fatty acids is not well understood. However, essential fatty acids affect the arachidonic acid levels in plasma lipids and platelet membranes. They affect production of inflammatory prostaglandins in the body, thereby reducing inflammation and pruritus. Essential oils may also play a role in restoring the skin barrier.

**Suggested Uses/Dosages**

If using spray: up to 2-3 times applications a day or as needed. If spot-on: treatment may vary from weekly to every 2 weeks or monthly. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

**Precautions/Adverse Effects**

No specific precautions or adverse effects are described for these products.

Human-Labeled Topical Essential Fatty Acids Products

Note: Several human over-the-counter products are available in the USA but may contain other ingredients. They are generally not used in dogs and cats.

**DIPHENHYDRAMINE HCL, TOPICAL**

(dye-fen-hy-dee-ram-in) Benadryl®

For systemic use, see the monograph found in the main section

**Indications/Actions**

A first generation antihistamine, diphenhydramine has some local anesthetic activity that probably is its main antipruritic mechanism of action. Diphenhydramine may be absorbed in small amounts transdermally, but should not cause systemic side effects.

**Suggested Dosages/Use**

Topical creams, gels, lotion or sprays are usually applied 2-3 times a day. The shampoos and conditioners are generally used once a day to once a week after bathing. Shampoos should remain in contact with skin for at least 10 minutes prior to rinsing.

**Precautions/Adverse Effects**

Avoid contact with eyes or mucous membranes. Do not apply to blistered or oozing areas of skin. Clients should wash hands after application or wear gloves when applying.

Prolonged use could potentially cause local irritation and/or hypersensitization. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.
Veterinary-Labeled Topical Diphenhydramine Products

Human-Labeled Topical Diphenhydramine Products

**LIDOCAINE, TOPICAL**

LIDOCAINE/PRILOCAINE (EMLA CREAM)  
(lye-do-kan; prye-loe-kane)

For systemic use of lidocaine, see the monograph found in the main section.

### Indications/Actions

Lidocaine is used topically as a dermal anesthetic or antipruritic and is included in several products used for acute moist dermatitis, pruritic lesions, or painful skin conditions. When combined with prilocaine (commonly called EMLA cream), it may be useful for dermal anesthesia prior to painful or invasive procedures (e.g., catheter placement, etc.).

Lidocaine exerts its anesthetic properties via alteration of cell membrane ion permeability, thereby inhibiting conduction from sensory nerves.

### Suggested Dosages/Use

Thin layers can be applied every 3-4 hours as needed.

### Precautions/Adverse Effects

Topical lidocaine may be absorbed systemically, but systemic toxicity is unlikely to occur unless used on a significant percentage of body area, for prolonged times or at high concentrations. Be extra vigilant in patients also receiving Class-I antiarrhythmics (e.g., lidocaine, mexiletine). Avoid contact with eyes and do not use in ears, unless specifically labeled for such. Clients should wash hands after application or wear gloves when applying.

Hypersensitivity reactions or skin irritation (burning, tenderness, etc.) are possible, but apparently do not occur commonly. Products containing prilocaine (EMLA) may be more likely to cause methemoglobinemia or systemic toxicity, but these occur rarely.

### Veterinary-Labeled Topical Lidocaine Products

#### Human-Labeled Topical Lidocaine Products

There are also several topical OTC products listed for human use, including sprays (2–2.5%), liquids (2–4%), creams (0.5–2%), gels (0.5–2.5%) and topical patches.

**PHYTOSPHINGOSINE**  
(fye-to-sfin-joe-seen) DOUXO®

### Indications/Actions

The Douxo® Calm products containing phytosphingosine are labeled as indicated for localized and generalized inflammatory conditions that may be associated with pruritus including allergic diseases such as atopic dermatitis. Douxo Gel® is also indicated as a liquid wound dressing for localized inflammation and after surgery (can be sprayed on sutures). There are also products marketed for seborrheic conditions and an otic cleanser.

Phytosphingosine is a modified pro-ceramide with salicylic acid and a key molecule in the natural defense mechanism of the skin. Ceramides comprise 40–50% of the main lipids responsible for maintaining the cohesion of the stratum corneum, therefore; restoring the skin lipid barrier, controlling local flora (antibacterial and antifungal effects), and maintaining the correct moisture balance. It is also anti-inflammatory as it has anti-IL-1 activity, impairing the production of PGE2 and inhibits kinase protein C.

### Suggested Dosages/Use

If using spray or gel: up to 2–3 times a day as needed for itching/pain relief. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

### Precautions/Adverse Effects

Skin redness or irritation may occur.

### Veterinary-Labeled Phytosphingosine Products

**Human-Labeled Phytosphingosine Products**

*Note:* There are several over-the-counter human cosmetic products containing phytosphingosine in the USA. These products target mostly lipid barrier restoration and are generally not used in dogs and cats.

**PRAMOXINE HCl**

**Indications/Actions**

Pramoxine is a surface and local anesthetic affecting peripheral nerves. It is not related structurally to procaine-type anesthetics. Pramoxine is often combined with other topical medications to reduce pain and/or itching. Precise mechanism of action is not known.

**Suggested Dosages/Use**

Depending on the product labeling, pramoxine 1% may be applied every 3–4 hours. Peak local anesthetic effects occur within 3–5 minutes of application. It provides only temporary effects. Shampoos are used once daily to once weekly and should remain in contact with the skin for at least 10 minutes prior to rinsing well.

**Precautions/Adverse Effects**

Avoid contact with eyes; pramoxine is too irritating for ophthalmic use. Depending on product labeling, clients should wash hands after application or wear gloves when applying. Adverse effects are unlikely, but localized dermatitis is possible.

**PHENOL/MENTHOL/CAMPHOR**

*(Ice-o-menthol; free-menthol)*

**Indications/Actions**

When used in low concentrations, these agents can be used as counterirritants and may be added to proprietary or compounded products primarily as antipruritics. Camphor and phenol may also have some antiseptic properties.

**Precautions/Adverse Effects**

These compounds may cause local irritation and should not be used around, or in eyes. Products containing phenol should not be used on cats.

**Veterinary-Labeled Phenol, Menthol, or Camphor Products**

*Note:* There are also several over the counter products not listed containing menthol, phenol or camphor used primarily on equine patients for overexertion, soreness, or stiffness. These include a variety of liniments (e.g., Cool Gel®, Ice-O-Gel®, Shin-O-Gel®, etc.).

**ZINC GLUCONATE (NEUTRALIZED), TOPICAL**

*For otic use, refer to the Otics section.*
Human-Labeled Topical Neutralized Zinc Products

There are several OTC zinc gluconate or zinc oxide products available for use in humans, and many of the products contain other ingredients. A common trade name is Calamine lotion, which contains zinc oxide and 0.5% iron(III) oxide.

Corticosteroids, Topical

Note: There are at least 20 chemical entities (plus a variety of salts) used in humans for topical corticosteroid therapy. The following section includes many veterinary topical products and some human products that may be of use in veterinary medicine. Also, see the Otics section for more products.

**BETAMETHASONE, TOPICAL**

(bet-ah-meth-ah-zone)

For systemic use, see the monograph found in the main section

**Indications/Actions**

Considered a high potency topical corticosteroid, betamethasone may be useful for adjunctive treatment of localized pruritic or inflammatory conditions. Because risks associated with betamethasone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, betamethasone products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products are in combination with gentamicin and labeled indications are for treatment of infected superficial lesions caused by bacteria sensitive to gentamicin. Additional otic products are available that contain gentamicin and clotrimazole, but these can be used in an extra-label manner for treating mixed bacterial and yeast infections when strong anti-inflammatory activity is desired. Sole ingredient betamethasone topical forms are available with human labeling.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

**Suggested Dosages/Use**

Betamethasone formulations are best suited for focal (e.g., pedal) or multifocal lesions for relatively short durations (e.g., less than 2 months). Initially, topical corticosteroids are usually used sparingly 1–4 times per day and then frequency is tapered when control is achieved. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible. Refer to individual product labeling for actual dosing recommendations for veterinary products.

**Precautions/Adverse Effects**

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not apply animal products to humans.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects, skin atrophy may be reduced by treating for only as long as necessary on as small an area as possible. Refer to individual product labeling for actual dosing recommendations for veterinary products.

**Veterinary-Labeled Topical Betamethasone Products**

Note: At time of writing there are no veterinary-labeled sole active ingredient betamethasone products in the USA.

**Human-Labeled Topical Betamethasone Products**

Note: Partial listing; there are also topical branded products (two common trade names are Diprosone® and Maxivate®) available with betamethasone dipropionate. Do not confuse products containing augmented betamethasone dipropionate (Diproleone®, etc.) with betamethasone dipropionate. Augmented betamethasone dipropionate is not equivalent with betamethasone dipropionate as it is more potent. For more information on human-labeled betamethasone products, refer to a comprehensive human drug reference (e.g., Facts and Comparisons) or contact a pharmacist.
HYDROCORTISONE, TOPICAL
(hye-droe-kor-ti-zen)

Indications/Actions
Considered a low potency topical corticosteroid, hydrocortisone may useful for adjunctive treatment of localized pruritic and/or inflammatory conditions. Because risks associated with hydrocortisone are significantly less when compared to higher potency corticosteroids, hydrocortisone is a reasonable first choice, particularly when treating large areas, or when used on smaller patients. Some products also contain the astringent Burow’s solution, which may have additional antipruritic effects.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Suggested Dosages/Use
Hydrocortisone formulations are best suited for focal (e.g., pedal) or multifocal lesions for relatively short durations (e.g., less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. In contrast to some of the more potent topical corticosteroids, hydrocortisone can be applied more frequently and over a greater surface area without undue risk for local or systemic adverse effects. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible.

Shampoos containing hydrocortisone are generally used once a day to once a week. They should remain in contact with skin for at least 10 minutes prior to rinsing. Refer to individual product labeling for actual dosing recommendations for veterinary products.

Precautions/Adverse Effects
Several veterinary topical products list tuberculosis of the skin or pregnancy as contraindications. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20-30 minutes after application.

Local skin reactions are possible, but unlikely to occur. Atrophy associated with skin fragility, superficial follicular cysts (milia) and comedones may be seen with long term, frequent use, but this occurs more commonly when using more potent, topical corticosteroids. Although systemic absorption is rare with hydrocortisone, long term use may lead to HPA axis suppression. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

ISOFLUPREDONE ACETATE, TOPICAL
Indications/Actions

Considered a highly potent topical corticosteroid, isoflupredone in combination with neomycin and tetracaine may be useful for adjunctive treatment of otic or topical localized pruritic or inflammatory conditions that may be associated with bacterial skin infection and pain. Because risks associated with isoflupredone (HPA axis suppression, systemic corticosteroid effects, skin atrophy) are greater than with hydrocortisone, these products are generally reserved for more serious localized pruritic conditions or when hydrocortisone is not effective. All veterinary-labeled products (Tritop® Ointment and Neo-Predef w/Tetracaine Powder®) have labeled indications for conditions associated with neomycin-susceptible organisms and/or allergy with anesthetic properties due to tetracaine, or as a superficial dressing applied to minor cuts, wounds, lacerations, and abrasions, and for post-surgical pain application where reduction in pain and inflammatory response is deemed desirable. In addition, Tritop® Ointment is also labeled for acute (and possibly chronic) otitis externa, acute moist dermatitis and anaerobic infection/infection, and Neo-Predef w/Tetracaine Powder® for acute otitis externa, acute moist dermatitis and interdigital dermatitis in dogs and cats.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Suggested Dosages/Use

Labeled dose for Tritop® when used on skin or mucous membranes: Cleanse area, apply a small amount and spread and rub in gently. Involved area may be treated 1–3 times daily and continued in accordance with clinical response.

Labeled dose for Neo-Predef w/Tetracaine Powder®: Cleanse area, apply by compressing bottle with short, sharp squeezes; once daily application usually sufficient, but may use 1–3 times as required.

Precautions/Adverse Effects

Several veterinary topical products containing corticosteroids list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected sites for at least 20–30 minutes after application. Isoflupredone may delay wound healing particularly if used longer than 7 days in duration.

Use care when treating large areas, or when used on smaller patients. Treat for only as long as necessary on as small an area as possible. Risk for HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing’s, gastrointestinal effects) and skin atrophy increase with prolonged duration of use. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur. Hypersensitivity reactions to neomycin and/or tetracaine are possible.

Veterinary-Labeled Topical Isoflupredone Products

Note: At time of writing there are no veterinary-labeled sole active ingredient isoflupredone products in the USA.

Human-Labeled Topical Isoflupredone Products

None

Indications

MOMETASONE FUROATE

(moe-met-a-soe fow-roe-ate)

For otic use, refer to the Otics section.

Precautions/Adverse Effects

Initially, topical corticosteroids are usually used sparingly 1–2 times per day, then tapered to less frequent use. Mometasone formulations are best suited for focal (e.g. dermatitis) where a strong anti-inflammatory effect is also needed. Mometasone is found in a veterinary-labeled suspension (MoMetaMax®) in combination with gentamicin and cloramphenicol indicated for otic use. It can also be used extra-label for yeast and/or bacterial skin infections sensitive to cloramphenicol and gentamicin, when a strong anti-inflammatory effect is also needed.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inducing phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc.). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

Suggested Dosages/Use

Labeled for acute otitis externa, acute moist dermatitis and interdigital dermatitis in dogs and cats.

Precautions/Adverse Effects

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects, skin atrophy particularly if used longer than 7 days in duration.

Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow the animal to lick or chew at affected areas for at least 20–30 minutes after application. Mometasone formulations are best suited for focal (e.g. dermatitis) where a strong anti-inflammatory effect is also needed.

Veterinary-Labeled Mometasone Products

Note: Partial listing; for more information on human-labeled mometasone products (nasal, etc), refer to a comprehensive human drug reference (e.g., Facts and Comparisons) or contact a pharmacist.

Human-Labeled Topical Mometasone Products

Note: For systemic use, see the monograph found in the main section.
BACITRACIN AND BACITRACIN COMBINATIONS, TOPICAL

**Antimicrobials, Topical**

**Antibacterial Agents**

See also the **Sulfur listing the keratolytic section**

BACITRACIN AND BACITRACIN COMBINATIONS, TOPICAL

Human-Labeled Topical Triamcinolone Acetonide Products

**Indications/Actions**

Considered a medium potency topical corticosteroid when used at concentrations less than 0.5% (high potency), triamcinolone acetonide may be useful for adjunctive treatment of pruritic conditions. Because risks associated with triamcinolone (HPA axis suppression, skin atrophy) are greater than with hydrocortisone, triamcinolone acetonide products are generally reserved for more serious pruritic conditions or when hydrocortisone is not effective. Triamcinolone can be found in a veterinary-labeled sole agent cream (Medalone®) or spray (Genesis®). It is also an ingredient in combination with antibiotics and anti-yeast ingredients in several veterinary products (e.g., Panalog®) that are labeled for otic use. However, these products can be used in an extra-label manner to treat bacterial and yeast skin infections sensitive to gentamicin and nystatin, including pododermatitis and anal sac disease, when a strong anti-inflammatory effect is needed.

Corticosteroids are non-specific anti-inflammatory agents. They probably act by inhibiting phospholipase A2 inhibitory proteins (lipocortins) in cells, thereby reducing the formation, activity, and release of endogenous inflammatory mediators (e.g., histamine, prostaglandins, kinins, etc). Corticosteroids also reduce DNA synthesis via an anti-mitotic effect on epidermal cells. Topically applied corticosteroids also inhibit the migration of leukocytes and macrophages to the area reducing erythema, pruritus and edema.

**Suggested Dosages/Use**

Triamcinolone formulations are best suited for focal (e.g., pedal) or multifocal lesions for relatively short durations (e.g., less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. Long term, frequent use can cause HPA axis suppression and risk can be reduced by treating for only as long as necessary on as small an area as possible. Refer to individual product labeling for actual dosing recommendations for veterinary products.

**Precautions/Adverse Effects**

Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20-30 minutes after application.

Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing’s, gastrointestinal effects) and skin atrophy (skin fragility, alopecia, localized pyoderma and comedones are other possible complications) occur as product concentration and duration of use increases. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

**Veterinary-Labeled Topical Triamcinolone Acetonide Products**

**Note:** Partial listing; there are several topical branded products (two common trade names are Aristocort® and Kenalog®, available with triamcinolone. For more information on human-labeled triamcinolone products, refer to a comprehensive human drug reference (e.g., Facts and Comparisons) or contact a pharmacist.

**Suggested Dosages/Use**

May be applied up to 3 times daily and be covered by a suitable dressing. Use is usually not recommended to continue more than one week.

**Precautions/Adverse Effects**

Bacitracin topical ointment should not be used in or around eyes, for the treatment of ulcerated lesions, or in patients known to be hypersensitive to it. There have been anecdotal reports of cats developing fatal anaphylactic reactions after administered ophthalmic “triple” antibiotic ointment. Deep puncture wounds, animal bites or deep cutaneous infections may require systemic antibiotic therapy. While topical administration generally results in negligible systemic levels, if used over large areas of the body or on serious burns or puncture wounds, measurable absorption and potential toxicity may occur. Do no let animal lick or chew at affected areas for at least 20-30 minutes after application. Clients should wash hands after application or wear gloves when applying.

**Veterinary-Labeled Bacitracin Topical Products**

Veterinary-labeled bacitracin formulations for topical use are not available. However, ophthalmic preparations containing bacitracin in combination with other antibiotics w/ or w/o hydrocortisone could be used in an extra-label manner.
**Bacitracin Ointment**

Bacitracin ointment is available alone as 500 Units/g in various tube sizes. There are many OTC human products available with formulas equivalent to the formally available veterinary-labeled triple antibiotic preparations that contained neomycin, polymyxin B, and bacitracin. A well-known trade name is *Neosporin®* or it is available generically as Triple Antibiotic Ointment. When combined with only polymyxin B, a common trade name is *Polysporin®*.

**BENZOYL PEROXIDE**

**Indications/Actions**

Benzoyl peroxide products are used topically either as gels or in shampoos. Shampoos are generally used for oily and scaly skin (seborrhea oleosa), superficial and deep pyodermas, crusty pyodermas (such as seborrheic dermatitis/pyoderma commonly seen in Cocker Spaniels), furunculosis, and as adjunctive therapy for generalized demodicosis and Schnauzer comedo syndrome. Gels may be useful for treating localized superficial and deep pyodermas, chin acne, fold pyodermas, and localized Demodex lesions.

Benzoyl peroxide possesses antimicrobial (especially antibacterial), comedolytic (“follicular flushing”), keratolytic and anti-seborrheic actions. It also is it has some mild antipruritic activity and wound healing effects, and is thought to increase follicular flushing. Benzoyl peroxide’s antimicrobial activity is due to the oxidative benzoyl peroxy radicals formed that disrupt cell membranes.

**Suggested Dosages/Use**

Gels are usually recommended for use once to twice daily and shampoos up to once daily. Shampoos should remain in contact with skin for at least 10 minutes before rinsing. For veterinary products, refer to product label for details on use.

**Precautions/Adverse Effects**

Avoid contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Benzoyl peroxide will bleach colored fabrics, jewelry, clothing or carpets and may bleach the patient’s fur. Clients should be advised to keep treated animals away from fabrics during treatment. Do not let animal lick or chew at affected areas for a few minutes after application.

Benzoyl peroxide can be drying or irritating (erythema, pruritus, pain) in some patients particularly at higher (>5%) concentrations. Reducing frequency of use, application of emollients after bathing, or using shampoos with moisturizing microvesicles may alleviate or prevent this problem. Benzoyl peroxide shampoos do not lather well.

**Veterinary-Labeled Topical Benzoyl Peroxide Products**

**CLINDAMYCIN, TOPICAL**

(klin-da-mye-sin) *Cleocin®, ClinzGard®*

*For systemic use, see the monograph found in the main section*

**Indications/Actions**

Topical clindamycin may be used for the treatment of feline acne or other localized skin infections caused by bacteria susceptible to it. The veterinary product (*CinzGard®*) is labeled as indicated for the treatment of anal sac and tissue abscesses, puncture wounds and surgical incisions. It has been recommended by some veterinary dermatologists that topical clindamycin only be used when other topical antibiotics such as gentamicin have failed. Ideally, treatment should be based on culture and susceptibility results.

Clindamycin inhibits bacterial protein synthesis by binding to the 50S ribosome; primary activity is against anaerobic and gram-positive aerobic bacteria. For more information on the pharmacology of clindamycin, refer to the monograph for systemic use found in the main section.

**Suggested Dosages/Use**

When used for feline acne, topical clindamycin is generally applied in a thin film once to twice daily. *ClinzGard®* is used as a single application that has sustained-release over 7-10 days. It must be applied to cleaned and, if necessary, debrided surfaces.

**Precautions/Adverse Effects**

Topical clindamycin should not be used in patients with a history of hypersensitivity to clindamycin or lincomycin. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Contact reactions (pain, burning erythema, itching, drying, peeling) are possible. Clindamycin lotions and gels may cause less burning than the topical solutions or foams. As clindamycin can be absorbed through the skin, systemic adverse effects are possible. Antibiotic associated diarrheas are potentially possible, but severe, life-threatening diarrheas (so-called Pseudomembranous colitis) are thought to occur very rarely in animal patients when clindamycin is used systemically.

**Veterinary-Labeled Topical Clindamycin Products**
GENTAMICIN SULFATE, TOPICAL
(jen-ta-my-ye-sin sul-fate) Gentocin®

For systemic use, see the monograph found in the main section.

Indications/Actions
Topical gentamicin can be useful for treating both primary and secondary superficial bacterial skin infections caused by bacteria susceptible to it. It can also be used prophylactically after lacerations/abrasions or after minor surgery. In small animal medicine, topical gentamicin is usually used in combination with the corticosteroid betamethasone to treat superficial lesions, including “hot spots” (acute moist dermatitis, pruritic lesions).

The products containing betamethasone or mometasone and clotrimazole are labeled for otic use, but can also be used in an extra-label manner for yeast and/or bacterial skin infections sensitive to gentamicin and clotrimazole, when an anti-inflammatory effect is also desired. Formulations containing betamethasone or mometasone are best suited for focal (e.g., pedal) or multifocal lesions for relatively short durations (e.g., less than 2 months). Initially, topical corticosteroids are usually used sparingly 1-4 times per day and then frequency is tapered when control is achieved. Sole ingredient gentamicin sulfate topical forms are available with human labeling.

Gentamicin has activity against many Streptococci, Staphylococci (coagulase negative/positive and some penicillinase-producing strains) and gram-negative bacteria including many Klebsiella, E. coli, and some strains of Pseudomonas. Gentamicin-resistant strains of Pseudomonas are an ongoing issue.

Suggested Dosages/Use
Topical gentamicin/betamethasone sprays are labeled for use 2–4 times day for up to 7 days. Topical gentamicin creams and ointments are generally applied to affected areas up to four times daily. Creams are generally used for secondary or greasy infections; ointments on dry skin infections.

Precautions/Adverse Effects
Topical gentamicin may be absorbed systemically if used on ulcers, burned or denuded skin. Creams are more likely to be absorbed than are ointments. Systemic toxicity is unlikely to occur unless used on a significant percentage of body area or for prolonged times. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

With products containing betamethasone or mometasone, long-term or frequent use can cause HPA axis suppression. Risk can be reduced by treating for only as long as necessary on as small an area as possible. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.

Refer to individual product labeling for actual dosing recommendations for veterinary products.

Veterinary-Labeled Topical Gentamicin Products

Human-Labeled Topical Gentamicin Products

MUPIROCIN (PSEUDOMONIC ACID A)
(myoo-pye-roe-sin Bactroban®, Bactrodern®)

Indications/Actions
Mupirocin is FDA-approved for treating infections in dogs (e.g., superficial pyoderma, fold pyoderma, interdigital cysts/draining tracts, acne, pressure point pyodermas, etc) caused by susceptible strains of Staphylococcus aureus or Staphylococcus (pseudo)intermedius, including beta-lactamase producing and methicillin-resistant strains. It may also be of use in other species and conditions (e.g., feline acne, equine pyoderma, superficial pyoderma, interdigital abscesses, pressure point pyodermas, etc). It may also be of use in feline acne. It also shows activity against other gram-positive pathogens, including strains of Corynebacterium, Clostridium; Proteus and Actinomyces.
Human-Labeled Silver Sulfadiazine Products

There are no topical products labeled for veterinary patients. An otic preparation (Baytril Otic®) contains SSD. See the Otics section for more information.

Veterinary-Labeled Silver Sulfadiazine Products

Mupirocin is not significantly absorbed through the skin into the systemic circulation, but does penetrate well into granulomatous deep pyoderma lesions. It is not suitable for application to burns.

Mupirocin is labeled for twice daily application on dogs. It requires 10 minutes of contact time to be active. In cats with feline acne, once a course of once to twice daily mupirocin therapy has been completed (control attained), some cats can be maintained with 1–2 applications per week.

Precautions/Adverse Effects
Mupirocin is contraindicated in patients with a history of hypersensitive reactions it or other ointments containing polyethylene glycol. Because the ointment has a polyethylene glycol base, the manufacturer warns that nephrotoxicity may potentially develop if used on extensive deep lesions. Avoid contact with eyes.

Mupirocin appears to be very well tolerated; contact reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use. Anecdotally, very rare renal toxicity has been reported.

Nitrofurazone is a nitrofuran antibacterial that can be used topically as an antibacterial for treating or preventing superficial infections. It is bactericidal for many bacteria, including E. coli, S. aureus, etc. Clinical efficacy demonstrating efficacy for the treatment of minor burns or surface bacterial infections is apparently unavailable.

Nitrofurazone’s mechanism of action is thought to be associated with inhibiting bacterial enzymes that primarily degrade glucose and pyruvate.

Indications/Actions
Nitrofurazone is a nitrofuran antibiotic that can be used topically as an antibacterial for treating or preventing superficial infections. It is bactericidal for many bacteria, including E. coli, S. aureus, etc. Clinical efficacy demonstrating efficacy for the treatment of minor burns or surface bacterial infections is apparently unavailable.

Nitrofurazone’s mechanism of action is thought to be associated with inhibiting bacterial enzymes that primarily degrade glucose and pyruvate.

Suggested Dosages/Use
Apply once daily until lesions resolve or as directed by the veterinarian. For veterinary products, refer to product label for details on individual use.

Precautions/Adverse Effects
As nitrofurazone has been shown to cause mammary tumors when fed in high doses to rats and ovarian tumors in mice, U.S.A. federal law prohibits the use of nitrofurazone products in (or on) food animals, including horses to be used for food.

The soluble dressing contains polyethylene glycols and if used on large areas of denuded skin significant amounts of polyethylene glycol could be absorbed and cause nephrotoxicity.

Avoid ointment contact with eyes or mucous membranes. Clients should wash hands after application or wear gloves when applying. Do not allow animal to lick or chew treated area for at least 30 minutes. Avoid exposure to sunlight, strong fluorescent lighting, excessive heat, or alkaline materials.

Topical nitrofurazone appears to be well tolerated; hypersensitivity or skin reactions (pain, erythema, itching) are possible, but thought to occur rarely. Overgrowth of non-susceptible organisms (superinfection) is also possible with prolonged use.

**Indications/Actions**

Indicated for the treatment of skin infections caused by bacteria including *Staphylococcus* spp., *Pseudomonas* spp. and yeast such as *Malassezia* spp. Also indicated for fold dermatitis, acute moist dermatitis, pododermatitis, and seborrhea oleosa. Some products contain other antimicrobials such as chlorhexidine and ketoconazole or antiinflammatory agents such as hydrocortisone for anti-pruritic effects.

Acetic and boric acids are potent antibacterial and antifungal agents with a rapid killing effect. They also possess ceruminolytic, keratolytic, keratoplastic, and astringent activities.

**Suggested Uses/Dosages**

If using spray or wipes: up to 2–3 times a day. If shampoo or conditioner: daily to weekly baths/after baths according to the veterinarian’s recommendations. Leave shampoos in contact with the skin for at least 10 minutes prior to rinsing. Refer to the product for individual label directions.

**Precautions/Adverse Effects**

Skin redness and irritation may occur. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

**Veterinary-Labeled Topical Acetic and Boric Acid Products**

Human-Labeled Topical Acetic and Boric Acid Products

There are several OTC human products available containing acetic acid or boric acid (alone or containing other ingredients). For more information on human-labeled acetic acid or boric acid products, refer to a comprehensive human drug reference (e.g., *Facts and Comparisons*) or contact a pharmacist.

**Indications/Actions**

A topical antiseptic, chlorhexidine has activity against many bacteria, but apparently, it is not predictably active against *Pseudomonas* or *Serratia* spp. It is available with veterinary labels in many different forms (solutions, shampoos, scrubs, ointments, sprays, etc).

Because it causes less drying and is usually less irritating than benzoyl peroxide, it is sometimes used in patients that cannot tolerate benzoyl peroxide. However, it does not have the keratolytic, comedolytic or degreasing effects of benzoyl peroxide. Chlorhexidine possesses some residual effects and can remain active on skin after rinsing. Chlorhexidine products may also contain other ingredients such as antifungals (ketoconazole and miconazole), salicylic acid, phytohormones, etc.

At usual concentrations, chlorhexidine acts by damaging bacterial cytoplasmic membranes. Antifungal activity can be obtained with 2% or higher concentrations.

**Suggested Dosages/Use**

For wound irrigation or foot soaking, 0.05–0.1% dilution in water is recommended. If using spray or wipes/pads: 1-2 times a day. If using shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

**Precautions/Adverse Effects**

Skin redness and irritation may occur. Do not let animal lick or chew at affected areas for at least 20-30 minutes after application.

**Veterinary-Labeled Topical Chlorhexidine Products**

Keep away from eyes as chlorhexidine products can damage eyes. Clients should wash hands after application or wear gloves when applying. Chlorhexidine is safe used on cats, although irritation and corneal ulcers have been reported.

Hypersensitivity and local skin irritant reactions are possible. Likelihood of irritation increases with increased concentrations. Chlorhexidine may retard wound healing; not recommended for long-term use particularly on granulating lesions.
Veterinary-Labeled Topical Chlorhexidine Products

There are several teat dip and udder wash products, a lubricant, and oral rinses are available. There are several trade names used for chlorhexidine products, including Nolvasan®, Chlorhexiderm®, Dermachlor®, Chlorasan®, Chloradine®, Privasan®, and Chlorhex®.

Human-Labeled Topical Chlorhexidine Products

There are several topical skin cleansers available in the 2–4% range. Trade names include: Hibiclens®, Hibistat®, Betasept®, Exidine®, Dyna-Hex® and Bactoshield®.
CHLOROXYLENOL (PCMX)

For otic use, refer to the Otics section

Indications/Actions
Chloroxylenol is an antimicrobial disinfectant with demonstrated efficacy against gram-negative and gram-positive bacteria, in addition to a wide variety of fungal organisms, and against RNA and DNA viruses. It can be used in pre-surgical preparation of skin, cleaning wounds and in the treatment of bacterial, fungal and yeast skin infections. Chloroxylenol, also known as PCMX, is a chlorinated phenolic antiseptic. Its antibacterial action is due to disruption of bacterial cytoplasmic membranes by blocking production of adenosine triphosphate.

Suggested Uses/Dosages
If using shampoo, leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. Refer to product label for details on individual use.

Precautions/Adverse Effects
May cause skin irritation.

Veterinary-Labeled Topical Chloroxylenol Products
This list contains only products where chloroxylenol is one of the main active ingredients. For more products containing chloroxylenol (PCMX), see other topical compounds in this section.

Human-Labeled Topical Chloroxylenol Products
There are several topical products available containing chloroxylenol usually combined with other ingredients such as hydrocortisone, menthol, pramoxine, and benzocaine. They are presented in different forms (creams, ointments, lotions and shampoos), but are not commonly used in dogs and cats. Trade names include: Aurinol®, Calamycin®, Cortamox®, Cortane-B®, Dermacoat® and Foille®

ENZYMES, TOPICAL (LACITPEROXIDASE, LYSOZYME, LACTOFERRIN)

For otic use, refer to the Otics section

Indications/Actions
These products may be useful for bacterial and fungal skin infections and are reported to be effective against Staphylococcus spp., Pseudomonas spp., Malassezia spp., Candida albicans, Microsporum spp. They can be used alone, or especially with products containing hydrocortisone, for mild itching or as an adjunctive treatment for more pruritic conditions such as atopic dermatitis.

The veterinary products contain the milk-derived enzymes lactoperoxidase, lysozyme and lactoferrin. These enzymes are reported to be effective against bacterial, fungal and viral microorganisms. Lactoperoxidase combined with hydrogen peroxide, thiocyanate, and/or iodide produce hypothiocyanate or hypoiodite ions that are bactericidal by oxidizing components of bacterial cell walls. Hypoiodite also is fungicidal. Lactoferrin acts as a bacteriostatic agent against many bacteria by depriving them of iron.

Suggested Uses/Dosages
If using spray, cream or wipes: 1–2 times a day applications. If shampoo or rinse: daily to weekly baths/after baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing well. May be applied to affected areas 2 times a day or as needed to relief itching and soothe the skin. Refer to product label for details on individual use.

Precautions/Adverse Effects
Overall appears to be safe. No reported side effects, but skin irritation is possible.

ETHYL LACTATE

Indications/Actions
Ethyl lactate shampoos can be used for bacterial skin infections, including surface and superficial pyoderma. It also has a keratolytic effect, which provides anti-seborrheic activity. A lipid soluble compound, ethyl lactate rapidly penetrates hair follicles and sebaceous glands where bacterial lipases convert it into lactic acid and ethanol, which are responsible for its antibacterial action. Ethanol helps solubilize fats and reduces sebaceous secretions. It is not as active as benzoyl peroxide against staphylococcal organisms, but it is less irritating and drying.

Suggested Dosages/Use
Daily to 2–3 weekly baths. Shampoo should remain in contact with the skin for at least 10 minutes prior to rinsing well. Refer to product label for details on individual use.

Precautions/Adverse Effects
Ethyl lactate shampoos are often used in conjunction with oral antibiotics and are usually used 2–3 times per week initially; frequency of use may be reduced when pyoderma is under control. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.
Adverse effects are unlikely, but local effects (erythema, pain, itching) are possible.

### HYPOCHLOROUS ACID

**SODIUM HYPOCHLORITE**

(hye-poe-klor-ass-ide)

#### Indications/Actions

The proprietary products, Vetericyn® and Microcyn® contain hypochlorous acid and sodium hypochlorite and are labeled for the management of wounds, abscesses, cuts, abrasions, skin irritations, ulcers, post surgical incision sites, burns and wound odors and to accelerate healing. It may be used for prevention of bacterial skin infections or as an adjunctive topical therapy for bacterial skin infections, including Methicillin-Resistant Staphylococcus spp. and Pseudomonas spp. Hypochlorous acid also has anti-fungal and antiviral properties and is reported to reduce inflammation, pain and itching.

This is a proprietary formulation and have broad-spectrum antimicrobial activity and act rapidly against gram-positive and gram-negative bacteria and fungal/yeast organisms. They may also be effective against viruses. The products Vetericyn® and Microcyn® contain oxychlorine (bleach-like) compounds and have a neutral pH. Mode of action is to disrupt the cellular membrane of single cell organisms. Because mode of action is primarily chemical in nature, resistance does not appear to be an issue.

#### Suggested Dosages/Use

Clip hair if necessary and apply spray or gel to affected areas up to 3 times a day; may be used with dressing applications on wounds. Refer to product label for details on individual use. No rinsing is required. Labeled as safe to use around eyes, nose and mouth.

#### Precautions/Adverse Effects

No precautions or adverse effects reported. Reported as non-toxic; does not sting or irritate the skin, however treated area may become reddened secondary to increased blood flow.

### POVIDONE IODINE

(poe-vo-dun eye-oh-dine) Betadine®

#### Indications/Actions

Povidone iodine can be used as a topical pre-surgical skin cleanser/antiseptic and may be used for superficial pyoderma and Malassezia dermatitis, however, it is infrequently used in small animal dermatology due to its drying, irritating and staining effects.

An iodophore antiseptic, povidone iodine is rapidly bactericidal (against gram-positive and –negative bacteria) at low concentration. It is also fungicidal and sporicidal (as a 1% aqueous solution). Povidone acts by slowly releasing iodine to tissues. It has prolonged activity (4–6 hours), but not as long as chlorhexidine. Povidone iodine also has mild degreasing and debriding activity.

#### Suggested Dosages/Use

For veterinary products, refer to product label for details on individual use

#### Precautions/Adverse Effects

Povidone may be drying, irritating and staining to skin, hair and fabrics. Can be extremely irritating to the scrotal skin and external ears. Use with emollients may alleviate the drying effects. Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Systemic absorption can result in renal and thyroid dysfunction.

### Veterinary-Labeled Topical Povidone Iodine Products

There are several trade names used for povidone iodine products, including Poviderm®, Prodine®, Vetadine®, Betadine®, Lanodine®, Viodine® and Povidine®. There are also (not listed) hoof dressings, teat dips, and udder washes available that contain povidone iodine.

**Note:** 10% povidone iodine yields 1% titratable iodine and so forth. Labels may be confusing.
Human-Labeled Topical Povidone Iodine Products
There are several trade names used for povidone iodine products, including Betadine®, Betagen®, Biodine®, Etodine®, Mallisol®, Minidyne®, Polydine® and Povidine®. There are also (not listed) vaginal gels, swabs, and foaming skin cleansers available.

TRICLOSAN (IRGASAN)
(trye-klose-san)

Indications/Actions
Found in several products, often with other active ingredients, triclosan’s antibacterial effects may be useful in treating superficial pyoderma. Veterinary products labeled for small animals containing triclosan as the sole active ingredient are all shampoos.

Triclosan is a bis-phenol disinfectant/antiseptic. It has activity against a wide range of organisms, including both gram-positive and gram-negative bacteria and acts via inhibiting bacterial fatty acid synthesis leading to disruption of cell membrane integrity. Triclosan reportedly is not effective against Pseudomonas spp. and may be less effective against staphylococci than either chlorhexidine or ethyl lactate.

Suggested Dosages/Use
Daily to weekly baths; leave shampoo in contact with the skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

Precautions/Adverse Effects
Triclosan should not be used on burned or denuded skin, or mucous membranes. Avoid contact with eyes.

Veterinary-Labeled Triclosan Products
There are also triclosan products labeled for use as teat sealants (Uddergold Dry®) in cattle.

Human-Labeled Triclosan Products
There are several human triclosan products labeled as hand, face or body washes for acne treatment. Trade names include Septisoft®, Clearasil Antibacterial®, Clearasil Daily Face Wash®, Stri-Dex®, Oxy Medicated Soap®, and ASC®.

Antifungals
CLOTRIMAZOLE, TOPICAL
(kloo-trye-ma-zole) Lotrimin®

Indications/Actions
Topical clotrimazole has activity against dermatophytes and yeasts; it may be useful for localized lesions associated with Malassezia. It is not very effective in treating dermatophytosis in cats. Most veterinary products contain gentamicin and either, betamethasone or mometasone, and are labeled for otic use. However, these products may be used in an extra-label manner for bacterial and yeast skin infections with concurrent inflamed/pruritic skin.

Clotrimazole inhibits the biosynthesis of ergosterol, a component of fungal cell membranes leading to increased membrane permeability and probable disruption of membrane enzyme systems.

Suggested Dosages/Use
If sprays, twice daily applications are usually recommended. Ointments are generally applied to affected areas up to four times daily. For veterinary products, refer to product label for details on individual use.

Precautions/Adverse Effects
Products with clotrimazole alone:
Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible, but unlikely to occur with products containing only clotrimazole.

If using products containing betamethasone or mometasone:
Several veterinary topical products list tuberculosis of the skin or pregnancy as a contraindication. Systemic corticosteroids can be teratogenic or induce parturition during the third trimester of pregnancy in animals. If considering use during pregnancy, weigh the respective risks with treating versus potential benefits. Clients should wash hands after application or wear gloves when applying. Avoid contact with eyes. Do not allow animal to lick or chew at affected sites for at least 20–30 minutes after application. Residual activity may affect intradermal or allergy serum tests; it has been suggested to stop use 2 weeks prior to allergy testing.

Use care when treating large areas, or when used on smaller patients. Risks can be reduced by treating for only as long as necessary on as small an area as possible. Increased risks of HPA axis suppression, systemic corticosteroid effects (polydipsia/polyuria, Cushing’s, gastrointestinal effects) and skin atrophy (skin fragility, alopecia, localized pyodermas and comedones are other possible complications) occur as product concentration and duration of use increases. Betamethasone may delay wound healing particularly if used longer than 7 days in duration. Vomiting and diarrhea have been reported with use of the products containing betamethasone. Local skin reactions (burning, itching, redness) are possible, but unlikely to occur.

Veterinary-Labeled Topical Clotrimazole Products

ENILCONAZOLE

Although no dosage forms are currently commercially available for topical use in the USA, enilconazole is used topically for treating dermatophytosis in small animals and horses using compounded products. A commercially available topical rinse Imaverol® (Janssen) 10% is available with canine, bovine and equine use labeling in many countries. Intranasal instillation of enilconazole after plaque debridement has also been shown useful in treating nasal aspergillosis in small animals.

Use of topical enilconazole on cats with dermatophytosis is somewhat controversial as there are apparently no products with feline labeling available in Europe or Canada. There are reports of safely and successfully using enilconazole on dermatophytic cats alone, or in combination with oral itraconazole.

A topical product and a poultry environmental disinfectant product (Clinafarm EC®) are available in the USA. This formulation has been used off-label to treat dermatophytosis at a dilution of 55.6 ml per gallon water as a topical antifungal. However, it is technically illegal to use this product other than it is labeled, as it is an EPA-licensed product in the USA.

Suggested Dosages/Use

Using Imaverol®: dilute as directed and wash or dip 4 times, at 3-day intervals or as directed by veterinarian. Refer to product label for details on individual use.

Precautions/Adverse Effects

Avoid contact with eyes. Clients should wear gloves when applying and use eye protection.

When used topically in cats, hypersalivation, vomiting, anorexia/weight loss, muscle weakness, and a slight increase in serum ALT levels have been reported.

None

KETOCONAZOLE, TOPICAL

(kee-toe-kon-a-zole) Nizoral®, Ketochlor®

For systemic use, see the monograph found in the main section

For otic use, see the Otics section

Indications/Actions

Topical ketoconazole has activity against dermatophytes and yeasts and ketoconazole shampoos can be effective treatment for Malassezia dermatitis. Patients with severe, generalized infections may require additional systemic therapy. Topical ketoconazole shampoos are generally ineffective (or minimally effective) when used alone for dermatophytosis.

Suggested Dosages/Use

If using spray or wipes/pads: 1–2 times a day. If shampoo or conditioner: daily to weekly baths/after baths; leave shampoo in contact with skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

Precautions/Adverse Effects

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible.

Human-Labeled Topical Ketoconazole Products

LIME SULFUR (SULFURATED LIME SOLUTION)
(lime sul-fur-lime sul-fur)

Indications/Actions
Lime sulfur applications are very effective and relatively inexpensive as a generalized topical treatment for dermatophytosis. Both lime sulfur and enilconazole are thought to have the most topical activity against *M. canis* of commercially available compounds. In addition, it is the most efficacious treatment of surface demodicosis (*Demodex gatoi*) in cats. Lime sulfur can also be useful in the adjunctive treatment of Malassezia dermatitis, Cheyletiellosis, Chiggers, Sarcoptic and Notoedric mange, fur mites, lice, canine demodicosis and sarcoptic mange.

Lime sulfur has antibacterial and antifungal (and some anti-yeast) properties secondary to the formation of pentathionic acid and hydrogen sulfide after application. Both lime sulfur and enilconazole are thought to have the most topical activity against *M. canis*. Lime sulfur may also have keratolytic, keratoplastic, antiparasitic, and antipruritic effects.

Suggested Dosages/Use
Labeled dose for *LymDyp®* and *Vet Solutions Lime Sulfur Dip®*: Shake well; dilute 4 oz. of concentrate in one gal of water. Mix well. Apply as a rinse or dip at 5–7 day intervals. Do not rinse. For more chronic or resistant cases, may be used at 8 oz per gal.

Labeled dose for *LimePlus Dip®* and *Lime Sulfur Dip®*: Pour 4 oz. of concentrate in one gal of water. Mix well. Bathe animal prior to application. Rinse off shampoo. Pour entire contents of diluted *LimePlus Dip®* onto pet and work into skin. Apply as a rinse, spray or dip at 5–7 day intervals. Allow to dry on the animal. Do not rinse. When used for dermatophytosis, once to twice weekly treatments have been recommended, if patients can tolerate the treatment’s irritating effects, until 2 consecutive negative cultures are obtained. When used for confirmed cases of feline surface demodicosis, applications are recommended every 5–7 days for a total of 6 treatments. If using lime sulfur as a treatment trial for surface demodicosis, 3 applications should be performed and if there is significant improvement in clinical signs, 3 more applications should be performed to complete treatment. If no significant improvement is seen after 3 applications, demodicosis should be ruled out and other diagnosis should be considered.

Precautions/Adverse Effects
Avoid contact with eyes and mucous membranes. Can stain porous surface (*e.g.*, concrete, porcelain) or permanently discolor jewelry. Clients should wear gloves and protect skin and eyes from solution. Because of its very unpleasant odor, application should be performed in a well-ventilated area or clients should wear a protective (respirator-type) mask.

While reasonably non-toxic, lime sulfur may cause skin irritation or drying. Adding mineral oil to the solution may reduce its drying effects. Lime sulfur can stain (temporarily) light colored fur and rarely cause hair loss on the pinnae in cats. Lime sulfur’s odor may persist on treated animals, but generally is tolerable once the patient dries. Oral ingestion can rarely cause nausea and oral ulcers, mainly in cats; an Elizabethan collar may help prevent this from occurring.

Veterinary-Labeled Lime Sulfur Products

Human-Labeled Lime Sulfur Products

None

MICONAZOLE, TOPICAL
(mye-kon-ah-zole)

For ote use, refer to the Otics section

Indications/Actions
Topical miconazole has activity against dermatophytes and yeast. It is especially effective for the treatment of *Malassezia* dermatitis. Patients with severe, generalized infections may require systemic therapy. Lotions, sprays and creams are generally used for localized lesions associated with *Malassezia* sp. or dermatophytes. Topical miconazole products are generally ineffective (or minimally effective) when used alone for dermatophytosis.
and creams are generally used for localized lesions associated with Malassezia sp. or dermatophytes. Topical miconazole products are generally ineffective (or minimally effective) when used alone for dermatophytosis; adjunctive systemic treatment is usually required.

**Suggested Dosages/Use**

If using spray, creams, lotions or wipes/pads: 1–2 times a day applications. If using a shampoo or conditioner: daily to weekly baths; leave in contact with skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

**Precautions/Adverse Effects**

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Do not allow animal lick or chew at affected areas for at least 20-30 minutes after application.

Skin irritation is possible, but unlikely to occur, but in very inflamed, eroded or ulcerated skin, the pledgets, wipes, towelettes, and spray containing alcohol (Malaseb®) can be severely irritating.

**Veterinary-Labeled Topical Miconazole Products**

**Note:** Miconazole nitrate is the salt generally used in pharmaceutical products. While technically, a 1% concentration of miconazole nitrate contains less than 1% miconazole, the following products are rounded to the closest full percent regardless of how much miconazole base is actually in each product.

**Suggested Dosages/Use**

If using spray, creams, lotions or wipes/pads: 1–2 times a day applications. If using a shampoo or conditioner: daily to weekly baths; leave in contact with skin for at least 10 minutes prior to rinsing. For veterinary products, refer to product label for details on individual use.

**Precautions/Adverse Effects**

Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying. Do not allow animal lick or chew at affected areas for at least 20-30 minutes after application.

Skin irritation is possible, but unlikely to occur, but in very inflamed, eroded or ulcerated skin, the pledgets, wipes, towelettes, and spray containing alcohol (Malaseb®) can be severely irritating.

**Human-Labeled Topical Miconazole Products**

*Note:* NYSTATIN is not usually used alone in small animal medicine. The combination products (*e.g.*, Panalog®, etc.) can be useful for topical lesions caused by yeasts or yeast-like organisms; they have been used for treated otitis infections for many years.

**Indications/Actions**

Nystatin has efficacy against many yeasts and yeast-like organisms (*Malassezia*). Its mechanism of action is believed secondary to binding to sterols in the fungal cell membranes thereby increasing membrane permeability with leakage of intracellular components. Nystatin does not have activity against bacteria and is ineffective against other fungi.

**Suggested Dosages/Use**

Nystatin (topical) is rarely used alone in veterinary medicine. In humans, the cream is usually used instead of the ointment in treating candidal infections involving intertriginous areas; nystatin topical powder is best used for very moist lesions.

Nystatin products that contain triamcinolone are best suited for focal (*e.g.*, pedal) or multifocal lesions for relatively short durations (*e.g.*, less than 2 months). Initially, topical corticosteroids are usually used sparingly 1–4 times per day and then frequency is tapered when control is achieved.
Precautions/Adverse Effects
Avoid contact with eyes. Clients should wash hands after application or wear gloves when applying.
Nystatin alone is very safe, although hypersensitivity reactions are possible. The combination veterinary products are usually well tolerated when used on skin. Neomycin can cause localized sensitivity and those containing glucocorticoids can potentially cause cutaneous atrophy HPA-axis suppression.

(si-len-ee-um sul-fide)

Indications/Actions
Selenium sulfide may be useful in seborrheic disorders (mainly for seborrhea oleosa) and for adjunctive treatment of Malassezia dermatitis, particularly in dogs exhibiting signs of waxy, greasy or scaly (seborrheic) dermatitis. There may be some residual activity on the skin.
Selenium sulfide possesses antifungal (including sporicidal activity), keratolytic, keratoplastic and degreasing properties. It affects cells of the epidermis and follicular epithelium (alters the epidermal turnover) and interferes with hydrogen bond formation of keratin thereby reducing corneocyte production. Selenium sulfide’s antifungal mechanism of action is not well understood.

Suggested Dosages/Use
Frequency of shampooing will vary according to the patient’s needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3-5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

Precautions/Adverse Effects
Selenium sulfide products should not be used on cats. Avoid contact with eyes. Selenium sulfide can discolor jewelry. Clients should wear gloves when using these products. Selenium sulfide can be irritating, cause excessive drying and hair-coat staining. Mucous membranes and scrotal areas may be particularly sensitive to the irritating effects of the drug. After discontinuation, a rebound seborrhea can occur where signs could be worse than prior to treatment. Gastrointestinal effects (nausea, vomiting, diarrhea) may occur selenium sulfide is ingested orally. Neurologic signs are possible if large quantities are ingested. Contact an animal poison center if a substantial oral ingestion occurs.

Veterinary-Labeled Topical Selenium Sulfide Products
There apparently are no labeled veterinary products containing selenium sulfide currently available in the USA; Seleen® may be available in other countries.

TERBINAFINE HCL, TOPICAL
(ter-bin-a-fee-en)

For systemic use, see the monograph found in the main section

Indications/Actions
An allylamine antifungal agent, terbinafine may be useful for localized lesions associated with Malassezia. With its current topical dosage forms, it does not appear to be very useful for treating dermatophytosis in cats.
Terbinafine inhibits the biosynthesis of ergosterol, but its mechanism for inhibiting ergosterol is different from the azole antifungals. Terbinafine inhibits the fungal squalene epoxidase enzyme. The resultant depletion of ergosterol within the fungal cell membrane and the intracellular accumulation of squalene are believed to be responsible for the fungicidal effect of terbinafine. It is fungicidal against dermatophytes, but may only be fungistatic against yeasts.

Suggested Dosages/Use
Topical terbinafine is not commonly used in veterinary medicine at present, but it could be used topically to affected areas once to twice a day.

Precautions/Adverse Effects
Avoid contact with eyes and mucous membranes. Clients should wash hands after application or wear gloves when applying. Skin irritation is possible, but unlikely to occur.

### Salicylic Acid

**Indications/Actions**

Often combined with sulfur, salicylic acid shampoos are employed to treat patients with seborrheic disorders (seborrhea sicca and oleosa) exhibiting mild to moderate scaling, with mild waxy and keratinous debris. When combined with benzoyl peroxide, salicylic acid and sulfur containing shampoos can also be used to manage seborrhea oleosa. In higher concentrations, topicals such as Kerasolv® Gel (6.6% salicylic acid) can be used to remove localized excessive tissues associated with hyperkeratotic disorders, such as calluses and idiopathic thickening of the planum nasale and footpads.

Salicylic acid has mildly antipruritic, antibacterial (bacteriostatic), keratoplastic and keratolytic actions. Lower concentrations are primarily keratoplastic and higher concentrations, keratolytic. Salicylic acid lowers skin pH, increases cornocyte hydration and dissolves the intercellular binder between cornocytes. Salicylic acid and sulfur are thought to be synergistic in their keratolytic actions.

**Suggested Dosages/Use**

Frequency of shampooing will vary according to the patient’s needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3-5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

**Precautions/Adverse Effects**

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Burning, itching, pain, erythema, swelling can occur from salicylic acid, particularly when used in higher concentrations (> 2%). A rebound seborrheic effect can occur.

### Human-Labeled Topical Salicylic Acid Products

**Note:** There are many topical salicylic acid products labeled for human use, including topical creams, ointments, transdermal patches, liquids and gels that are principally labeled for wart removal. Except for one product (Salex®, 6% cream), they are available OTC. There are also many OTC skin cleansers and shampoos containing salicylic acid and usually sulfur (sometimes coal tar or menthol). As there are several similar products formulated and labeled for animal use, human products will not be listed. For more information on these products, refer to a comprehensive human drug reference or contact a pharmacist.
Indications/Actions

Sulfur-containing shampoos are often employed to treat patients with seborrheic disorders exhibiting mild to moderate scaling, with mild waxiness and keratinous debris.

Sulfur has keratoplastic and keratolytic actions. Lower concentrations of sulfur are primarily keratoplastic secondary to assisting conversion of cysteine to cystine, thought an important factor in the maturation of corneocytes. Like salicylic acid, sulfur’s keratolytic effects increase with concentration. Salicylic acid and sulfur are believed synergistic in their keratolytic actions. Sulfur also has mild degreasing effects and can be mildly antipruritic.

Sulfur also has antibacterial, antifungal, and antiparasitic effects secondary to sulfur conversion to hydrogen sulfide and pentathionic acid by bacteria and keratocytes.

Suggested Dosages/Use

Frequency of shampooing will vary according to the patient’s needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3–5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

Precautions/Adverse Effects

Avoid contact with eyes, mucous membranes and open sores/cuts. Clients should wash hands after application or wear gloves when applying.

Skin irritation is possible. Sulfur can be drying, cause pruritus and be irritating. Residual odor is often bothersome to clients. Sulfur may stain fabrics and hair. A rebound seborrheic effect can occur when using shampoo products containing sulfur.

Human-Labeled Topical Sulfur Products

Note: There are several topical products containing sulfur labeled for human use, including topical creams, lotions, shampoos, soaps and masks that are principally labeled for acne or dandruff. For more information on these products, refer to a comprehensive human drug reference (e.g., Facts and Comparisons) or contact a pharmacist.

COAL TAR
(kole tar)

Indications/Actions

Use of coal tar containing shampoos in veterinary medicine is somewhat controversial, particularly since almost all veterinary-labeled products have been withdrawn from the market. However, coal tar shampoos have been used in dogs for treating greasy dermatoses (seborrhea oleosa) for many years.

Coal tar possesses keratoplastic, keratolytic, vasoconstrictive, antipruritic, and degreasing actions. Coal tar’s mechanism of keratoplastic (keratoregulating) action is probably secondary to decreasing mitosis and DNA synthesis of basal epidermal cells.

Suggested Dosages/Use

Frequency of shampooing will vary according to the patient’s needs. When using a medicated shampoo allow 10 minutes contact time. Another acceptable regimen is to allow the shampoo act for 3–5 minutes, rinse it thoroughly and thereafter repeat the procedure. Completely rinse to prevent skin irritation and/or excessive drying.

Precautions/Adverse Effects

The carcinogenic risks associated with coal tar products are hotly debated. At present, most (including the FDA) believe that coal tar products with concentrations of 5% or less are safe for human use. However, should they be used on animals, clients should wear gloves when applying and wash off any product that contacts their skin. Carcinogenic risk assessment for dogs using coal tar products was not located.

Coal tar products should not be used on cats, patients who have prior sensitivity reactions to tar products or have dry scaling dermatoses. Be careful in comparing coal tar concentrations on labels. Coal tar solution contains approximately 20% coal tar extract or refined tar. For example, a 10% coal tar solution contains approximately 2% coal tar (refined).

Photosensitization, skin drying and skin irritation are possible with tar therapy. Adverse effects are more likely with tar concentrations greater than 3%. Residual odor is often bothersome to clients. Tar may stain fabrics or haircoats and discolor jewelry.

Veterinary-Labeled Coal Tar-Containing Products
Human-Labeled Coal Tar-Containing Products
There are several products labeled for human use that contain coal tar, including ointments, lotions, creams, and shampoos available in concentrations ranging from 0.5% to 5% coal tar (not coal tar extract).

Antiseborrheic Products

Immunomodulators, Topical

IMIQUIMOD, TOPICAL
(im-i-koe-mo-d) Aldara®

Indications/Actions
An immune response modifier, imiquimod may be useful in the treatment of a variety of topical conditions in animals. It is labeled for use on humans as a treatment for genital or perianal warts, superficial basal cell carcinomas and actinic keratoses of the face and scalp. In dogs and cats, imiquimod potentially may be of benefit in treating feline herpes virus dermatitis, actinic keratosis, squamous cell carcinoma and Bowen’s disease, squamous cell carcinoma in situ (SCCis), and papillomas. Imiquimod may also be beneficial in the treatment of feline herpes virus dermatitis, actinic keratosis and squamous cell carcinoma in dogs. Imiquimod may not be effective for the treatment of tumors that arise from hair follicles. Imiquimod may not be able to control the disease.

Suggested Dosages/Use
Use in animals is limited. Clients administering the drug should wear gloves when handling or applying the cream. It is advised to avoid getting in eyes or on mucous membranes. Cats and dogs with oral mucosal papillomas have been treated without visible side effects.

Precautions/Adverse Effects
Local skin reactions are common with imiquimod therapy and include application site reactions: erythema, burning, tenderness, pain, irritation, oozing/exudate, and erosion. Treatment duration and frequency may need to be adjusted depending on patient response and adverse reactions.

Veterinary-Labeled Imiquimod Products
None

Human-Labeled Imiquimod Products

PIMECROLIMUS, TOPICAL
(pim-e-kro-li-mus) Elidel®

Indications/Actions
A relatively new addition to the human topical armamentarium, pimecrolimus cream may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo, and for perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy). Unlike topical corticosteroids, tacrolimus or pimecrolimus do not have atrophogenic or metabolic effects associated with long-term or large area treatment.

Suggested Dosages/Use
Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled, then reduce application frequency to the fewest times that allow control of the disease.

Precautions/Adverse Effects
Both tacrolimus and pimecrolimus have FDA-mandated “black box” warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (e.g., a Q-tip) when applying the cream. The long-term adverse effects of topical pimecrolimus are currently unknown; therefore, it is prudent to avoid using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that keeps the disease under control.

Topical pimecrolimus appears well tolerated in dogs, but localized irritation and pruritus have been reported in horses and dogs using the drug. Early anecdotal reports state that pimecrolimus may be less irritating than tacrolimus in dogs, but that it also may not be as effective. The cost of the medication may be prohibitive for some clients.

Veterinary-Labeled Topical Pimecrolimus Products
None

Human-Labeled Topical Pimecrolimus Products

TACROLIMUS, TOPICAL
(ta-cro-li-mus) Protopic®

Indications/Actions
Tacrolimus ointment may be of benefit in veterinary patients in the adjunctive treatment of atopic dermatitis, discoid lupus erythematosus, pemphigus erythematosus or foliaceous, pinnal vascular disease, alopecia areata, vitiligo and for perianal fistulas (terminal phase or maintenance treatment after cyclosporine therapy). Unlike topical corticosteroids, tacrolimus or pimecrolimus do not have atrophogenic or metabolic effects associated with long-term or large area treatment.
Amitraz acts similarly as cyclosporine, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils.

**Suggested Dosages/Use**

Only limited experience has occurred with this drug in veterinary patients. Most dosing recommendations are to use the product twice daily until signs are controlled, then reduce application frequency to the fewest times that allow control of the disease.

**Precautions/Adverse Effects**

Both tacrolimus and pimecrolimus have FDA-mandated “black box” warnings that use may increase risks for skin cancer and lymphomas in humans, although a causal relationship has not been established. Because of the rarity of these occurrences in humans, these drugs are probably relatively safe to use in veterinary patients. However, clients should be informed and instructed to wear gloves or use an applicator (e.g., a Q-tip) when applying the ointment. The long-term adverse effects of topical tacrolimus are currently unknown; therefore, it is prudent to avoid using this medication on a continuous maintenance basis. When long-term treatment is required, the ultimate goal should be to achieve the lowest possible dose that keeps the disease under control.

The commercially available ointment should not be used as, or compounded into an ophthalmic preparation for treating KCS in dogs as it contains propylene carbonate, a known ocular toxin.

Thus far, topical tacrolimus is appears to be well tolerated in dogs, but localized irritation and pruritus have been reported in humans and dogs using the drug. Early anecdotal reports state that pimecrolimus may be less irritating than tacrolimus in dogs, but that it may also not be as effective. The cost of the medication may be cost prohibitive for some clients.

**Veterinary-Labeled Topical Tacrolimus Products**

None

**Retinoids, Topical**

**TRETINOIN (TRANS-RETINOIC ACID; VITAMIN A ACID)**

(derivatives of Retino-A)

**Indications/Actions**

Topical tretinoin may be useful in treating localized follicular or hyperkeratotic disorders such as acanthosis nigricans, idiopathic nasal and footpad hyperkeratosis, callous pyodermas, or chin acne.

Tretinoin’s exact mechanism of action is not well understood, but it stimulates cellular mitotic activity, increases cell turnover, and decreases the cohesiveness of follicular epithelial cells.

**Antiparasitic Agents, Topical**

For agents such as eprinomectin, ivermectin, levamisole, moxidectin and selamectin that may be administered topically, but absorbed through the skin to treat internal parasites as well as external parasites, refer to the monographs in the main (systemic drugs) section of the Handbook. Also see monographs in the main section for those products administered orally for their external parasitic actions, including fenbendazole, fenbendazole, milbemycin, and spinosad.

**AMITRAZ**

(a-mitra; Mitaban®, Taktic® EC, Preventic®, ProMeris® for Dogs)

**Indications/Actions**

In dogs, amitraz solution is used topically primarily in the treatment of generalized demodicosis. A topical spot-on solution (ProMeris® for Dogs) and a collar (Preventic®) are available for treatment and prevention of flea and tick infestation. It is also used as a general insecticidal/miticidal agent in several other species (see label information). The pharmacologic action of amitraz is not well understood, but it is a monoamine oxidase (MAO) inhibitor (in mites) and may have effects on the CNS of susceptible organisms. It apparently also possesses alpha-2 adrenergic activity and inhibits prostaglandin synthesis. Amitraz can cause a significant increase in plasma glucose levels, presumably by inhibiting insulin release via its alpha2-adrenergic activity. Yohimbine (alpha2 blocker) or atipamezole can antagonize this effect.

**Suggested Dosages/Use**

**INDOGS:**

For treatment of generalized demodicosis:

**Note:** The general rule of thumb for therapy duration independent of the protocol chosen involves treating for 30 days past two consecutive negative skin scrapings.

**Labeled Dose Protocol**

Long and medium haired dogs should be clipped closely and given a shampoo with mild soap and water prior to first treatment. Topically treat at a concentration of 250 ppm (one 10.6 mL bottle of Mitaban® in 2 gallons of warm water), by applying to entire animal and allowing to air dry. DO NOT rinse or towel dry. Use a freshly prepared dilution for additional dogs or additional treatments. Repeat every 14 days for 3–6 treatments (continue until six treatments done or two successive skin scrapings demonstrate no live mites). Chronic cases may require additional courses of therapy. (Package Insert; Mitaban®—Upjohn)

**Extra-label Protocols:**

1) For dogs whose owners accept the risk of using the drug in an “unlicensed” manner with the goal of increasing efficacy, first try the 250 ppm solution (as above) once weekly for 4 weeks. If positive response is seen, continue treatment for an additional 30 days after obtaining two consecutive negative skin scrapings (rule of thumb). If weekly 250 ppm application fails, a 500 ppm solution may be tried (1 bottle in 1 gallon of water) weekly as above. In dogs failing 500 ppm, 1000 ppm may also be attempted, but likelihood of toxicity increases and the authors have no experience using this high concentration. If these methods fail, the dog is unlikely to respond. The general rule of thumb for therapy duration independent of the protocol chosen involves treating for 30 days past two consecutive negative skin scrapings.

2) Prepare a 0.125% solution by diluting 1 mL of the 12.5% commercially available large animal product (Taktic®) in 100 mL of water. Use a sponge rub the diluted solution (0.125%) onto one-half of the dog’s body and apply a collar (Preventic®) as described above. This is then reduced to as needed. In animals unable to tolerate therapy, concentration may be reduced to 0.025–0.01% in an attempt to balance efficacy with adverse effects.

**Precautions/Adverse Effects**

Adverse effects can include hypersensitivity reactions or local irritation (erythema, dryness, peeling, pruritus).

**Precautions/Adverse Effects**

Avoid sun exposure during treatment with tretinoin. Avoid contact with eyes, nostrils, inner ears, or mouth. Clients should wear gloves when applying the product.

**Veterinary-Labeled Topical Tretinoin Products**

None

**Human-Labeled Topical Tretinoin Products**

For treatment of generalized demodicosis, namely inhibiting T-lymphocyte activation primarily by inhibiting the phosphatase activity of calcineurin. It also inhibits the release of inflammatory cytokines and mediators from mast cells and basophils.

No experience using this high concentration. If these methods fail, the dog is unlikely to respond. The general rule of thumb for therapy duration independent of the protocol chosen involves treating for 30 days past two consecutive negative skin scrapings. Extra-label Protocols:

1) For dogs whose owners accept the risk of using the drug in an “unlicensed” manner with the goal of increasing efficacy, first try the 250 ppm solution (as above) once weekly for 4 weeks. **Precautions/Adverse Effects**

Avoid sun exposure during treatment with tretinoin. Avoid contact with eyes, nostrils, inner ears, or mouth. Clients should wear gloves when applying the product.
Deltamethrin is a synthetic pyrethroid and acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

Indications/Actions
Crotamiton is a topical miticide/scabicide and has been used primarily for adjunctive treatment (with ivermectin) for treating mite infections (e.g., Knemidopkoptes) in birds. Crotamiton has both miticidal and antipruritic actions, but the mechanism for each is not known.

Suggested Dosages/Use
Once to twice daily applications are usually recommended.

Precautions/Adverse Effects
Do not apply around eyes or mouth. Little is known of the compound’s safety profile; irritation or hypersensitivity reactions are possible.

Veterinary-Labeled Crotamiton Products
None

Deltamethrin

Indications/Actions
In the United States, deltamethrin-impregnated collars are labeled for killing fleas and ticks on dogs. In countries where leishmaniasis is a problem, deltamethrin-impregnated collars are also indicated for repelling and killing the phlebotomine sandfly vectors.

Deltamethrin is a synthetic pyrethroid and acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

Suggested Dosages/Use
The manufacturer recommends applying a new collar every 6 months and claims that maximum effect may not occur before 2 to 3 weeks after collar placement. Follow label for specific use instructions.
Fipronil is a phenylpyrazole antiparasitic agent that interferes with the passage of chloride ions in GABA-regulated chloride channels, thereby disrupting central nervous system (CNS) activity causing death of the flea or tick. The compound is effective against a wide range of external parasites, including fleas, ticks, and chewing lice. It is highly active against several resistant flea genotypes, including those resistant to pyrethroidicides, organophosphates, and carbamates.

**Indications/Actions**

In the USA, Fipronil is indicated for the treatment of fleas, ticks, and chewing lice infestations in dogs and cats. It has also been used successfully for Trombicula autumnalis (chigger) infestation, sarcoptic mange, cheyletiellosis, chewing lice, and otocariosis.

Fipronil is a phenylpyrazole antiparasitic agent that invertebrates interfere with the passage of chloride ions in GABA-regulated chloride channels, thereby disrupting CNS activity causing death of the flea or tick. The manufacturer states that fipronil collects in the oils of the skin and hair follicles and continues to be released over a period of time resulting in long residual activity. Topically applied, the drug apparently spreads over the body in approximately 24 hours via translocation.

When fipronil is combined with the insect growth regulator (S)-methoprene (Frontline® Plus), additionally flea eggs and flea larvae are killed. (S)-methoprene mimics flea juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced.

**Suggested Dosages/Use**

For fleas, ticks, or chewing lice:

Monthly treatments are usually recommended when used for fleas, ticks or chewing lice. See product labels for specific directions on administration and recommendations on bathing/swimming, etc after administration.

For Trombicula autumnalis infestation:

Fipronil spray (0.25%) is recommended. Monthly applications throughout the trombiculid season at the dose of 3 to 6 mL/kg. It is important to thoroughly wet the coat with special emphasis on the areas typically affected (feet, ears, face, perineum and tail). In some cases, the interval between applications needs to be shortened to every 14 days.

For otocariosis:

Apply 0.05 mL of fipronil solution inside each ear canal and 0.4 mL between the shoulder blades. Resolution of clinical signs can be seen as early as seven days post-treatment. Additional applications may be needed. Fipronil needs to be applied in the ear canals to be effective.

**Precautions/Adverse Effects**

Collars containing deltamethrin should not be used in dogs younger than 12 weeks of age. Avoid contact with eyes, skin or clothing. Consult a veterinarian before using on debilitated, pregnant, nursing, old or medicated animals. Skin reactions at the application site may occur. Mammalian exposure to deltamethrin is classified as safe; however, it should be used very carefully around water because deltamethrin is highly toxic to aquatic animals, especially fish.

**Human-Labeled Deltamethrin Products**

None

**DINOTEFURAN + PYRIPROXYFEN (± PERMETHRIN)**

**Indications/Actions**

The product containing dinotefuran and pyriproxyfen (Vectra®) labeled for dogs and cats is used for control of adult and immature flea stages including eggs, larvae, and pupae. The exclusive dog product contains in addition to dinotefuran and pyriproxyfen, permethrin (Vectra 3D®), which kills and repels adult and immature fleas, ticks, and mites.

Dinotefuran is a nitroguanidine, neonicotinoid insecticide with a structure similar to acetylcholine. It permanently binds to the same insect receptor sites as acetylcholine and activates the nerve impulse at the synapse causing stimulation, which results in tremors, incoordination, and insect death. Dinotefuran does not bind to mammalian acetylcholine receptor sites.

The commercially available products also contain pyriproxyfen (a second-generation insect growth regulator) and, in the case of Vectra 3D (for dogs only), permethrin.

**Suggested Dosages/Use**

Refer to the package information for specific directions on application and dosages of dinotefuran-containing products. Monthly applications are recommended for dogs and cats. It is labeled for cats and kittens 8 weeks of age or older and dogs or puppies 7 weeks of age or older. Apparently bathing or swimming does not interfere with efficacy; however, the authors do not recommend bathing the pet until two days after application.

**Precautions/Adverse Effects**

The dog product containing permethrin (Vectra 3D®) must not be used on cats or on dogs that cohabit with a cat. The manufacturer recommends not using Vectra 3D® or Vectra® on debilitated, aged, medicated, pregnant or nursing animals and animals known to be sensitive to pesticide products. Mild temporary skin erythema may occur at the application site. Avoid eye and oral contact since Dinotefuran can cause substantial, but temporary eye irritation.

**Veterinary-Labeled Topical Dinotefuran Products**

**Human-Labeled Dinotefuran Products**

None

**FIPRONIL ± (S)-METHOPRENE**

(S)-methoprene (Frontline®, Frontline® Plus, Vectra® 3D®) labeled for dogs and cats is used for control of adult and immature flea stages including eggs, larvae, and pupae. The exclusive dog product contains in addition to dinotefuran and pyriproxyfen, permethrin (Vectra 3D®), which kills and repels adult and immature fleas, ticks, and mites.

**Indications/Actions**

In the USA, Fipronil is indicated for the treatment of fleas, ticks, and chewing lice infestations in dogs and cats. It has also been used successfully for Trombicula autumnalis (chigger) infestation, sarcotic mange, cheyletiellosis, chewing lice, and otocariosis.

Fipronil is a phenylpyrazole antiparasitic agent that invertebrates interfere with the passage of chloride ions in GABA-regulated chloride channels, thereby disrupting CNS activity causing death of the flea or tick. The manufacturer states that fipronil collects in the oils of the skin and hair follicles and continues to be released over a period of time resulting in long residual activity. Topically applied, the drug apparently spreads over the body in approximately 24 hours via translocation.

When fipronil is combined with the insect growth regulator (S)-methoprene (Frontline® Plus), additionally flea eggs and flea larvae are killed. (S)-methoprene mimics flea juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced.

**Suggested Dosages/Use**

For fleas, ticks or chewing lice:

Monthly treatments are usually recommended when used for fleas, ticks or chewing lice. See product labels for specific directions on administration and recommendations on bathing/swimming, etc after administration.

For Trombicula autumnalis infestation:

Fipronil spray (0.25%) is recommended. Monthly applications throughout the trombiculid season at the dose of 3 to 6 mL/Ag. It is important to thoroughly wet the coat with special emphasis on the areas typically affected (feet, ears, face, perineum and tail). In some cases, the interval between applications needs to be shortened to every 14 days.

For otocariosis:

Apply 0.05 mL of fipronil solution inside each ear canal and 0.4 mL between the shoulder blades. Resolution of clinical signs can be seen as early as seven days post-treatment. Additional applications may be needed. Fipronil needs to be applied in the ear canals to be effective.

**Precautions/Adverse Effects**

Do not use on puppies or kittens less than 8 weeks of age. Avoid contact with eyes, skin or clothing. Consult a veterinarian before using on debilitated, pregnant, nursing, old or medicated animals. Skin reactions at the application site may occur. Mammalian exposure to deltamethrin is classified as safe; however, it should be used very carefully around water because deltamethrin is highly toxic to aquatic animals, especially fish.

The manufacturer recommends consulting a veterinarian before using on debilitated, aged, or medicated patients.

Do not contaminate food or water and dispose of container properly. Avoid human contact with skin, eyes or clothing and wear gloves when applying/spraying. If using spray, do so in a well-ventilated area. Avoid contact with animal until dry. Wash well with soap and water if contact occurs.
Veterinary-Labeled Imidacloprid Topical Products

Decreasing frequency included hypersalivation, vomiting, lethargy, and hiding. Common findings in dogs recorded in decreasing frequency included vomiting, hypersalivation, and trembling. Common findings in cats recorded in decreasing frequency included vomiting, hypersalivation, and trembling. In these cases, 57 were dogs with 25 showing clinical signs, 60 cases were cats in which 42 showed clinical signs, 1 case was a turtle that showed clinical signs.

Most problems are seen following oral dosing of topical products. Signs include hypersalivation and vomiting, oral ulcers have been rarely reported in cats. There were 119 exposures to imidacloprid reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 57 were dogs with 25 showing clinical signs, 60 cases were cats in which 42 showed clinical signs, 1 case was a turtle that showed clinical signs and the remaining case was a lagomorph that showed no clinical signs.

Precautions/Adverse Effects

The manufacturer lists the following contraindications for imidacloprid (alone): Do not use in puppies younger than 2 weeks old or kittens younger than 8 weeks old. The manufacturer recommends consulting a veterinarian before using on debilitated, aged, pregnant, or nursing animals or those on medication.

The combination product with permethrin (K9 Advantix®) must not be used on cats. Use with caution in households with both dogs and cats, particularly if cats are in close contact or will groom dogs in the household. When used as directed, adverse effects are unlikely. Because the drug is bitter tasting, oral contact may cause excessive salivation. Do not get product in eyes. If eye contact occurs (human or animal), flush well with tap water or ophthalmic irrigation solution or water. While gloving is not mandated it should be encouraged, as contact with skin should be avoided. Wash hands with soap and water after handling. Keep out of reach of children and do not contaminate feed or food. Dispose of product carefully (in the trash); the permethrin-containing product is extremely toxic to fish.

Indications/Actions

Imidacloprid topical solution (Advantage®) is indicated for the treatment of adult and larval stage fleas in dogs and cats. The combination product with permethrin (K9 Advantix®) is indicated for adulticide/larvicide for fleas, to repel and kill ticks, and mosquitoes in dogs only. The canine combination product with moxidectin (Advantage® Multi for Dogs in USA and Advocate® in Europe) is indicated for the prevention of heartworm disease, adult fleas, adult and immature hookworms, adult roundworms, and adult whipworms. It has been also used successfully for the treatment of sarcotic mange, cheyletiellosis and mild cases of demodicosis.

The feline combination product (Advantage® Multi for Cats) is indicated for the prevention of heartworm disease, adult fleas, ear mites, adult and immature hookworms, and adult roundworms. Imidacloprid’s mechanism of action as an insecticide is to act on nicotinic acetylcholine receptors on the post synaptic membrane causing CNS impairment and death. Certain insect species are more sensitive to these agents than are mammalian receptors. This is a different mechanism of action than other insecticidal agents (organophosphates, pyrethrins, carbamates, insect growth regulators (IGR’s) and insect development inhibitors (IDI’s).

The manufacturer states that imidacloprid is non-teratogenic, non-hypersensitizing, non-mutagenic, non-allergenic, non-carcinogenic, and non-photo sensitizing. The manufacturer states that when applied topically the compound is not absorbed into the bloodstream or internal organs. One combination product for dogs (K9 Advantix®) also contains permethrin, a pyrethroid (synthetic pyrethrin) that will kill and repel ticks and mosquitoes. Permethrin’s insecticidal activity is as a neurotoxin in susceptible species by slowing sodium ions through sodium channels in neuron membranes. Moxidectin is found in combination products (Advantage® Multi for Dogs and Cats) with imidacloprid. Moxidectin is a macroyclic lactone that binds to the glutamate-gated ion channels specific to parasites thereby increasing the influx of chloride ions resulting in hyperpolarization of neuronal cells causing paralysis and death.

Suggested Dosages/Use

Refer to the package information for specific instructions on application of imidacloprid products. They are generally administered once monthly. While swimming, bathing, and rain do not apparently significantly affect the duration of action, repeated shampooing may require additional treatment(s) before the monthly dosing interval is completed. Do not reapply more often than once weekly for these animals.

Overdose/Acute Toxicity

Most problems are seen following oral dosing of topical products. Signs include hypersalivation and vomiting, oral ulcers have been rarely reported in cats. There were 119 exposures to imidacloprid reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 57 were dogs with 25 showing clinical signs, 60 cases were cats in which 42 showed clinical signs, 1 case was a turtle that showed clinical signs and the remaining case was a lagomorph that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, hypersalivation, and trembling. Common findings in cats recorded in decreasing frequency included hypersalivation, vomiting, lethargy, and hiding.

METAFLUMIZONE

(meta-flu-mih-zone) ProMeris®

Indications/Actions
The canine product (ProMeris® For Dogs) contains metaflumizone and amitraz (see amitraz monograph for more information) and is labeled for control of fleas (Ctenocephalides spp.), ticks, chewing lice and Demodectic mange mites on dogs and puppies 8 weeks of age and older. The feline product (ProMeris® For Cats) is labeled for control of fleas (Ctenocephalides spp.) on cats and kittens 8 weeks of age and older.

Metaflumizone blocks the influx of sodium required to propagate a nerve impulse along the axon and dendrite of the neuron causing a reduction in feeding, loss of coordination, paralysis and death of the parasite. Amitraz is a formamidine compound that acts by inhibiting mixed function oxidases in addition to monoamine oxidase. It apparently also has alpha2 adrenergic activity and inhibits prostaglandin synthesis.

Suggested Dosages/Use
Refer to the package information for specific instructions on recommended dosages and application of metaflumizone products. For cats, the label states that a single dose is effective for up to 7 weeks in controlling fleas. Apply a single dose prior to exposure. Reapplication at monthly intervals may be appropriate depending upon the level of flea challenge and animal sensitivities (i.e. flea allergy dermatitis). Do not apply more than once monthly.

For dogs, the product’s label states: A single dose is effective for up to 6 weeks in controlling fleas and up to 4 weeks for ticks. Apply a single dose prior to exposure. Monthly application is recommended for effective control of fleas, ticks, chewing lice and Demodectic mange mites and to prevent re-infestation of fleas, ticks and chewing lice. Do not apply more than once monthly.

Precautions/Adverse Effects
The manufacturer does not recommend using in lactating/nursing dogs or cats until at least 5 days post delivery. However, it can be used in breeding dogs (males and females) as well as in pregnant dogs and cats. The canine formulation must not be used in cats because it contains amitraz. The manufacturer recommends consulting a veterinarian before applying these products in aged or debilitated animals or animals on medications. The manufacturer also advises contacting a veterinarian if skin irritation, behavior changes, vomiting or diarrhea occurs and persists after application of these products.

Human-Labeled Metaflumizone Products

None

(S)-METHOPRENE COMBINATIONS

(meth-oh-preen)

Also see the Fipronil & (s)-Methoprene listing

Indications/Actions
Methoprene is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability prevent maturation of eggs or larva. (s)-methoprene mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (e.g., permethrin, fipronil, phenothrin) all stages of the parasite are killed and re-infestation is less likely.

Suggested Dosages/Use
For specific use and dosage recommendations, refer to the actual product’s label.

Precautions/Adverse Effects
Methoprene may be found in products also containing permethrin or phenothrin, which can be toxic to cats, particularly small kittens. Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats. Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes.

Methoprene (used alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur. As methoprene is broken down by UV light, protect unused product from light.

Veterinary-Labeled (s)-Methoprene Topical Products
Permethrin is synthetic pyrethroid that acts as an adulticide insecticide/miticide. It has knockdown activity against fleas, lice, ticks, and certain mites (e.g., Cheyletiella, Sarcoptes scabiei). Permethrin also has repellent activity. In small animal medicine, it is used primarily for fleas and ticks on dogs. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use for flies, lice, mites, mosquitoes, ticks and keds.

Permethrin acts by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death.

### Suggested Dosages/Use

For specific dosage recommendations, refer to the actual product’s label.

### Precautions/Adverse Effects

Permethrin and other synthetic pyrethroids can be toxic to cats, particularly small kittens. Only use products containing pyrethroids labeled for use on cats on this species. Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes. Clients should wear gloves when applying and wash off any product that contacts their skin.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

### Veterinary-Labeled Topical Permethrin Products

Not inclusive; many shampoos, pour-ons, sprays, dusts are available.

</tbody>
</table>
**Human-Labeled Topical Permethrin Products**

**PYRETHRINS AND PYRETHRIN COMBINATIONS, TOPICAL**

*For otic use, refer to the Otics section*

**Indications/Actions**

Pyrethrins are naturally derived insecticides that act as adulticide insecticides/miticides. They have knockdown activity against fleas, lice, ticks, and Cheyletella. In small animal medicine, pyrethrins are used primarily for fleas and ticks on dogs and cats. In large animal and food animal medicine, there are many products (not listed below) available for pour-on, dusting, and spray use.

Pyrethrins act by disrupting the sodium channel current in arthropod nerve cell membranes, resulting in paralysis and death. Pyrethrins are often found in combination with the insect growth regulators, methoprene or pyriproxyfen and with the synergist piperonyl butoxide. Piperonyl butoxide inhibits insect metabolic enzymes (P450 system) allowing a lower dose of primary insecticide to be used.

**Suggested Dosages/Use**

For specific dosage recommendations, refer to the actual product’s label.

**Precautions/Adverse Effects**

Pyrethrins are among the safest insecticidal products available, but cats should not be allowed to groom wet product after using dips or sprays. Hypersensitivity can occur to these compounds. Do not use in eyes or on mucous membranes. Avoid hypothermia when using liquid products (sprays, dips, etc), particularly in small animals and when ambient temperatures are low.

Pruritus or mild skin irritation can occur at application site, but occur uncommonly.

Clients should wear gloves when applying and wash off any product that contacts their skin.

**Veterinary-Labeled Pyrethrin Products**

Not an inclusive list, but representative of the types of products available; many shampoos, pour-ons, sprays, dusts, ointments are available.
**Human-Labeled Pyrethrin Products**

None

**PYRPROXYFEN & PYRPROXYFEN COMBINATIONS, TOPICAL**

(pye-ri-proks-i-fen; Nylar®)

*Also see to the Dinotefuran listing*

**Indications/Actions**

Pyriproxyfen is a second-generation insect growth regulator and is added to premise sprays and topical products to eliminate insects (usually fleas) via its ability to prevent maturation of eggs or larva.

Pyriproxyfen mimics insect juvenile growth hormone, halting development during metamorphosis and larval development. It also concentrates in female flea ovaries, causing non-viable eggs to be produced. When combined with an adulticide (e.g., permethrin, fipronil) all stages of the parasite are killed and re-infestation is less likely. It is more resistant to UV light than is methoprene.

**Suggested Dosages/Use**

For specific dosage recommendations, refer to the actual product’s label.

**Precautions/Adverse Effects**

Pyriproxyfen may be found in products also containing permethrin, which can be toxic to cats, particularly small kittens. Only use in cats those products containing permethrin or other pyrethroids labeled specifically for use on cats.

Pyriproxyfen (used alone) has low toxicity in mammals. Potentially, skin irritation or hypersensitivity reactions could occur.

Clients should wear gloves when applying products containing permethrin or other insecticides and wash off any product that contacts their skin.

**Veterinary-Labeled Topical Pyriproxyfen Products**

Not necessarily inclusive, there are premise sprays and other topical products containing pyriproxyfen.

**Human-Labeled Pyrethrin Topical Products**

None

**SPINETORAM**

**Indications/Actions**

Topical spinetoram is labeled for the prevention and treatment of flea infestations in cats and kittens 8 weeks of age or older.

Spinetoram is a spinosyn compound related to spinosad. It activates the nicotinic acetylcholine receptors (nAChRs) causing the death of fleas.

**Suggested Dosages/Use**

For specific dosage recommendations, refer to the actual product’s label.
Suggested Dosages/Use
One low-volume dose treats cats of all sizes/body weights. The manufacturer recommends applying the tube content topically to the skin at the base of the cat’s neck once monthly. The manufacturer claims that the product starts working within 30 minutes and kills 98%–100% of fleas within 12 hours.

Precautions/Adverse Effects
None reported by the manufacturer.

Topical antiseptic ear flushes include acetic acid, chlorhexidine and ketoconazole containing products. These products are typically used as adjunctive therapy for ear infections (e.g., bacterial and/or yeast) but can also be used as sole treatment in mild, first time infections. Acetic acid works as an acidifying and antimicrobial agent. Chlorhexidine has activity against gram-positive and gram-negative bacteria and fungi. Chlorhexidine containing products should be used cautiously in ear canals with ruptured tympanic membranes because of potential for ototoxicity. Ketoconazole is a fungistic antifungal. When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become more redder or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

### Antibiotic Potentiating Agents

Tromethamine-ethylenediaminetetraacetic acid (tris-EDTA) has antimicrobial and antibiotic potentiating activity. It is alkalinizing (pH8), blocks the *Pseudomonas* efflux pump, potentiates antibiotics such as enrofloxacin and aminoglycosides, disrupts the bacterial cell wall by chelating metal ions and making it more porous, inhibits the effects of ulcerating bacterial enzymes. Tris-EDTA is non-ototoxic and safe to use in the middle ear. Tris-EDTA containing products are most effective when applied 15-30 minutes before the topical antibiotic. Products containing tris-EDTA are available as a sole ingredient or combined with chlorhexidine or ketoconazole. When recommending ear flushing as part of the treatment regimen, it is important to demonstrate the cleaning technique in the examination room and advise the client to discontinue application and contact the veterinarian if the ears become redder or more inflamed at any time during the course of cleaning. The frequency of cleaning varies according to the needs of the individual patient.

### Corticosteroid Preparations

Corticosteroid-containing ear medications are used in cases of acute or chronic otitis with the goal of reducing inflammation, edema, tissue hyperplasia, pain and pruritus. In addition, they are helpful in decreasing secretions from sebaceous and apocrine glands thereby reducing the build up of debris in ear canals. Ear cleaning solutions that contain glucocorticoids without an antibiotic can be used as maintenance therapy in cases of allergic otitis, but use the least potent glucocorticoid at the lowest possible frequency to balance efficacy and prevent undesirable side effects.

### Corticosteroid + Antibiotic Preparations

Most otic antimicrobial preparations commercially available combine an antifungal, an antibiotic and a glucocorticoid agent. These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more redder or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.

### Antifungals

Refer also to Corticosteroid Preparations and Injectable Antimicrobial (Antibacterial) Preparations

Antifungal ear preparations are used to treat infections caused by *Malassezia* spp and rare otic candidiasis. Most of the commercially available products also contain an antibiotic and/or a glucocorticoid. Listed here are exclusively the products without an antibiotic agent. These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more redder or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.

### Corticosteroid + Antimicrobial Preparations

Most otic antimicrobial preparations commercially available combine an antifungal, an antibiotic and a glucocorticoid agent. These products should be used two to three times daily in adequate amounts to coat the entire ear canal. Advise the client to discontinue the medication and contact the veterinarian if the ears become more redder or more inflamed at any time during treatment. Patients should be rechecked before discontinuing treatment.
Antiparasitic Preparations

Refer also to the Selamectin and Fipronil monographs

Included are only preparations labeled to be applied directly into the ear canals for the treatment of otocariosis. However, parasiticides with systemic or more generalized effect such as, selamectin or fipronil are preferred because <i>Otodectes cynotis</i> mites are known to also live outside ear canals and can re-infest the ears.

Overdose and Toxin Exposure Decontamination Guidelines

CAMILLE DECLEMENTI, VMD, DABT
ASPCA Animal Poison Control Center

All patients should be stabilized prior to attempts at decontamination. Once stabilization has been accomplished, decontamination should be considered to prevent systemic absorption of the toxicant. The specific method of decontamination chosen in each case must be guided by the species exposed and the exposure circumstances. When a patient has ingested a potentially toxic dose of a substance, the clinician has many options for decontamination including dilution, induction of emesis, gastric lavage, the use of adsorbents, cathartics, and administration of enemas. In many cases, the best treatment plan will include more than one of these methods.

Dilution using a small amount of milk or water is recommended in cases where irritant or corrosive materials have been ingested. A dose of 2-6 ml/kg is suggested (Mathews, 2006), which for an average-sized cat, would...
**Enemas** are usually most effective if used within 2-3 hours after the ingestion (Rosendale, 2002) but in some cases, emesis may be effective even after that time frame. If the substance ingested could coalesce to form a bolus in the stomach or a timed-released medication was ingested, emesis may be effective later than 3 hours after the ingestion. Chocolate (Albreten, 2004) and chewable medications are examples of products, which may form boluses. Enemas generally empty 40-60% of the stomach contents (Beasley and Dorman, 1990). Feeding a small milk meal before inducing vomiting can increase the chances of an adequate emesis.

**Gastric lavage** can be considered in cases where emesis is contraindicated, not possible or has been unsuccessful. For example, lavage is an option if the patient is agitated, seizing or recumbent or has other health concerns, such as recent abdominal surgery, that increase the risks associated with induction of emesis. Gastric lavage should be considered in rabbits and rodents, which are unable to vomit safely. Lavage should also not be used to remove caustic materials or volatile hydrocarbons for the same reasons enemesis is contraindicated in such cases (Rosendale, 2002).

**Adsorbs** may be utilized instead of or in addition to using an enema or performing gastric lavage to prevent further systemic absorption of a toxicant. These agents act by adsorbing to a chemical or toxicant in the gastrointestinal tract and facilitating its excretion in the feces. Activated charcoal is the most commonly used adsorbent.

Activated charcoal is composed of large porous particles that adsorb to and therefore trap a wide range of organic compounds within the gastrointestinal tract. It is created from materials such as coal, wood, yew, chestnut and coconut shells through a process using acid and steam treatments. The surface binding area of activated charcoal is large, in the range of 900–1500 m²/g (Rosendale, 2002). Charcoal tablets and capsules available over the counter, which are used to control flatulence, and bloating are not likely to be as effective as adsorbents as the commercially prepared products (Buck and Bratich, 1986). The concentration of charcoal in the capsules is often low and the binding area much smaller.

Repeated doses of activated charcoal should be considered in certain instances where toxicants are known to undergo enterohepatic recirculation. In enterohepatic recirculation, the toxicant is first carried to the liver by the portal or via the hepatic circulation from gastrointestinal luminal. Once in the liver, the toxin enters the bile and is excreted into the gastrointestinal tract where it is again available for absorption. Examples of toxicants known to undergo this type of recycling include morphine, codeine, and heroin. Activated charcoal is not effective in patients with bowel obstruction. However, in cases where it is effective, it can cause a false negative on an ethylene glycol test since propylene glycol is found in many antifreeze products.

Conversion Tables for Weight in Kilograms to Body Surface Area (m²)

The following tables are derived from the equation:

Approximate surface area in m² = \[ \frac{10.1 \times (1000 \text{for cats}) 	imes (\text{weight in grams})^{2/3}}{10000} \]

### ARCI UCGFS Classifications

The Association of Racing Commissioners International, Inc. is a non-profit corporation whose mission and vision is: To protect and uphold the integrity of the pari-mutuel sports of horse racing, dog racing and jai-alai through an informed membership, by encouraging forceful and uniform regulation, by promoting the health and welfare of the industry through various programs and projects. In the ARCI classification system, Class 1 drugs have the most potential to affect performance; subsequent classes have less potential. The information in the monographs is taken from the Uniform Classification Guidelines for Foreign Substances and Recommended Penalties and Model Rule document (April 2005). See the ARCI website for the most up-to-date information at [http://www.arci.com](http://www.arci.com).

### Importation of Unapproved New Animal Drugs into the USA

As of October 2009, the Food and Drug Administration’s Center for Veterinary Medicine is no longer accepting requests nor issuing “no objection” letters facilitating veterinarians’ personal importation of foreign animal drugs that are not approved for use in the United States. FDA previously allowed licensed veterinarians to apply for permission to import small amounts of unapproved animal drugs under the Medically Necessary Personal Import Policy (a 13 step letter detailing the intended use for a specific patient under specific circumstances, such as when the drug posed no threat to human or animal health and there were no adequate drug substitutes available.) The burden of importation now appears to rest upon the exporter in completing necessary Customs and Border Patrol (CBP) documents that will allow the drugs to clear US Customs upon entry into the United States. It is important to note that drug shipments may still be seized by US Customs and returned to the exporter in spite of efforts to provide necessary documentation.

Veterinarians seeking to import these types of foreign animal drugs are now directed to FDA’s guidance on the Coverage of Personal Importation, which is available at: [http://goo.gl/GiWys](http://goo.gl/GiWys)

This supplier from the U.K. has been recommended to the author and may be able to assist U.S. veterinarians in obtaining medically necessary products from abroad:

### Tables of Parenteral Fluids

(Not a complete listing; includes both human- and veterinary-approved products)
Abbreviations Used in Prescription Writing

A warning and the strange case of S.I.D.: Although prescription abbreviations are used throughout many references and they are generally fairly well recognized, they do increase the potential for mistakes to occur. When writing a prescription, this author recommends writing out the directions in plain English and avoiding the use of abbreviations entirely. If abbreviations are to be used, definitely avoid q.d., q.o.d., q.i.d. and s.i.d. because they can be easily confused with other abbreviations.

S.I.D. is an abbreviation virtually unknown to health professionals outside of veterinary medicine and the vast majority of pharmacists have never seen it. S.I.D. should be eliminated from all veterinary usage and replaced with “once a day.” The additional time to write out “once a day” versus “SID” is approximately 3 seconds, but by doing so, a potentially serious, avoidable error could be prevented.
Solubility Definitions

The following definitions are used throughout the book in the chemistry section for each agent:

<table>
<thead>
<tr>
<th>Descriptive Term</th>
<th>Parts of Solvent for 1 Part of Solute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very Soluble</td>

</table>

Conversion: Weights; Temperature; Liquids

1 pound (lb) = 0.454 kg = 454 grams = 16 ounces
1 kilogram (kg) = 2.2 pounds = 1000 grams
1 gram (gr.) = 64.8 mg (often rounded to 60 or 65 mg)
1 ounce = 28.4 grams
1 gram = 15.43 grains = 1000 mg
1 milligram (mg) = 1000 micrograms (µg)
1 microgram (mcg or µg) = 1000 nanograms (ng)

TEMPERATURE CONVERSION:

°C to °F = (°C × 1.8) + 32 = °F
°F to °C = (°F – 32) × 0.555 = °C

LIQUID MEASURE:

1 gallon (gal.) = 4 quarts = 8 pints = 128 fluid ounces = 3.785 liters = 3785 milliliters
1 quart (qt) = 2 pints = 32 fluid ounces = 946 milliliters
1 pint = 2 cups = 16 fluid ounces = 473 milliliters
1 cup = 8 fluid ounces = 237 milliliters = 16 tablespoons
1 tablespoon = 15 milliliters = 3 teaspoons
1 teaspoon = 5 milliliters
4 liters = 1.057 gallons
1 liter = 1000 milliliters = 10 deciliters
1 deciliter (dl) = 100 milliliters
1 milliliter (mL) = 1 cubic centimeter (cc) = 1000 microliters (µL; mcl)

Milliequivalents & Molecular Weights

Milliequivalents: The term milliequivalents (mEq) is usually used to express the quantities of electrolytes administered to patients. A mEq is 1/1000 of an equivalent (Eq). For pharmaceutical purposes an equivalent may be thought of as equal to the equivalent weight of a given substance. This, in practical terms, is the molecular weight of the substance divided by the valence or the radical. For example:

How many milligrams are equivalent to 1 mEq of potassium chloride (KCl)?

1. Determine the equivalent weight = gram atomic weight × valence; Molecular weight of KCl = 74.5; Valence = 1 (K+; Cl–); Equivalent weight = 74.5 ÷ 1 = 74.5 grams
1. Determine the equivalent weight = gram atomic weight ÷ valence; Molecular weight of KCl = 74.5; Valence = 1 (K+; Cl–); Equivalent weight = 74.5 ÷ 1 = 74.5 grams

2. Determine the mEq weight: Equivalent weight ÷ 1000; 74.5 ÷ 1000 = 74.5 mg = 1 mEq of KCl = 1 mEq of K+ & 1 mEq of Cl–

If the substance would have been CaCl₂, the process would be identical using the gram molecular weight of CaCl₂ (MW 111 if anhydrous; 147 if dihydrate) and a valence of 2.

Listed below are several commonly used electrolytes with their molecular weights and valences in parentheses:

<table>

Temperature (Rectal): Temperatures will normally fluctuate over the course of the day. The following may increase body temperature: Time of day (evening), food intake, muscular activity, approaching estrus, during gestation, high external temperatures. The following may decrease body temperature: intake of large quantities of cool fluids, time of day (morning), and low atmospheric temperature. Small breed dogs tend to have higher normal temperatures than large breeds.

Conversion of Conventional Chemistry Units to SI Units

The Système Internationale d'Unites (SI), or the International System of Units was recommended for use in the health professions by the World Health Assembly in 1977. It is slowly being adopted in the United States and many journals now require its use. The following is an abbreviated table of conversion values for some of the more commonly encountered tests that may now be reported in SI Units.

<table>
<thead>

Companion Animal Diet Websites
The Nutrition Support Service at The Ohio State University Veterinary Hospital maintains a website at: http://vet.osu.edu/vmc/nutrition-support-service
This site has a variety of useful information for the veterinary professional, including a Body Condition Scoring Chart, Diet Manual, Food and Feeding Management Guide and information on Home-Made Diets. The diet search function on this site is particularly useful. It can be found at: http://goo.gl/xVaMJ

Dog and Cat Food Company Websites
The following are links to some of the major canine and feline dog food companies in the USA.

TRANQUILIZERS/SEDATIVES
Acetazolamide (D, C, Fc, P, B, H, Sw, Sh, Z)
Alprazolam (D, C)
Azaperone (Sw)
Chlordiazepoxide (D, C)
Detomidine (H, B, Sh, L, A)
Dexmedetomidine (D, C)
Diazepam (D, C, Po, Fer, A, B, H, Sw, Sh, Z)
Doxepin (D, C, A)
Lorazepam (D, C)
Medetomidine (D, C, Po, A, H, Z)
Romifidine (D, C, H, B)
Tiletamine/Zolazepam (D, C, Po, B, Sh, Fer, H, R, A, Z)
Xylazine (D, C, Po, Fer, A, B, H, Sh, L, Z)

ANESTHETIC AGENTS, BARBITURATES
Methohexital Sodium (D, C)
Pentobarbital (D, C, Po, B, H, Sw, Sh)
Thiopental (D, C, Po, B, H, Sw, Sh)

ANESTHETIC AGENTS, INHALANTS
Desflurane
Halothane (D, C, Po, H)
Isoflurane (D, C, Po, R, A)
Sevoflurane (D, C)

ANESTHETIC AGENTS, MISCELLANEOUS
Alfaxalone (D, C, Po)
Alfentanil (D)
Bromazepam (D, C, Fe, Po)
Buprenorphine (D, C, Fer, Po, H, Sh, Sw)
Ketamine (D, C, Po, Fer, B, H, Sw, Sh, L, R, A, Z)
Propofol (D, C, Po, R, Z)
Remifentanil (D, C)
Sufentanil (D, C)
Tiletamine/Zolazepam (D, C, Po, B, Sh, Fer, H, R, A, Z)
Xylazine (D, C, Po, Fer, A, B, H, Sh, L, Z)

REVERSAL AGENTS
Atipamezole (D, C, Po, B, Sh, A, R, Z)
Flumazenil (D, C, Z)
Naloxone (D, C, Po, H)
Naltrexone (D, C, Z)
Neostigmine (D, C, B, H, Sw, Sh)
Telaradine (D, C, H, L, A, Sh, B, Z)
Yohimbine (D, Po, A, B, H, L, Z)

ANTICONVULSANTS
Bromides (D, C)
Carbamazepine (D, H)
Clonazepam (D, C)
Clorazepate (D, C, 328)
Diazepam (D, C, Po, Fer, A, B, H, Sw, Sh, Z)
Felbamate (D)
Gabapentin (D, C)
Levetiracetam (D, C)
Lorazepam (D, C)
Phenobarbital (D, C, Po, B, H)
Phenytoin (D, C, H)
Pregabalin (D, C)
Primidone (D, C)
Topiramate (D, C)
Valproic Acid (D)
Zonisamide (D, C)

MUSCLE RELAXANTS, SKELETAL
Atracurium (D, C, Po, H)
Baclofen (D)
Dantrolene (D, C, H, Sw)
Guaifenesin (D, C, H, Sw, Sh, B, L, Z)
Guaifenesin (D, B, H, L, Sh)
Methocarbamol (D, C, B, H)
Pancuronium (D, C, Po)
Rocuronium (D, C, H)
Succinylcholine (D, C, H, R)
Vecuronium (D, C)
Euthanasia Agents
Pentobarbital/Phenytoin (D, C)
Cardiovascular Agents
INOTROPIC AGENTS
Digoxin (D, C, Fer, Po, B, H, A)
Dobutamine (D, C, H)
Imipramine Lactate (D, C)
Pimobendan (D, C)
ANTIARRHYTHMIC DRUGS
Amiodarone (D, H)
Disopyramide (D)
Lidocaine (D, C, H)
Mexiletine (D)
Procaïnamide (D, C, H)
Quinidine (D, C, H)
Verapamil (D, C, H, Po)
ANTICHOLINERGICS
Atropine (D, C, B, H, Po, Fer, Sw, Sh, A, R)
Glycopyrrolate (D, C, Fer, Po, H, R)
Hyoscyamine (D)
ACE INHIBITORS
Benzapril (D, C)
Captopril (D, C)
Enalapril (D, C, Fer, A)
Lisinopril (D, C)
Ramipril (D, C, H)
CALCIUM CHANNEL BLOCKING AGENTS
Amlodipine (D, C)
Diltiazem (D, C, Fer)
Verapamil (D, C, H, Po)
VASODILATING AGENTS
Hydralazine (D, C, H)
Isosorbide (D, C)
Isosorbide (H, D)
Nitroglycerin (D, C, Fer)
Nitroprusside (D, C)
Sildenafil (D, C)
Tadalafil (D)
AGENTS USED IN TREATMENT OF SHOCK
Dobutamine (D, C, H)
Dopamine
Epinephrine (D, C, A, H, B, Sh, Sw)
Isoproterenol HCl (D, C, H)
Phenytoine HCl (D, C, H)
ALPHA-ADRENERGIC BLOCKING AGENTS
Phenoxybenzamine (D, C, H)
Prazosin (D, C)
BETA-ADRENERGIC BLOCKING AGENTS
Atenolol (D, C, Fer)
Carvedilol (D)
Esmolol (D, C)
Metoprolol (D, C)
Propranolol (D, C, Fer, H)
Sotalol HCl (D, C)
ANTIHYPERTENSIVE AGENTS
Irbesartan (D)
Nitroprusside (D, C)
OTHER CARDIOVASCULAR AGENTS
Carnitine (D, C)
Taurine (D, C)
Respiratory Drugs
SYMPATHOMIMETICS
Albuterol (D, C, H)
Clonidine (H)
Epinephrine (D, C)
Epinephrine (D, C, A, H, B, Sh, Sw)
Isoproterenol HCl (D, C, H)
XANTHINES
Aminophylline/Theophylline (D, C, Fer, H)

ANTITUSSIVES
Butorphanol (D, C, Fer, Po, B, H, A, L, R, Z)
Codeine (D, C, Po)
Hydrocodone (D, C)

MUCOLYRICS
Acetylcysteine (D, C, H)

OTHER RESPIRATORY AGENTS
Cromolyn Sodium (H)
Ipratropium Br (H, Po)
Montelukast (C)
Zafirlukast (D, C)

Renal & Urinary Tract Agents
DIURETICS, CARBONIC ANHYDRASE INHIBITORS
Acetazolamide (D, C, B, H, Sh, Sw)
Dichlorphenamide (D, C)
Methazolamide (D, C)

DIURETICS, THIAZIDES
Chlorothiazide (D, C, B)
Hydrochlorothiazide (D, C, H)

DIURETICS, LOOP
Furosemide (D, C, Fer, Po, B, H, A, R)
Torsemide (D, C)

DIURETICS, POTASSIUM SPARING
Spirinolactone (D, C)
Triamterene (D)

DIURETICS, OSMOTIC
Glycerine, Oral (D, C, B)
Mannitol (D, C, B, Sw, Sh, H)

AGENTS FOR URINARY INCONTINENCE/RETENTION
Baclofen (D)
Bethanechol (D, C, H, B)
Ephedrine (D, C)
Flavoxate (D)

AGENTS FOR UROLITHIASIS
Acetohydroxamic Acid (D)
Allopurinol (D, A, R)
Ammonium Chloride (D, C, H, B, Sh)
Citrate Salts (D, C)
Methionine (D, C, B, H)
Tiopronin (D)

MISCELLANEOUS RENAL/URINARY AGENTS
Amitriptyline (D, C, A)
Pentosan (D, C, H)
Probenecid (R)

Gastrointestinal Agents

ANTIEMETIC AGENTS
Chlorpromazine (D, C, B, H, Sw, Sh)
Dimenhydrinate (D, C)
Diphenhydramine (D, C, Fer, Po, A, H, B)
Dolasetron (D, C)
Granisetron (D, C)
Maropitant (D, C)
Metoclopramide (D, C, Po, H)
Mirtazapine (D, C)
Ondansetron (D, C)

OXYTOTICS

- Oxytocin (D, C, Po, B, H, Sw, Sh, A, L, R)

ADRENAL CORTICAL STEROIDS

- Corticotropin-ACTH (D, C, B, H, A)
- Cortisone Acetate (D)
- Cosyntropin (D, C, H)

MINERALOCORTICOIDS

- Desoxycorticosterone Piv. (D, C)
- Fluorocorticosterone (D, C, Fer)

GLUCOCORTICOIDS

- Betamethasone (D, H)
- Dexamethasone (D, C, Po, B, H, Sw, L, A, R)
- Flumethasone (D, C, H)
- Fluticasone (D, C, H)
- Hydrocortisone (D, C, B, H)
- Itraconazole (B, H, Sw)
- Methylprednisolone (D, C, H)
- Prednisolone (D, C, Po, Fer, B, H, L, Sw, A, R)
- Prednisone (D, C, Po, Fer, B, H, L, Sw, A, R)
- Triamcinolone (D, C, B, H)

ADRENAL STEROID INHIBITORS

- Ketoconazole (D, C, H, Po, A, R)
- Metyrapone (C)
- Mitotane (D, Fer)
- Selegiline (C, C)
- Trioxostane (D, C, H)

ANTIDIABETIC AGENTS

- Acarbose (D, C)
- Chlorpropamide (D, C)
- Chromium (C)
- Glimepiride (C)
- Gliclazide (C)
- Glyburide (C)
- Insulin (D, C, Fer, B, H, A, 710)
- Metformin (C, A)
- Vanadyl (C)

GLUCOSE ELEVATING AGENTS

- Diazoxide, Oral (D, C, Fer)
- Glucagon (D, C, B)
- Octreotide Acetate (D, C, Fer)

THYROID HORMONES

- Levothyroxine (D, C, H, A, R)
- Liothyronine (D, C)
- Thyrotropin (D, A)

ANTITHYROID DRUGS

- Carbimazole (C)
- Iopodate Sodium (C)
- Methimazole (D, C)

PROSTAGLANDINS

- Cloprostenol (D, B, H, Sw, Sh, L)
- Dinoprost (D, C, B, H, Sw, Sh)

MISC. ENDOCRINE/REPRODUCTIVE DRUGS

- Aglepristone (D, C)
- Bromocriptine (D, C, H)
- Cabergoline (D, C, A)
- Chorionic Gonadotropin-HCG (D, C, Fer, Po, A, B, H)

</tbody>
</table>
Cefoxitin (D, C, H)
Cefpodoxime Proxetil (D, C, H)
Ceftazidime (D, C, R)
Ceftiofur (D, C, A, B, Sw, Sh, H, R, Z)
Ceftriaxone (D, C, H)
Cefuroxime (D)
Cephalexin (D, C, Po, Fer, H, A)
Cephapirin (B)

ANTIBIOTICS, MACROLIDES
Azithromycin (D, C, H, Po, A)
Clarithromycin (D, C, Fer, H)
Erythromycin (D, C, Fer, A, B, H, Sw, Sh)
Tulathromycin (B, Sw, H)
Tylosin (D, C, Fer, Po, B, Sw, Sh, A, R)

ANTIBIOTICS, PENICILLINS
Amoxicillin (D, C, Po, Fer, H, A, R)
Amoxicillin/Clavulanate (D, C, Fer, A)
Ampicillin (D, C, B, H, Fer, Sw, Po, A, R)
Ampicillin/Sulbactam (D, C)
Clavulanic acid (D, C, B)
Dicloxacillin (D, C)
Oxacillin (D, C, H)
Penicillin G (D, C, Sw, H, A, R)
Penicillin V (D, C, H)
Piperacillin (D, C, H, A, R)
Piperacillin/Tazobactam (D, C, A)
Ticarcillin/Clavulanate (D, C, H)

ANTIBIOTICS, TETRACYCLINES
Chlortetracycline (D, C, Po, A, B, Sw)
Doxycycline (D, C, Po, H, A, R)
Minocycline HCl (D, C)
Oxytetracycline (D, C, Po, B, Sw, H, A, R)
Tetracycline (D, C, Po, B, Sh, H, Sw, A)

ANTIBIOTICS, LINCOSAMIDES
Clindamycin (D, C, Fer, A, R)
Lincomycin (D, C, Fer, Sw)
Pirlimycin (B)
Tilmicosin (B, Sh, Po)

ANTIBIOTICS, QUINOLONES
Ciprofloxacin (D, C, Fer, Po, A)
Danofoxacin (B)
Diloxacin (D, H)
Enrofloxacin (D, C, H, B, Fer, Po, R, A, L)
Ibafloxacin (D, C)
Marbofloxacin (D, C, R)
Oribifloxacin (D, C, H)

ANTIBIOTICS, SULFONAMIDES
Sulfachloropyridazine (B, Sw, A)
Sulfadiazine/Trimethoprim (D, C, Fer, Po, B, H, Sw, A, R)
Sulfamethoxazole/Trimethoprim (D, C, Fer, Po, B, H, Sw, A, R)
Sulfadimethoxine (D, C, Po, B, Sh, H, L, R)
Sulfadimethoxine/Ormetoprim (D)

MISCELLANEOUS ANTIBIOTICS, ANTIBACTERIALS
Aztreonam (D, Fi)
Chloramphenicol (D, C, Po, Fer, H, A, R)
Clindamycin (D, C, A)
Daptomycin (D, C, H)
Flunixin (D, C, A)
Florfenicol (D, C, B, Sh, Sw)
Fosfomycin (D, H)
Isoniazid (D, C)
Metronidazole (D, C)
Nitrofurantoin (D, C, H)
Novobiocin (D, B)
Rifampin (D, H, A)
Sodium Iodide (D, C, B, Sh, H)
Tiamulin (Sw)
Tinidazole (D, C, H)
Vancomycin (D, C)

ANTIFUNGAL AGENTS
Amphotericin B (D, C, H, Po, L, A, R)
Caspofungin (D, C)
Flucytosine (D, C, A)
Griseofulvin (D, C, Po, B, Sh, H, Sw, A)
Itraconazole (D, C, Po, A, H)
Ketoconazole (D, C, Po, H, A, R)
Ketoconazole
Nystatin
Terbinafine HCl
Voriconazole

ANTIVIRAL AGENTS
Acyclovir
Amantadine
Famciclovir
Interferon Alfa
Interferon Omega
Lysine
Oseltamivir
Zidovudine (AZT)

Blood Modifying Agents

ANTICOAGULANTS/ANTITHROMBOTICS
Aspirin
Clopidogrel
Dalteparin
Enoxaparin
Heparin
Warfarin

ERYTHROPOIETIC AGENTS
Cyanocobalamin
Darbepoetin
Epoetin Alfa (Erythropoietin)
Ferrous Sulfate
Folic Acid
Iron Dextran

MISC. BLOOD MODIFYING AGENTS
Aminocaproic Acid
Filgrastim
Gemfibrozil
Hemoglobin Glutamer
Pentoxifylline
Phytonadione
Protamine Sulfate

FLUID & ELECTROLYTE MODIFIERS
Albumin
Aluminum Hydroxide
Butaphosphan
Calcitonin
Calcitriol
Calcium Acetate
Calcium Salts
Dextran
Dihydrotachysterol
Ergocalciferol
Glycerine, Oral
Hydroxyethyl Starch
Lanthanum Carbonate
Magnesium
Mannitol
Pamidronate
Phosphate
Potassium
Sodium Polystyrene Sulfonate

Antineoplastics

ANTINEOPLASTICS, ALKYLATING AGENTS
Busulfan
Carboplatin
Chlorambucil
Cisplatin
Cyclophosphamide
Dacarbazine
Ifosfamide
Lomustine
Mechlorethamine
Melphalan
Procarbazine
Thiotepa

ANTINEOPLASTICS, ANTIMETABOLITES
Cytarabine
Fluorouracil (5-FU)
Mercaptopurine
Methotrexate
Thioguanine
ANTINEOPLASTICS, ANTIBIOTICS

Bleomycin (D, C)
Dactinomycin (D)
Doxorubicin (D, C, Fer)
Streptozocin (D)

ANTINEOPLASTICS, MITOTIC INHIBITORS

Vinblastine (D, C)
Vincristine (D, C, H)

ANTINEOPLASTICS, MISCELLANEOUS

Asparaginase (D, C)
Gemcitabine (D, C)
Hydroxyurea (D, C)
Mitoxantrone (D, C)
Piroxicam (D, C, H, Po)
Toceranib (D)

Immnomodulators

IMMUNOSUPPRESSIVE DRUGS

Azathioprine (D, C, Fer, H)
Cyclophosphamide (D, C, H, Po)
Cyclosporine (D, C)
Dexamethasone (D, C, Po, B, H, L, Sw, A, R)
Flumethasone (D, C, H)
Immune Globulin (Human, Intravenous) (D)
Leflunomide (D, C)
Mercaptopurine (D)
Methotrexate (D, C)
Methotrexate sodium (D, C, H)
Prednisone (D, C, Po, Fer, B, H, L, Sw, A, R)
Prednisolone (D, C, Po, Fer, B, H, L, Sw, A, R)
Triamcinolone (D, C, B, H)

GOLD COMPOUNDS

Aurothioglucose (D, C, H)
Auranofin (D, C)
Gold Sodium Thiomalate (D, C, H)

IMMUNOSTIMULANTS

Acemannan (D, C)
Mycobacterial Cell Wall Fraction Immunomodulator (D, H)
Parapox Ovis Virus Immunomodulator (H)
Pseudomonas aeruginosa Inj. (D, C, H)
Staphylococcal Phage Lysate (D)

Antidotes

Acetylcysteine (D, C, H)
Ammonium Molybdate (Sh)
Ammonium Tetrahydroborate (Sh)
Antivenin Black Widow Spider (D, C)
Antivenin Coral Snake (D, C, H)
Atipamezole (D, C, Po, Fer, B, H, L, Sw, A, R, Z)
Chelate Activated (D, C, H, B, Sh)
Deferoxamine (D, C)
Dextrorphan (D)
Dimercaprol (D, C, H, B, Sw)
Dextran Sodium (D, C, Po, H, A, B, Sw, Sh)
Fibrinol (D, C)
Faj Emulsion, Intravenous
Fomepizole (D, C)
Fonepizole (D, C)
Leucovorin Calcium (D, C, H)
Methylene Blue (D, C, B, Sh, H)
Naloxone (D, C, Po, H)
Penicillamine (D, C, B, Sh, A)
Physostigmine (D, H, B)
Phytonadione (D, C, Po, B, H, Sw, Sh, A)
Pyridoxine (D, C, B, Sh, H, A)
Protamine Sulfate (D, C, B)
Pyridoxine (D, C)
SAMe (D, C)
Silverman (D, C)
Sodium Polystyrene Sulfonate (D)
Sodium Sulfate (B, Sh, Sw)
Sodium Thiosulfate (D, C, H, B, Sh)
Succinylcholine (D, C, A)
Thiamine (D, C, B, H, Sw, Sh, L)
Trientine HCl (D)
Zinc Acetate/Sulfate (D, C)

Bone/Joint Agents

Alendronate Sodium (D, C)
Allopurinol (D, A, R)
Glucosamine Chondroitin (D, C, H)
Hyaluronate (D, H)
Fridronate (D, C)
Pentosan (D, C, H)
Polyviologylated Glucosaminopolyglycan (H, D, C, Po)
Tiludronate Disodium (H)

Dermatologic Agents (Systemic)
Acetretin (D, C)
Fatty Acids, Essential (D, C)
Isotretinoin (D, C)
Pentoxifylline (D, H)

Vitamins & Minerals/Nutrients
Ascorbic Acid (C, Po, H, B)
Carnitine (D, C)
Cyanocobalamin (D, C, H, Sw, B, Sh)
Fatty Emulsion, Intravenous (D, C)
Folic Acid (D, C, H)
Medium Chain Triglycerides (D)
Nicotinamide (D)
Pyridoxine (D, C)
Thiamine (D, C, H, Sw, Sh, L)
Vitamin E/Selenium (D, C, H)
Zinc (D, C)

Cholinergic Muscle Stimulants
Edrophonium Chloride (D, C)

Systemic Acidifiers
Acetazolamide (D, C, B, H, Sw, Sh)
Acetic Acid (B, Sh, H)

Systemic Alkalinizers
Sodium Bicarbonate (D, C, H, B, Sh, A)

Unclassified
Aminocaproic Acid (D)
Colchicine (D, A)
Johesol (D, C, A)

| Cefazolin Sodium          |  |  |
| Cefepime HCl              |  |  |
| Cefixime                  |  |  |
| Cefotaxime Sodium         |  |  |
| Cefotetan Disodium        |  |  |
| Cefovein Sodium           |  |  |
| Cefoxacin Sodium          |  |  |
| Cefpodoxime Proxetil      |  |  |
| Cetirizine HCl            |  |  |
| Charcoal, Activated       |  |  |
| Chlorambucil              |  |  |
| Chloramphenicol           |  |  |
| Chlorothiazide            |  |  |
| Chlorpheniramine Maleate  |  |  |
| Chlorpromazine HCl        |  |  |
| Chlorpropanide            |  |  |
| Chlorotetraycline         |  |  |
| Chorionic Gonadotropin    |  |  |
| Chromium                  |  |  |
| Cimetidine                |  |  |
| Ciprofloxacin             |  |  |
| Cisapride                 |  |  |
| Cisplatin                 |  |  |
| Citrate Salts             |  |  |
| Clarithromycin            |  |  |
| Clemastine Fumarate       |  |  |
| Clonazepam                |  |  |
| Clonidine                 |  |  |
| Clopidogrel Bisulfate     |  |  |
| Clopamate Disodium        |  |  |
| Clopidogrel               |  |  |
| Clobazam                  |  |  |
| Codeine                   |  |  |
| Codeine                   |  |  |
| Colchicine                |  |  |
| Corticosterone            |  |  |
| Cortisone Acetate         |  |  |
| Coughlin                  |  |  |
| Cromolyn Sodium           |  |  |
| Cyclomycin                |  |  |
| Cytarabine                |  |  |
| Dalteparin Sodium         |  |  |
| Danazol                   |  |  |
| Danofloxacin Mesylate     |  |  |
| Dapoxetine                |  |  |
| Darbepoetin Alfa          |  |  |
| Decoquinate               |  |  |
| Deferoxamine Mesylate     |  |  |
| Deracoxib                 |  |  |
| Desflurane                |  |  |
| Deslorelin Acetate        |  |  |
| Desmopressin Acetate      |  |  |
| Desoxycorticosterone Pivalate |  |  |
| Dexamethasone             |  |  |
| Dexmedetomidine           |  |  |
| Dexpanthenol              |  |  |
| Dextroamphetamine        |  |  |
| Diazepam                  |  |  |
| Diazoxide, Oral           |  |  |
| Dichlorphenylamide        |  |  |
Appendix
Ophthalmic Products

Routes of Administration for Ophthalmic Drugs

Diagnostic Agents
- Fluorescein Sodium
- Lissamine Green
- Phenol Red Thread
- Rose Bengal
- Schirmer Tear Test

Ocular Anesthetics
- Proparacaine
- Tetracaine
- Benoxinate

Glaucoma, Topical Agents
- Parasympathomimetics (Miotics)
  - Carbachol
  - Pilocarpine
  - Demecarium
  - Echotoxin Iodide
- Sympathomimetics (Alpha2-Agonists)
  - Apraclonidine
  - Brimonidine
