## With Appreciation

I'd like to give a special thank you to my wife, Shirley, who spent countless hours assisting with the preparation of this reference and perhaps most importantly, kept me sane (mostly) during the long process of writing and updating the work.

## Preface to the Seventh Edition

In this edition, *Plumb's Veterinary Drug Handbook* continues with its mission to serve as a single volume reference to assist veterinarians, other health professionals, and animal caretakers in providing optimal drug therapy for veterinary patients. In addition to updating all the monographs, 20+ new systemic drug full monographs (see below) and several new ophthalmic and topical dermatologic drug monographs have been added. Additional information on compounding dosage forms has been added to many monographs.

Several monographs have been “retired” in this edition, primarily due to their withdrawal from the marketplace and/or being replaced in therapy with newer, ostensibly better, drug compounds. Two sections have been removed from the appendix. After consulting with several veterinary oncologists, I decided that listing chemotherapy drug protocols was not in the best interest of patient care. They change often and the drugs used have enough inherent safety issues that I believe “chemo” use in private practices must be carefully considered, in collaboration with oncologists and oncology-specific resources. The therapeutic diet tables have also been removed, again because they rapidly change and are outdated shortly after publication. Links to websites that provide this information are listed in the appendix.

New Systemic Monographs: Albumin, Alfaxalone, Butaphosphan (+Cyanocobalamin), Carbamazepine, Cefovecin, Cortisone Acetate, Desflurane, Fosfomycin, Immune Globulin, Fat Emulsion (IV), Lanthanum Carbonate, Mavacoxib, Metergoline, Metyrapone, Miltefosine, Pregabalin, Remifentanil, Robenacoxib, Rocuronium, Toceranib, Trazodone, and Trypan Blue.

“Retired” Systemic Monographs: Carbenicillin, Cefoperazone, Ethacrynic Acid, Ipecac Syrup, Methoxyflurane, Streptokinase, and Ticarcillin (alone).

Donald Plumb  
March 2011

## About the Author

Donald C. Plumb, PharmD., was formerly Director of Pharmacy Services and Hospital Director at the University of Minnesota's Veterinary Medical Center. Now retired from the University of Minnesota, he focuses full-time on providing veterinary drug information to veterinarians, other health professionals, and animal caretakers.

## Notes and Cautions

### Dosages and Extra-Label Use of Medications

Dosages for the various species for the drugs listed in this reference come from a variety of sources and are referenced to their source in the appendix. While a sincere effort has been made to assure that the dosages and information included in this book are accurate and reflect the original source's information, errors can occur; it is recommended that the reader refer to the original reference or the approved labeling information of the product for additional information and verification of all dosages.

Except for labeled dosages for veterinary-approved products (for a given species and indication,) dosages listed in this reference should be considered “extra-label” and are not necessarily endorsed by the manufacturer, the Food and Drug Administration (FDA) or this author. Veterinarians are responsible as per the Animal Medical Drug Use Clarification Act (AMDUCA) for the appropriate use of medications. The Animal Medicinal Drug Use Clarification Act of 1994 (AMDUCA) allows veterinarians to prescribe extralabel uses of certain approved animal drugs and approved human drugs for animals under certain conditions. Extralabel (or extra-label) use refers to the use of an approved drug in a manner that is not in accordance with the approved label directions. The key constraints of AMDUCA are that any extralabel use must be by or on the order of a veterinarian within the context of a veterinarian-client-patient relationship, must not result in violative residues in food-producing animals, and the use must be in conformance with the implementing regulations published at 21 CFR Part 530. A list of drugs specifically prohibited from extra-label use appears in the Code of Federal Regulations. For additional information go to the FDA-Center for Veterinary Medicine Website at: <http://www.fda.gov/cvm/>

### Abbreviations: OTC & Rx

In addition to the abbreviations used in writing prescriptions (*e.g.*, *tid*, q8h, etc.—see the abbreviation list in the appendix), the terms OTC or Rx are found in parentheses after a listed dosage form. If Rx, the drug is considered to be a prescription or legend product, and requires a prescription. OTC denotes that the item is available “over-the-counter” and does not legally require a prescription for purchase.

### Trade and Proprietary Names

The notation used to signify trade names or proprietary names is an italicized, capitalized name followed by a ® (*e.g.*, *Amoxi-Tabs*®). This notation may not accurately

represent the drug's official registered copyright, trademark, or licensed status (e.g., ™, etc.). For clarity, no use of ® or *italics* are used in the index.

## Drug Interactions

Drug interaction identification and evaluation is in its infancy in veterinary medicine, as relatively little specific information is known on the subject for the variety of species treated. While drug interactions can be clinically significant and potentially life-threatening in veterinary patients, most of the interactions listed in the monographs are derived from human medicine (which is only slightly more informed than veterinary medicine on this topic) and are often included primarily to serve as cautions to the prescriber to be alert for unforeseen outcomes, or to enhance monitoring associated with the drug therapy. Additionally, it is likely there are potentially many other clinically significant interactions between drugs that are not listed; prescribers are reminded that the risk for adverse drug interactions occurring increases with the number of different drugs given to an individual patient.

## Disclaimer

The author/publisher/distributor assume no responsibility for and make no warranty with respect to results that may be obtained from the uses, procedures, or dosages listed, and do not necessarily endorse such uses, procedures, or dosages. The author/publisher shall not be liable to any person whatsoever for any damages, or equivalencies, or by reason of any misstatement or error, negligent or otherwise obtained in this work. Should the purchaser not wish to be bound by the above, he/she may return the reference to the distributor for a full refund.

## How To Search Within This Reference

As e-books on digital devices ostensibly can be searched rapidly for a given term, a traditional index is not required. Enter the desired term in the search box for your particular reader/device. Usually this is the most rapid method to find the search term desired. However, due to the large size of this reference, some digital devices may take significant time to do a search through the entire reference. If so, alternatively:

- If you know the generic name for the drug, browse through the listings in the [Table of Contents](#) and select the appropriate monograph or section desired;
- If you know the trade name (e.g., Anipryl®) or a synonym (e.g., L-deprenyl) for a systemic drug, but cannot recall the generic name (e.g., selegiline), browse through the listings in the [Index of Systemic Drug Common Trade Names & Synonyms](#) and select the trade name desired to go directly to the monograph for that trade name or synonym. Another link to this section is found at the end of the Table of Contents.
- If you want to see a listing of [Systemic Drugs Sorted by Therapeutic Class or Major Indication](#) (e.g., all the ACE Inhibitors that have doses listed for a given species class); go to that section and browse and select as above. Another link to this section is found near the end of the Table of Contents.

### **ACARBOSE**

(ay-kar-bose) Precose®

ORAL ANTIDIABETIC

#### **Prescriber Highlights**

- Antihyperglycemic agent that reduces the rate & amount of glucose absorbed from the gut after a meal; may be useful for mild reductions in blood glucose in dogs or cats. Unlikely to be effective when used as sole therapy.
  - **Contraindications:** Underweight animals, known hypersensitivity, diabetic ketoacidosis, inflammatory bowel disease, colonic ulceration, partial intestinal obstruction or predisposition to obstruction, chronic intestinal disease with marked disorders of digestion or absorption & when excessive gas formation would be detrimental.
  - Dose-dependent loose stools, diarrhea & flatulence are the adverse effects most likely to be noted.
  - Give with meals (preferably right before); drug is not very useful if feeding ad libitum.
  - Expense may be an issue, but generics are now available.
-

## Uses/Indications

May be useful for mild reductions in blood glucose concentrations (250–350 mg/dL range) in dogs and cats with non-insulin-dependent diabetes mellitus and as adjunctive treatment of insulin dependent diabetes mellitus. Acarbose is unlikely to give adequate glucose control when used alone and most recommend dietary therapy and other antihyperglycemic agents (*e.g.*, insulin) instead.

## Pharmacology/Actions

Acarbose competitively inhibits pancreatic alpha-amylase and alpha-glucosidases found in the small intestine. This delays the digestion of complex carbohydrates and disaccharides to glucose and other monosaccharides. Glucose is absorbed lower in the GI tract in lesser amounts than is normal thereby reducing insulin requirements during the postprandial hyperglycemic phase. Acarbose has no effect on lactase.

## Pharmacokinetics

In dogs about 4% of an oral dose is absorbed; in humans only about 2% of an oral dose is absorbed from the gut that is then excreted by the kidneys. Practically all remaining drug in the gut is metabolized in the GI tract by intestinal bacteria. Patients with severe renal dysfunction attain serum levels approximately 5 times those of normal subjects.

## Contraindications/Precautions/Warnings

Acarbose is contraindicated in patients with known hypersensitivity to the drug, diabetic ketoacidosis, inflammatory bowel disease, colonic ulceration, partial intestinal obstruction or predisposition to obstruction, chronic intestinal disease with marked disorders of digestion or absorption, and when excessive gas formation would be detrimental. Acarbose is not indicated in patients of low body weight (some say normal body weight as well) as it may have deleterious effects on nutrition status. Use caution in patients with renal dysfunction or severe liver disease.

## Adverse Effects

Adverse effects reported in cats include flatulence, soft stools and diarrhea; in dogs, diarrhea and weight loss. Adverse effects are more likely at higher doses.

While acarbose alone does not cause hypoglycemia, it may contribute to it by reducing the rate and amount of glucose absorbed when the patient is receiving other hypoglycemic agents (insulin, oral hypoglycemics).

## Reproductive/Nursing Safety

Safety in pregnancy has not been established; weigh any potential risks versus benefits in pregnant animals. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

## Overdosage/Acute Toxicity

Acute overdosages are likely to cause only diarrhea and flatulence. No treatment should be necessary. Should acute hypoglycemia occur secondary to other antihypoglycemics, parenteral glucose should be administered. If treating orally, use glucose (do not use sucrose).

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acarbose and may be of significance in veterinary patients:

- **CHARCOAL:** Intestinal adsorbents may reduce the efficacy of acarbose
- **DIGOXIN:** Acarbose may reduce digoxin blood concentrations
- **HYPERGLYCEMIC AGENTS (corticosteroids, thiazides, estrogens, phenothiazines, thyroid hormones, and calcium channel blockers):** May negate the effects of acarbose
- **PANCREATIN, PANCRELIPASE, OR AMYLASE:** Exogenous enzyme formulations may reduce the efficacy of acarbose

## Laboratory Considerations

- Increased **serum aminotransferase** levels have been noted in some humans taking high dosages for a long period

## Doses

### ■ DOGS:

- a) For dogs poorly controlled with insulin and dietary therapy when another reason for the poor control cannot be identified: Initially 12.5–25 mg total dose per dog PO with each meal. Give only at the time of feeding. May increase dose after two weeks to 50 mg per dog and then to 100 mg per dog (in large dogs, >25 kg) if response has been inadequate. There is a greater chance of diarrhea at the higher dosages. (Nelson 2005)
- b) 12.5–20 mg (total dose) per meal PO (Daminet 2003)

### ■ CATS:

- a) 12.5–25 mg (total dose) PO with meals. When acarbose is used with a low carbohydrate diet it may improve glycemic control and reduce insulin dependence. (Scherk 2005)
- b) 12.5 mg per cat PO twice daily with meals. May be able to reduce insulin dosage and thereby reduce hypoglycemia occurrence. (Greco 2002)
- c) 12.5–20 mg (total dose) per meal PO (Daminet 2003)

## Monitoring

- Serum glucose
- Adverse effects (diarrhea)

## Client Information

Give right before feeding for best results.

Give light before feeding for best results.

- Diarrhea and/or gas most likely side effect(s); contact veterinarian if serious or continues.
- Acarbose does not cause low blood sugar, but it may add to it if the animal is getting other drugs (including insulin) that lower blood sugar; watch for signs of low blood sugar: seizures (convulsions), collapse, rear leg weakness or paralysis, muscle twitching, unsteadiness, tiredness, or depression. If these occur call veterinarian immediately.
- May take up to two weeks for the drug to work at its peak effect.

### Chemistry/Synonyms

A complex oligosaccharide antihyperglycemic agent, acarbose occurs as white to off-white powder, is soluble in water and has a pKa of 5.1.

Acarbose may also be known as: Bay-g-5421, *Precose*®, *Asucrose*®, *Glicobase*®, *Glucobay*®, *Glucor*®, *Glumida*®, or *Prandase*®.

### Storage/Stability

Do not store tablets above 25°C (77°F); protect from moisture.

### Compatibility/Compounding Considerations

Tablets may be split or crushed and mixed with food just prior to administration.

### Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS: None

### HUMAN-LABELED PRODUCTS:

Acarbose Oral Tablets: 25 mg, 50 mg & 100 mg; *Precose*® (Bayer), generic; (Rx)

## ACEMANNAN

(*ase-man-in*)

NON-SPECIFIC IMMUNOSTIMULANT/ANTIVIRAL

### Prescriber Highlights

- **Non-specific injectable immunostimulant that has been tried in FeLV-, FIV, or FIP-positive cats, & vaccine-induced fibrosarcomas (intralesional)**
- **Use is controversial; little, if any controlled study documentation supporting efficacy in veterinary medicine**
- **Adverse effects include: Possible hypersensitivity reactions, localized necrosis at injection sites; bolus IV administration can cause salivation, weakness, collapse, tachycardia, tachypnea; intralesional injection can cause prolonged pain at site; intraperitoneal injection can cause monocyte infiltrates on peritoneal surfaces, liver, & spleen with resultant abdominal pain, diarrhea and vomiting.**
- **Topical products available; potentially can reduce wound healing time**

---

### Uses/Indications

Veterinary acemannan injection is labeled for use in dogs or cats as an aid in the treatment (*i.e.*, surgery) and clinical management of fibrosarcoma. It has been tried as a treatment for FeLV, FIV, and FIP infections in cats, but clinical efficacy has not been adequately proven by controlled clinical studies.

Acemannan has been used in dogs as an intralesional injection for papillomatosis. It reportedly has been used in horses, but no specific information on this was located.

### Pharmacology/Actions

Acemannan's immunostimulant activity is thought as a result of inducing increases in TNF-alpha, interferon, and IL-1. At injection sites, increased lymphocytic infiltration and accumulation have been noted. In tissue cultures, acemannan has suppressed HIV replication.

### Pharmacokinetics

No information was located.

### Contraindications/Precautions/Warnings

The manufacturer lists no contraindications to using acemannan, however, it should not be used in patients who have demonstrated past severe hypersensitivity reactions to it.

### Adverse Effects

While the manufacturer does not list any specific adverse effects associated with use, hypersensitivity or localized injection reactions (*e.g.*, necrosis) are possible. Hyperactivity, lethargy, fever and hypotension have been reported with systemic use of the drug.

Bolus IV administration can cause salivation, weakness, collapse, hypotension, tachycardia and tachypnea. Intralesional injection can cause bleeding or prolonged

Dolus IV administration can cause salivation, weakness, collapse, hypotension, tachycardia and tachypnea. Intralesional injection can cause bleeding or prolonged pain at the injection site. Intraperitoneal injection can cause monocyte infiltrates on peritoneal surfaces, lung, liver, and spleen. Abdominal pain, vomiting and diarrhea have been reported with high dose, intraperitoneal injections.

### Reproductive/Nursing Safety

No specific information was located on reproductive or nursing safety. The product label states, “The effects of this compound have not been studied in pregnant animals” and, also, “...the chemical nature of acemannan and the absence of significant toxicity in several animal species suggest the compound is not a teratogen.”

### Overdosage/Acute Toxicity

Single IP injections of 50 mg/kg in dogs resulted in no significant signs of toxicity. Acemannan fed orally to dogs at rates of up to 1.5 g/kg/day for 90 days showed no significant effects.

### Drug Interactions

None were identified.

### Laboratory Considerations

None were identified.

### Doses

#### ■ DOGS/CATS:

For labeled indications (aid in treatment and management of fibrosarcoma):

a) Prior to use, reconstitute with 10 mL sterile diluent. Five to 10 minutes may be necessary for complete dissolution. Shake well before using. Use within 4 hours after rehydration. Administer by concurrent intraperitoneal (IP) and intralesional injections weekly for a minimum of 6 treatments. Recommended IP dose is 1 mg/kg. Recommended intralesional dose is 2 mg injected deep into each tumor mass. When used as a prelude to surgery, give concurrent IP and intralesional injections weekly. Continue until delineation, necrosis or maximum tumor enlargement due to edema and immune cellular infiltration occur. Rapid necrosis, which accompanies this response, may happen within 2 to 4 weeks. Surgical excision is recommended immediately upon delineation, necrosis or maximum tumor enlargement. (Label Information; *Acemannan Immunostimulant—VPL*)

### Monitoring

- Clinical efficacy
- Adverse effects (most likely local reactions)

### Client Information

- This compound is recommended for use by veterinary professionals only
- Clients should be made aware of the “investigational” nature of using acemannan systemically; adverse effects are possible

### Chemistry

Acemannan is a water soluble, complex carbohydrate polymer that is derived from Aloe vera. It is a long-chained polydispersed beta-(1,4)-acetylated polymannose with interspersed *O*-acetyl groups with a mannose:acetyl ratio of approximately 1:1.

### Storage/Stability

Acemannan injection should be stored at temperatures less than 35°C (95°F); protect from extremes of heat or light.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Acemannan 10 mg vial with 10 mL vial of diluent (sterile saline) in kits of two vials (one of each) or eight vials (4 of each): *Acemannan Immunostimulant*® (VPL); OTC Biologic. Labeled for use in dogs or cats. **Note:** This product is a USDA-licensed biologic and is not an FDA-approved product.

**Note:** There are also topical products labeled for veterinary use that contain acemannan including a wound dressing and cleansing foam. Trade name is *CarraVet*® (VPL).

**HUMAN-LABELED PRODUCTS:** No systemic products located

---

## ACEPROMAZINE MALEATE

(*ase-pro-ma-zeen*) PromAce®, Aceproject®

PHENOTHIAZINE SEDATIVE/TRANQUILIZER

### Prescriber Highlights

- Negligible analgesic effect
- Dosage may need to be reduced in debilitated or geriatric animals, those with hepatic or cardiac disease, or when combined with other agents
- Inject IV slowly; do not inject into arteries
- Certain dog breeds (e.g., giant breeds, sight hounds) and dogs with the MDR1 mutation may be overly sensitive to effects and require dosage reduction

- May cause significant hypotension, cardiac rate abnormalities, hypo- or hyperthermia
  - May cause penis protrusion in large animals (esp. horses)
- 

## Uses/Indications

Acepromazine is FDA-approved for use in dogs, cats, and horses. Labeled indications for dogs and cats include: "... as an aid in controlling intractable animals ... alleviate itching as a result of skin irritation; as an antiemetic to control vomiting associated with motion sickness" and as a preanesthetic agent. The use of acepromazine as a sedative/tranquilizer in the treatment of adverse behaviors in dogs or cats has largely been supplanted by newer, effective agents that have fewer adverse effects. Its use for sedation during travel is controversial and many no longer recommend drug therapy for this purpose. In combination with analgesics (*e.g.*, opioids), acepromazine can potentiate their analgesic effect (neuroleptanalgesia).

In horses, acepromazine is labeled "... as an aid in controlling fractious animals," and in conjunction with local anesthesia for various procedures and treatments. It is also commonly used in horses as a pre-anesthetic agent at very small doses to help control behavior.

Although not FDA-approved, it is used as a tranquilizer (see doses) in other species such as swine, cattle, rabbits, sheep and goats. Acepromazine has also been shown to reduce the incidence of halothane-induced malignant hyperthermia in susceptible pigs.

## Pharmacology/Actions

Acepromazine is a phenothiazine neuroleptic agent. While the exact mechanisms of action are not fully understood, the phenothiazines block post-synaptic dopamine receptors in the CNS and may also inhibit the release of, and increase the turnover rate of dopamine. They are thought to depress portions of the reticular activating system that assists in the control of body temperature, basal metabolic rate, emesis, vasomotor tone, hormonal balance, and alertness. Additionally, phenothiazines have varying degrees of anticholinergic, antihistaminic, antispasmodic, and alpha-adrenergic blocking effects.

The primary desired effect for the use of acepromazine in veterinary medicine is its tranquilizing action. Additional pharmacologic actions that acepromazine possess, include antiemetic, antispasmodic, and hypothermic actions. Some researchers have reported that acepromazine has anticonvulsant activity, but in veterinary medicine it is generally felt that phenothiazines should not be used in epileptic animals or those susceptible to seizures (*e.g.*, post-myelography) as it may precipitate seizures.

Acepromazine may decrease respiratory rates, but studies have demonstrated that little or no effect occurs with regard to the blood gas picture, pH or oxyhemoglobin saturation. A dose dependent decrease in hematocrit is seen within 30 minutes after dosing in horses and dogs. Hematocrit values in horses may decrease up to 50% of pre-dose values; this is probably due to increased splenic sequestration of red cells.

Besides lowering arterial blood pressure in dogs, acepromazine causes increases in central venous pressure, a vagally induced bradycardic effect and transient sinoatrial arrest. The bradycardia may be negated by a reflex tachycardic effect secondary to decreases in blood pressure. Acepromazine also has antidysrhythmic effects. Acepromazine has been demonstrated to inhibit the arrhythmias induced by ultra-short acting barbiturates, and protect against the ventricular fibrillatory actions of halothane and epinephrine. Other pharmacologic actions are discussed in the adverse effects section below.

## Pharmacokinetics

The pharmacokinetics of acepromazine has been studied in the horse (Ballard *et al.* 1982). The drug has a fairly high volume of distribution (6.6 L/kg), and is more than 99% protein bound. The onset of action is fairly slow, requiring up to 15 minutes following IV administration, with peak effects seen in 30–60 minutes. The elimination half-life in horses is approximately 3 hours.

Acepromazine is metabolized in the liver with both conjugated and unconjugated metabolites eliminated in the urine. Metabolites may be found in equine urine up to 96 hours after dosing.

## Contraindications/Precautions/Warnings

Animals may require lower dosages of general anesthetics following acepromazine. Use cautiously and in smaller doses in animals with hepatic dysfunction, mild cardiac disease, or general debilitation. Because of its hypotensive effects, acepromazine is relatively contraindicated in patients with significant cardiac disease, hypovolemia, hypotension or shock. Acepromazine has been said to decrease platelet aggregation and its use avoided in patients with coagulopathies or thrombocytopenia, but a study in 6 healthy dogs showed no platelet inhibition (Conner *et al.* 2009). Phenothiazines are relatively contraindicated in patients with tetanus or strychnine intoxication due to effects on the extrapyramidal system.

Intravenous injections should be made slowly. Do not administer intra-arterially in horses since it may cause severe CNS excitement/depression, seizures and death. Because of its effects on thermoregulation, use cautiously in very young or debilitated animals.

Two retrospective studies in dogs (McConnell *et al.* 2007), (Tobias & Marioni-Henry 2006) did not show any increase in seizure activity after administration of acepromazine.

When used alone, acepromazine has no analgesic effects; treat animals with appropriate analgesics to control pain. The tranquilization effects of acepromazine can be overridden and it cannot always be counted upon when used as a restraining agent. Do not administer to racing animals within 4 days of a race.

In dogs, acepromazine's effects may be individually variable and breed dependent. Dogs with MDR1 mutations (many Collies, Australian shepherds, etc.) may develop a more pronounced sedation that persists longer than normal. The Veterinary Clinical Pharmacology Lab at Washington State recommends reducing the dose by 25% in dogs heterozygous for the MDR1 mutation (mutant/normal) and by 30–50% in dogs homozygous for the MDR1 mutation (mutant/mutant). (WSU-VetClinPharmLab 2009)

Acepromazine should be used very cautiously as a restraining agent in aggressive dogs as it may make the animal more prone to startle and react to noises or other sensory inputs. In geriatric patients, very low doses have been associated with prolonged effects of the drug. Giant breeds and greyhounds may be extremely sensitive to the drug while terrier breeds are somewhat resistant to its effects. Atropine may be used with acepromazine to help negate its bradycardic effects.

In addition to the legal aspects (not FDA-approved) of using acepromazine in cattle, the drug may cause regurgitation of ruminal contents when inducing general anesthesia.

## Adverse Effects

Acepromazine's effect on blood pressure (hypotension) is well described and an important consideration in therapy. This effect is thought to be mediated by both central mechanisms and through the alpha-adrenergic actions of the drug. Cardiovascular collapse (secondary to bradycardia and hypotension) has been described in all major species. Dogs may be more sensitive to these effects than other animals.

Acepromazine has been shown to decrease tear production in cats (Ghaffari *et al.* 2010).

In male large animals acepromazine may cause protrusion of the penis in horses; this effect may last 2 hours. Stallions should be given acepromazine with caution.

In male large animals acepromazine may cause protrusion of the penis, in horses, this effect may last 2 hours. Stallions should be given acepromazine with caution as injury to the penis can occur with resultant swelling and permanent paralysis of the penis retractor muscle. Other clinical signs that have been reported in horses include excitement, restlessness, sweating, trembling, tachypnea, tachycardia and, rarely, seizures and recumbency.

Acepromazine's effects of causing penis extension in horses and prolapse of the membrana nictitans in horses and dogs, may make its use unsuitable for show animals. There are also ethical considerations regarding the use of tranquilizers prior to showing an animal or having the animal examined before sale.

Occasionally an animal may develop the contradictory clinical signs of aggressiveness and generalized CNS stimulation after receiving acepromazine. IM injections may cause transient pain at the injection site.

## Reproductive/Nursing Safety

In humans, the FDA categorizes phenothiazines as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *B* (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

## Overdosage/Acute Toxicity

The LD<sub>50</sub> in mice is 61 mg/kg after IV dosage and 257 mg/kg after oral dose. While a toxicity study in dogs reported no adverse effects in dogs receiving 20–40 mg/kg over 6 weeks, since 2004 the ASPCA Animal Poison center has documented adverse effects in dogs receiving single doses between 20–42 mg/kg. Dogs have survived oral dosages up to 220 mg/kg, but overdoses can cause serious hypotension, CNS depression, pulmonary edema and hyperemia.

There were 70 exposures to acepromazine maleate reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 49 were dogs with 37 showing clinical signs and the remaining 21 reported cases were cats with 17 cats showing clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, sedation, lethargy, depression, and protrusion of the third eyelid, somnolence, bradycardia, and recumbency. Common findings in cats recorded in decreasing frequency included sedation, ataxia, lethargy, protrusion of the third eyelid, and depression.

Because of the apparent relatively low toxicity of acepromazine, most overdoses can be handled by monitoring the animal and treating clinical signs as they occur; massive oral overdoses should definitely be treated by emptying the gut if possible. Hypotension should not be treated initially with fluids; alpha-adrenergic pressor agents (epinephrine, phenylephrine) can be considered if fluids do not maintain adequate blood pressure. Seizures may be controlled with barbiturates or diazepam. Doxapram has been suggested as an antagonist to the CNS depressant effects of acepromazine.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acepromazine or other phenothiazines and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Possible increased risk for hypothermia
- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTIDIARRHEAL MIXTURES** (*e.g.*, **Kaolin/pectin, bismuth subsalicylate mixtures**): May cause reduced GI absorption of oral phenothiazines
- **CNS DEPRESSANT AGENTS** (**barbiturates, narcotics, anesthetics**, etc.): May cause additive CNS depression if used with acepromazine
- **DOPAMINE:** Acepromazine may impair the vasopressive action of dopamine.
- **EMETICS:** Acepromazine may reduce the effectiveness of emetics
- **EPINEPHRINE, EPHEDRINE:** Phenothiazines block alpha-adrenergic receptors; concomitant use of epinephrine or ephedrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- **METOCLOPRAMIDE:** May increase risks for extrapyramidal adverse effects
- **OPIATES:** May enhance the hypotensive effects of acepromazine; dosages of acepromazine are generally reduced when used with an opiate
- **ORGANOPHOSPHATE AGENTS:** Acepromazine should not be given within one month of worming with these agents as their effects may be potentiated
- **PHENYTOIN:** Metabolism may be decreased if given concurrently with phenothiazines
- **PROCAINE:** Activity may be enhanced by phenothiazines
- **PROPRANOLOL:** Increased blood levels of both drugs may result if administered with phenothiazines
- **QUINIDINE:** With phenothiazines may cause additive cardiac depression

## Doses

**Note:** The manufacturer's dose of 0.5–2.2 mg/kg for dogs and cats is considered by many clinicians to be 10 times greater than is necessary for most indications. Give IV doses slowly; allow at least 15 minutes for onset of action.

- **DOGS:**
  - a) 0.55–2.2 mg/kg PO or 0.55–1.1 mg/kg IV, IM or SC (Package Insert; *PromAce*®—Fort Dodge)
  - b) Restraint/sedation: 0.025–0.2 mg/kg IV; maximum of 3 mg or 0.1–0.25 mg/kg IM; Preanesthetic: 0.1–0.2 mg/kg IV or IM; maximum of 3 mg; 0.05–1 mg/kg IV, IM or SC (Morgan 1988)
  - c) To reduce anxiety in the painful patient (not a substitute for analgesia): 0.05 mg/kg IM, IV or SC; do not exceed 1 mg total dose (Carroll 1999)
  - d) Premedication: 0.03–0.05 mg/kg IM or 1–3 mg/kg PO at least one hour prior to surgery (not as reliable) (Hall & Clarke 1983)
  - e) As a premedicant with morphine: acepromazine 0.05 mg/kg IM; morphine 0.5 mg/kg IM (Pablo 2003)

- **CATS:**
  - a) 1.1–2.2 mg/kg PO, IV, IM or SC (Package Insert; *PromAce*®—Fort Dodge)
  - b) To reduce anxiety in the painful patient (not a substitute for analgesia): 0.05 mg/kg IM, IV or SC; do not exceed 1 mg total dose (Carroll 1999)
  - c) Restraint/sedation: 0.05–0.1 mg/kg IV, maximum of 1 mg (Morgan 1988)
  - d) 0.11 mg/kg with atropine (0.045–0.067 mg/kg) 15–20 minutes prior to ketamine (22 mg/kg IM). (Booth 1988)

## ■ FERRETS:

- As a tranquilizer: 0.25–0.75 mg/kg IM or SC; has been used safely in pregnant jills; use with caution in dehydrated animals. (Finkler 1999)
- 0.1–0.25 mg/kg IM or SC; may cause hypotension/hypothermia (Williams 2000)

## ■ RABBITS/RODENTS/SMALL MAMMALS:

- Rabbits: As a tranquilizer: 1 mg/kg IM, effect should begin in 10 minutes and last for 1–2 hours (Booth 1988)
- Rabbits: As a premed: 0.1–0.5 mg/kg SC; 0.25–2 mg/kg IV, IM, SC 15 minutes prior to induction. No analgesia; may cause hypotension/hypothermia. (Ivey & Morrissey 2000)
- Mice, Rats, Hamsters, Guinea pigs, Chinchillas: 0.5 mg/kg IM. Do *not* use in Gerbils. (Adamcak & Otten 2000)

## ■ CATTLE:

- Sedation: 0.01–0.02 mg/kg IV or 0.03–0.1 mg/kg IM (Booth 1988)
- 0.05–0.1 mg/kg IV, IM or SC (Howard 1986)
- Sedative one hour prior to local anesthesia: 0.1 mg/kg IM (Hall & Clarke 1983)

## ■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- 0.044–0.088 mg/kg (2–4 mg/100 lbs. body weight) IV, IM or SC (Package Insert; *PromAce*® —Fort Dodge)
- For mild sedation: 0.01–0.05 mg/kg IV or IM. Onset of action is about 15 minutes for IV; 30 minutes for IM (Taylor, P. 1999)
- 0.02–0.05 mg/kg IM or IV as a preanesthetic (Booth 1988)
- Neuroleptanalgesia: 0.02 mg/kg given with buprenorphine (0.004 mg/kg IV) or xylazine (0.6 mg/kg IV) (Thurmon & Benson 1987)
- For adjunctive treatment of laminitis (developmental phase): 0.066–0.1 mg/kg 4–6 times per day (Brumbaugh *et al.* 1999)

## ■ SWINE:

- 0.1–0.2 mg/kg IV, IM, or SC (Howard 1986)
- 0.03–0.1 mg/kg (Hall & Clarke 1983)
- For brief periods of immobilization: acepromazine 0.5 mg/kg IM followed in 30 minutes by ketamine 15 mg/kg IM. Atropine (0.044 mg/kg IM) will reduce salivation and bronchial secretions. (Lumb & Jones 1984)

## ■ SHEEP & GOATS:

- 0.05–0.1 mg/kg IM (Hall & Clarke 1983)

## ■ ZOO, EXOTIC, WILDLIFE SPECIES:

For use of acepromazine in zoo, exotic and wildlife medicine refer to specific references, including:

- Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.
- Handbook of Wildlife Chemical Immobilization, 3rd Ed.* Kreeger, T.J. and J.M. Arnemo. 2007.
- Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995
- Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005
- The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

## Monitoring

- Cardiac rate/rhythm/blood pressure if indicated and possible to measure
- Degree of tranquilization
- Male horses should be checked to make sure penis retracts and is not injured
- Body temperature (especially if ambient temperature is very hot or cold)

## Client Information

- May discolor the urine to a pink or red-brown color; this is not abnormal
- Acepromazine is FDA-approved for use in dogs, cats, and horses not intended for food

## Chemistry/Synonyms

Acepromazine maleate (formerly acetylpromazine) is a phenothiazine derivative that occurs as a yellow, odorless, bitter tasting powder. One gram is soluble in 27 mL of water, 13 mL of alcohol, and 3 mL of chloroform.

Acepromazine Maleate may also be known as: acetylpromazine maleate, “ACE”, ACP, *Aceproject*®, *Aceprotabs*®, *PromAce*®, *Plegicil*®, *Notensil*®, and *Atravet*®.

## Storage/Stability

Store protected from light. Tablets should be stored in tight containers. Acepromazine injection should be kept from freezing.

Although controlled studies have not documented the compatibility of these combinations, acepromazine has been mixed with atropine, buprenorphine, chloral hydrate, ketamine, meperidine, oxymorphone, and xylazine. Both glycopyrrolate and diazepam have been reported to be physically **incompatible** with phenothiazines, however, glycopyrrolate has been demonstrated to be **compatible** with promazine HCl for injection.

## Compatibility/Compounding Considerations

A study (Taylor, B.J. *et al.* 2009) evaluating the stability, sterility, pH, particulate formation and efficacy in laboratory rodents of compounded ketamine, acepromazine and xylazine (KAX) supported the finding that the drugs are stable and efficacious for at least 180 days after mixing if stored at room temperature in the dark.

Combinations of acepromazine mixed with atropine, buprenorphine, chloral hydrate, meperidine, and oxymorphone have been commonly used, but studies

Combinations of acepromazine mixed with atropine, buprenorphine, emtoral hydrate, meperidine, and oxymorphone have been commonly used, but studies documenting their compatibility and stability were not located. Both glycopyrrolate and diazepam have been reported to be physically **incompatible** with phenothiazines, however glycopyrrolate has been demonstrated to be **compatible** with promazine HCl for injection.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Acepromazine Maleate for Injection: 10 mg/mL for injection in 50 mL vials; *PromAce*® (Fort Dodge); generic; (Rx). FDA-approved forms available for use in dogs, cats and horses not intended for food.

Acepromazine Maleate Tablets: 5 mg, 10 mg & 25 mg in bottles of 100 and 500 tablets; *PromAce*® (Fort Dodge); generic; (Rx). FDA-approved forms available for use in dogs, cats and horses not intended for food.

When used in an extra-label manner in food animals, it is recommended to use the withdrawal periods used in Canada: Meat: 7 days; Milk: 48 hours. Contact FARAD (see appendix) for further guidance.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS: None

## ACETAMINOPHEN

(ah-seet-a-min-a-fen) Tylenol®, APAP, Paracetamol

ORAL ANALGESIC, ANTIPYRETIC

### Prescriber Highlights

- **Contraindicated in cats at any dosage; ferrets may be as sensitive to acetaminophen as cats**
- **At recommended dosages, not overly toxic to dogs, rodents, or rabbits. Dogs are more susceptible to red blood cell toxicity than are humans, so dose carefully.**
- **Often used in combined dosage forms with [codeine](#); see codeine monograph for more information**

---

## Uses/Indications

Acetaminophen is occasionally used as an oral analgesic in dogs and small mammals. It may be particularly beneficial in dogs with renal dysfunction for the treatment of chronic pain conditions. In situations where moderate pain occurs, it may be used in combination products containing codeine, hydrocodone, or tramadol. See the [codeine](#), [hydrocodone](#) and [tramadol](#) monographs for more information on the use of acetaminophen combination preparations.

## Pharmacology/Actions

Acetaminophen's exact mechanism of actions are not completely understood; it produces analgesia and antipyresis via a weak, reversible, isoform-nonspecific inhibition of cyclooxygenase (COX-3; Cox-1–v1). Unlike aspirin, it does not possess significant antiinflammatory activity nor inhibit platelet function when given at clinically recommended dosages.

## Pharmacokinetics

Specific pharmacokinetic information in domestic animals was not located. In humans, acetaminophen is rapidly and nearly completely absorbed from the gut and is rapidly distributed into most tissues. Approximately 25% is plasma protein bound. Dogs apparently exhibit dose dependent metabolism (saturable).

## Contraindications/Precautions/Warnings

Acetaminophen is contraindicated in cats at any dosage. Severe methemoglobinemia, hematuria, and icterus can be seen. Cats are unable to significantly glucuronidate acetaminophen leading to toxic metabolites being formed and resultant toxicity. Acetaminophen should not be used in ferrets as they may be as sensitive to acetaminophen as are cats. At this time, acetaminophen should not be used in Sugar Gliders or Hedgehogs as its safety has not been determined.

Dogs do not metabolize acetaminophen as well as humans and its use must be judicious. While dogs are not as sensitive to acetaminophen as cats, they may also be susceptible to methemoglobinemia when given high dosages. In dogs, it is generally not recommended to use acetaminophen during the immediate post-operative phase (first 24 hours) due to an increased risk of hepatotoxicity.

## Adverse Effects

Because acetaminophen is not routinely used in veterinary medicine, consultation with an animal poison control center is highly recommended (see appendix). At suggested dosages in dogs, there is some potential for renal, hepatic, GI, and hematologic effects occurring.

### Reproductive/Nursing Safety

Absolute reproductive safety has not been established, but acetaminophen is apparently relatively safe for occasional use in pregnancy (no documented problems in humans). Animal data was not located. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Acetaminophen is excreted in milk in low concentrations with reported milk:plasma ratios of 0.91 to 1.42 at 1 and 12 hours, respectively. In nursing human infants, no adverse effects have been reported.

### Overdosage/Acute Toxicity

Because of the potentially severe toxicity associated with acetaminophen, consultation with an animal poison control center is highly recommended (see appendix). Effects can include methemoglobinemia, liver necrosis, renal effects, facial and paw swelling, and keratoconjunctivitis sicca (KCS). Liver effects are more common in dogs; facial and paw swelling and methemoglobinemia are more common in cats.

There were 1192 exposures to acetaminophen reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 1083 were dogs with 187 showing clinical signs, 99 were cats with 47 showing clinical signs, 6 were birds with 1 showing clinical signs, 1 was a pig that showed clinical signs. The remaining 3 cases involved 2 ferrets and 1 lagomorph that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, methemoglobinemia, edema of the face, elevated ALT, chemosis (conjunctival swelling/edema), and trembling. Common findings in cats recorded in decreasing frequency included methemoglobinemia, cyanosis, lethargy, vomiting, hypothermia, and anorexia.

For overdosage in dogs or cats, standard gut emptying techniques and supportive care should be administered when applicable. Further treatment with acetylcysteine, s-adenosyl methionine (SAMe), oxygen, and blood transfusions may be warranted (Richardson 2000), (Aronson & Drobatz 1996), (Mariani & Fulton 2001), (Steenbergen 2003).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acetaminophen and may be of significance in veterinary patients:

- **OTHER ANALGESICS:** Chronic use with acetaminophen may lead to renal pathologies
- **BARBITURATES:** Increased conversion of acetaminophen to hepatotoxic metabolites; potentially increased risk for hepatotoxicity
- **DOXORUBICIN:** May deplete hepatic glutathione, thereby leading to increased hepatic toxicity
- **HALOTHANE:** Acetaminophen is not recommended for use for post-operative analgesia in animals that received halothane anesthesia
- **ISONIAZID:** Possible increased risk of hepatotoxicity
- **PHENOTHIAZINES:** Possible increased risk for hypothermia
- **PROPYLENE GLYCOL:** Foods containing propylene glycol (often found in wet cat foods) may increase the severity of acetaminophen-induced methemoglobinemia or Heinz body formation.
- **WARFARIN:** While acetaminophen is relatively safe to use, large doses may potentiate anticoagulant effects

### Laboratory Considerations

- False positive results may occur for urinary **5-hydroxyindoleacetic acid**

### Doses

**Note:** For dosages of acetaminophen/codeine, and acetaminophen/hydrocodone combination products refer to the codeine and hydrocodone monographs.

#### ■ DOGS:

As an analgesic:

- a) 15 mg/kg PO q8h (Dodman 1992), (McLaughlin 2000)
- b) 10 mg/kg PO q12h (Kelly 1995)
- c) 10–15 mg/kg PO q12h for 5 days (Gaynor 2008)
- d) In the treatment of degenerative myelopathy (in German Shepherds): 5 mg/kg PO (not to exceed 20 mg/kg per day) (Clemmons 1991)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

As an analgesic:

- a) Using Children's *Tylenol*®: 1–2 mg/mL in drinking water. Effective for controlling low-grade nociception. (Huerkamp 2000)
- b) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 1–2 mg/mL in drinking water (Adamcak & Otten 2000)

### Monitoring

- When used at recommended doses for pain control in otherwise healthy patients, little monitoring should be necessary. However, with chronic therapy, occasional liver, renal and hematologic monitoring may be warranted, particularly when clinical signs occur.

### Client Information

- Follow directions carefully; do not exceed dosage or increase dosing frequency. Do not administer to cats or ferrets for any reason. Keep out of reach of children.

### Chemistry/Synonyms

A synthetic non-opiate analgesic, acetaminophen (also known as paracetamol) occurs as a crystalline, white powder with a slightly bitter taste. It is soluble in boiling water and freely soluble in alcohol. Acetaminophen is known in the U.K. as paracetamol.

Acetaminophen may also be known as: paracetamol, MAPAP or APAP; many trade names are available.

## Storage/Stability

Acetaminophen products should be stored at temperatures less than 40°C. Do not freeze oral solution or suspension.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

There are many different trade names and products of acetaminophen available. The most commonly known trade name is *Tylenol*®. Acetaminophen is commonly available in 325 mg, 500 mg, 650 mg tablets; 80 mg chewable tablets; 650 mg extended release tablets; 160 mg, 500 mg, & 650 mg caplets; 500 mg gelcaps; 325 mg, & 500 mg capsules, 80 mg and 160 mg sprinkle capsules; 80 mg/0.8 mL drops; 80 mg/2.5 mL, 80 mg/5 mL, 120 mg/5 mL, & 160 mg/5 mL elixirs; 160 mg/5 mL, 500 mg/15 mL, and 100 mg/mL liquids and solutions; 80 mg, 120 mg, 125 mg, 300 mg, 325 mg and 650 mg suppositories. Combinations with other analgesics (aspirin, codeine phosphate, hydrocodone, tramadol, oxycodone or propoxyphene) are also available.

## ACETAZOLAMIDE

### ACETAZOLAMIDE SODIUM

(ah-seet-a-zole-a-mide)

Diamox®, Dazamide®

CARBONIC ANHYDRASE INHIBITOR DIURETIC; ANTIGLAUCOMA AGENT

### Prescriber Highlights

- **Used sometimes for metabolic alkalosis or glaucoma in small animals; HYPP in horses**
- **Contraindicated in patients with significant hepatic, renal, pulmonary or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis or electrolyte imbalance**
- **Give oral doses with food if GI upset occurs**
- **Electrolytes & acid/base status should be monitored with chronic or high dose therapy**
- **Monitor with tonometry if using for glaucoma**

---

## Uses/Indications

Acetazolamide has been used principally in veterinary medicine for its effects on aqueous humor production in the treatment of glaucoma, metabolic alkalosis, and for its diuretic action. It may be useful as an adjunctive treatment for syringomyelia in dogs. Acetazolamide's use in small animals is complicated by a relatively high occurrence of adverse effects.

In horses, acetazolamide is used as an adjunctive treatment for hyperkalemic periodic paralysis (HYPP).

In humans, the drug has been used as adjunctive therapy for epilepsy and for acute high-altitude sickness.

## Pharmacology/Actions

The carbonic anhydrase inhibitors act by a noncompetitive, reversible inhibition of the enzyme carbonic anhydrase. This reduces the formation of hydrogen and bicarbonate ions from carbon dioxide thereby reducing the availability of these ions for active transport into body secretions.

Pharmacologic effects of the carbonic anhydrase inhibitors include: decreased formation of aqueous humor, thus reducing intraocular pressure, increased renal tubular secretion of sodium and potassium and, to a greater extent, bicarbonate, leading to increased urine alkalinity and volume. Acetazolamide has some anticonvulsant activity, which is independent of its diuretic effects (mechanism is not fully understood, but may be due to carbonic anhydrase or a metabolic acidosis effect).

In anesthetized cats, methazolamide did not, but acetazolamide did reduce the hypoxic ventilatory response. The authors believe this not as a result of carbonic anhydrase inhibition, but due to acetazolamide's effects on carotid bodies or type I cells (Teppema *et al.* 2006).

## Pharmacokinetics

The pharmacokinetics of this agent have apparently not been studied in domestic animals. One report (Roberts 1985) states that after a dose of 22 mg/kg, the onset of action is 30 minutes; maximal effects occur in 2–4 hours; duration of action is about 4–6 hours in small animals.

In humans, the drug is well absorbed after oral administration with peak levels occurring within 1–3 hours. It is distributed throughout the body with highest levels

In humans, the drug is well absorbed after oral administration with peak levels occurring within 1–3 hours. It is distributed throughout the body with highest levels found in the kidneys, plasma and erythrocytes. Acetazolamide has been detected in the milk of lactating dogs and it crosses the placenta (in unknown quantities). Within 24 hours of administration, an average of 90% of the drug is excreted unchanged into the urine by tubular secretion and passive reabsorption processes.

### Contraindications/Precautions/Warnings

Carbonic anhydrase inhibitors are contraindicated in patients with significant hepatic disease (may precipitate hepatic coma), renal or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis, or electrolyte imbalance. They should not be used in patients with severe pulmonary obstruction that are unable to increase alveolar ventilation or in those who are hypersensitive to them. Long-term use of carbonic anhydrase inhibitors is contraindicated in patients with chronic, noncongestive, angle-closure glaucoma as angle closure may occur and the drug may mask the condition by lowering intraocular pressures.

Acetazolamide should be used with caution in patients with severe respiratory acidosis or having preexisting hematologic abnormalities. Cross sensitivity between acetazolamide and antibacterial sulfonamides may occur.

### Adverse Effects

Potential adverse effects that may be encountered include: GI disturbances, CNS effects (sedation, depression, weakness, excitement, etc.), hematologic effects (bone marrow depression), renal effects (crystalluria, dysuria, renal colic, polyuria), hypokalemia, hyperglycemia, hyponatremia, hyperuricemia, hepatic insufficiency, dermatologic effects (rash, etc.), and hypersensitivity reactions.

At the dosages used for HYPP in horses adverse effects are reportedly uncommon.

### Reproductive/Nursing Safety

Acetazolamide has been implicated in fetal abnormalities in mice and rats when used at high (10X) dosages and fetal toxicity has been noted when the drug has been used in pregnant humans. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

In humans, the manufacturer states that either nursing or the drug must be discontinued if the mother is receiving acetazolamide. Veterinary significance is not clear.

### Overdosage/Acute Toxicity

Information regarding overdosage of this drug was not located. In the event of an overdose, it is recommended to contact an animal poison control center. Monitor serum electrolytes, blood gases, volume status, and CNS status during an acute overdose; treat symptomatically and supportively.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acetazolamide and may be of significance in veterinary patients:

- **ALKALINE URINE:** Drugs where acetazolamide-caused alkaline urine may affect their excretion rate: Decreased urinary excretion of **quinidine, procainamide, tricyclic antidepressants**; Increased urinary excretion of **salicylates, phenobarbital**
- **ASPIRIN** (or **other salicylates**): Increased risk of acetazolamide accumulation and toxicity; increased risk for metabolic acidosis
- **DIGOXIN:** As acetazolamide may cause hypokalemia, increased risk for toxicity
- **INSULIN:** Rarely, carbonic anhydrase inhibitors interfere with the hypoglycemic effects of insulin
- **METHENAMINE COMPOUNDS:** Acetazolamide may negate methenamine effects in the urine
- **DRUGS AFFECTING POTASSIUM** (**corticosteroids, amphotericin B, corticotropin, or other diuretics**): Concomitant use may exacerbate potassium depletion
- **PRIMIDONE:** Decreased primidone concentrations

### Laboratory Considerations

- By alkalinizing the urine, carbonic anhydrase inhibitors may cause false positive results in determining **urine protein** when using bromphenol blue reagent (*Albustix®*, *Albutest®*, *Labstix®*), sulfosalicylic acid (*Bumintest®*, *Exton's Test Reagent*), nitric acid ring test, or heat and acetic acid test methods
- Carbonic anhydrase inhibitors may **decrease iodine uptake** by the thyroid gland in hyperthyroid or euthyroid patients

### Doses

Directions for reconstitution of injection: Reconstitute 500 mg vial with at least 5 mL of Sterile Water for Injection; use within 24 hours after reconstitution.

#### ■ DOGS:

For adjunctive treatment of metabolic alkalosis:

- a) 10 mg/kg four times daily (may aggravate volume contraction and hypokalemia) (Hardy and Robinson 1986)

For adjunctive therapy of glaucoma:

- a) 10–25 mg/kg divided 2–3 times daily (Brooks 2002)
- b) 50–75 mg/kg PO 2–3 times a day (Bedford 2003)
- c) 50 mg/kg IV one time; 7 mg/kg, PO three times daily (Vestre 1985)

For adjunctive therapy of hydrocephalus in pediatric patients:

- a) 0.1 mg/kg PO q8h (Coates 2002)

#### ■ CATS:

For adjunctive therapy of glaucoma:

- a) 50 mg/kg IV once; 7 mg/kg, PO three times daily (Vestre 1985)

#### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

For adjunctive therapy of hyperkalemic periodic paralysis (HYPP):

- a) 2.2–4.4 mg/kg PO twice daily (Schott II 2004)

- b) 0.5–2.2 mg/kg PO twice daily (Seibert 1986)
- c) 2–3 mg/kg PO q8-12h when diet adjustment does not control episodes. (Valberg 2008)

#### ■ RUMINANTS:

- a) 6–8 mg/kg IV, IM, or SC (Howard 1986)

#### ■ SWINE:

- a) 6–8 mg/kg IV, IM, or SC (Howard 1986)

### Monitoring

- Intraocular pressure tonometry (if used for glaucoma)
- Blood gases if used for alkalosis
- Serum electrolytes
- Baseline CBC with differential and periodic retests if using chronically
- Other adverse effects

### Client Information

- Give with food if using oral preparation and GI upset occurs
- Notify veterinarian if abnormal bleeding or bruising occurs or if animal develops tremors or a rash

### Chemistry/Synonyms

A carbonic anhydrase inhibitor, acetazolamide occurs as a white to faintly yellowish-white, odorless, crystalline powder with pKas of 7.4 and 9.1. It is very slightly soluble in water, sparingly soluble in hot water (90–100°C) and alcohol. Acetazolamide sodium occurs as a white lyophilized solid and is freely soluble in water. The injection has a pH of 9.2 after reconstitution with Sterile Water for Injection.

Acetazolamide may also known as: acetazolam, acetazolamidum, or sodium acetazolamide; many trade names are available.

### Storage/Stability

Acetazolamide products should be stored at room temperature.

To prepare parenteral solution: reconstitute with at least 5 mL of Sterile Water for Injection. After reconstitution, the injection is stable for one week when refrigerated, but as it contains no preservatives, it should be used within 24-hours.

### Compatibility/Compounding Considerations

Acetazolamide sodium for injection is reportedly physically **compatible** with all commonly used IV solutions and cimetidine HCl for injection.

**COMPOUNDED PREPARATION STABILITY:** Acetazolamide oral suspension compounded from commercially available tablets has been published (Allen, 1996). Triturating twelve (12) 250 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® SF) yields a 25 mg/mL suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. The stability of acetazolamide aqueous liquids decreases at pH values above 9. The optimal stability is reported to be between 3 and 5. Compounded preparations of acetazolamide should be protected from light.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

Acetazolamide Oral Tablets: 125 mg, 250 mg; generic; (Rx)

Acetazolamide Extended-Release Oral Capsules: 500 mg; *Diamox Sequels*® (Barr); generic (Rx)

Acetazolamide Injection (lyophilized powder for solution): 500 mg; generic; (Rx)

## ACETIC ACID

(ah-see-tick ass-id) Vinegar

GI ACIDIFIER

### Prescriber Highlights

- Used primarily for treatment of non-protein nitrogen-induced ammonia toxicosis (secondary to urea poisoning, etc.) in ruminants or enterolith prevention in horses

- **Contraindicated if potential lactic acidosis (grain overload, rumen acidosis) is possible**
  - **Given via stomach tube**
- 

### Uses/Indications

Acetic acid is used via its acidifying qualities in ruminants to treat non-protein nitrogen-induced (*e.g.*, urea poisoning) ammonia toxicosis. It is also used as a potential treatment to prevent enterolith formation in horses by reducing colonic pH.

### Pharmacology/Actions

Acetic acid in the rumen lowers pH due to shifting ammonia to ammonium ions and reducing absorption. It may also slow the hydrolysis of urea.

### Pharmacokinetics

No information was noted.

### Contraindications/Precautions/Warnings

Should not be administered to ruminants until potential lactic acidosis (grain overload, rumen acidosis) is ruled out.

### Adverse Effects

Because of the unpleasant taste and potential for causing mucous membrane irritation, acetic acid is generally recommended for administration via stomach tube.

### Overdosage/Acute Toxicity

When used for appropriate indications there is little likelihood of serious toxicity occurring after minor overdoses. Due to its potential corrosiveness, the greatest concern would occur if a concentrated form of acetic acid was mistakenly used. However, one human patient who had glacial acetic acid used instead of 5% acetic acid during colposcopy (cervix) demonstrated no detectable harm.

### Drug Interactions

There are no documented drug interactions with oral acetic acid, but because of its acidic qualities it could, potentially, affect the degradation of several drugs in the gut.

### Doses

#### ■ CATTLE/RUMINANTS:

For cattle with putrefaction of rumen associated with a high rumen pH:

- a) 4–10 liters of vinegar (Constable 1993)

For treatment of urea poisoning:

- a) Using 5% acetic acid (vinegar) infuse 2–6 liters (for cattle) into rumen; may be repeated as necessary if clinical signs reoccur. Recovery ranges from 8–24 hours. A post-recovery pro-biotic rumen inoculation may enhance the gain and productivity of urea poisoned animals. (Hall 2006)

#### ■ HORSES:

For enterolith prevention:

- a) Using vinegar: 250 mL/450 kg body weight PO once daily (Robinson 1992)

### Chemistry/Synonyms

Glacial acetic acid is C<sub>2</sub>H<sub>4</sub>O<sub>2</sub>. Acetic acid has a distinctive odor and a sharp acid taste. It is miscible with water, alcohol or glycerin. Much confusion can occur with the percentages of C<sub>2</sub>H<sub>4</sub>O<sub>2</sub> contained in various acetic acid solutions. Acetic Acid USP is defined as having a concentration of 36–37% C<sub>2</sub>H<sub>4</sub>O<sub>2</sub>. Diluted Acetic Acid NF contains 5.7–6.3% w/v of C<sub>2</sub>H<sub>4</sub>O<sub>2</sub>. Solutions containing approximately 3–5% w/v of C<sub>2</sub>H<sub>4</sub>O<sub>2</sub> are commonly known as vinegar. Be certain of the concentration of the product you are using and your dilutions.

Acetic acid may also be known as: E260, eisessig (glacial acetic acid), essigsäure, etanoico, or ethanoic acid.

### Storage/Stability

Acetic acid solutions should be stored in airtight containers.

### Compatibility/Compounding Considerations

If diluting more concentrated forms of acetic acid to concentrations equivalent to vinegar (3–5%), use safety precautions to protect eyes and skin. It is strongly recommended to have someone check your calculations to prevent potentially serious consequences.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

There are no systemic products commercially available. Acetic acid (in various concentrations) may be purchased from chemical supply houses. Distilled white vinegar is available in gallon sizes from grocery stores.

## ACETOHYDROXAMIC ACID

(ah-seet-oh-hy-drox-am-ik) Lithostat®, AHA

UREASE INHIBITOR

### Prescriber Highlights

- Used occasionally in dogs for persistent struvite uroliths & persistent urease-producing bacteriuria
  - Contraindicated in patients with renal impairment & during pregnancy; do not use in cats
  - Adverse effects are common & can include GI effects (anorexia, vomiting, mouth/esophageal ulcers), hemolytic anemia, hyperbilirubinemia & bilirubinuria
  - Monitor renal function (incl. urinalysis), CBC's, & bilirubin levels
- 

### Uses/Indications

Acetohydroxamic acid can be used in dogs as adjunctive therapy in some cases of recurrent urolithiasis or in the treatment of persistent urinary tract infections caused by the following bacteria: *E. coli*, *Klebsiella*, *Morganella morganii*, *Staphylococci* spp., and *Pseudomonas aeruginosa*. Adverse effects limit its usefulness.

### Pharmacology/Actions

AHA inhibits urease thereby reducing production of urea and subsequent urinary concentrations of ammonia, bicarbonate and carbonate. While the drug does not directly reduce urine pH, by reducing ammonia and bicarbonate production by urease-producing bacteria, it prevents increases in urine pH. The drug may act synergistically with several antimicrobial agents (*e.g.*, carbenicillin, gentamicin, clindamycin, trimethoprim-sulfa or chloramphenicol) in treating some urinary tract infections. The drug's effects on urinary pH and infection also indirectly inhibit the formation of urinary calculi (struvite, carbonate-apatite).

### Pharmacokinetics

No canine specific data was located. In humans, the drug is rapidly absorbed after PO administration. Absolute bioavailability "in animals" is reported to be 50–60%. AHA is well distributed throughout body fluids. It is partially metabolized to acetamide, which is active; 36–65% of a dose is excreted in the urine unchanged, and 9–14% excreted in the urine as acetamide. The remainder is reportedly excreted as CO<sub>2</sub> via the respiratory tract.

### Contraindications/Precautions/Warnings

AHA is contraindicated in patients with poor renal function (*e.g.*, serum creatinine >2.5 mg/dL) or when it is not specifically indicated (see Indications).

Acetohydroxamic acid is reportedly very toxic in cats and should not be used in felines.

### Adverse Effects

In dogs, GI effects (anorexia, vomiting, mouth/esophageal ulcers), hemolytic anemia, hyperbilirubinemia and bilirubinuria have been reported. Other potential adverse effects include: CNS disturbances (anxiety, depression, tremulousness), hematologic effects (reticulocytosis, bone marrow depression), phlebitis, and skin rashes/alopecia. Effects on bilirubin metabolism have also been reported.

### Reproductive/Nursing Safety

AHA use is considered contraindicated during pregnancy. In pregnant beagles, doses of 25 mg/kg/day caused cardiac, coccygeal, and abdominal wall abnormalities in puppies. At high doses (>750 mg/kg) leg deformities have been noted in test animals. Higher doses (1500 mg/kg) caused significant encephalopathologies. In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

### Overdosage/Acute Toxicity

In humans, mild overdoses have resulted in hemolysis after several weeks of treatment, particularly in patients with reduced renal function. Acute overdoses are expected to cause clinical signs such as anorexia, tremors, lethargy, vomiting and anxiety. Increased reticulocyte counts and a severe hemolytic reaction are laboratory findings that would be expected. Treatment for an acute overdose may include intensive hematologic monitoring with adjunctive supportive therapy, including possible transfusions.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acetohydroxamic acid (AHA) and may be of significance in veterinary patients:

- **IRON:** AHA may chelate iron salts in the gut if given concomitantly
- **METHENAMINE:** AHA may have a synergistic effect with methenamine in inhibiting the urine pH increases caused by urease-producing *Proteus* spp.; AHA may also potentiate the antibacterial effect of methenamine against these bacteria
- **ALCOHOL:** In humans, AHA with alcohol has resulted in rashes

### Laboratory Considerations

- Although AHA is a true urease inhibitor, it apparently does not interfere with urea nitrogen determination using one of the following: urease-Berthelot, urease-glutamate dehydrogenase or diacetyl monoxime methods.

### Doses

#### ■ DOGS:

For adjunctive therapy of persistent struvite uroliths and persistent urease-producing bacteria after treating with antibiotics and calculolytic diets:

a) 12.5 mg/kg twice daily PO (Osborne *et al.* 1993), (Lulich *et al.* 2000)

## Monitoring

- CBC
- Renal/Hepatic (bilirubin) function
- Efficacy

## Client Information

- This medication can cause several adverse effects in dogs; contact veterinarian if dog develops persistent or severe vomiting, has a lack of appetite, a change in urine color, develops yellowing of the whites of the eyes, or has decreased energy/activity.

## Chemistry/Synonyms

An inhibitor of urease, acetohydroxamic acid occurs as a white crystal having a pKa of 9.32–9.4 and a pH of about 9.4. 850 mg are soluble in one mL of water, and 400 mg are soluble in one mL of alcohol.

Acetohydroxamic acid may also be known as: AHA, Acetic acid oxime, N-Acetylhydroxylamide, N-Hydroxyacetamide, *Lithostat*® or *Uronefrefex*®.

## Storage/Stability

Tablets should be stored in tight containers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** Acetohydroxamic Acid Oral Tablets: 250 mg; *Lithostat*® (Mission); (Rx)

## ACETYLCYSTEINE

(assah-teel-sis-tay-een) N-acetylcysteine, Mucomyst®, NAC

ANTIDOTE; MUCOLYTIC

### Prescriber Highlights

- **Used primarily as a treatment for acetaminophen toxicity or other hepatotoxic conditions where glutathione synthesis is inhibited or oxidative stress occurs.**
- **Also has been used as an inhaled solution for its mucolytic effect and, anecdotally for treating degenerative myelopathy**
- **Acetylcysteine is used as a topical ophthalmic (see the Topical Ophthalmic section in the appendix)**
- **Has caused hypersensitivity & bronchospasm when used in pulmonary tree**
- **Administer via gastric- or duodenal tube for acetaminophen poisoning in animals on an empty stomach**

---

## Uses/Indications

Acetylcysteine is used in veterinary medicine as both a mucolytic agent in the pulmonary tree and as a treatment for acetaminophen, xylitol, or phenol toxicity in small animals. Acetylcysteine is used investigatively as an antiinflammatory for chronic upper respiratory disease in cats, as an adjunct in heavy metal removal, and topically in the eye to halt the melting effect of collagenases and proteinases on the cornea.

It has been used anecdotally with aminocaproic acid to treat degenerative myelopathy in dogs, but data is lacking showing efficacy.

In horses with strangles, acetylcysteine instilled into the guttural pouch has been used to help break up chondroids and avoid the need for surgical removal. Acetylcysteine enemas have been used in neonatal foals to break up meconium refractory to repeated enemas.

## Pharmacology/Actions

When administered into the pulmonary tree, acetylcysteine reduces the viscosity of both purulent and nonpurulent secretions and expedites the removal of these secretions via coughing, suction, or postural drainage. The free sulfhydryl group on the drug is believed to reduce disulfide linkages in mucoproteins; this effect is most pronounced at a pH from 7–9. The drug has no effect on living tissue or fibrin.

Acetylcysteine can reduce the extent of liver injury or methemoglobinemia after ingestion of acetaminophen or phenol, by providing an alternate substrate for conjugation with the reactive metabolite of acetaminophen, thus maintaining or restoring glutathione levels.

## Pharmacokinetics

When given orally, acetylcysteine is absorbed from the GI tract. When administered via nebulization or intratracheally into the pulmonary tract, most of the drug is involved in the sulfhydryl-disulfide reaction and the remainder is absorbed. Absorbed drug is converted (deacetylated) into cysteine in the liver and then further metabolized.

## Contraindications/Precautions/Warnings

Acetylcysteine is contraindicated (for pulmonary indications) in animals hypersensitive to it. There are no contraindications for its use as an antidote.

Because acetylcysteine may cause bronchospasm in some patients when used in the pulmonary system, animals with bronchospastic diseases should be monitored carefully when using this agent.

### Adverse Effects

When given orally for acetaminophen toxicity, acetylcysteine can cause GI effects (nausea, vomiting) and rarely, urticaria. Because the taste of the solution is very bad, taste-masking agents (*e.g.*, colas, juices) have been used. Since oral dosing of these drugs may be very difficult in animals, gastric or duodenal tubes may be necessary.

Intravenous administration appears to be very well tolerated in veterinary patients. IV boluses in humans have caused changes in blood pressure (hyper-, hypotension), GI effects and allergic reactions.

Rare adverse effects reported when acetylcysteine is administered into the pulmonary tract, include: hypersensitivity, chest tightness, bronchoconstriction, and bronchial or tracheal irritation.

### Reproductive/Nursing Safety

Reproduction studies in rabbits and rats have not demonstrated any evidence of teratogenic or embryotoxic effects when used in doses up to 17 times normal. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if acetylcysteine enters milk. Use caution when administering to a nursing dam.

### Overdosage/Acute Toxicity

The LD<sub>50</sub> of acetylcysteine in dogs is 1 g/kg (PO) and 700 mg/kg (IV). It is believed that acetylcysteine is quite safe (with the exception of the adverse effects listed above) in most overdose situations.

### Drug Interactions

■**ACTIVATED CHARCOAL:** The use of activated charcoal as a gut adsorbent of acetaminophen is controversial, as charcoal may also adsorb acetylcysteine.

Because cats can develop methemoglobinemia very rapidly after ingestion of acetaminophen, do not delay acetylcysteine treatment and preferably give the first dose intravenously. If using the solution (not labeled for injectable use), it is preferable to use a 0.2 micron in-line filter.

### Doses

#### ■**DOGS:**

For acetaminophen toxicity:

- A 2–3 hour wait between activated charcoal and PO administration of acetylcysteine (NAC) is necessary. Give NAC as an initial oral loading dose of 140 mg/kg (dilute to 5% in dextrose or sterile water), followed by 70 mg/kg PO four times daily (q6h) for 7 treatments. With ingestion of massive quantities, some authors suggest using a 280 mg/kg loading dose and continuing treatment for 12–17 doses. May also be given IV after diluting to 5% and given via slow IV over 15–20 minutes. Additional therapy may include IV fluids, blood or *Oxyglobin*®, ascorbic acid and SAME. (Wisner 2006)
- 150 mg/kg PO or IV initially, then 50 mg/kg q4h for 17 additional doses (Bailey 1986)
- Loading dose of 140 mg/kg PO, then 70 mg/kg PO every 6 hours for 7 treatments (Grauer & Hjelle 1988)

For phenol toxicity:

- 140 mg/kg PO or IV initially, then 50 mg/kg q4h for 3 days. May be partially effective to reduce hepatic and renal injury. Resultant methemoglobinemia should be treated with ascorbic acid or methylene blue. (Dorman & Dye 2005)

For hepatotoxicity secondary to xylitol poisoning:

- Acetylcysteine at 140–280 mg/kg loading dose IV, PO; followed by 70 mg/kg four times daily; vitamin K (phytonadione) at 1.25–2.5 mg/kg PO twice daily; plasma, SAME at 20 mg/kg/day PO; vitamin E at 100–400 Units twice daily PO; and silymarin 20–50 mg/kg/day PO. (Talcott 2008)

For degenerative myelopathy:

- 25 mg/kg PO q8h for 2 weeks, then q8h every other day. The 20% solution should be diluted to 5% with chicken broth or suitable diluent. Used in conjunction with aminocaproic acid (500 mg per dog PO q8h indefinitely). Other treatments may include prednisone (0.25–0.5 mg/kg PO daily for 10 days then every other day), Vitamin C (1000 mg PO q12h) and Vitamin E (1000 Units PO q12h). **Note:** No treatment has been shown to be effective in published trials. (Shell 2003)

#### ■**CATS:**

For acetaminophen toxicity:

- A 2–3 hour wait between activated charcoal and PO administration of acetylcysteine (NAC) is necessary. Give NAC as an initial oral loading dose of 140 mg/kg (dilute to 5% in dextrose or sterile water), followed by 70 mg/kg PO four times daily (q6h) for 7 treatments. With ingestion of massive quantities, some authors suggest using a 280 mg/kg loading dose and continuing treatment for 12–17 doses. May also be given IV after diluting to 5% and given via slow IV over 15–20 minutes. Additional therapy may include IV fluids, blood or *Oxyglobin*®, ascorbic acid and SAME. (Wisner 2006)

For phenol toxicity:

- 140 mg/kg PO or IV initially, then 50 mg/kg q4h for 3 days. May be partially effective to reduce hepatic and renal injury. Resultant methemoglobinemia should be treated with ascorbic acid or methylene blue. (Dorman & Dye 2005)

For adjunctive treatment of hepatic lipidosis (see also Carnitine):

- Identify underlying cause of anorexia and provide a protein replete feline diet, give acetylcysteine (NAC) at 140 mg/kg IV over 20 minutes, then 70 mg/kg IV q12h; dilute 10% NAC with saline 1:4 and administer IV using a 0.25 micron filter; correct hypokalemia and hypophosphatemia, beware of electrolyte changes with re-feeding phenomenon (Center 2006)

#### ■**HORSES:**

To help break up chondroids in the guttural pouch:

- Instill 20% solution (Foreman 1999)

In neonatal foals to break up meconium refractory to repeated enemas:

- 8 grams in 20 g sodium bicarbonate in 200 mL water (pH of 7.6), give as enema as needed to effect (Freeman 1999)
- With foal in lateral recumbency, insert a 30 french foley catheter with a 30 cc bulb for a retention enema. Using gravity flow, infuse slowly 100–200 mL of 4% acetylcysteine solution and retain for 30–45 minutes. IV fluids and pain medication should be considered. Monitor for possible bladder distention. (Pusterla *et al.* 2003)

## Monitoring

When used for acetaminophen poisoning:

- Hepatic enzymes (particularly in dogs)
- Acetaminophen level, if available (particularly in dogs)
- Hemogram, with methemoglobin value (particularly in cats)
- Serum electrolytes, hydration status

## Client Information

- This agent should be used in a clinically supervised setting only

## Chemistry/Synonyms

The N-acetyl derivative of L-cysteine, acetylcysteine occurs as a white, crystalline powder with a slight acetic odor. It is freely soluble in water or alcohol.

Acetylcysteine may also be known as: N-acetylcysteine or N-acetyl-L-cysteine, NAC, 5052 acetylcysteinum, NSC-111180, *Acetadote*®, *Mucomyst*® or *ACC*®.

## Storage/Stability

When unopened, vials of sodium acetylcysteine should be stored at room temperature (15–30°C). After opening, vials should be kept refrigerated and used within 96 hours. The product labeled for IV use states to use within 24 hours.

## Compatibility/Compounding Considerations

Acetylcysteine is **incompatible** with oxidizing agents; solutions can become discolored and liberate hydrogen sulfide when exposed to rubber, copper, iron, and during autoclaving. It does not react to aluminum, stainless steel, glass or plastic. If the solution becomes light purple in color, potency is not appreciably affected, but it is best to use non-reactive materials when giving the drug via nebulization. Acetylcysteine solutions are **incompatible** with amphotericin B, ampicillin sodium, erythromycin lactobionate, tetracycline, oxytetracycline, iodized oil, hydrogen peroxide and trypsin.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Acetylcysteine injection: 20% (200 mg/mL) in 30 mL single-dose vials, preservative free; *Acetadote*® (Cumberland); (Rx)

Acetylcysteine Oral Solution: 10% & 20% (as sodium) in 4 mL, 10 mL, & 30 mL vials; *Mucomyst*® (Sandoz); generic; (Rx)

Acetylcysteine Inhalation Solution: 10% & 20% (as sodium) in 4 mL, 10 mL, 30 mL vials & 100 mL vials (20% only); *Mucomyst*® (Apothecon); generic (Rx) **Note:** If using this product for dilution and then intravenous dosing, it is preferable to use a 0.2 micron in-line filter.

Acetylcysteine is also available in the USA as an oral OTC nutritional product. It is usually labeled as NAC N-Acetylcysteine and is commonly found as 600 mg capsules.

## ACITRETIN

(*ase-a-tre-tin*) Soriatane®

RETINOID

**Note:** Originally etretinate was used for certain dermatologic indications in small animals (primarily dogs). It has been withdrawn from the market and replaced with acitretin, an active metabolite of etretinate with the same indications, but a much shorter half-life. Much of the information below is extrapolated from etretinate data.

### Prescriber Highlights

- Retinoid that may be useful for certain dermatologic conditions in small animals**
- Contraindications:** Pregnancy; **Caution:** Cardiovascular disease, hypertriglyceridemia or sensitivity to retinoids
- Adverse Effects:** Limited experience; appears to be fairly well tolerated in small animals **Potentially:** anorexia/vomiting or diarrhea, cracking of foot

pads, pruritus, ventral abdominal erythema, polydipsia, lassitude, joint pain/stiffness, eyelid abnormalities & conjunctivitis (KCS), swollen tongue, & behavioral changes

- **Known teratogen; do not use in households with pregnant women present (Plumb's recommendation)**
  - **May be very expensive; may need to compound smaller capsules for small dogs or cats**
  - **Drug-drug; drug-lab interactions**
- 

### Uses/Indications

Acitretin may be useful in the treatment of canine lamellar ichthyosis, solar-induced precancerous lesions in Dalmatians or bull Terriers, actinic keratoses, squamous cell carcinomas, and intracutaneous cornifying epitheliomas (multiple keratoacanthomas).

While the drug has provided effective treatment of idiopathic seborrhea (particularly in cocker spaniels), it is not effective in treating the ceruminous otitis that may also be present. Results have been disappointing in treating idiopathic seborrheas seen in basset hounds and West Highland terriers.

Acitretin's usage in cats is very limited, but etretinate has shown some usefulness in treating paraneoplastic actinic keratosis, solar-induced squamous cell carcinoma and Bowen's Disease in this species.

### Pharmacology/Actions

Acitretin is a synthetic retinoid agent potentially useful in the treatment of several disorders related to abnormal keratinization and/or sebaceous gland abnormalities in small animals. The drug has some antiinflammatory activity, but its exact mechanism of action is not known.

### Pharmacokinetics

Acitretin absorption is enhanced by food in the gut and is highly bound to plasma proteins. The drug is metabolized to conjugate forms that are excreted in the bile and urine. Terminal half-life averages 50 hours in humans.

### Contraindications/Precautions/Warnings

Acitretin use should not be considered when the following conditions exist: cardiovascular disease, hypertriglyceridemia or known sensitivity to acitretin. Use with caution in patients with renal or hepatic failure.

### Adverse Effects

Veterinary experience with this medication is limited, but the incidence of adverse effects appears to be less in companion animals than in people. Most animals treated (thus far) do not exhibit adverse effects. Potential adverse effects include: anorexia/vomiting/diarrhea, cracking of foot pads, pruritus, ventral abdominal erythema, polydipsia, lassitude, joint pain/stiffness, eyelid abnormalities and conjunctivitis (KCS), swollen tongue, and behavioral changes.

The most common adverse effect seen in cats is anorexia with resultant weight loss. If cats develop adverse effects, the time between doses may be prolonged (*e.g.*, Every other week give every other day) to reduce the total dose given.

### Reproductive/Nursing Safety

Acitretin is a known teratogen. Major anomalies have been reported in children of women receiving acitretin. It should not be handled by pregnant women nor used in a household where women are pregnant or planning to become pregnant. It should be considered absolutely contraindicated in pregnant veterinary patients. In humans, the FDA categorizes this drug as category *X* for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

Acitretin is excreted in rat milk. At this time, it cannot be recommended for use in nursing dams.

### Overdosage/Acute Toxicity

Information on overdoses with this agent remains limited. One oral overdose (525 mg) in a human patient resulted only in vomiting. The oral LD<sub>50</sub> in rats and mice is >4 grams/kg.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acitretin and may be of significance in veterinary patients:

- **ALCOHOL:** Acitretin can form etretinate in the presence of alcohol; etretinate is a teratogen with an extremely long terminal half-life and (can persist in adipose tissue for years)
- **HEPATOTOXIC DRUGS** (especially **methotrexate** and potentially **anabolic steroids, androgens, asparaginase, erythromycins, estrogens, fluconazole, halothane, ketoconazole, sulfonamides** or **valproic acid**): May be increased potential for hepatotoxicity
- **OTHER RETINOIDS** (**isotretinoin, tretinoin, or vitamin A**): May cause additive toxic effects.
- **TETRACYCLINES:** Acitretin with tetracyclines may increase the potential for the occurrence of pseudotumor cerebri (cerebral edema and increased CSF pressure)

### Laboratory Considerations

- In humans, acitretin may cause significant increases in **plasma triglycerides, serum cholesterol, serum ALT (SGPT), serum AST (SGOT), and serum LDH concentrations. Serum HDL** (high density lipoprotein) concentrations may be decreased. Veterinary significance of these effects is unclear.

### Doses

#### ■ DOGS:

For dermatologic conditions where retinoids may be useful:

- a) 0.5–1 mg/kg PO once daily (Kwochka 2003)
- b) 0.5–2 mg/kg PO once daily (Merchant 2000)

c) For sebaceous adenitis: 0.5–1 mg/kg once daily PO (Bloom 2006)

#### ■CATS:

For actinic keratosis/solar-induced squamous cell carcinoma; or Bowen's Disease:

- 10 mg per cat once daily PO. (Power & Ihrke 1995) **Note:** This dose is for etretinate, but as the smallest capsule is 10 mg, this dose may need to suffice as well for cats.
- For Bowen's Disease: 3 mg/kg/day (Guaguere *et al.* 1999), (Hnilica 2003)

#### Monitoring

- Efficacy
- Liver function tests (baseline and if clinical signs appear)
- Schirmer tear tests (monthly—especially in older dogs)

#### Client Information

- Acitretin should not be handled by pregnant women in the household; veterinarians must take responsibility to educate clients of the potential risk of ingestion by pregnant females
- Food will increase the absorption of acitretin. To reduce variability of absorption, either have clients consistently give with meals or when fasted
- Long-term therapy can be quite expensive

#### Chemistry/Synonyms

Acitretin, a synthetic retinoid occurs as a yellow to greenish-yellow powder.

Acitretin may also be known as: acitretinum, etretin, Ro-10-1670, Ro-10-1670/000, *Soriatane*®, *Acetrizic Acid*®, or *Iodophil Viscous*®.

#### Storage/Stability

Store at room temperature and protected from light. After bottle is opened, protect from high temperature and humidity.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### HUMAN-LABELED PRODUCTS:

Acitretin Capsules: 10 mg, 17.5 mg, 22.5 mg & 25 mg; *Soriatane*® (Connetics); (Rx)

#### ACYCLOVIR

(ay-sye-kloe-vir) Zovirax®

ANTIVIRAL (HERPES)

#### Prescriber Highlights

- Used primarily in birds for Pacheco's disease; may be useful in cats for Herpes infection
  - If given rapidly IV, may be nephrotoxic
  - Oral use may cause GI distress
  - Reduce dosage with renal insufficiency
  - May be fetotoxic at high dosages
- 

#### Uses/Indications

Acyclovir may be useful in treating herpes infections in a variety of avian species and in cats with corneal or conjunctival herpes infections. Its use in veterinary medicine is not well established, however, and it should be used with caution. Acyclovir has relatively mild activity against *Feline Herpesvirus-1* when compared to some of the newer antiviral agents (*e.g.*, ganciclovir, cidofovir, or penciclovir).

Acyclovir is being investigated as a treatment for equine herpes virus type-1 myeloencephalopathy in horses, but clinical efficacy has not yet been proven and the drug's poor oral bioavailability is problematic. There continues to be interest in finding a dosing regimen that can achieve therapeutic levels and be economically viable, particularly since the drug's use during a recent outbreak appeared to have some efficacy in reducing morbidity and mortality (not statistically proven). Also, intravenous acyclovir may be economically feasible to treat some neonatal foals.

## Pharmacology/Actions

Acyclovir has antiviral activity against a variety of viruses including herpes simplex (types I and II), cytomegalovirus, *Epstein-Barr*, and *varicella-Zoster*. It is preferentially taken up by these viruses, and converted into the active triphosphate form where it inhibits viral DNA replication.

## Pharmacokinetics

In dogs, acyclovir bioavailability varies with the dose. At doses of 20 mg/kg and below, bioavailability is about 80%, but declines to about 50% at 50 mg/kg.

Bioavailability in horses after oral administration is very low (<4%) and oral doses of up to 20 mg/kg may not yield sufficient levels to treat equine herpes virus. Elimination half-lives in dogs, cats and horses are approximately 3 hours, 2.6 hours, and 10 hours, respectively.

In humans, acyclovir is poorly absorbed after oral administration (approx. 20%) and absorption is not significantly affected by the presence of food. It is widely distributed throughout body tissues and fluids including the brain, semen, and CSF. It has low protein binding and crosses the placenta. Acyclovir is primarily hepatically metabolized and has a half-life of about 3 hours in humans. Renal disease does not significantly alter half-life unless anuria is present.

## Contraindications/Precautions/Warnings

Acyclovir is potentially contraindicated (assess risk vs. benefit) during dehydrated states, pre-existing renal function impairment, hypersensitivity to it or other related antivirals, neurologic deficits, or previous neurologic reactions to other cytotoxic drugs.

## Adverse Effects

With parenteral therapy potential adverse effects include thrombophlebitis, acute renal failure, and ecephalopathologic changes (rare). GI disturbances may occur with either oral or parenteral therapy.

Preliminary effects noted in cats, include leukopenia and anemias, which are apparently reversible with discontinuation of therapy.

## Reproductive/Nursing Safety

Acyclovir crosses the placenta, but rodent studies have not demonstrated any teratogenic effects thus far. Acyclovir crosses into maternal milk but associated adverse effects have not been noted. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Acyclovir concentrations in milk of women following oral administration have ranged from 0.6 to 4.1 times those found in plasma. These concentrations would potentially expose the breastfeeding infant to a dose of acyclovir up to 0.3 mg/kg/day. Data for animals was not located. Use caution when administering to a nursing patient.

## Overdosage/Acute Toxicity

Acute oral overdosage is unlikely to cause significant toxicity. GI signs predominate although renal failure is possible with higher doses. Crystalluria and elevated renal values occurred at 188.7 mg/kg in a dog. There were 85 exposures to acyclovir reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 75 were dogs with 9 showing clinical signs. The remaining 10 cases were cats with 4 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, diarrhea, and lethargy. Common findings in cats include vomiting.

Consider decontamination at 150 mg/kg or higher. Below 150 mg/kg, GI signs will likely predominate.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving acyclovir and may be of significance in veterinary patients:

- **NEPHROTOXIC MEDICATIONS:** Concomitant administration of IV acyclovir with nephrotoxic medications may increase the potential for nephrotoxicity occurring. Amphotericin B may potentiate the antiviral effects of acyclovir but it also increases chances for development of nephrotoxicity.
- **ZIDOVUDINE:** Concomitant use with zidovudine may cause additional CNS depression.

## Doses

### ■ BIRDS:

For treatment of Pacheco's Disease:

- 80 mg/kg PO q8h or 40 mg/kg q8h IM (do not use parenterally for more than 72 hours as it can cause tissue necrosis at site of injection) (Oglesbee & Bishop 1994)
- 80 mg/kg in oral suspension once daily PO; mix suspension with peanut butter or add to drinking water 50 mg in 4 oz of water for 7–14 days) (Jenkins 1993)
- When birds are being individually treated: 80 mg/kg PO or IM twice daily (Speer 1999)
- For prophylaxis: Exposed birds are given 25 mg/kg IM once (give IM with caution as it is very irritating), and then acyclovir is added to drinking water at 1 mg/mL and to the food at 400 mg/quart of seed for a minimum of 7 days. Quaker parrots have been treated with a gavage of acyclovir at 80 mg/kg q8h for 7 days. (Johnson-Delaney 2005)

### ■ CATS:

For Herpesvirus-1 infections:

- 10–25 mg/kg PO twice daily. Never begin therapy until diagnostic evaluation is completed. May be toxic in cats; monitor CBC every 2–3 weeks. (Lappin 2003)

### ■ HORSES:

- Although efficacy is undetermined, anecdotal use of acyclovir orally at 10 mg/kg PO 5 times daily or 20 mg/kg PO q8h may have had some efficacy in preventing or treating horses during EHV-1 outbreaks. *However, the drug's very low oral bioavailability suggests that oral dosing is unlikely to be of much benefit. Additional studies may further clarify the usefulness of such dosing regimens—Plumb 2010; based upon (Wilkins 2004) & (Henninger et al. 2007)*

## Monitoring

- Renal function tests (BUN, Serum Cr) with prolonged or IV therapy
- Cats: CBC

## Chemistry/Synonyms

An antiviral agent, acyclovir (also known as ACV or acycloguanosine), occurs as a white, crystalline powder. 1.3 mg are soluble in one mL of water. Acyclovir sodium has a solubility of greater than 100 mg/mL in water. However, at a pH of 7.4 at 37°C it is practically all unionized and has a solubility of only 2.5 mg/mL in water. There is 4.2 mEq of sodium in each gram of acyclovir sodium.

Acyclovir may be known as: aciclovirum, acycloguanosine, acyclovir, BW-248U, *Zovirax*®, *Acic*®, *Aciclobene*®, *Aciclotyrol*®, *Acivir*®, *Acyrax*®, *Cicloviral*®, *Geavir*®, *Herpotern*®, *Isavir*®, *Nycovir*®, *Supraviran*®, *Viclovir*®, *Virherpes*®, *Viroxy*®, *Xorox*®, or *Zovirax*®.

## Storage/Stability

Acyclovir capsules and tablets should be stored in tight, light resistant containers at room temperature. Acyclovir suspension and sodium sterile powder should be stored at room temperature.

## Compatibility/Compounding Considerations

When reconstituting acyclovir sodium do not use bacteriostatic water with parabens as precipitation may occur. The manufacturer does not recommend using bacteriostatic water for injection with benzyl alcohol because of the potential toxicity in neonates. After reconstitution with 50–100 mL of a standard electrolyte or dextrose solution, the resulting solution is stable at 25°C for 24 hours. Acyclovir is reportedly **incompatible** with biologic or colloidal products (*e.g.*, blood products or protein containing solutions). It is also **incompatible** with dopamine HCl, dobutamine, fludarabine phosphate, foscarnet sodium, meperidine and morphine sulfate. Many other drugs have been shown to be **compatible** in specific situations. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Acyclovir Oral Tablets: 400 mg & 800 mg; *Zovirax*® (GlaxoSmithKline); generic; (Rx)

Acyclovir Oral Capsules: 200 mg; *Zovirax*® (GlaxoSmithKline); generic; (Rx)

Acyclovir Oral Suspension: 200 mg/5 mL in 473 mL; *Zovirax*® (GlaxoSmithKline); generic; (Rx)

Acyclovir Sodium Injection (for IV infusion only): 50 mg/mL (as sodium); generic; (Rx)

Acyclovir Powder for Injection: 500 mg/vial (as sodium) in 10 mL vials; 1000 mg/vial (as sodium) in 20 mL vials; generic; (Rx)

Acyclovir Ointment: 5% (50 mg/g) in 15 g; *Zovirax*® (Biovail); (Rx)

Acyclovir Cream: 5% (50 mg/g) in 2g tubes; *Zovirax*® (Biovail); (Rx)

---

## AGLEPRISTONE

(a-gle-pris-tone) Alizin®, Alizine®

INJECTABLE PROGESTERONE BLOCKER

### Prescriber Highlights

- **Injectable progesterone blocker indicated for pregnancy termination in bitches; may also be of benefit in inducing parturition or in treating pyometra complex in dogs & progesterone-dependent mammary hyperplasia in cats**
- **Not currently available in USA; marketed for use in dogs in Europe, South America, etc.**
- **Localized injection site reactions are most commonly noted adverse effect; other adverse effects reported in >5% of patients include: anorexia (25%), excitation (23%), depression (21%), & diarrhea (13%)**

---

## Uses/Indications

Aglepristone is labeled (in the U.K. and elsewhere) for pregnancy termination in bitches up to 45 days after mating.

In dogs, aglepristone may prove useful in inducing parturition or treating pyometra complex (often in combination with a prostaglandin F analog such as cloprostenol).

In cats, it may be of benefit for pregnancy termination (one study documented 87% efficacy when administered at the recommended dog dose at day 25) or in treating mammary hyperplasias or pyometras.

## Pharmacology/Actions

Aglepristone is a synthetic steroid that binds to the progesterone (P4) receptors thereby preventing biological effects from progesterone. In dogs, it has an affinity for uterine progesterone receptors approximately three times that of progesterone. In queens, affinity is approximately nine times greater than the endogenous hormone. As progesterone is necessary for maintaining pregnancy, pregnancy can be terminated or parturition induced. Abortion occurs within 7 days of administration.

Benign feline mammary hyperplasias (fibroadenomatous hyperplasia; FAHs) are usually under the influence of progesterone and aglepristone can be used to medically treat this condition.

When used for treating pyometra in dogs, aglepristone can cause opening of the cervix and resumption of miometrial contractility.

Within 24 hours of administration, aglepristone does not appreciably affect circulating plasma levels of progesterone, cortisol, prostaglandins or oxytocin. Plasma levels of prolactin are increased within 12 hours when used in dogs during mid-pregnancy which is probably the cause of mammary gland congestion often seen in these dogs.

Aglepristone also binds to glucocorticoid receptors but has no glucocorticoid activity; it can prevent endogenous or exogenously administered glucocorticoids from binding and acting at these sites.

### Pharmacokinetics

In dogs, after injecting two doses of 10mg/kg 24 hours apart, peak serum levels occur about 2.5 days later and mean residence time is about 6 days. The majority (90%) of the drug is excreted via the feces.

### Contraindications/Precautions/Warnings

Aglepristone is contraindicated in patients who have documented hypersensitivity to it and during pregnancy, unless used for pregnancy termination or inducing parturition.

When being considered for use in treating pyometra in bitches, peritonitis must be ruled out before using.

Because of its antagonistic effects on glucocorticoid receptors, the drug should not be used in patients with hypoadrenocorticism or in dogs with a genetic predisposition to hypoadrenocorticism.

The manufacturer does not recommend using the product in patients in poor health, with diabetes, or with impaired hepatic or renal function as there is no data documenting its safety with these conditions.

### Adverse Effects

As the product is in an oil-alcohol base, localized pain and inflammatory reactions (edema, skin thickening, ulceration, and localized lymph node enlargement) can be noted at the injection site. Resolution of pain generally occurs shortly after injection; other injection site reactions usually resolve within 2–4 weeks. The manufacturer recommends light massage of the injection site after administration. Larger dogs should not receive more than 5 mL at any one subcutaneous injection site. One source states that severe injection reactions can be avoided if the drug is administered into the scruff of the neck.

Systemic adverse effects reported from field trials include: anorexia (25%), excitation (23%), depression (21%), vomiting (2%), diarrhea (13%) and uterine infections (3.4%). Transient changes in hematologic (RBC, WBC indices) or biochemical (BUN, creatinine, chloride, potassium, sodium, liver enzymes) laboratory parameters were seen in <5% of dogs treated.

When used for pregnancy termination, a brown mucoid vaginal discharge can be seen approximately 24 hours before fetal expulsion. This discharge can persist for an additional 3–5 days. If used in bitches after the 20th day of gestation, abortion may be accompanied with other signs associated with parturition (*e.g.*, inappetence, restlessness, mammary congestion).

Bitches may return to estrus in as little as 45 days after pregnancy termination.

### Reproductive/Nursing Safety

Unless used for pregnancy termination or at term to induce parturition, aglepristone is contraindicated during pregnancy.

One study (Baan *et al.* 2005) using aglepristone to induce parturition (day 58) demonstrated no significant differences in weight gain between those puppies in the treatment group versus the control group suggesting that aglepristone did not have effect on milk production of treated bitches.

### Overdosage/Acute Toxicity

When administered at 3X (30mg/kg) recommended doses, bitches demonstrated no untoward systemic effects. Localized reactions were noted at the injection site, presumably due to the larger volumes injected.

### Drug Interactions

No documented drug interactions were noted. Theoretically, the following interactions may occur with aglepristone:

- **PROGESTINS (natural or synthetic):** Could reduce the efficacy of aglepristone
- **GLUCOCORTICIDS:** Aglepristone could reduce the efficacy of glucocorticoid treatment
- **KETOCONAZOLE, ITRACONAZOLE, ERYTHROMYCIN:** The manufacturer states that although there is no data, these drugs may interact with aglepristone

### Laboratory Considerations

None were noted

### Doses

**WARNING:** As accidental injection of this product can induce abortion; it should not be administered or handled by pregnant women. Accidental injection can also cause severe pain, intense swelling and ischemic necrosis that can lead to serious sequelae, including loss of a digit. In cases of accidental injection, prompt medical attention must be sought.

#### ■ DOGS:

To terminate pregnancy (up to day 45):

- a) 10 mg/kg (0.33 mL/kg) subcutaneous injection only. Repeat one time, 24 hours after the first injection. A maximum of 5 mL should be injected at any one site. Light massage of the injection site is recommended after administration. (Label information; *Alizin*®—Virbac U.K.)

To induce parturition:

- a) At day 60 (post-estimated LH surge): 15 mg/kg SC and another dose 24 hours later. Subsequently, give oxytocin 0.15 Units/kg SC at hourly intervals until last pup is delivered. Additional studies confirming efficacy and safety are warranted before routine clinical application can be recommended. (Fieni, F. & Gogny 2009)

b) On or after day 58 of pregnancy: 15 mg/kg subcutaneously; repeat in 9 hours. In treated group, expulsion of first pup occurred between 32 and 56 hours after treatment. Use standard protocols to assist with birth (including oxytocin to assist in pup expulsion if necessary) or to intervene if parturition does not proceed. (Baan *et al.* 2005)

As an adjunct to treating pyometra/metritis:

a) When attempting to preserve fertility (mating should occur in the first or second estrus post-treatment) in bitches up to 5 years old with a lack of detectable ovarian cysts: Treatment begun at week 2-4 of diestrus with a single SC injection of aglepristone at 10 mg/kg. Doses are repeated at days 2, 7, and 14. During first 7 days, daily injections of amoxicillin/clavulanic acid were also given. (Jurka *et al.* 2010)

b) For closed cervix: 6 mg/kg twice daily on the first day followed by the same dose once daily on days 2, 3, and 4. Some prefer using larger doses (10mg/kg) once daily on days 1, 3, and 8, then follow up also on days 15 and 28 depending on the bitch's condition. (Romagnoli 2003)

c) For metritis: 10 mg/kg subcutaneously once daily on days 1, 2 and 8.

For open or closed pyometra: aglepristone 10 mg/kg subcutaneously once daily on days 1, 2 and 8 and cloprostenol 1 microgram/kg subcutaneously on days 3 to 7. Bitches with closed pyometra or with elevated temperature or dehydration should also receive intravenous fluids and antibiotics (*e.g.*, amoxicillin/clavulanate at 24 mg/kg/day on days 1-5). If pyometra has not resolved, additional aglepristone doses should be given on days 14 and 28. (Fieni, F 2006)

d) 10 mg/kg SC on days 1, 2, 8, 15, & 29. Give misoprostol 10 micrograms/kg PO twice daily on days 3 through 12. Approximately 75% of cases show significant clinical improvement without developing the adverse effects associated with the prostaglandins (F2alpha, cloprostenol). (Fontbonne 2007)

#### ■CATS:

For treating mammary fibroadenomatous hyperplasia:

a) 20 mg/kg aglepristone subcutaneously once weekly until resolution of signs. Cats who present with heart rates greater than 200 BPM should receive atenolol at 6.25 mg (total dose) until heart rate is less than 200 BPM with regression in size of the mammary glands. (Gorlinger *et al.* 2002)

b) 10 mg/kg SC on two consecutive days, once weekly. Complete mammary regression occurs on average 3-4 weeks once treatment begun. Relapses can occur, particularly in cats that have been treated with a long acting progestin (medroxyprogesterone acetate). These cats should be treated with aglepristone for 5 weeks. (Jurka & Max 2009)

To terminate pregnancy (up to day 45):

a) 15 mg/kg SC twice 24 hours apart. Efficacy is 95% if administered before implantation, 85% if after implantation. Termination occurs within 3 days in 50% of queens. (Fontbonne 2007)

### Monitoring

- Clinical efficacy
- For pregnancy termination: ultrasound 10 days after treatment and at least 30 days after mating
- Adverse effects (see above)

### Client Information

- Only veterinary professionals should handle and administer this product
- When used for pregnancy termination in the bitch, clients should understand that aglepristone might only be 95% effective in terminating pregnancy when used between days 26-45
- A brown mucoid vaginal discharge can be seen approximately 24 hours before fetal expulsion
- Bitch may exhibit the following after treatment: lack of appetite, excitement, restlessness or depression, vomiting, or diarrhea
- Clients should be instructed to contact veterinarian if bitch exhibits a purulent or hemorrhagic discharge after treatment or if vaginal discharge persists 3 weeks after treatment
- When used for pyometra, there is a substantial risk of treatment failure and ovario-hysterectomy may be required

### Chemistry/Synonyms

Aglepristone is a synthetic steroid. The manufactured injectable dosage form is in a clear, yellow, oily, non-aqueous vehicle that contains arachis oil and ethanol. No additional antimicrobial agent is added to the injection.

Aglepristone may also be known as RU-534, *Alizine*®, or *Alizin*®.

### Storage/Stability

Aglepristone injection should be stored below 25°C and protected from light. The manufacturer recommends using the product within 28 days of withdrawing the first dose.

### Compatibility/Compounding Considerations

Although no incompatibilities have been reported, due to the product's oil/alcohol vehicle formulation it should not be mixed with any other medication.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

**Note:** Not presently available or approved for use in the USA. In several countries:

Aglepristone 30 mg/mL in 5 mL & 10 mL vials; *Alizine*® or *Alizin*® (Virbac); (Rx)

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

**HUMAN-LABELED PRODUCTS:** None

## ALBENDAZOLE

(al-ben-da-zole) Albenza®, Valbazen®

### ANTIPARASITIC

### Prescriber Highlights

- **Broad spectrum against a variety of nematodes, cestodes & protozoa; labeled for cattle & sheep (suspension only)**
  - **Contraindicated with hepatic failure, pregnancy, lactating dairy cattle**
  - **May cause GI effects (including hepatic dysfunction) & rarely blood dyscrasias (aplastic anemia)**
  - **Do not use in pigeons, doves or crias**
- 

## Uses/Indications

Albendazole is labeled for the following endoparasites of cattle (not lactating): *Ostertagia ostertagi*, *Haemonchus* spp., *Trichostrongylus* spp., *Nematodius* spp., *Cooperia* spp., *Bunostomum phlebotomum*, *Oesphagostomum* spp., *Dictacaulus viviparus* (adult and 4th stage larva), *Fasciola hepatica* (adults), and *Moniezia* spp.

In sheep, albendazole is FDA-approved for treating the following endoparasites: *Ostertagia circumcincta*, *Marshallagia marshalli*, *Haemonchus contortus*, *Trichostrongylus* spp., *Nematodius* spp., *Cooperia* spp., *Oesphagostomum* spp., *Chibertia ovina*, *Dictacaulus filaria*, *Fasciola hepatica*, *Fascioides magna*, *Moniezia expansa*, and *Thysanosoma actinoides*.

Albendazole is also used (extra-label) in small mammals, goats and swine for endoparasite control.

In cats, albendazole has been used to treat *Paragonimus kellicotti* infections. In dogs and cats, albendazole has been used to treat capillariasis. In dogs, albendazole has been used to treat Filaroides infections. It has been used for treating giardia infections in small animals, but concerns about bone marrow toxicity have diminished enthusiasm for the drug's use.

## Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

## Pharmacokinetics

Pharmacokinetic data for albendazole in cattle, dogs and cats was not located. The drug is thought better absorbed orally than other benzimidazoles. Approximately 47% of an oral dose was recovered (as metabolites) in the urine over a 9-day period.

After oral dosing in sheep, the parent compound was either not detectable or only transiently detectable in plasma due to a very rapid first-pass effect. The active metabolites, albendazole sulphoxide and albendazole sulfone, reached peak plasma concentrations 20 hours after dosing.

## Contraindications/Precautions/Warnings

The drug is not FDA-approved for use in lactating dairy cattle. The manufacturer recommends not administering to female cattle during the first 45 days of pregnancy or for 45 days after removal of bulls. In sheep, it should not be administered to ewes during the first 30 days of pregnancy or for 30 days after removal of rams.

Pigeons and doves may be susceptible to albendazole and fenbendazole toxicity (intestinal crypt epithelial necrosis and bone marrow hypoplasia).

Nine alpaca crias receiving albendazole at dosages from 33–100 mg/kg/day once daily for 4 consecutive days developed neutropenia and severe watery diarrhea. All required treatment and 7 of 9 animals treated died or were euthanized secondary to sepsis or multiple organ failure. (Gruntman & Nolen-Walston 2006)

In humans, caution is recommended for use in patients with liver or hematologic diseases.

Albendazole was implicated as being an oncogen in 1984, but subsequent studies were unable to demonstrate any oncogenic or carcinogenic activity of the drug.

## Adverse Effects

Albendazole is tolerated without significant adverse effects when dosed in cattle or sheep at recommended dosages.

Dogs treated at 50 mg/kg twice daily may develop anorexia. Cats may exhibit clinical signs of mild lethargy, depression, anorexia, and resistance to receiving the medication when albendazole is used to treat *Paragonimus*. Albendazole has been implicated in causing aplastic anemia in dogs, cats, and humans.

## Reproductive/Nursing Safety

Albendazole has been associated with teratogenic and embryotoxic effects in rats, rabbits and sheep when given early in pregnancy. The manufacturer recommends not administering to female cattle during the first 45 days of pregnancy or for 45 days after removal of bulls. In sheep, it should not be administered to ewes during the first 30 days of pregnancy or for 30 days after removal of rams.

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Safety during nursing has not been established.

## Knowledge & Toxicity

## Overdosage/Toxicity

Doses of 300 mg/kg (30X recommended) and 200 mg/kg (20X) have caused death in cattle and sheep, respectively. Doses of 45 mg/kg (4.5X those recommended) did not cause any adverse effects in cattle tested. Cats receiving 100 mg/kg/day for 14–21 days showed signs of weight loss, neutropenia and mental dullness.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving albendazole and may be of significance in veterinary patients:

■ **CIMETIDINE:** Increased albendazole levels in bile and cystic fluid

■ **DEXAMETHASONE:** May increase albendazole serum levels

■ **PRAZIQUANTEL:** May increase albendazole serum levels

## Doses

### ■ DOGS:

For *Filaroides hirthi* infections:

a) 50 mg/kg q12h PO for 5 days; repeat in 21 days. Clinical signs may suddenly worsen during therapy, presumably due to a reaction to worm death. (Hawkins *et al.* 1989)

b) 25 mg/kg PO q12h for 5 days; may repeat in 2 weeks (also for *Oslerus osleri*) (Reinemeyer 1995)

For *Filaroides osleri* (also known as *Oslerus osleri*) infections:

a) 9.5 mg/kg for 55 days or 25 mg/kg PO twice daily for 5 days. Repeat therapy in 2 weeks. (Todd *et al.* 1985)

For *Capillaria plica*:

a) 50 mg/kg q12h for 10–14 days. May cause anorexia. (Brown & Barsanti 1989)

For *Paragonimus kellicotti*:

a) 25 mg/kg PO q12h for 14 days (Reinemeyer 1995)

For Giardia:

a) 25 mg/kg PO twice daily for 5 days (Barr & Bowman 1994)

b) 25 mg/kg PO twice daily for 2–5 days (Lappin 2000)

For Leishmaniasis:

a) 10 mg/kg PO once daily for 30 days or 5 mg/kg PO q6h for 60 days (Greene and Watson 1998)

### ■ CATS:

For *Paragonimus kellicotti*:

a) 25 mg/kg PO q12h for 14 days (Reinemeyer 1995)

For Giardia:

a) 25 mg/kg PO q12h for 3–5 days; may cause bone marrow suppression in dogs and cats. (Vasilopoulos 2006)

For treatment of liver flukes (*Platynosum* or *Opisthorchiidae* families):

a) 50 mg/kg PO once daily until ova are gone (Taboada 1999)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** For *Encephalitozoon phagoclasticus* uveitis: 30 mg/kg PO once daily for 30 days, then 15 mg/kg PO once daily for 30 days (Ivey & Morrisey 2000)

b) **Rabbits:** For *E. cuniculi*: 20 mg/kg PO once daily for 10 days. (Bryan 2009)

c) **Chinchillas:** For Giardia: 50–100 mg/kg PO once a day for 3 days (Hayes 2000)

### ■ CATTLE:

For susceptible parasites:

a) 10 mg/kg PO (Labeled directions; *Valbazen*®—Pfizer)

b) 7.5 mg/kg PO; 15 mg/kg PO for adult liver flukes (Roberson 1988)

c) For adult liver flukes: 10 mg/kg PO; best used in fall when the majority are adults (little or no efficacy against immature forms). A second treatment in winter may be beneficial. (Herd 1986)

d) For gastrointestinal cestodes: 10 mg/kg PO (Herd 1986a)

### ■ SWINE:

For susceptible parasites:

a) 5–10 mg/kg PO (Roberson 1988)

### ■ SHEEP & GOATS:

For susceptible parasites:

a) 7.5 mg/kg PO (0.75 mL of the suspension per 25 lb. body weight). (Labeled directions; *Valbazen*® Suspension—Pfizer)

b) 7.5 mg/kg PO; 15 mg/kg PO for adult liver flukes (Roberson 1988)

c) For adult liver flukes in sheep: 7.6 mg/kg (Paul 1986)

d) For treatment of nematodes in sheep: 3 mL of suspension per 100 lbs of body weight PO (Bulgin 2003)

### ■ BIRDS:

a) **Parrots:** Using the suspension: 1 mL/22 lb. of body weight twice daily for 3 days; repeat in 2 weeks. Has efficacy against flagellate parasites and tapeworms.

a) Raltes: Using the suspension: 1 mL/22 kg of body weight for 5 days, or 2 weeks. Efficacy against flagellate parasites and tapeworms. (Jenson 1998)

## Monitoring

- Efficacy
- Adverse effects if used in non-FDA-approved species or at dosages higher than recommended
- Consider monitoring CBC's and liver enzymes (q4–6 weeks) if treating long-term (>1 month)

## Client Information

- Shake well before administering
- Contact veterinarian if adverse effects occur (*e.g.*, vomiting, diarrhea, yellowish sclera/mucous membranes or skin)

## Chemistry/Synonyms

A benzimidazole anthelmintic structurally related to mebendazole, albendazole has a molecular weight of 265. It is insoluble in water and soluble in alcohol. Albendazole may also be known as albendazolum, SKF-62979, *Valbazen*® or *Albenza*®; many other trade names are available.

## Storage/Stability

Albendazole suspension should be stored at room temperature (15–30°C); protect from freezing. Shake well before using. Albendazole paste should be stored at controlled room temperature (15–30°C); protect from freezing.

## Dosage Forms/ Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Albendazole Suspension: 113.6 mg/mL (11.36%) in 500 mL, 1 liter, 5 liters; *Valbazen*® Suspension (Pfizer); (OTC). FDA-approved for use in cattle (not female cattle during first 45 days of pregnancy or for 45 days after removal of bulls, or of breeding age) and sheep (do not administer to ewes during the first 30 days of pregnancy or for 30 days after removal of rams). Slaughter withdrawal for cattle = 27 days at labeled doses. Slaughter withdrawal for sheep = 7 days at labeled dose. Since milk withdrawal time has not been established, do not use in female dairy cattle of breeding age. A milk withdrawal time of 7 milkings has been proposed for sheep (Athanasίου *et al.* 2009).

Albendazole Paste: 30% in 205 g (7.2 oz); *Valbazen*® (Pfizer); (OTC). FDA-approved for use in cattle (not female cattle during first 45 days of pregnancy or for 45 days after removal of bulls or of breeding age). Slaughter withdrawal = 27 days at labeled doses. Since withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age.

### HUMAN-LABELED PRODUCTS:

Albendazole Oral Tablets: 200 mg; *Albenza*® (GlaxoSmithKline); (Rx)

---

## ALBUMIN, HUMAN

## ALBUMIN, CANINE

(*al-byoo-min*)

NATURAL PROTEIN COLLOID

### Prescriber Highlights

- Natural colloid that may be useful in increasing intravascular oncotic pressure and organ perfusion and decreasing edema secondary to crystalloid fluid replacement, particularly in critically ill animals with reversible diseases/conditions when hypoalbuminemia is present
- Significant concerns with adverse effects, especially immune-mediated reactions when using xeno-albumin products (*i.e.*, human albumin in dogs); “thoughtful consideration and extreme care” must be taken when deciding whether to use
- Canine albumin product (lyophilized) available commercially in USA, but little data available on its safety and efficacy
- Treatment can be relatively expensive, but may be cheaper than plasma and may reduce intensive care unit stays

---

## Uses/Indications

Albumin (human or canine) may be useful as colloid fluid replacement therapy in critically ill small animals. Conditions where albumin therapy may be considered

albumin (human or canine) may be used as colloid fluid replacement therapy in critically ill small animals. Conditions where albumin therapy may be considered include times when the patient is severely hypoalbuminemic (albumin <2.0 g/dL), severely edematous, or has systemic inflammatory response syndrome/sepsis and increased vascular leak. Because of availability, human albumin is usually used in small animals, but this “xeno-albumin” use poses considerable risks. There is little information available on the use of human albumin in cats.

A retrospective study evaluating 25% albumin (human) in critically ill dogs and cats, found that it could be safely administered to critically ill animals, and increase albumin levels and systemic blood pressure (Mathews & Barry 2005). However, another retrospective study (Trow *et al.* 2008) evaluating albumin (human) use in 73 critically ill dogs, found that while albumin increased serum albumin, total protein, and colloid osmotic pressure, 23% of treated dogs developed at least one adverse effect that could potentially have been caused by albumin. The authors caution that given the risks for complications and uncertain positive influence, thoughtful consideration and extreme care must be taken when deciding whether to administer human albumin transfusions to critically ill dogs, and these concerns should be discussed with clients; frequent monitoring should always be used.

An Italian retrospective study evaluating 5% human albumin in 418 dogs and 170 cats with critical illnesses, severe hypersensitivity reactions such as anaphylaxis, angioedema, and urticaria were not noted in any patient record. In no case was it necessary to discontinue or interrupt the albumin infusion due to adverse effects. Diarrhea, hyperthermia, or tremors were noted in 43% of dogs and 36% of cats treated. A combination of these adverse reactions was seen in 32% of dogs and 34% of cats treated. Adverse reactions that developed one day or more after treatment were noted in 28% of dogs and 11% of cats treated. Reactions beyond Day 3 were not recorded. Perivascular inflammation at catheter sites following albumin were seen in 17% of dogs and 34% of cats. This study did not measure changes in total protein, colloid oncotic pressure or albumin.

All these studies were retrospective in nature, and prospective, controlled studies are necessary before albumin’s true benefit and risk profiles are known.

### Pharmacology/Actions

Albumin provides 75-80% of the oncotic pressure of plasma. When replacing endogenous albumin that has been lost, albumin helps prevent additional crystalloid fluids from leaking from capillaries by reducing hydrostatic pressure. This can allow using less volume of crystalloids and increase perfusion, with less risk for edema. Albumin (for a given species) also has other actions, including binding and transport of drugs, ions, hormones, lipids, and metals (including iron), maintenance of endothelial integrity and permeability control, antioxidant properties, metabolic and acid-base functions, decrease platelet aggregation, augment antithrombin and serving as a thiol-group. It is unknown what effect, if any, xeno-albumin has on these actions.

### Pharmacokinetics

Endogenous circulating albumin represents 30-40% of total body albumin. Elimination of exogenously administered canine albumin is estimated to be between 20-24 days with a half-life of 8-10 days. The kinetics of human albumin in dogs or cats is not well described.

### Contraindications/Precautions/Warnings

A history of hypersensitivity to albumin (human or canine) is a specific contraindication for use. Because of the risk for hypersensitivity, repeat administration of xeno-albumin is relatively contraindicated and in otherwise healthy animals (volume depleted) albumin use should be avoided.

The label for the canine albumin products states: Dogs with a pre-existing condition resulting in volume overload should be monitored carefully during administration of hyperosmolar products like canine albumin. Dogs with anemia or extreme dehydration should not receive canine albumin unless concurrent red blood cell products or appropriate fluid therapy is first administered.

### Adverse Effects

The incidence of adverse effects reported in retrospective studies in dogs and cats with human albumin vary widely, but they can be serious. Hypersensitivity, both immediate (anaphylactoid; anaphylactic) and delayed (type III hypersensitivity; serum sickness) is an issue when using human albumin in dogs. These effects can be serious and deaths have occurred. Immediate adverse effects reported include facial edema, vomiting, urticaria, hyperthermia, and shock. Should facial edema occur, diphenhydramine should be given at 1–2 mg/kg IM and repeated every 8 hours as required (Mathews 2008). Delayed adverse effects can include lethargy, lameness, edema, cutaneous lesions/vasculitis, vomiting, inappetence, renal failure and coagulopathies.

While the risk appears low, transmission of infectious agents from albumin products is possible.

The incidence of adverse effects in dogs associated with human albumin appears to be higher in healthy dogs than in critically ill dogs possibly due to the blunted immune response that can be seen in critically ill patients. In a study in 6 healthy dogs given 2 mL/kg of 25% human albumin during a 1-hour period an immediate hypersensitivity reaction (vomiting, facial edema) was seen in 1 dog and delayed adverse reactions were seen 5 to 13 days after albumin in all 6 dogs and included lethargy, lameness, peripheral edema, ecchymoses, vomiting, and anorexia. Delayed complications in 2 of these dogs resulted in death due to renal failure and coagulopathy and were suspected to have occurred because of serum sickness secondary to type III hypersensitivity reactions. Another dog had shock and sepsis secondary to a multi-drug resistant *E. coli* infection (Francis *et al.* 2007). Another study in 9 healthy dogs that were given one or two infusions of human albumin 25% at an initial infusion rate of 0.5 mL/kg/hour that was increased incrementally to a maximum of 4 mL/kg/hour, adverse effects were seen after the first or second infusion in 3 dogs. Anaphylactoid reactions were observed in 1 of 9 dogs during the first infusion and in the 2 dogs that were administered a second infusion. Two dogs developed severe edema and urticaria 6 or 7 days after the initial infusion. All dogs developed anti-HSA antibodies (Cohn *et al.* 2007).

Rash, nausea, vomiting, tachycardia and hypotension have been reported in humans, but hypersensitivity reactions are very rare.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) However, it is unlikely to pose much risk to the fetus, particularly when used appropriately. Albumin excretion into maternal milk is not known, but is unlikely to be harmful.

### Overdosage/Acute Toxicity

To avoid the effects of hyperalbuminemia/hyperproteinemia, albumin levels should be followed. Most believe that serum albumin should not exceed 2.5 grams/dL (some say 2 grams/dL) when used clinically.

### Drug Interactions

While the administration of exogenous albumin could bind drugs that are highly bound to plasma proteins and affect the amount of free drug circulating, this does not appear to be of significance when albumin is used clinically.

### Laboratory Considerations

■ Exogenous administration of albumin may temporarily decrease serum concentrations of calcium

## Doses

### ■ DOGS/CATS

a) Dogs: In a review of albumin (human) 25% (HSA) use in small animals the author describes when he considers using 25% human albumin: Patients with: **1)** refractory hypotension; **2)** Severe hypoalbuminemic patients [albumin <1.5 g/dL or (<1.8 g/dL during dehydration and hypovolemia) with ongoing losses (e.g., peritonitis, pleural effusion)]; **3)** Combined with FFP in hypoalbuminemic septic patients; **4)** Patients that have protein-losing enteropathy before surgical biopsy; **5)** Markedly hypoalbuminemic patients that continue to vomit (likely attributable to bowel edema); **6)** Refractory hypotension associated with gastric dilation-volvulus. The following is an edited dosage protocol (see the reference for more detailed information on use, etc.): When time permits (non-emergent situation), a test dose of 0.25 mL/kg/h is given over 15 minutes while monitoring heart rate, respiratory rate, and temperature (baseline before transfusion and at end of test dose). Discontinue infusion if adverse signs (facial swelling, or other signs of anaphylaxis or anaphylactoid reaction) develop. The maximum volume administered to any dog by the author is 25 mL/kg (6.25 g/kg) administered continuously over 72 hours; the mean volume administered to any dog overall is 5 mL/kg (1.25 g/kg). The maximum volume given as a slow push or bolus to treat hypotension is 4 mL/kg (1 gram/kg), with a mean volume of 2 mL/kg (0.5 g/kg). The range for a continuous rate infusion (CRI) after a bolus administration is 0.1 to 1.7 mL/kg/h (0.025–0.425 g/kg) over 4 to 72 hours. Infusions are empirically selected to meet low normal values. The shorter infusion times are most commonly used for refractory hypotension. (Mathews 2008)

b) Dogs: The administration of 10% human albumin may be useful in dogs with reversible disease and clinically affected by marked hypoalbuminemia (serum albumin, <1.5 g/dL) and low colloid osmotic pressure (colloid osmotic pressure, <14 mm Hg), but given the risks for complications and uncertain positive influence, thoughtful consideration and extreme care must be taken when deciding whether to administer human albumin transfusions to critically ill dogs, and these concerns should be discussed with clients and frequent monitoring performed. Reasonable goals for human albumin administration may be to increase serum albumin to 2 to 2.5 g/dL and colloid osmotic pressure to 14 to 20 mm Hg. Dogs with surgical diseases and septic peritonitis should be especially considered because of the role of albumin in wound healing. The protocol most often used for calculating the dosage of human albumin in the study was: albumin deficit (g) = 10X (serum albumin desired–serum albumin of patient) X body weight (kg) X 0.3. Alternatively, some dogs received 0.5 to 1.25 g/kg. In the authors' institution, the calculated dosage of human albumin was aseptically diluted to a 10% solution with saline (0.9% NaCl) solution and administered over a 12-hour period with a transfusion filter. Because of the antigenicity of human albumin in dogs, no dog was eligible for receiving additional human albumin after 7 days following initial human albumin administration. (Trow *et al.* 2008)

c) Dogs: Using the canine albumin lyophilized product (5 gram) for the treatment of hypovolemic shock or hypoalbuminemia regardless of the etiology: Dilute to 16% (add 30 mL of diluent such as sterile normal saline, *Normasol*® or dextrose 5%; see Compatibility/Compounding below) and administer IV at a dosage rate of 1 mL/min. A total of 2.5–5 mL/kg body weight is recommended. Albumin may be diluted in 0.9% saline or Normosol for administration. (Product label; Canine Albumin 5gm lyophilized— Animal Blood Resources)

### Monitoring

- Pre and post serum albumin. Depending on the source, most suggest a target for serum albumin concentrations of 2–2.5 g/dL
- Pre and post colloid osmotic pressure (if possible)
- Adverse effects: body temperature, respiratory rate, blood pressure and heart rate
- Signs of volume overload
- Monitor for delayed reactions, which can occur weeks after administration

### Client Information

- The medication must be given in an inpatient setting.
- Clients should understand and accept the risks, costs, and monitoring associated with albumin's use.

### Chemistry/Synonyms

Human albumin is a highly soluble, globular protein with a molecular weight of 66,500. The 5% solution has a colloid osmotic pressure (COP) similar to that of normal plasma. Amino acid homology of human and canine albumin is about 79%, but the canine albumin molecule is 2 kDalton larger and has a different relative charge and isoelectric point.

Albumin (human) may also be known as Alb, albumine, HSA, or albuminum. “Salt-poor” albumin is a misnomer, but still occasionally used as a designation for 25% albumin. There are a variety of tradename products, including: *Albuminar*®, *Albutein*®, *Buminat*®, *Plasbumin*®, and *Flexbumin*®.

### Storage/Stability

5% solution: Albumin (human) 5% solution is stable for 3 years, providing storage temperature does not exceed 30°C (89°F). Protect from freezing. 25% and 20% solutions: Store at room temperature not exceeding 30°C (86°F). Do not freeze. Do not use after expiration date.

Do not use solutions of they appear turbid or if sediment is noted. Solutions should not be used if more than 4 hours have passed since the container has been entered as it contains no preservatives. Do not use solutions that have been frozen.

The lyophilized canine albumin product should be stored at 4–6°C (refrigerated) until use. Product is stable for 15 months as labeled. After rehydration, it should not be stored longer than 24 hours. Refrigerated storage for rehydrated product is recommended.

### Compatibility/Compounding Considerations

Albumin may be administered either in conjunction with or combined with other parenteral products such as whole blood, plasma, saline, glucose, or sodium lactate. It is reportedly **compatible** with usual carbohydrate or electrolyte solutions, diltiazem or midazolam at a Y-site.

**Do not** mix albumin with protein hydrolysates, amino acid solutions or solutions containing alcohol.

When preparing human albumin for administration use only 16-gauge needles or dispensing pins with 20 mL vial sizes and larger. Needles or dispensing pins should only be inserted within the stopper area delineated by the raised ring. The stopper should be penetrated perpendicular to the plane of the stopper within the ring.

Canine albumin 5 gram lyophilized, should be rehydrated by adding 30 mL of 0.9% sterile saline or *Normosol*® to make a 16% canine albumin solution. Dextrose 5% solution may also be used as a diluent. **DO NOT** use sterile water to rehydrate the product. After addition of the diluent, gently swirl the solution until all powder is rehydrated. Once diluent is added, the vial may be warmed in a 37°C water bath to speed rehydration. Add 49 mL of appropriate diluent to obtain a 10% albumin solution and 100 mL to obtain a 5% solution.

### Dosage Forms/Regulatory Status

## VETERINARY-LABELED PRODUCTS:

Albumin, Canine, 98% lyophilized 5 g, without preservatives or plasma byproducts. (Animal Blood Resources Intl.). Product labeled for intravenous use in dogs and only to be used by or on the order of licensed veterinarian.

## HUMAN-LABELED PRODUCTS:

Albumin, Human 5% in 50 mL, 100 mL, 250 mL & 500 mL glass containers, and 25% in 20 mL, 50 mL & 100 mL vials or flex containers; *Albuminar*® (ZLB Behring), *Albutein*® (Grifols), *Albuminate*® (Baxter), *Flexbumin*® (flexible container; Baxter), *Plasbumin*® (Talecris), generic; (Rx)

## ALBUTEROL SULFATE

(*al-byoo-ter-ole*) Salbutamol, Proventil®, Ventolin®

BETA-ADRENERGIC AGONIST

### Prescriber Highlights

- Used primarily as a bronchodilator after PO or inhaled dosing
- Use with caution in patients with cardiac dysrhythmias or dysfunction, seizure disorders, hypertension or hyperthyroidism
- May be teratogenic (high doses) or delay labor

---

## Uses/Indications

Albuterol is used principally in dogs and cats for its effects on bronchial smooth muscle to alleviate bronchospasm or cough. It is also used in horses as a bronchodilator.

## Pharmacology/Actions

Like other beta-agonists, albuterol is believed to act by stimulating production of cyclic AMP through activation of adenylyl cyclase. Albuterol is considered to be predominantly a beta2 agonist (relaxation of bronchial, uterine, and vascular smooth muscles). At usual doses, albuterol possesses minimal beta1 agonist (heart) activity. Beta-adrenergics can promote a shift of potassium away from the serum and into the cell, perhaps via stimulation of Na<sup>+</sup>-K<sup>+</sup>-ATPase. Temporary decreases in either normal or high serum potassium levels are possible.

## Pharmacokinetics

The specific pharmacokinetics of this agent have apparently not been thoroughly studied in domestic animals. In general, albuterol is absorbed rapidly and well after oral administration. Effects occur within 5 minutes after oral inhalation; 30 minutes after oral administration (*e.g.*, tablets). It does not cross the blood-brain barrier but does cross the placenta. Duration of effect generally persists for 3–6 hours after inhalation and up to 12 hours (depending on dosage form) after oral administration. The drug is extensively metabolized in the liver principally to the inactive metabolite, albuterol 4'-O-sulfate. After oral administration the serum half-life in humans has been reported as 2.7–5 hours.

## Contraindications/Precautions/Warnings

Albuterol is contraindicated in patients hypersensitive to it. It should be used with caution in patients with diabetes, hyperthyroidism, hypertension, seizure disorders, or cardiac disease (especially with concurrent arrhythmias).

Use during the late stages of pregnancy may inhibit uterine contractions.

## Adverse Effects

Most adverse effects are dose-related and those that would be expected with sympathomimetic agents including increased heart rate, tremors, CNS excitement (nervousness) and dizziness. These effects are generally transient and mild and usually do not require discontinuation of therapy. Decreased serum potassium values may be noted; rarely is potassium supplementation required.

The S-form of albuterol may potentially increase airway inflammation in cats. As “regular” albuterol is the racemic form (R,S-albuterol) it may also increase airway inflammation and its use in cats should probably be limited to acute, rescue treatment only and not for chronic treatment. (Reinero 2008), (Reinero 2009). Additionally, cats don’t like the “hiss” occurring during actuation of the metered-dose inhaler or the taste of the drug/vehicle.

## Reproductive/Nursing Safety

In very large doses, albuterol is teratogenic in rodents. It should be used (particularly the oral dosage forms) during pregnancy only when the potential benefits outweigh the risks. Like some other beta agonists, it may delay pre-term labor after oral administration. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Clinical signs of significant overdose after systemic administration (including when dogs bite an aerosol canister) may include: arrhythmias (tachycardia and extrasystole), hypertension, fever, vomiting, mydriasis, tremors, and CNS stimulation. Hypokalemia and hypophosphatemia may occur. There were 658 exposures to Albuterol reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 656 were dogs with 610 showing clinical signs, and

Albuterol reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 636 were dogs with 610 showing clinical signs, and 2 were cats with both showing clinical signs. Common findings in dogs recorded in decreasing frequency included tachycardia, lethargy, vomiting, hypokalemia, panting, agitation, trembling, and tachypnea. Common findings in cats included tachycardia.

If there is a recent ingestion of tablets, and if the animal does not have significant cardiac or CNS effects, it should be handled like other overdoses (empty gut, give activated charcoal and a cathartic). For inhalation exposure (when a dog bites an aerosol canister) decontamination is generally not effective. If cardiac arrhythmias require treatment a beta-blocking agent (*e.g.*, atenolol, metoprolol) can be used. Diazepam can be used for tremors. Potassium supplementation may be required. The oral LD 50 of albuterol in rats is reported to be greater than 2 g/kg. Contact an animal poison control center for further information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving albuterol (primarily when albuterol is given orally and not via inhalation) and may be of significance in veterinary patients:

■ **BETA-ADRENERGIC BLOCKING AGENTS** (*e.g.*, **propranolol**): May antagonize the actions of albuterol

■ **DIGOXIN**: Albuterol may increase the risk of cardiac arrhythmias

■ **INHALATION ANESTHETICS** (*e.g.*, **halothane, isoflurane, methoxyflurane**): Albuterol may predispose the patient to ventricular arrhythmias, particularly in patients with preexisting cardiac disease—use cautiously

■ **OTHER SYMPATHOMIMETIC AMINES**: Used with albuterol may increase the risk of developing adverse cardiovascular effects

■ **TRICYCLIC ANTIDEPRESSANTS OR MONOAMINE OXIDASE INHIBITORS**: May potentiate the vascular effects of albuterol

## Doses

### ■ DOGS:

**WARNING:** There are several older references that state that the oral dose is 50 mg/kg q8h. **This is an obvious overdose and should not be followed.** A more reasonable dose orally in dogs is: 0.05 mg/kg (50 micrograms/kg) PO q8–12h.

a) 0.05 mg/kg (50 micrograms/kg) PO q8h (Johnson 2000)

b) 0.02 mg/kg PO q12h for 5 days; if no improvement and no adverse effects may increase to 0.05 mg/kg PO q8–12h. If patient responds, reduce to lowest effective dose. (Church 2003)

c) For inhalation, based on a 60 lb dog: 0.5 mL of the 0.5% solution for nebulization in 4 mL of saline nebulized every 6 hours (McConnell & Hughey 1992)

### ■ CATS:

a) For bronchodilation in feline asthma using the 90 micrograms/puff aerosol albuterol inhaler and an appropriate spacer and mask:

For mild symptoms give one puff albuterol as needed with one puff of 110 micrograms fluticasone twice daily.

Moderate symptoms may be treated with albuterol one puff as needed with a 5 day course of prednisone at 1 mg/kg PO daily, and 220 micrograms of fluticasone twice daily.

Severely affected cats should be treated on an emergency basis with oxygen, an intravenous dose of a glucocorticoid, 90 micrograms (one puff) albuterol every 30 minutes as needed.

Chronic therapy should include fluticasone 220 micrograms twice daily, 90 micrograms albuterol as needed and 1 mg/kg prednisone every other day. (Dowling 2003)

b) For intermittent (not daily) signs (*e.g.*, wheeze, increased cough or respiratory rate and effort at rest) of feline asthma: two puffs into an appropriate spacer (*e.g.*, *Aerokat*®) twice daily; cat should breathe through the mask and spacer for 7–10 seconds. Positive clinical effect should be seen within 5–10 minutes. Can be used every 1/2 hour for 2–4 hours in crisis. (Padrid 2006)

### ■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

a) For rescue therapy in horses demonstrating respiratory difficulty at rest: 360 micrograms (4 puffs) inhaled; if severe airway obstruction, may give at 15 minute increments for up to 2 hours. Continue as needed every 4-6 hours. Beneficial effects may last approximately 1 hour in severely affected horses. Longer acting beta agonists may be necessary. Combination therapy with corticosteroids reduces tolerance that develops and enhances beta-adrenergic receptor protein expression.

For moderate to severe disease: 360 micrograms followed in 5 minutes with aerosolized corticosteroid (beclomethasone or fluticasone) therapy. (Davis & Rush 2002)

b) 2–3 micrograms/kg via inhalation using a specially designed mask and spacer (*Aeromask*® and *Aerovent*®) (Foreman 1999)

c) For heaves: 0.8–2 micrograms/kg in a metered dose inhaler (Lavoie 2003)

d) For short-acting bronchodilation: 450–900 micrograms (5–10 puffs) as needed, not to exceed 4 times per week unless in conjunction with a corticosteroid (Mazan 2003)

e) For heaves: 360 micrograms (4 puffs) inhaled as needed. Tolerance develops rapidly if used as a sole therapy. (Rush 2006)

## Monitoring

■ Clinical symptom improvement; auscultation, blood gases (if indicated)

■ Cardiac rate, rhythm (if warranted)

■ Serum potassium, early in therapy if animal is susceptible to hypokalemia

## Client Information

■ Contact veterinarian if animal's condition deteriorates or it becomes acutely ill.

■ If using the aerosol, shake well before using. Be certain how to appropriately administer the product to maximize effectiveness. Do not puncture or use near an open flame; do not allow exposure to temperatures greater than 120°F. Keep out of reach of children and pets.

## Chemistry/Synonyms

## Chemistry/Nonionics

A synthetic sympathomimetic amine, albuterol sulfate occurs as a white, almost tasteless crystalline powder. It is soluble in water and slightly soluble in alcohol. One mg of albuterol is equivalent to 1.2 mg of albuterol sulfate.

Albuterol sulfate may also be known as: salbutamol hemisulphate, salbutamol sulphate, or salbutamoli sulfas; many trade names are available.

## Storage/Stability

Oral albuterol sulfate products should be stored at 2–30°C. The inhaled aerosol should be stored at room temperature; do not allow exposure to temperatures above 120°F or the canister may burst. The 0.5% nebs should be stored at room temperature; the 0.083% nebs should be stored in the refrigerator. Discard solutions if they become colored.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Albuterol Oral Tablets: 2 mg & 4 mg; generic; (Rx)

Albuterol Extended Release Oral Tablets: 4 mg & 8 mg; *VoSpire® ER* (Dava); generic (Mylan); (Rx)

Albuterol Oral Syrup: 2 mg (as sulfate)/5 mL in 473 mL; generic; (Rx)

Albuterol Aerosol: Each actualization delivers 90 micrograms albuterol in 6.7g, 6.8g, 8.5g, 18g; *ProAir HFA®* (Teva); *Proventil HFA®* (Key); *Ventolin HFA®* (GlaxoSmithKline); generic; (Rx).

Albuterol Solution for Inhalation (“Neb”): 0.083% (2.5 mg/3 mL) in 3 mL UD vials; 0.5% (5 mg/mL) in 0.5 mL vials & 20 mL with dropper; 0.021% preservative-free (0.63 mg/3mL) & 0.042% preservative-free (1.25 mg/3 mL), in 3 mL UD vials *Proventil®* (Schering); *AccuNeb®* (Dey); generic; (Rx)

Also available: 14.7 g aerosol metered dose inhaler containing 18 mcg ipratropium bromide (an inhaled anticholinergic) and 103 mcg albuterol sulfate per puff; *Combivent®* (B-I); (Rx) and 3 mL unit dose solution for inhalation (neb) containing 0.5 mg ipratropium bromide and 3 mg albuterol, *DuoNeb®* (Dey); (Rx)

## ALENDRONATE SODIUM

(*a-len-droe-nate*) Fosamax®

ORAL BIPHOSPHONATE BONE RESORPTION INHIBITOR

### Prescriber Highlights

- **Orally dosed bisphosphonate that reduces osteoclastic bone resorption**
- **Potentially useful for refractory hypercalcemia, FORLs, osteosarcoma**
- **Very limited clinical experience with use of this drug in animals; adverse effect profile, dosages, etc. may significantly change with more experience & clinical research**
- **Potentially can cause esophageal erosions; risks are not clear for dogs or cats**
- **Accurate dosing may be difficult & bioavailability is adversely affected by food, etc.**
- **Cost may be an issue**

---

## Uses/Indications

Alendronate use in small animals has been limited, but it may prove useful for treating refractory hypercalcemia in dogs or cats, feline odontoclastic resorptive lesions (FORLs), and as an osteosarcoma treatment adjuvant.

## Pharmacology/Actions

Alendronate, like other bisphosphonates, inhibits osteoclastic bone resorption by inhibiting osteoclast function after binding to bone hydroxyapatite. Secondary actions that may contribute to therapeutic usefulness in osteogenic neoplasms include promoting apoptosis and inhibiting osteoclastogenesis, angiogenesis and cancer cell proliferation.

## Pharmacokinetics

Specific pharmacokinetic values are limited for dogs and apparently unavailable for cats. Oral bioavailability in all species studied is less than 2%. In humans, alendronate sodium has very low oral bioavailability (<1%) and the presence of food can reduce bioavailability further to negligible amounts. In women, taking the medication with coffee or orange juice reduced bioavailability by 60% when compared to plain water.

Potentially can cause esophageal erosions; risks are not clear for dogs or cats. Be sure adequate liquid is consumed after dosage and, ideally, do not feed for at least 30 minutes after dosing. See Adverse Effects for suggestions to minimize risks in dogs and cats.

## Chemistry/Synonyms

Alendronate sodium is a synthetic analog of pyrophosphonate with the chemical name: (4-amino-1-hydroxy-1-phosphono-butyl) phosphonic acid. One mg is soluble in one liter of water.

Alendronate may also be known as: Alendronic acid, *Acide Alendronique*, *Acido Alendronico*, *Acidum Alendronicum*, *Adronat*®, *Alendros*®, *Arendal*®, *Onclast*® or *Fosamax*®.

## Storage/Stability

Alendronate tablets should be stored in well-closed containers at room temperature. The oral solution should be stored at room temperature; do not freeze.

## Dosage Forms/Regulatory Status

**VETERINARY PRODUCTS:** None

**HUMAN PRODUCTS:**

Alendronate Sodium Oral Tablets: 5 mg, 10 mg, 35 mg, 40 mg, & 70 mg; *Fosamax*® (Merck); generic; (Rx)

Alendronate Oral Solution: 70 mg (as base) in 75 mL; raspberry flavor; *Fosamax*® (Merck); (Rx)

## ALFAXALONE

*Al-fax-a-lone* **Alfaxan**®

**INTRAVENOUS ANESTHETIC**

### Prescriber Highlights

- **Injectable anesthetic for small animals available in some countries (U.K. Australia, New Zealand)**
  - **Negligible analgesic effects**
  - **Respiratory depression/apnea can occur, particularly if administered rapidly IV**
  - **Use with premeds allows lower dose (and cost)**
- 

## Uses/Indications

Alfaxalone may be used in dogs or cats as an intravenous induction agent prior to inhalation anesthesia or as a sole anesthetic agent for the induction and maintenance of anesthesia for the performance of examination or surgical procedures. It can also be administered deep IM to cats as a deep sedative/light anesthetic.

## Pharmacology/Actions

Alfaxalone is a neuroactive steroid molecule with properties of a general anesthetic. The primary mechanism for the anesthetic action of alfaxalone is the modulation of neuronal cell membrane chloride ion transport, induced by binding of alfaxalone to GABA cell surface receptors. Alfaxalone has negligible analgesic properties at clinical doses.

## Pharmacokinetics

In dogs, alfaxalone's volume of distribution after a single injection of clinical doses (2 mg/kg) is approximately 2.5 L/kg. At this dose, clearance is about 54 mL/kg/minute and elimination terminal half-life around 27 minutes (Ferre *et al.* 2006). A study done in Greyhounds showed similar results when dogs were not premedicated; however, premedicated (acepromazine/morphine) Greyhounds had substantially longer (5X) anesthetic durations and elimination half-life was approximately 19% longer and clearance about 24% lower than when they were not premedicated (Pasloske *et al.* 2009).

In cats, the volume of distribution of alfaxalone is approximately 2 L/kg. Clearance is dosage dependent with doses of 5 mg/kg (clinical dose) averaging 25.1 mL/kg/minute and doses of 25 mg/kg (supraclinical dose) averaging 14.8 mL/kg/min. The elimination half-lives at these doses were 45.2 and 76.6 min respectively. Alfaxalone has nonlinear pharmacokinetics in the cat, but with multiple doses there was no clinically relevant accumulation. (Whitem *et al.* 2008)

Cat and dog hepatocyte (*in vitro*) studies show that alfaxalone undergoes both Phase I (cytochrome P450 dependent) and Phase II (conjugation dependent) metabolism in both species. Both cats and dogs form the same five Phase I metabolites. Phase II metabolites in cats are alfaxalone sulfate and alfaxalone glucuronide, while only alfaxalone glucuronide is found in dogs. Alfaxalone metabolites are likely to be eliminated from both the dog and cat by the hepatic/fecal and renal routes, similarly to other species studied.

At usual dosages, dogs or cats are expected to recover to sternal recumbency in 60-80 minutes.

## Contraindications/Precautions/Warnings

Alfaxalone should not be used with other injectable general anesthetic agents. As post-induction apnea can occur, alfaxalone should only be used in circumstances where endotracheal (ET) intubation, positive pressure ventilation and oxygen support can be administered. Following induction, ET intubation with oxygen is recommended.

Use with caution in patients with significant hepatic dysfunction as they may require lower dosages or increased dosing intervals to maintain anesthesia. Use with

caution in elderly, critically ill or debilitated animals.

Patients should be in appropriate facilities and under sufficient supervision during the post-anesthesia recovery period. During recovery, it is preferable that animals are not handled or disturbed as psychomotor excitement may occur. Premedication with only a benzodiazepine may increase this likelihood.

As alfaxalone does not provide analgesia, appropriate pain control should be provided.

Safety of alfaxalone has not been established in animals less than 12 weeks of age.

## Adverse Effects

Respiratory depression and apnea are the biggest concerns with this agent. In clinical studies, 44% of dogs and 19% of cats experienced post-induction apnea (defined as the cessation of breathing for 30 seconds or more). The mean duration of apnea in these animals was 100 seconds in dogs and 60 seconds in cats. Giving the drug slowly IV with persistent monitoring should occur when using this agent. When sufficient anesthesia is induced, endotracheal intubation and oxygen supplementation should be done. Cardiac arrhythmias may occur, but are thought to occur primarily due to hypoxemia/hypercapnia; O<sub>2</sub> therapy is recommended as the primary treatment should these occur, followed by appropriate cardiotherapy if required.

## Reproductive/Nursing Safety

The safety has not been established in pregnancy or during lactation. Studies in pregnant mice, rats and rabbits have not demonstrated deleterious effects on gestation of the treated animals or on the reproductive performance of their offspring. Alfaxalone's effects upon fertility have not been evaluated.

## Overdosage/Acute Toxicity

Hypoventilation, apnea, and hypotension are the most likely consequences of overdoses up to 25 mg/kg. Cardiac arrhythmias are possible. Extended monitoring with appropriate cardiopulmonary support may be required.

## Drug Interactions

The New Zealand label states that alfaxalone has been safely used in combination with the premeds acepromazine, atropine, methadone, butorphanol, diazepam and xylazine. The concomitant use with other CNS depressants is expected to potentiate the depressant effects of either drug, and appropriate dose adjustments should be made. A study evaluating the effects that medetomidine (4 microgram/kg) and/or butorphanol (0.1 mg/kg) had on the induction doses required for alfaxalone in dogs found that when either was used alone average induction dose was 1.2 mg/kg and when used together average alfaxalone induction dose was 0.8 mg/kg (Madden *et al.* 2010).

**Propofol, Thiopental:** The label states that alfaxalone *should not* be used with **other injectable anesthetics**.

## Laboratory Considerations

None noted.

## Doses

### ■ DOGS/CATS:

#### a) INDUCTION:

**Dogs:** Premedicated: 3 mg/kg IV; Not premedicated 2 mg/kg IV.

**Cats:** Premedicated or not premedicated: 5 mg/kg IV.

The rate of administration should be that, if required, the total dose is given over the first 60 seconds. After that, if intubation is still not possible, one further similar dose may be administered to effect. Administration should continue until the clinician is satisfied that the depth of anesthesia is sufficient for endotracheal intubation or until the entire dose has been administered.

#### MAINTENANCE:

Following induction, the animal may be intubated and maintained on alfaxalone or an inhalation anesthetic agent. Maintenance doses of alfaxalone may be given as supplemental boluses or as constant-rate infusion. Alfaxalone has been used safely and effectively in both dogs and cats for procedures lasting for up to one hour. The following doses suggested for maintenance of anesthesia are based on data taken from controlled laboratory and field studies and represent the average amount of drug required to provide maintenance anesthesia for a dog or cat; however, the actual dose will be based on the response of the individual patient.

	DOGS		CATS	
	Unpre-medicated	Pre-medicated	Unpre-medicated	Pre-medicated
Dose for constant rate infusion				
mg/kg/ hour	8-9	6-7	10-11	7-8
mg/kg/ minute	0.13-0.15	0.1-0.12	0.16-0.18	0.11-0.13
mL/kg/ minute	0.013-0.015	0.01-0.012	0.016-0.018	0.011-0.013
Bolus dose for each 10 minutes maintenance				
mg/kg	1.3-1.5	1-1.2	1.6-1.8	1.1-1.3
mL/kg	0.13-0.15	0.1-0.12	0.16-0.18	0.11-0.13

Where maintenance of anesthesia is with alfaxalone for procedures lasting more than 5 to 10 minutes, a butterfly needle or catheter can be left in the vein, and small amounts of alfaxalone injected subsequently to maintain the required level and duration of anesthesia. In most cases the average duration of recovery when using alfaxalone for maintenance will be longer than if using an inhalant gas as a maintenance agent. (Adapted from label; *Alfaxan*®—Vetoquinol U.K.)

#### b) INDUCTION:

**Dogs:** 1-2 mg/kg IV slowly over 20-30 seconds while assessing the degree of anesthesia achieved.

**Cats:** 2-5 mg/kg IV slowly over 20-30 seconds while assessing the degree of anesthesia achieved.

#### MAINTENANCE:

Following induction, the animal may be maintained on alfaxalone or an inhalation anesthetic agent. Where maintenance of anesthesia is with alfaxalone for

procedures lasting more than 5 to 10 minutes, a needle or catheter can be left in the vein, and small amounts of alfaxalone may be injected up to a total dose of 5–12 mg/kg (0.5–1.2 mL/kg). A total dose of 5–7 mg/kg (0.5–0.7 mL) would be expected to provide sufficient anesthesia for short surgical procedures such as castration. For longer procedures, a total dose of 8–12 mg/kg (0.8–1.2 mL/kg) may be required. Recovery is not prolonged significantly following incremental doses of alfaxalone.

**As a deep sedative/light anesthetic in cats:** 5–10 mg/kg IM (deep) (0.5–1 mL/kg). The suggested site of injection is the quadriceps muscle mass. A dose of 10 mg/kg IM is expected to induce deep sedation or light anesthesia sufficient to allow venepuncture or the practice of some minor surgical techniques such as the drainage of an abscess or the repair of small superficial wounds. (Adapted from label; *Alfaxan-CD RTU*®—Jurox N.Z.)

#### ■SMALL MAMMALS:

a) **Rabbits:** 6–9 mg/kg IV; 9 mg/kg IM. It is prudent to administer oxygen concurrently by facemask. Apnea can occur so the author recommends not using intravenous induction unless the operator is confident with intubation. Published doses of injectable agents are for surgical anesthesia in *healthy* rabbits without the concurrent use of a volatile agent and thus should be considered as the maximum dose, which may not be necessary in many cases. In practice, the combination of an injectable induction using lower doses of the agents than required for surgical anesthesia, followed by intubation and maintenance on isoflurane, is probably the most common approach.

#### Monitoring

- Level of anesthesia/CNS effects
- Respiratory depression
- Cardiovascular status (cardiac rate/rhythm; blood pressure)

#### Chemistry/Synonyms

Alfaxalone is 3-alpha-hydroxy-5-alpha-pregnane-11,20-dione and has a molecular weight of 332.5. It occurs as a white to creamy white powder. It is practically insoluble in water or mineral spirits, soluble in alcohol, and freely soluble in chloroform.

The commercial injection occurs as a clear, colorless sterile solution without preservatives. It is a water-soluble formulation containing 2-hydroxypropyl-beta-cyclodextrin (HPCD) as the solubilizing agent. Another product containing alfaxalone, *Saffan*® was marketed in the 1970's as an intravenous anesthetic agent for cats, but contained a polyethoxylated castor oil as the solubilizing agent which caused significant histamine release via mast cell degranulation. This product was subsequently removed from the market.

The UK labels states to discard any remaining solution in the vial after use, but the New Zealand label states that “Contents of broached vials should preferably be used within 24 hours, but may be stored if necessary at 4°C for up to 7 days provided contamination is avoided. Do not use broached vials if the solution is not clear, colorless and free from particulate matter.”

Alfaxalone may also be known as alfaksaloni, alfaxalon, alfaxalona, alfaxalonum, alphaxalone, or GR-2/234. A common tradename is *Alfaxan*®.

#### Storage/Stability

Alfaxalone solution for injection should be stored at room temperature (<30°C) and protected from light. Do not freeze.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA.

Alfaxalone is available in several other countries, including UK, New Zealand, and Australia as a 10 mg/mL injection and depending on the market, in 10 mL and 20 mL vials. Trade name is *Alfaxan*® (Vetoquinol, Jurox). It requires a veterinary prescription.

**HUMAN-LABELED PRODUCTS:** None

### ALFENTANIL HCL

(*al-fen-ta-nil*) *Alfenta*®

OPIATE ANESTHETIC ADJUNCT

#### Prescriber Highlights

- **Injectable, potent opiate that may be useful for adjunctive anesthesia, particularly in cats**
  - **Marginal veterinary experience & little published data available to draw conclusions on appropriate usage in veterinary species**
  - **Dose-related respiratory & CNS depression are the most likely adverse effects seen**
  - **Dose may need adjustment in geriatric patients & those with liver disease**
  - **Class-II controlled substance; relatively expensive**
- 

#### Uses/Indications

An opioid analgesic, alfentanil may be useful for anesthesia, analgesia, or sedation similar to fentanyl; fentanyl is generally preferred because of the additional experience with its use in veterinary patients and cost. Alfentanil may be particularly useful in cats as adjunctive therapy during anesthesia to reduce other anesthetic

(i.e., propofol or isoflurane) concentrations.

## Pharmacology/Actions

Alfentanil is a potent *mu* opioid with the expected sedative, analgesic, and anesthetic properties. When comparing analgesic potencies after IM injection, 0.4–0.8 mg of alfentanil is equivalent to 0.1–0.2 mg of fentanyl and approximately 10 mg of morphine.

## Pharmacokinetics

The pharmacokinetics of alfentanil have been studied in the dog. The drug's steady state volume of distribution is about 0.56 L/kg, clearance is approximately 30 mL/kg/minute, and the terminal half-life is approximately 20 minutes.

In humans, onset of anesthetic action occurs within 2 minutes after intravenous dosing, and within 5 minutes of intramuscular injection. Peak effects occur approximately 15 minutes after IM injection. The drug has a volume of distribution of 0.4–1 L/kg. About 90% of the drug is bound to plasma proteins. Alfentanil is primarily metabolized in the liver to inactive metabolites that are excreted by the kidneys into the urine; only about 1% of the drug is excreted unchanged into the urine. Total body clearance in humans ranges from 1.6–17.6 mL/minute/kg. Clearance is decreased by about 50% in patients with alcoholic cirrhosis or in those that are obese. Clearance is reduced by approximately 30% in geriatric patients. Elimination half-life in humans is about 100 minutes.

## Contraindications/Precautions/Warnings

Alfentanil is contraindicated in patients hypersensitive to opioids. Because of the drug's potency and potential for significant adverse effects, it should only be used in situations where patient vital signs can be continuously monitored. Initial dosage reduction may be required in geriatric or debilitated patients, particularly those with diminished cardiopulmonary function.

## Adverse Effects

Adverse effects are generally dose related and consistent with other opiate agonists. Respiratory depression, bradycardia, and CNS depression are most likely to be encountered. Bradycardia is usually responsive to anticholinergic agents. Dose-related skeletal muscle rigidity is not uncommon and neuromuscular blockers are routinely used. Alfentanil has rarely been associated with asystole, hypercarbia and hypersensitivity reactions.

Respiratory or CNS depression may be exacerbated if alfentanil is given with other drugs that cause those effects.

## Reproductive/Nursing Safety

In humans, the FDA categorizes alfentanil as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). If alfentanil is administered systemically to the mother close to giving birth, offspring may show behavioral alterations (hypotonia, depression) associated with opioids. Although high dosages given for 10–30 days to laboratory animals have been associated with embryotoxicity, it is unclear if this is a result of direct effects of the drug or as a result of maternal toxicity secondary to reduced food and water intake.

The effects of alfentanil on lactation or its safety for nursing offspring is not well defined, but it is unlikely to cause significant effects when used during anesthetic procedures in the mother.

## Overdosage/Acute Toxicity

Intravenous, severe overdoses may cause circulatory collapse, pulmonary edema, seizures, cardiac arrest and death. Less severe overdoses may cause CNS and respiratory depression, coma, hypotension, muscle flaccidity and miosis. Treatment is a combination of supportive therapy, as necessary, and the administration of an opiate antagonist such as naloxone. Although alfentanil has a relatively rapid half-life, multiple doses of naloxone may be necessary. Because of the drug's potency, the use of a tuberculin syringe to measure dosages less than 1 mL with a dosage calculation and measurement double-check system, are recommended.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving alfentanil and may be of significance in veterinary patients:

■ **DRUGS THAT INHIBIT HEPATIC ISOENZYME CYP3A4**, such as **erythromycin, cimetidine, ketoconazole, itraconazole, fluconazole or diltiazem**: May increase the half-life and decrease the clearance of alfentanil leading to prolonged effect and an increased risk of respiratory depression

■ **DRUGS THAT DEPRESS CARDIAC FUNCTION OR REDUCE VAGAL TONE**, such as **beta-blockers** or **other anesthetic agents**: May produce bradycardia or hypotension if used concurrently with alfentanil

## Laboratory Considerations

■ Patients receiving opiates may have increased plasma levels of **amylase** or **lipase** secondary to increased biliary tract pressure. Values may be unreliable for 24 hours after administration of alfentanil.

## Doses

(**Note**: in very obese patients, figure dosages based upon lean body weight.)

### ■ DOGS:

As a premed:

a) 5 micrograms/kg alfentanil with 0.3–0.6 mg of atropine IV 30 seconds before injecting propofol can reduce the dose of propofol needed to induce anesthesia to 2 mg/kg, but apnea may still occur. (Hall *et al.* 2001b)

As a constant rate infusion for pain:

a) Loading dose of 0.5–1 micrograms/kg, then a CRI of 0.5–1 micrograms/kg per minute. (Grint 2008)

As an analgesic supplement to anesthesia:

a) 2–5 micrograms/kg IV q20 minutes. (Hall *et al.* 2001b), (Hall *et al.* 2001a)

b) For intra-operative analgesia in patients with intracranial disease: 0.2 micrograms/kg/minute (Raisis 2005)

## Monitoring

■ Anesthetic and/or analgesic efficacy

- Cardiac and respiratory rate
- Pulse oximetry or other methods to measure blood oxygenation when used for anesthesia

## Client Information

- Alfentanil is a potent opiate that should only be used by professionals in a setting where adequate patient monitoring is available

## Chemistry/Synonyms

A phenylpiperidine opioid anesthetic-analgesic related to fentanyl, alfentanil HCl occurs as a white to almost white powder. It is freely soluble in alcohol, water, chloroform or methanol. The commercially available injection has a pH of 4–6 and contains sodium chloride for isotonicity. Alfentanil is more lipid soluble than morphine, but less so than fentanyl.

Alfentanil may also be known as: alfentanyl, *Alfenta*®, *Fanaxal*®, *Fentalim*®, *Limifen*®, or *Rapifen*®.

## Storage/Stability

Alfentanil injection should be stored protected from light at room temperature.

## Compatibility/Compounding Considerations

In concentrations of up to 80 micrograms/mL, alfentanil injection has been shown to be **compatible** with Normal Saline, D5 in Normal Saline, D5W, and Lactated Ringers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Alfentanil HCl for injection: 500 micrograms (as base)/mL in 2, 5 mL, 10 mL, & 20 mL amps; preservative-free; *Alfenta*® (Akorn); generic (Abbott); (Rx, C-II).

## ALLOPURINOL

(al-oh-pyoor-i-nol) Zylprim®

XANTHINE OXIDASE INHIBITOR; PURINE ANALOG

### Prescriber Highlights

- Used as a uric acid reducer in dogs, cats, reptiles & birds & as an alternative treatment Leishmaniasis & Trypanosomiasis in dogs
- Use with caution (dosage adjustment may be required) in patients with renal or hepatic dysfunction
- Contraindicated in red-tailed hawks & should be used with caution, if at all, in other raptors
- Diet may need to be adjusted to lower purine
- GI effects are most likely adverse effects, but hypersensitivity, hepatic & renal effects can occur
- Many potential drug interactions

---

## Uses/Indications

The principle veterinary uses for allopurinol are for the prophylactic treatment of recurrent uric acid uroliths and hyperuricosuric calcium oxalate uroliths in dogs, particularly Dalmatians. It has also been used in an attempt to treat gout in pet birds and reptiles.

Allopurinol has been recommended as an alternative treatment for canine Leishmaniasis. Although it appears to have clinical efficacy, it must be used for many months of treatment and does not apparently clear the parasite in most dogs at usual dosages. Allopurinol may also be useful for American Trypanosomiasis.

## Pharmacology/Actions

Allopurinol and its metabolite, oxypurinol, inhibit the enzyme xanthine oxidase. Xanthine oxidase is responsible for the conversion of oxypurines (*e.g.*, hypoxanthine, xanthine) to uric acid. Hepatic microsomal enzymes may also be inhibited by allopurinol. It does not increase the renal excretion of uric acid nor does it possess any antiinflammatory or analgesic activity.

Allopurinol is metabolized by *Leishmania* into an inactive form of inosine that is incorporated into the organism's RNA leading to faulty protein and RNA synthesis.

Allopurinol, by inhibiting xanthine oxidase, can inhibit the formation of superoxide anion radicals, thereby providing protection against hemorrhagic shock and myocardial ischemia in laboratory conditions. The clinical use of the drug for these indications requires further study.

## Pharmacokinetics

In Dalmatians, absorption rates were variable between subjects. Peak levels occur within 1–3 hours after oral dosing. Elimination half-life is about 2.7 hours. In dogs

(not necessarily Dalmatians), the serum half-life of allopurinol is approximately 2 hours and for oxypurinol, 4 hours. Food does not appear to alter the absorption of allopurinol in dogs.

In horses, oral bioavailability of allopurinol is low (approximately 15%). Allopurinol is rapidly converted to oxypurinol in the horse as the elimination half-life of allopurinol is approximately 5–6 minutes. Oxypurinol has an elimination half-life of about 1.1 hours in the horse.

In humans, allopurinol is approximately 90% absorbed from the GI tract after oral dosing. Peak levels after oral allopurinol administration occur 1.5 and 4.5 hours later, for allopurinol and oxypurinol, respectively.

Allopurinol is distributed in total body tissue water but levels in the CNS are only about 50% of those found elsewhere. Neither allopurinol nor oxypurinol are bound to plasma proteins, but both drugs are excreted into milk.

Xanthine oxidase metabolizes allopurinol to oxypurinol. In humans, the serum half-life for allopurinol is 1–3 hours and for oxypurinol, 18–30 hours. Half-lives are increased in patients with diminished renal function. Both allopurinol and oxypurinol are dialyzable.

### Contraindications/Precautions/Warnings

Allopurinol is contraindicated in patients who are hypersensitive to it or have previously developed a severe reaction to it. It should be used cautiously and with intensified monitoring in patients with impaired hepatic or renal function. When used in patients with renal insufficiency, dosage reductions and increased monitoring are usually warranted.

Allopurinol does not appear to be effective in dissolving urate uroliths in dogs with portovascular anomalies.

Red-tailed hawks appear to be sensitive to the effects of allopurinol. Doses at 50 mg/kg PO once daily caused clinical signs of vomiting and hyperuricemia with renal dysfunction. Doses of 25 mg/kg PO once daily were safe but not effective in reducing plasma uric acid.

### Adverse Effects

Adverse effects in dogs are apparently uncommon with allopurinol when fed low purine diets. There has been one report of a dog developing hemolytic anemia and trigeminal neuropathy while receiving allopurinol. Xanthine coatings have formed around ammonium urate uroliths in dogs that have been fed diets containing purine. If the drug is required for chronic therapy, reduction of purine precursors in the diet with dosage reduction should be considered.

Several adverse effects have been reported in humans including GI distress, bone marrow suppression, skin rashes, hepatitis, and vasculitis. Human patients with renal dysfunction are at risk for further decreases in renal function and other severe adverse effects unless dosages are reduced. Until further studies are performed in dogs with decreased renal function, the drug should be used with caution and at reduced dosages.

### Reproductive/Nursing Safety

While the safe use of allopurinol during pregnancy has not been established, dosages of up to 20 times normal in rodents have not demonstrated decreases in fertility. Infertility in males (humans) has been reported with the drug, but a causal effect has not been firmly established. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Allopurinol and oxypurinol may be excreted into milk; use caution when allopurinol is administered to a nursing dam.

### Overdosage/Acute Toxicity

Vomiting has been seen in dogs at doses >44 mg/kg per the APCC database. A human ingesting 22.5 grams did not develop serious toxicity. The oral LD 50 in mice is 78 mg/kg.

There were 52 exposures to allopurinol reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 51 were dogs with 6 showing clinical signs. The remaining 1 reported case was a cat that showed no symptoms. Common findings recorded in decreasing frequency included vomiting and trembling.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving allopurinol and may be of significance in veterinary patients:

- **AMINOPHYLLINE** or **THEOPHYLLINE**: Large doses of allopurinol may decrease metabolism thereby increasing their serum levels
- **AMOXICILLIN** or **AMPICILLIN**: In humans, concomitant use with allopurinol has been implicated in increased occurrences of skin rashes; the veterinary significance of this interaction is unknown
- **AZATHIOPRINE** or **MERCAPTOPYRINE**: Allopurinol may inhibit metabolism and increase toxicity; if concurrent use is necessary, dosages of the antineoplastic/immunosuppressive agent should be reduced initially to 25–33% of their usual dose and then adjusted, dependent upon patient's response
- **CHLORPROPAMIDE**: Allopurinol may increase risks for hypoglycemia and hepato-renal reactions
- **CYCLOPHOSPHAMIDE**: Increased bone marrow depression may occur in patients receiving both allopurinol and cyclophosphamide
- **CYCLOSPORINE**: Allopurinol may increase cyclosporine levels
- **DIURETICS (Furosemide, Thiazides, Diazoxide, and Alcohol)**: Can increase uric acid levels
- **ORAL ANTICOAGULANTS (e.g., Warfarin)**: Allopurinol may reduce the metabolism of warfarin thereby increasing effect
- **TRIMETHOPRIM/SULFAMETHOXAZOLE**: In a few human patients, thrombocytopenia has occurred when used with allopurinol
- **URICOSURIC AGENTS (e.g., Probenecid, Sulfinpyrazone)**: May increase the renal excretion of oxypurinol and thereby reduce xanthine oxidase inhibition; in treating hyperuricemia the additive effects on blood uric acid may, in fact, be beneficial to the patient
- **URINARY ACIDIFIERS (e.g., Methionine, Ammonium Chloride)** May reduce the solubility of uric acid in the urine and induce urolithiasis

### Doses

#### ■ DOGS:

For urate uroliths:

- a) For dissolution: 15 mg/kg PO q12h; only in conjunction with low purine foods.

For prevention: 10–20 mg/kg/day; because prolonged high doses of allopurinol may result in xanthine uroliths, it may be preferable to minimize recurrence

with dietary therapy, with the exception of urate lith formation with dissolution protocols. (Osborne *et al.* 2003)

b) 7–10 mg/kg PO three times daily for both dissolution and prevention. Goal is to reduce urine urate:creatinine ratio by 50%. (Senior 1989)

For Leishmaniasis:

a) First line treatment: Meglumine antimoniate (N-methylglucamine antimoniate) 75 - 100 mg/kg once daily for 4-8 weeks plus allopurinol 10 mg/kg PO twice daily for 6-12 months. Second line treatment: Milofosine 2 mg/kg PO once daily for 4 weeks plus allopurinol 10 mg/kg PO twice daily for 6-12 months *OR* allopurinol alone at 10 mg/kg PO twice daily for 6-12 months. (Solano-Gallego *et al.* 2009)

b) Meglumine antimoniate (100 mg/kg/day SQ) until resolution, with allopurinol at 20 mg/kg PO q12h for 9 months.

An alternate protocol using allopurinol alone: allopurinol 10 mg/kg PO q8h or 10–20 mg/kg PO q12h for 1–4 months. (Brosey 2005)

c) If possible use with meglumine antimoniate, if not, use allopurinol alone at 10 mg/kg PO twice daily. If animal has renal insufficiency, use at 5 mg/kg PO twice daily. (Font 1999)

d) 15 mg/kg PO twice daily for months (Lappin 2000)

## ■BIRDS:

For gout:

a) In budgies and cockatiels: Crush one 100 mg tablet into 10 mL of water. Add 20 drops of this solution to one ounce of drinking water. (McDonald 1989)

b) For parakeets: Crush one 100 mg tablet into 10 mL of water. Add 20 drops of this solution to one ounce of drinking water or give 1 drop 4 times daily. (Clubb 1986)

## ■REPTILES:

a) For elevated uric acid levels in renal disease in lizards: 20 mg/kg PO once daily (de la Navarre 2003)

b) For gout: 20 mg/kg PO once daily. Suggested dosage based upon human data as dose is not established for reptiles. (Johnson-Delaney 2005)

c) For hyperuricemia in green iguanas: 25 mg/kg PO daily. (Hernandez-Divers *et al.* 2008)

## Monitoring

■ Urine uric acid (for urolithiasis)

■ Adverse effects

■ Periodic CBC, liver and renal function tests (*e.g.*, BUN, Creatinine, liver enzymes); especially early in therapy

## Client Information

■ Unless otherwise directed, administer after meals (usually 1 hour or so). Notify veterinarian if animal develops a rash, becomes lethargic or ill.

## Chemistry/Synonyms

A xanthine oxidase inhibitor, allopurinol occurs as a tasteless, fluffy white to off-white powder with a slight odor. It melts above 300° with decomposition and has an apparent pKa of 9.4. Oxypurinol (aka oxipurinol, alloxanthine), its active metabolite, has a pKa of 7.7. Allopurinol is only very slightly soluble in both water and alcohol.

Allopurinol may also be known as: allopurinolum, BW-56-158, HPP, or NSC-1390; many trade names are available.

## Storage/Stability

Allopurinol tablets should be stored at room temperature in well-closed containers. The drug is stated to be stable in both light and air. The powder for injection should be stored at 25°C; may be exposed to 15–30°C. Once diluted to a concentration ≤6 mg/mL, store at room temperature and use within 10 hours; do not refrigerate.

## Compatibility/Compounding Considerations

When using the injection, compatible IV solutions include D5W and normal saline.

**Compounded preparation stability:** Allopurinol oral suspension compounded from commercially available tablets has been published (Allen, 1996). Triturating eight (8) 300 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 20 mg/mL suspension that retains >95% potency for 60 days stored at both 5°C and 25°C. The optimal stability of allopurinol liquids is reported to be between 3.1 and 3.4. Compounded preparations of allopurinol should be protected from light.

Another extemporaneously prepared suspension containing 20 mg/mL allopurinol for oral use can be prepared from the commercially available tablets. Tablets are crushed and mixed with an amount of *Cologel*® suspending agent equal to 1/3 the final volume. A mixture of simple syrup and wild cherry syrup at a ratio of 2:1 is added to produce the final volume. This preparation has been reported to be stable for at least 14 days when stored in an amber bottle at either room temperature or when refrigerated.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Allopurinol Oral Tablets: 100 mg & 300 mg; Zylprim® (Faro); generic; (Rx)

Allopurinol Powder for Injection, lyophilized: 500 mg preservative-free in 30 mL vials; *Aloprim*® (Nabi); generic (Bedford Labs); (Rx)

## ALPRAZOLAM

(al-prah-zoe-lam) Xanax®

BENZODIAZEPINE SEDATIVE/TRANQUILIZER

### Prescriber Highlights

- **Oral benzodiazepine that may be useful for unwanted behaviors in dogs or cats**
  - **Contraindications: Aggressive animals (controversial), benzodiazepine hypersensitivity**
  - **Caution: Hepatic or renal disease**
  - **Adverse Effects: Sedation, behavior changes, & contradictory responses; physical dependence is a possibility; may impede training**
  - **C-IV controlled substance**
- 

### Uses/Indications

Alprazolam may be useful for adjunctive therapy in anxious, aggressive dogs or in those demonstrating panic reactions. (**Note:** Some clinicians believe that benzodiazepines are contraindicated in aggressive dogs as anxiety may actually restrain the animal from aggressive tendencies). It may be useful in cats to treat anxiety disorders.

Alprazolam may have less effect on motor function at low doses than does diazepam.

### Pharmacology/Actions

Subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by alprazolam and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

### Pharmacokinetics

The pharmacokinetics of alprazolam have not been described for either dogs or cats. In humans, alprazolam is well absorbed and is characterized as having an intermediate onset of action. Peak plasma levels occur in 1–2 hours.

Alprazolam is highly lipid soluble and widely distributed throughout the body. It readily crosses the blood-brain barrier and is somewhat bound to plasma proteins (80%).

Alprazolam is metabolized in the liver to at least two metabolites, including alpha-hydroxy-alprazolam which is pharmacologically active. Elimination half-lives range from 6–27 hours in people.

### Contraindications/Precautions/Warnings

Some clinicians believe that benzodiazepines are contraindicated in aggressive dogs as anxiety may actually restrain the animal from aggressive tendencies. This remains controversial. Alprazolam is contraindicated in patients with known hypersensitivity to the drug. Use cautiously in patients with hepatic or renal disease, narrow angle glaucoma and debilitated or geriatric patients. Benzodiazepines may impair the abilities of working animals.

### Adverse Effects

Benzodiazepines can cause sedation, increased appetite, and transient ataxia. Cats may exhibit changes in behavior (irritability, increased affection, depression, aberrant demeanor) after receiving benzodiazepines.

Dogs may rarely exhibit a contradictory response (CNS excitement) following administration of benzodiazepines.

Chronic usage of benzodiazepines may induce physical dependence. Animals appear to be less likely than humans to develop physical dependence at doses normally administered.

Benzodiazepines may impede the ability of the animal to learn and may retard training.

### Reproductive/Nursing Safety

Diazepam and other benzodiazepines have been implicated in causing congenital abnormalities in humans if administered during the first trimester of pregnancy. Infants born of mothers receiving large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, hypotonia, etc. Withdrawal symptoms have occurred in infants whose mothers chronically took benzodiazepines during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

### Overdosage/Acute Toxicity

Alprazolam overdoses are generally limited to CNS signs. CNS depression can be seen and the severity is generally dose dependant. Hypotension, respiratory depression, and cardiac arrest have been reported in human patients, but apparently, are quite rare. The reported LD<sub>50</sub> in rats for alprazolam is >330 mg/kg, but cardiac arrest occurred at doses as low as 195 mg/kg. Life threatening signs in small animals are rare. Some animals may present with a paradoxical type reaction (disorientation, vocalization, agitation, etc.). At times, those signs may be followed by CNS depression.

There were 695 exposures to alprazolam reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 658 were dogs with 330 showing clinical signs, 34 were cats with 19 showing clinical signs, 2 were birds with 1 reported as having symptoms, and 1 case was a chinchilla reported as

having symptoms. Common findings in dogs recorded in decreasing frequency included ataxia, hyperactivity, lethargy, agitation, disorientation, and vomiting. Common findings in cats recorded in decreasing frequency included ataxia, depression, hyperactivity, polyphagia, and vocalization.

Treatment of acute toxicity consists of standard protocols for decontamination. The decision to give activated charcoal should be weighed carefully, as in some cases the risk of activated charcoal may outweigh the benefit. Flumazenil (see separate monograph) may be used to reverse the sedative effects of benzodiazepines, but only if the CNS depression is significant, resulting in respiratory depression.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving alprazolam and may be of significance in veterinary patients:

- **ANTACIDS:** May slow the rate, but not the extent of oral absorption of alprazolam; administer 2 hours apart to avoid this potential interaction
- **CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.):** Additive effects may occur
- **DIGOXIN:** Serum levels may be increased; monitor serum digoxin levels or clinical signs of toxicity
- **FLUOXETINE, FLUVOXAMINE:** Increased alprazolam levels
- **HEPATICALLY METABOLIZED DRUGS (e.g., Cimetidine, erythromycin, isoniazid, ketoconazole, itraconazole):** Metabolism of alprazolam may be decreased and excessive sedation may occur
- **RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines
- **TRICYCLIC ANTIDEPRESSANTS (e.g., AMITRIPTYLINE, CLOMIPRAMINE, IMPRAMINE):** Alprazolam may increase levels of these drugs; clinical significance is not known and some state that clomipramine and alprazolam together may improve efficacy for phobias (e.g., thunderstorm phobia)

## Doses

### ■ DOGS:

- a) For treatment of canine anxiety disorders: 0.01–0.1 mg/kg PO as needed for panic, not to exceed 4 mg/dog/day. Start with 1–2 mg (total dose) for a medium-sized dog. (Overall 1997)
- b) For separation anxiety: 0.25 mg–2 mg (total dose) once daily to three times daily PO. (Hunthausen 2006)
- c) For storm phobias: 0.02–0.4 mg/kg PO q4h as needed; helps to minimize impact of experiencing a severe storm (Crowell-Davis 2003a);  
0.02 mg/kg PO as needed one hour before anticipated storm and every 4 hours as needed; used as an adjunct after behavior modification and prior clomipramine treatment (see [clomipramine](#) monograph for further information) (Crowell-Davis 2003b)
- d) For phobias, night waking: 0.01–0.1 mg/kg or 0.25–2 mg (total dose) per dog PO q6–12h PO (Siebert 2003)
- e) For acute anxiety: 0.05–0.1 mg/kg PO prn or three times a day. Administer 30–60 minutes prior to trigger event. (Neilson 2009)

### ■ CATS:

- a) For treatment of feline anxiety disorders: 0.125–0.25 mg/kg PO q12h (Start at 0.125 mg/kg PO) (Overall 1997)
- b) For refractory house soiling: 0.1 mg/kg or 0.125–0.25 mg (total dose) per cat PO q8–12h (Siebert 2003)
- c) For urine marking: 0.05–0.2 mg/kg PO q12–24h (Virga 2002)
- d) For fears/phobias/anxieties: 0.125–0.25 mg (total dose) PO once to three times a day. (Landsberg 2005)
- e) For acute anxiety: 0.05 mg/kg PO prn or three times a day. Administer 30–60 minutes prior to trigger event. (Neilson 2009)

## Monitoring

- Efficacy
- Adverse Effects
- Consider monitoring hepatic enzymes particularly when treating cats chronically

## Client Information

- Try to dose approximately one hour in advance of storms or other anticipated stimuli that evokes negative responses
- If difficulty with pilling the medication occurs, consider using the orally-disintegrating tablets; hands must be dry before handling
- If excessive sedation or yellowing of the whites of eyes (especially in cats) occurs, contact veterinarian

## Chemistry/Synonyms

A benzodiazepine, alprazolam occurs as a white to off-white, crystalline powder. It is soluble in alcohol and insoluble in water.

Alprazolam may also be known as D65 MT, U 31889, or alprazolamum; many trade names available internationally.

## Storage/Stability

Alprazolam tablets should be stored at room temperature in tight, light-resistant containers. The orally disintegrating tablets should be stored at room temperature and protected from moisture.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Alprazolam oral suspension compounded from commercially available tablets has been published (Allen, 1998). Triturating sixty (60) alprazolam 2 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® SF) yields a 1 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of alprazolam should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Alprazolam Oral Tablets: 0.25 mg, 0.5 mg, 1 mg & 2 mg; *Xanax*® (Pfizer); generic; (Rx; C-IV)

Alprazolam Extended-release Oral Tablets: 0.5 mg, 1 mg, 2 mg, & 3 mg; *Xanax XR*® (Pfizer); generic; (Rx; C-IV)

Alprazolam Orally Disintegrating Tablets: 0.25 mg, 0.5 mg, 1 mg, & 2 mg; *Niravam*® (Schwarz Pharma); (Rx; C-IV)

Alprazolam Oral Solution: 1 mg/mL in 30 mL; *Alprazolam Intensol*® (Roxane); (Rx; C-IV)

## ALTRENOGEST

(al-tre-noe-jest) *Regu-Mate*®, *Matrix*®

### ORAL PROGESTIN

### Prescriber Highlights

- **Progestational drug used in horses to suppress estrus or maintain pregnancy when progestin deficient; used in swine to synchronize estrus**
  - **May be used in dogs for luteal deficiency or as a treatment to prevent premature delivery**
  - **Many “handling” warnings for humans (see below)**
  - **Very sensitive to light**
- 

## Uses/Indications

Altrenogest (*Regu-Mate*®) is indicated (labeled) to suppress estrus in mares to allow a more predictable occurrence of estrus following withdrawal of the drug. It is used clinically to assist mares to establish normal cycles during the transitional period from anestrus to the normal breeding season often in conjunction with an artificial photoperiod. It is more effective in assisting in pregnancy attainment later in the transition period. Some authors (Squires et al. 1983) suggest selecting mares with considerable follicular activity (mares with one or more follicles 20 mm or greater in size) for treatment during the transitional phase. Mares that have been in estrus for 10 days or more and have active ovaries are also considered excellent candidates for progestin treatment.

Altrenogest is effective in normally cycling mares for minimizing the necessity for estrus detection, for the synchronization of estrus, and permitting scheduled breeding. Estrus will ensue 2–5 days after treatment is completed and most mares ovulate between 8–15 days after withdrawal. Altrenogest is also effective in suppressing estrus expression in show mares or mares to be raced. Although the drug is labeled as contraindicated during pregnancy, it has been demonstrated to maintain pregnancy in oophorectomized mares and may be of benefit in mares that abort due to sub-therapeutic progestin levels.

The product *Matrix*® is labeled for synchronization of estrus in sexually mature gilts that have had at least one estrous cycle. Treatment with altrenogest results in estrus (standing heat) 4–9 days after completion of the 14-day treatment period.

Altrenogest has been used in dogs for luteal insufficiency and as a treatment to prevent premature delivery.

## Pharmacology/Actions

Progestins are primarily produced endogenously by the corpus luteum. They transform proliferative endometrium to secretory endometrium, enhance myometrium hypertrophy and inhibit spontaneous uterine contraction. Progestins have a dose-dependent inhibitory effect on the secretion of pituitary gonadotropins and have some degree of estrogenic, anabolic and androgenic activity.

## Pharmacokinetics

In horses, the pharmacokinetics of altrenogest have been studied (Machnik et al. 2007). After oral dosing of 44 mg/kg PO, peak levels usually occur within 15–30 minutes post-dose; 24 hours post-dose, levels were below the level of quantification. Elimination half-lives are approximately 2.5–4 hours. Altrenogest appears to be primarily eliminated in the urine. Peak urine levels occur 3–6 hours after oral dosing. Urine levels were detectable up to 12 days post-administration.

## Contraindications/Precautions/Warnings

The manufacturer (*Regu-Mate*®—Intervet) lists pregnancy as a contraindication to the use of altrenogest, however it has been used clinically to maintain pregnancy in certain mares (see Dosages below). Altrenogest should also not be used in horses intended for food purposes.

## Adverse Effects

Adverse effects of altrenogest appear to be minimal when used at labeled dosages. One study (Shideler et al. 1983) found negligible changes in hematologic and most “standard” laboratory tests after administering altrenogest to 4 groups of horses (3 dosages, 1 control) over 86 days. Occasionally, slight changes in Ca<sup>++</sup>, K<sup>+</sup>, alkaline phosphatase and AST were noted in the treatment group, but values were only slightly elevated and only noted sporadically. No pattern or definite changes could be attributed to altrenogest. No outward adverse effects were noted in the treatment group during the trial.

Use of progestational agents in mares with chronic uterine infections should be avoided as the infection process may be enhanced.

## Overdosage/Acute Toxicity

The LD<sub>50</sub> of altrenogest is 175–177 mg/kg in rats. No information was located regarding the effects of an accidental acute overdose in horses or other species.

The LD<sub>50</sub> of altrenogest is 175–177 mg/kg in rats. No information was located regarding the effects of an accidental acute overdose in horses or other species.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving altrenogest and may be of significance in veterinary patients:

- **RIFAMPIN:** May decrease progestin activity if administered concomitantly. This is presumably due to microsomal enzyme induction with resultant increase in progestin metabolism. The clinical significance of this potential interaction is unknown.

## Laboratory Considerations

- Unlike exogenously administered progesterone, altrenogest does not interfere or cross-react with progesterone assays

## Doses

### ■ DOGS:

For luteal insufficiency:

- a) Document luteal insufficiency and rule out infectious causes of pregnancy loss. Best to avoid during first trimester. Give equine product (*Regumate*®) at 2 mL per 100 lbs of body weight PO once daily. Monitor pregnancy with ultrasound. Remember that exogenous progesterone is the experimental model for pyometra in the bitch, so monitor carefully. (Purswell 1999)
- b) For luteal insufficiency, pre-term labor: 0.1 mL per 10 lb body weight PO once daily. (Barber 2006)
- c) To maintain pregnancy if tocolytics (*e.g.*, terbutaline) do not control myometrial contractility: 0.088 mg/kg once daily (q24h). Must be withdrawn 2–3 days prior to predicted whelp date. (Davidson 2006)

### ■ HORSES:

To suppress estrus for synchronization:

- a) Administer 1 mL per 110 pounds body weight (0.044 mg/kg) PO once daily for 15 consecutive days. May administer directly on tongue using a dose syringe or on the usual grain ration. (Package insert; *Regu-Mate*®—Intervet)

For prevention of abortion/pregnancy loss:

- a) 0.088 mg/kg PO once daily. (Dascanio 2009)
- b) To maintain pregnancy in mares with deficient progesterone levels: 0.044 mg/kg PO once daily. Three options for treatment: 1) treatment until day 60 of pregnancy or greater AND measurement of endogenous progesterone level of >4 ng/mL; 2) treatment until day 120 of pregnancy; or 3) treatment until end of pregnancy. (McCue 2003)
- c) To maintain pregnancy in mares with placentitis: 22–44 mg (total dose; 10–20 mL) PO daily. (Valla 2003)

To suppress estrus (long-term):

- a) 0.044 mg/kg PO daily (Squires *et al.* 1983)

### ■ SWINE:

For synchronization of estrous in sexually mature gilts that have had at least one estrous cycle:

- a) Follow label directions for safe use. Administer 6.8 mL (15 mg) per gilt for 14 consecutive days. Apply as a top-dressing on a portion of gilt's daily feed allowance. Estrous should occur 4–9 days after completing treatment. (Package insert; *Matrix*®—Intervet)

## Client Information

- The manufacturer (*Regu-Mate*®, *Matrix*®—Intervet) lists the following people as those who should not handle the product:

1. Women who are or suspect that they are pregnant
2. Anyone with thrombophlebitis or thromboembolic disorders or with a history of these events
3. Anyone having cerebrovascular or coronary artery disease
4. Women with known or suspected carcinoma of the breast
5. People with known or suspected estrogen-dependent neoplasias
6. Women with undiagnosed vaginal bleeding
7. People with benign or malignant tumor that developed during the use of oral contraceptives or other estrogen containing products

Altrenogest can be absorbed after skin contact and absorption can be enhanced if the drug is covered by occlusive materials (*e.g.*, under latex gloves, etc.). If exposed to the skin, wash off immediately with soap and water. If the eyes are exposed, flush with water for 15 minutes and get medical attention. If the product is swallowed, do not induce vomiting and contact a physician or poison control center.

This medication is prohibited from use in an extra-label manner to enhance and/or fiber production in animals

## Chemistry/Synonyms

An orally administered synthetic progestational agent, altrenogest has a chemical name of 17 alpha-Allyl-17beta-hydroxyestra-4,9,11-trien-3-one.

Altrenogest may also be known as: allyl trenbolone, A-35957, A-41300, RH-2267, or RU-2267, *Regu-Mate*®, or *Matrix*®.

## Storage/Stability

Altrenogest oral solution should be stored at room temperature. Altrenogest is extremely sensitive to light; dispense in light-resistant containers.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Altrenogest 0.22% (2.2 mg/mL) in oil solution in 150 mL and 1000 mL bottles; *Regu-Mate*® (Intervet); (Rx). FDA-approved for use in horses not intended for food.

This medication is banned in racing animals in some countries.

Altrenogest 0.22% (2.2 mg/mL) in 1000 mL bottles; *Matrix*® (Intervet); (OTC, but extra-label use prohibited). FDA-approved for use in sexually mature gilts that have had at least one estrous cycle. Gilts must not be slaughtered for human consumption for 21 days after the last treatment. The FDA prohibits the extra-label use of this medication to enhance food and/or fiber production in animals.

**HUMAN-LABELED PRODUCTS:** None

## ALUMINUM HYDROXIDE

(ah-loo-min-um hye-droks-ide) Amphogel®

ORAL ANTACID/PHOSPHATE BINDER

### Prescriber Highlights

- Used to treat hyperphosphatemia in small animal patients & sometimes as a gastric antacid for ulcers
  - Chronic use may lead to electrolyte abnormalities; possible aluminum toxicity
  - Many potential drug interactions
  - Bulk, dried powder available from several sources
- 

## Uses/Indications

Orally administered aluminum hydroxide is used to reduce hyperphosphatemia in patients with renal failure when dietary phosphorus restriction fails to maintain serum phosphorus concentrations in the normal range.

## Pharmacology/Actions

Aluminum salts reduce the amount of phosphorus absorbed from the intestine by physically binding to dietary phosphorus.

## Contraindications/Precautions/Warnings

Aluminum-containing antacids may inhibit gastric emptying; use cautiously in patients with gastric outlet obstruction.

## Adverse Effects

In small animals, the most likely side effect of aluminum hydroxide is constipation. If the patient is receiving a low phosphate diet and the patient chronically receives aluminum antacids, hypophosphatemia can develop.

Potentially, aluminum toxicity could occur with prolonged use. While previously believed unlikely to occur in small animal patients, at least 2 dogs in renal failure have been documented to have developed aluminum toxicity after receiving aluminum-containing phosphate binders (Segev *et al.* 2008). Aluminum-containing and calcium-containing phosphate binders may be used in combination to reduce the dose of each to reduce the risk of aluminum toxicity or hypercalcemia.

## Reproductive/Nursing Safety

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), these drugs are categorized as in class: *A (Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.)*

## Overdosage/Acute Toxicity

Acute toxicity is unlikely with an oral overdose. If necessary, GI and electrolyte imbalances that occur with chronic or acute overdose should be treated symptomatically.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral aluminum salts and may be of significance in veterinary patients:

Aluminum salts can **decrease** the amount absorbed or the pharmacologic effect of:

■ALLOPURINOL

■CHLOROQUINE

■CORTICOSTEROIDS

■DIGOXIN

■ETHAMBUTOL

■FLUOROQUINOLONES

■H-2 ANTAGONISTS (RANITIDINE, FAMOTIDINE, etc.)

## ■ IRON SALTS

## ■ ISONIAZID

## ■ PENICILLAMINE

## ■ PHENOTHIAZINES

## ■ TETRACYCLINES

## ■ THYROID HORMONES

Separate oral doses of aluminum hydroxide and these drugs by two hours to help reduce this interaction.

## Doses

### ■ DOGS:

For hyperphosphatemia:

- Aluminum hydroxide: 30–100 mg/kg/day PO with meals. (Adams 2009)
- Aluminum hydroxide gel, dried powder: 30–90 mg/kg/day PO prior to meals. The dried powder is virtually tasteless and accepted readily by most cats when mixed with canned food. (Wolf 2008)
- 15–45 mg/kg PO q12h (Bartges 2002)

For adjunctive therapy for gastric ulcers:

- Aluminum hydroxide suspension or aluminum hydroxide/magnesium hydroxide suspension: 2–10 mL PO q2–4h (Hall & Twedt 1989)
- Aluminum hydroxide tablets: ½–1 tablet or strength PO q6h (Matz 1995)

### ■ CATS:

For hyperphosphatemia:

- Aluminum hydroxide: Initially at 30–90 mg/kg per day. Dosage must be individualized. Capsules or suspension are preferred as they are more easily mixed with food and dispersed throughout ingesta. Evaluate serum phosphate levels at 10–14 day intervals to determine optimum dosage. (Polzin & Osborne 1985)
- 15–45 mg/kg PO q12h (Bartges 2002)

As an antacid:

- Aluminum hydroxide tablets: ¼ tablet PO q6h (Matz 1995)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

- Chinchillas: Aluminum hydroxide gel: 1 mL/animal PO as needed  
Guinea pigs: 0.5–1 mL/animal PO as needed (Adamcak & Otten 2000)

### ■ CATTLE:

As an antacid:

- Aluminum hydroxide: 30 grams/animal (Jenkins 1988)

### ■ HORSES:

For adjunctive gastroduodenal ulcer therapy in foals:

- Aluminum/magnesium hydroxide suspension: 15 mL (total dose) 4 times a day (Clark and Becht 1987)

## Monitoring

- Serum phosphorus (after a 12-hour fast), initially at 10–14 day intervals; once “stable”, at 4–6 week intervals
- For aluminum toxicity: neuromuscular effects, progressive decreases in mean cell volume (MCV) and microcytosis

## Client Information

- Oral aluminum hydroxide products are available without prescription (OTC), but should be used under the supervision of the veterinarian.
- Bulk, powder, tablets or capsules (may be compounded) are easier to administer than human liquids or suspensions
- Give either just before feeding or mixed in food
- Report any unusual neuromuscular signs such as weakness, difficulty walking, or stumbling to veterinarian

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Aluminum Hydroxide Oral Capsules: 500 mg, *Dialume*® (RPR): (OTC)

Aluminum Hydroxide Oral Tablets: 600 mg, *Amphojel*® (Wyeth-Ayerst): (OTC)

Aluminum Hydroxide Concentrated Gel Suspension/Liquid (Note: These products are usually flavored (mint) and not well accepted by dogs or cats.):

320 mg/5 mL in 360 & 480 mL, UD 15 & 30 mL; generic; (OTC)

450mg/5 mL in 500 mL and UD 30 mL; generic (Roxane); (OTC)

675 mg/5 mL in 180 and 500 mL, UD 20 and 30 mL; generic; (OTC)

Aluminum Hydroxide Concentrated Gel Liquid: 600 mg/5 mL in 30, 150, 180, 360 & 480 mL; *AlternaGEL*® (J & J-Merck); generic; (OTC)

Aluminum Hydroxide Gel, Dried Powder, USP; Bulk powder is available from a variety of sources including many compounding pharmacies. See:

<http://goo.gl/11YIk> for additional source information

**Note:** There are also many products available that have aluminum hydroxide and a magnesium or calcium salt (*e.g.*, *Maalox*®, etc.) that are used as antacids. All oral aluminum and magnesium hydroxide preparations are OTC.

## AMANTADINE HCL

(a-man-ta-deen) Symmetrel®

ANTIVIRAL (INFLUENZA A); NMDA ANTAGONIST

### Prescriber Highlights

- **Antiviral drug with NMDA antagonist properties; may be useful in adjunctive therapy of chronic pain in small animals & treatment of equine influenza in horses**
- **Very limited clinical experience; dogs may exhibit agitation & GI effects, especially early in therapy**
- **Large interpatient variations of pharmacokinetics in horses limit its therapeutic usefulness**
- **Overdoses are potentially very serious; fairly narrow therapeutic index in dogs & cats; may need to be compounded**
- **Extra-label use prohibited (by FDA) in chickens, turkeys & ducks**

---

## Uses/Indications

While amantadine may have efficacy and clinical usefulness against some veterinary viral diseases, presently the greatest interest for its use in small animals is as a NMDA antagonist in the adjunctive treatment of chronic pain, often in those tolerant to opioids. It is generally used in combination with an NSAID, when the NSAID alone does not offer sufficient pain relief. It is also used as an adjunct drug for treating neuropathic pain. It has been suggested for use as an early intervention in the treatment of pain associated with osteosarcomas (Gaynor, J.S. 2008).

Amantadine has also been investigated for treatment of equine-2 influenza virus in the horse. However, because of expense, interpatient variability in oral absorption and other pharmacokinetic parameters, and the potential for causing seizures after intravenous dosing, it is not commonly used for treatment.

In humans, amantadine is used for treatment and prophylaxis of influenza A, parkinsonian syndrome, and drug-induced extrapyramidal effects. As in veterinary medicine, amantadine's effect on NMDA receptors in humans are of active interest, particularly its use as a co-analgesic with opiates and in the reduction of opiate tolerance development.

## Pharmacology/Actions

Like ketamine, dextromethorphan and memantine, amantadine antagonizes the N-methyl-D-aspartate (NMDA) receptor. Within the central nervous system, chronic pain can be maintained or exacerbated when glutamate or aspartate bind to this receptor. It is believed that this receptor is particularly important in allodynia (sensation of pain resulting from a normally non-noxious stimulus). Amantadine alone is not a particularly good analgesic, but in combination with other analgesics (*e.g.*, opiates, NSAIDs), it is thought that it may help alleviate chronic pain.

Amantadine's antiviral activity is primarily limited to strains of influenza A. While its complete mechanism of action is unknown, it does inhibit viral replication by interfering with influenza A virus M2 protein.

Amantadine's antiparkinsonian activity is not well understood. The drug does appear to have potentiating effects on dopaminergic neurotransmission in the CNS and anticholinergic activity.

## Pharmacokinetics

The pharmacokinetics of this drug have apparently not been described in dogs or cats. In horses, amantadine has a very wide interpatient variability of absorption after oral dosing; bioavailability ranges from 40–60%. The elimination half-life in horses is about 3.5 hours and the steady state volume of distribution is approximately 5 L/kg.

In humans, the drug is well absorbed after oral administration with peak plasma concentrations occurring about 3 hours after dosing. Volume of distribution is 3–8 L/kg. Amantadine is primarily eliminated via renal mechanisms. Oral clearance is approximately 0.28 L/hr/kg; half-life is around 17 hours.

## Contraindications/Precautions/Warnings

In humans, amantadine is contraindicated in patients with known hypersensitivity to it or rimantadine, and in patients with untreated angle-closure glaucoma. It should be used with caution in patients with liver disease, renal disease (dosage adjustment may be required), congestive heart failure, active psychoses, eczematoid dermatitis or seizure disorders. In veterinary patients with similar conditions, it is advised to use the drug with caution until more information on its safety becomes available.

In 2006, the FDA banned the use of amantadine and other influenza antivirals in chickens, turkeys and ducks.

## Adverse Effects

There is very limited experience in domestic animals with amantadine and its adverse effect profile is not well described. It has been reported that dogs given amantadine occasionally develop agitation, loose stools, flatulence or diarrhea, particularly early in therapy. Experience in cats is limited; an adverse effect profile has yet to be fully elucidated, but the safety margin appears to be narrow.

## Reproductive/Nursing Safety

In humans, the FDA categorizes amantadine as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). High dosages in rats demonstrated some teratogenic effects.

Amantadine does enter maternal milk. The manufacturer does not recommend its use in women who are nursing. Veterinary significance is unclear.

## Overdosage/Acute Toxicity

Toxic dose reported for cats is 30 mg/kg and behavioral effects may be noted at 15 mg/kg in dogs and cats.

In humans, overdoses as low as 2 grams have been associated with fatalities. Cardiac dysfunction (arrhythmias, hypertension, tachycardia), pulmonary edema, CNS toxicity (tremors, seizures, psychosis, agitation, coma), hyperthermia, renal dysfunction and respiratory distress syndrome have all been documented. There is no known specific antidote for amantadine overdose. Treatment should consist of gut emptying, if possible, intensive monitoring and supportive therapy. Forced urine acidifying diuresis may increase renal excretion of amantadine. Physostigmine has been suggested for cautious use in treating CNS effects.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amantadine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC DRUGS:** May enhance the anticholinergic effects of amantadine
- **CNS STIMULANTS** (including **selegiline**): Concomitant use with amantadine may increase the drug's CNS stimulatory effects
- **TRIMETHOPRIM/SULFA, QUINIDINE, QUININE, THIAZIDE DIURETICS OR TRIAMTERENE:** May decrease the excretion of amantadine, yielding higher blood levels
- **URINARY ACIDIFIERS** (*e.g.*, **methionine, ammonium chloride, ascorbic acid**): May increase the excretion of amantadine

## Laboratory Considerations

- No laboratory interactions identified

## Doses

### ■ DOGS:

As adjunctive therapy for chronic pain:

- a) For osteoarthritis pain when NSAIDs alone are not effective: 3–5 mg/kg PO once daily in addition to an NSAID (meloxicam at approved doses used for this study) (Lascelles, B.D.X. *et al.* 2008)
- b) 3–5 mg/kg PO once daily. (Gaynor, J. 2002), (Gaynor, J.S. 2008)
- c) To decrease wind-up: 3–5 mg/kg PO once daily for one week. (Perkowski 2006)

### ■ CATS:

As adjunctive therapy for chronic pain:

- a) 3 mg/kg PO once daily. May be useful addition to NSAIDs; not been evaluated for toxicity. May need to be compounded. (Lascelles, D. *et al.* 2003)
- b) 3–5 mg/kg PO once daily. (Gaynor, J. 2002), (Gaynor, J.S. 2008)
- c) 3 mg/kg PO once daily. (Hardie 2006)

### ■ HORSES:

For acute treatment of equine-2 influenza:

- a) 5 mg/kg IV q4h (Rees *et al.* 1997)

## Monitoring

- Adverse effects (GI, agitation)
- Efficacy

## Client Information

- When used in small animals, the drug must be given as prescribed to be effective and may take a week or so to show effect.
- Gastrointestinal effects (loose stools, gas, diarrhea) or some agitation may occur, particularly early in treatment. Contact the veterinarian if these become serious or persist.
- Overdoses with this medication can be serious; keep well out of reach of children and pets.

## Chemistry/Synonyms

An adamantane-class antiviral agent with NMDA antagonist properties, amantadine HCl occurs as a white to practically white, bitter tasting, crystalline powder with a pKa of 9. Approximately 400 mg are soluble in 1 mL of water; 200 mg are soluble in 1 mL of alcohol.

Amantadine HCl may also be known as: adamantanamine HCl, *Adekin*®, *Amanta*®, *Amantagamma*®, *Amantan*®, *Amantrel*®, *Amixx*®, *Antadine*®, *Antiflu-DES*®, *Atarin*®, *Atenegine*®, *Cerebramed*®, *Endantadine*®, *Infectoflu*®, *Influ-A*®, *Lysovir*®, *Mantadine*®, *Mantadix*®, *Mantidan*®, *Padiken*®, *Symadine*®, *Symmetrel*®, *Viroifral*® and *Virucid*®.

## Storage/Stability

Tablets, capsules and the oral solution should be stored in tight containers at room temperature. Limited exposures to temperatures as low as 15°C and as high as 30°C are permitted. Avoid freezing the liquid.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Amantadine HCl Oral Tablets & Capsules: 100 mg; *Symmetrel*® (Endo); generic; (Rx)

Amantadine HCl Oral Syrup: 10 mg/mL in 480 mL; *Symmetrel*® (Endo); generic; (Rx). Note: It is reported that the oral liquid has a very bad taste.

In 2006, the FDA banned the extra-label use of amantadine and other influenza antivirals in chickens, turkeys and ducks.

**AMIKACIN SULFATE**

(am-i-kay-sin) Amikin®, Amiglyde-V®

AMINOGLYCOSIDE ANTIBIOTIC

**Prescriber Highlights**

- **Parenteral aminoglycoside antibiotic that has good activity against a variety of bacteria, predominantly gram-negative aerobic bacilli**
- **Adverse Effects: Nephrotoxicity, ototoxicity, neuromuscular blockade**
- **Cats may be more sensitive to toxic effects**
- **Risk factors for toxicity: Preexisting renal disease, age (both neonatal & geriatric), fever, sepsis & dehydration**
- **Now usually dosed once daily when used systemically**

**Uses/Indications**

While parenteral use is only FDA-approved in dogs, amikacin is used clinically to treat serious gram-negative infections in most species. It is often used in settings where gentamicin-resistant bacteria are a clinical problem. The inherent toxicity of the aminoglycosides limit their systemic use to serious infections when there is either a documented lack of susceptibility to other, less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Amikacin is also FDA-approved for intrauterine infusion in mares. It is used with intra-articular injection in foals to treat gram-negative septic arthritis.

**Pharmacology/Actions**

Amikacin, like the other aminoglycoside antibiotics, act on susceptible bacteria presumably by irreversibly binding to the 30S ribosomal subunit thereby inhibiting protein synthesis. It is considered a bactericidal concentration-dependent antibiotic.

Amikacin's spectrum of activity includes: coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *E. coli*, *Klebsiella*, *Proteus*, *Pseudomonas*, *Salmonella*, *Enterobacter*, *Serratia*, and *Shigella*, *Mycoplasma*, and *Staphylococcus*. Several strains of *Pseudomonas aeruginosa*, *Proteus*, and *Serratia* that are resistant to gentamicin will still be killed by amikacin.

Antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment.

The aminoglycoside antibiotics are inactive against fungi, viruses and most anaerobic bacteria.

**Pharmacokinetics**

Amikacin, like the other aminoglycosides is not appreciably absorbed after oral or intrauterine administration, but is absorbed from topical administration (not from skin or the urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. After IM administration to dogs and cats, peak levels occur from ½–1 hour later. Subcutaneous injection results in slightly delayed peak levels and with more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids; high levels are found in sputum, bronchial secretions and bile. Aminoglycosides are minimally protein bound (<20%, streptomycin 35%) to plasma proteins. Aminoglycosides do not readily cross the blood-brain barrier nor penetrate ocular tissue. CSF levels are unpredictable and range from 0–50% of those found in the serum. Therapeutic levels are found in bone, heart, gallbladder and lung tissues after parenteral dosing. Aminoglycosides tend to accumulate in certain tissues such as the inner ear and kidneys, which may help explain their toxicity. Volumes of distribution have been reported to be 0.15–0.3 L/kg in adult cats and dogs, and 0.26–0.58 L/kg in horses. Volumes of distribution may be significantly larger in neonates and juvenile animals due to their higher extracellular fluid fractions. Aminoglycosides cross the placenta; volumes of concentrations range from 15–50% of those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. The approximate elimination half-lives for amikacin have been reported to be 5 hours in foals, 1.14–2.3 hours in adult horses, 2.2–2.7 hours in calves, 1–3 hours in cows, 1.5 hours in sheep, and 0.5–2 hours in dogs and cats. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

**Contraindications/Precautions/Warnings**

Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections, there are no other absolute contraindications to their use. However, they should be used with extreme caution in patients with preexisting renal disease with

concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs (*e.g.*, “seeing-eye,” herding, dogs for the hearing impaired, etc.).

Aminoglycosides should be used with caution in patients with neuromuscular disorders (*e.g.*, myasthenia gravis) due to their neuromuscular blocking activity.

Sighthound dogs may require reduced dosages of aminoglycosides as they have significantly smaller volumes of distribution.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are generally considered contraindicated in rabbits/hares as they adversely affect the GI flora balance in these animals.

## Adverse Effects

The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity is usually manifested by: increases in BUN, creatinine, nonprotein nitrogen in the serum, and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic and amikacin less nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest by either auditory and/or vestibular clinical signs and may be irreversible. Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but either form can occur with any of these drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain/inflammation at injection site, peripheral neuropathy and hypersensitivity reactions. Rarely, GI clinical signs, hematologic and hepatic effects have been reported.

## Reproductive/Nursing Safety

Aminoglycosides can cross the placenta and while rare, may cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Aminoglycosides are excreted in milk. While potentially, amikacin ingested with milk could alter GI flora and cause diarrhea, amikacin in milk is unlikely to be of significant concern after the first few days of life (colostrum period).

## Overdosage/Acute Toxicity

Should an inadvertent overdosage be administered, three treatments have been recommended. Hemodialysis is very effective in reducing serum levels of the drug but is not a viable option for most veterinary patients. Peritoneal dialysis also will reduce serum levels but is much less efficacious. Complexation of drug with either carbenicillin or ticarcillin (12–20 g/day in humans) is reportedly nearly as effective as hemodialysis. Since amikacin is less affected by this effect than either tobramycin or gentamicin, it is assumed that reduction in serum levels will also be minimized using this procedure.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amikacin and may be of significance in veterinary patients:

- **BETA-LACTAM ANTIBIOTICS (penicillins, cephalosporins):** May have synergistic effects against some bacteria; some potential for physical inactivation of aminoglycosides *in vitro* (do not mix together) and *in vivo* (patients in renal failure)
- **CEPHALOSPORINS:** The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).
- **DIURETICS, LOOP (*e.g.*, furosemide, torsemide) or OSMOTIC (*e.g.*, mannitol):** Concurrent use with loop or osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides
- **NSAIDS:** Because NSAIDs may cause nephrotoxic effects, some believe that concurrent use with aminoglycosides should be avoided.
- **NEPHROTOXIC DRUGS, OTHER (*e.g.*, cisplatin, amphotericin B, polymyxin B, or vancomycin):** Potential for increased risk for nephrotoxicity
- **NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL:** Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

## Laboratory Considerations

- Amikacin serum concentrations may be falsely decreased if the patient is also receiving **beta-lactam antibiotics** and the serum is stored prior to analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

## Doses

**Note:** Most infectious disease clinicians now agree that aminoglycosides should be dosed once a day in most patients (mammals). This dosing regimen yields higher peak levels with resultant greater bacterial kill, and as aminoglycosides exhibit a “post-antibiotic effect”, surviving susceptible bacteria generally do not replicate as rapidly even when antibiotic concentrations are below MIC. Periods where levels are low may also decrease the “adaptive resistance” (bacteria take up less drug in the presence of continuous exposure) that can occur. Once daily dosing may decrease the toxicity of aminoglycosides as lower urinary concentrations may mean less uptake into renal tubular cells. However, patients who are neutropenic (or otherwise immunosuppressed) may benefit from more frequent dosing (q8h). Patients with significantly diminished renal function who must receive aminoglycosides may need to be dosed at longer intervals than once daily. Clinical drug monitoring is strongly suggested for these patients.

## ■ DOGS:

For susceptible infections:

- a) 15 mg/kg IV q24h or 20 mg/kg SC/IM q24h. In Greyhounds (and potentially other sighthounds) reduce dose to 10 mg/kg IV q24 or 15mg/kg SC/IM q24h. (KuKanich 2008)
- b) 15 mg/kg (route not specified) once daily (q24h). Neutropenic or immunocompromised patients may still need to be dosed q8h (dose divided). (Trepanier 1999)
- c) Sepsis: 20 mg/kg once daily IV (Hardie 2000)
- d) For empiric therapy: 15–30 mg/kg (*route not specified, assume IV, IM or SC—Plumb*) (Autran de Morais 2009)

#### ■CATS:

For susceptible infections:

- a) For empiric therapy: 10–15 mg/kg (*route not specified, assume IV, IM or SC—Plumb*) (Autran de Morais 2009)
- b) 15 mg/kg (route not specified) once daily (q24h). Neutropenic or immunocompromised patients may still need to be dosed q8h (dose divided). (Trepanier 1999)
- c) Sepsis: 20 mg/kg once daily IV (Hardie 2000)

#### ■FERRETS:

For susceptible infections:

- a) 8–16 mg/kg IM or IV once daily (Williams 2000)
- b) 8–16 mg/kg/day SC, IM, IV divided q8–24h (Morrisey & Carpenter 2004)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

- a) **Rabbits:** 8–16 mg/kg daily dose (may divide into q8h–q24h) SC, IM or IV. Increased efficacy and decreased toxicity if given once daily. If given IV, dilute into 4 mL/kg of saline and give over 20 minutes. (Ivey & Morrisey 2000)
- b) **Rabbits:** 5–10 mg/kg SC, IM, IV divided q8–24h
  - Guinea pigs:** 10–15 mg/kg SC, IM, IV divided q8–24h
  - Chinchillas:** 10–15 mg/kg SC, IM, IV divided q8–24h
  - Hamster, rats, mice:** 10 mg/kg SC, IM q12h
  - Prairie Dogs:** 5 mg/kg SC, IM q12h (Morrisey & Carpenter 2004)
- c) **Chinchillas:** 2–5 mg/kg SC, IM q8–12h (Hayes 2000)

#### ■CATTLE:

For susceptible infections:

- a) 10 mg/kg IM q8h or 25 mg/kg q12h (Beech 1987)
- b) 22 mg/kg/day IM divided three times daily (Upson 1988)

#### ■HORSES:

For susceptible infections:

- a) 21 mg/kg IV or IM once daily (q24h) (Moore 1999b); (Foreman 1999)
- b) In neonatal foals: 21 mg/kg IV once daily (Magdesian *et al.* 2004)
- c) In neonatal foals: Initial dose of 25 mg/kg IV once daily; strongly recommend to individualize dosage based upon therapeutic drug monitoring. (Bucki *et al.* 2004)
- d) Adults: 10 mg/kg IM or IV once daily (q24h)
  - Foals (<30 days old): 20–25 mg/kg IV or IM once daily (q24h). (Geor & Papich 2003)
- e) For treatment of septic joints: 20 mg/kg IV once daily. Usually used with a penicillin, at least until a definitive culture is obtained. (Moll 2009)

For uterine infusion:

- a) 2 grams mixed with 200 mL sterile normal saline (0.9% sodium chloride for injection) and aseptically infused into uterus daily for 3 consecutive days (Package insert; *Amiglyde-V®*—Fort Dodge)
- b) 1–2 grams intrauterine (Perkins 1999)

For intra-articular injection as adjunctive treatment of septic arthritis in foals:

- a) If a single joint is involved, inject 250 mg daily or 500 mg every other day; frequency is dependent upon how often joint lavage is performed. Use cautiously in multiple joints as toxicity may result (particularly if systemic therapy is also given). (Moore 1999a)

For regional intravenous limb perfusion (RILP) administration in standing horses:

- a) Usual dosages range from 500 mg–2 grams; dosage must be greater than 250 mg when a cephalic vein is used for perfusion and careful placement of tourniquets must be performed. (Parra-Sanchez *et al.* 2006)

#### ■BIRDS:

For susceptible infections:

- a) For sunken eyes/sinusitis in macaws caused by susceptible bacteria: 40 mg/kg IM once or twice daily. Must also flush sinuses with saline mixed with appropriate antibiotic (10–30 mL per nostril). May require 2 weeks of treatment. (Karpinski & Clubb 1986)
- b) 15 mg/kg IM or SC q12h (Hoeffler 1995)
- c) For gram-negative infections resistant to gentamicin: Dilute commercial solution and administer 15–20 mg/kg (0.015 mg/g) IM once a day or twice a day (Clubb 1986)
- d) Ratites: 7.6–11 mg/kg IM twice daily; air cell: 10–25 mg/egg; egg dip: 2000 mg/gallon of distilled water pH of 6 (Jenson 1998)

## ■REPTILES:

For susceptible infections:

- For snakes: 5 mg/kg IM (forebody) loading dose, then 2.5 mg/kg q72h for 7–9 treatments. Commonly used in respiratory infections. Use a lower dose for *Python curtus*. (Gauvin 1993)
- Study done in gopher snakes: 5 mg/kg IM loading dose, then 2.5 mg/kg q72h. House snakes at high end of their preferred optimum ambient temperature. (Mader *et al.* 1985)
- For bacterial shell diseases in turtles: 10 mg/kg daily in water turtles, every other day in land turtles and tortoises for 7–10 days. Used commonly with a beta-lactam antibiotic. Recommended to begin therapy with 20 mL/kg fluid injection. Maintain hydration and monitor uric acid levels when possible. (Roskopf 1986)
- For Crocodylians: 2.25 mg/kg IM q 72–96h (Jacobson 2000) (Jacobson 2000)
- For gram-negative respiratory disease: 3.5 mg/kg IM, SC or via lung catheter every 3–10 days for 30 days. (Klaphake 2005)

## ■FISH:

For susceptible infections:

- 5 mg/kg IM loading dose, then 2.5 mg/kg every 72 hours for 5 treatments. (Lewbart 2006)

## Monitoring

- Efficacy (cultures, clinical signs, WBC's and clinical signs associated with infection). Therapeutic drug monitoring is highly recommended when using this drug systemically. Attempt to draw samples at 1, 2, and 4 hours post dose. Peak level should be at least 40 micrograms/mL and the 4-hour sample less than 10 micrograms/mL.
- Adverse effect monitoring is essential. Pre-therapy renal function tests and urinalysis (repeated during therapy) are recommended. Casts in the urine are often the initial sign of impending nephrotoxicity.
- Gross monitoring of vestibular or auditory toxicity is recommended.

## Client Information

- With appropriate training, owners may give subcutaneous injections at home, but routine monitoring of therapy for efficacy and toxicity must still be done
- Clients should also understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication
- Use in food producing animals is controversial as drug residues may persist for long periods

## Chemistry/Synonyms

A semi-synthetic aminoglycoside derived from kanamycin, amikacin occurs as a white, crystalline powder that is sparingly soluble in water. The sulfate salt is formed during the manufacturing process. 1.3 grams of amikacin sulfate is equivalent to 1 gram of amikacin. Amikacin may also be expressed in terms of units. 50,600 Units are equal to 50.9 mg of base. The commercial injection is a clear to straw-colored solution and the pH is adjusted to 3.5–5.5 with sulfuric acid.

Amikacin sulfate may also be known as: amikacin sulphate, amikacini sulfas, or BB-K8; many trade names are available.

## Storage/Stability

Amikacin sulfate for injection should be stored at room temperature (15–30°C); freezing or temperatures above 40°C should be avoided. Solutions may become very pale yellow with time but this does not indicate a loss of potency.

Amikacin is stable for at least 2 years at room temperature. Autoclaving commercially available solutions at 15 pounds of pressure at 120°C for 60 minutes did not result in any loss of potency.

## Compatibility/Compounding Considerations

When given intravenously, amikacin should be diluted into suitable IV diluent *etc.* normal saline, D5W or LRS) and administered over at least 30 minutes.

Amikacin sulfate is reportedly **compatible** and stable in all commonly used intravenous solutions and with the following drugs: amobarbital sodium, ascorbic acid injection, bleomycin sulfate, calcium chloride/gluconate, cefoxitin sodium, chloramphenicol sodium succinate, chlorpheniramine maleate, cimetidine HCl, clindamycin phosphate, colistimethate sodium, dimenhydrinate, diphenhydramine HCl, epinephrine HCl, ergonovine maleate, hyaluronidase, hydrocortisone sodium phosphate/succinate, lincomycin HCl, metaraminol bitartrate, metronidazole (with or without sodium bicarbonate), norepinephrine bitartrate, pentobarbital sodium, phenobarbital sodium, phytonadione, polymyxin B sulfate, prochlorperazine edisylate, promethazine HCl, secobarbital sodium, sodium bicarbonate, succinylcholine chloride, vancomycin HCl and verapamil HCl.

The following drugs or solutions are reportedly **incompatible** or only **compatible in specific situations** with amikacin: aminophylline, amphotericin B, ampicillin sodium, carbenicillin disodium, cefazolin sodium, cephalothin sodium, cephapirin sodium, chlorothiazide sodium, dexamethasone sodium phosphate, erythromycin gluceptate, heparin sodium, methicillin sodium, nitrofurantoin sodium, oxacillin sodium, oxytetracycline HCl, penicillin G potassium, phenytoin sodium, potassium chloride (in dextran 6% in sodium chloride 0.9%; stable with potassium chloride in “standard” solutions), tetracycline HCl, thiopental sodium, vitamin B-complex with C and warfarin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

*In vitro* inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented. While amikacin is less susceptible to this effect, it is usually recommended to avoid mixing these compounds together in the same syringe or IV bag unless administration occurs promptly. See also the information in the Drug Interaction and Drug/Lab Interaction sections.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Amikacin Sulfate Injection: 50 mg (of amikacin base) per mL in 50 mL vials; *Amiglyde-V*® (Fort Dodge), generic (Teva); (Rx). FDA-approved for use in dogs.

Amikacin Sulfate Intrauterine Solution: 250 mg (of amikacin base) per mL in 48 mL vials; *Amiglyde-V*® (Fort Dodge), generic (Teva); (Rx). FDA-approved for use in horses not intended for food.

**Warning:** Amikacin is not FDA-approved for use in cattle or other food-producing animals in the USA. Drug residues may persist for long periods, particularly in

renal tissue. For guidance with determining use and withdrawal times, contact FARAD (see Phone Numbers & Websites in the appendix for contact information).

## HUMAN-LABELED PRODUCTS:

Amikacin Injection: 50 mg/mL and 250 mg/mL in 2 mL & 4 mL vials and 2 mL syringes (250 mg/mL only); *Amikin*® (Apothecon); generic; (Rx)

## AMINOCAPROIC ACID

(a-mee-noc-ka-proe-ik) *Amicar*®

FIBRINOLYSIS INHIBITOR/ANTIPROTEASE

### Prescriber Highlights

- **May be useful for treating degenerative myelopathies in dogs; efficacy questionable**
- **Treatment may be very expensive, especially with large dogs**
- **Contraindicated in DIC**
- **Infrequently causes GI distress**

---

## Uses/Indications

Aminocaproic acid has been used as a treatment to degenerative myelopathy (seen primarily in German shepherds), but no controlled studies documenting its efficacy were located. One study (Polizopoulou *et al.* 2008) in 12 dogs where aminocaproic acid was used with acetylcysteine and vitamins B, C, and E, no improvement was noted with treatment and all dogs' neurological signs worsened with time. There is some interest in evaluating aminocaproic acid for adjunctive treatment of thrombocytopenia in dogs, but efficacy and safety for this purpose remains to be investigated. In humans, it is primarily used for treating hyperfibrinolysis-induced hemorrhage.

## Pharmacology/Actions

Aminocaproic acid inhibits fibrinolysis via its inhibitory effects on plasminogen activator substances and via some antiplasmin action.

Aminocaproic acid is thought to affect degenerative myelopathy by its antiprotease activity thereby reducing the activation of inflammatory enzymes that damage myelin.

## Pharmacokinetics

No pharmacokinetic data was located for dogs.

In a study where 70 mg/kg doses were given IV to horses over 20 minutes, the drug was distributed rapidly and plasma levels remained above the proposed therapeutic level of 130 micrograms/mL for one hour after the end of the infusion. Elimination half-life was 2.3 hours. The authors proposed that a constant rate infusion of 15 mg/kg/hr after the original infusion would maintain more prolonged therapeutic levels (Ross *et al.* 2006).

In humans, the drug is rapidly and completely absorbed after oral administration. The drug is well distributed in both intravascular and extravascular compartments and penetrates cells (including red blood cells). It is unknown if the drug enters maternal milk. It does not bind to plasma proteins. Terminal half-life is about 2 hours in humans and the drug is primarily renally excreted as unchanged drug.

## Contraindications/Precautions/Warnings

Aminocaproic acid is contraindicated in patients with active intravascular clotting. It should only be used when the benefits outweigh the risks in patients with preexisting cardiac, renal or hepatic disease.

## Adverse Effects

In dogs treated, about 1% exhibit clinical signs of GI irritation. It potentially can cause hyperkalemia particularly in renal impaired patients.

## Reproductive/Nursing Safety

Some, but not all, animal studies have demonstrated teratogenicity; use when risk to benefit ratio merits. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction*

use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

There is very limited information on overdoses with aminocaproic acid. The IV lethal dose in dogs is reportedly 2.3 g/kg. At lower IV overdoses, tonic-clonic seizures were noted in some dogs. There is no known antidote, but the drug is dialyzable.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aminocaproic acid and may be of significance in veterinary patients:

- **ESTROGENS:** Hypercoagulation states may occur in patients receiving aminocaproic acid and estrogens

### Laboratory Considerations

- Serum **potassium** may be elevated by aminocaproic acid, especially in patients with preexisting renal failure

### Doses

#### ■ DOGS:

For adjunctive treatment of degenerative myelopathy (seen primarily in German shepherds):

a) Aminocaproic acid 500 mg/dog PO q8h indefinitely. Used in conjunction with acetylcysteine at 25 mg/kg PO q8h for 2 weeks, then q8h every other day. The 20% solution should be diluted to 5% with chicken broth or suitable diluent. Other treatments may include prednisone (0.25–0.5 mg/kg PO daily for 10 days then every other day), Vitamin C (1000 mg PO q12h) and Vitamin E (1000 Int. Units PO q12). **Note:** No treatment has been shown to be effective in published trials. (Shell 2003)

As an antifibrinolytic:

a) No published doses for dogs, but has been used anecdotally at 50–100 mg/kg IV or PO q6h. (Hopper 2006)

### Client Information

- Drug costs to treat a German shepherd-sized dog can be substantial
- As no well controlled studies have documented that this drug is effective for treating degenerative myelopathy, its use should be considered investigational

### Chemistry/Synonyms

An inhibitor of fibrinolysis, aminocaproic acid is a synthetic monamino carboxylic acid occurring as a fine, white crystalline powder. It is slightly soluble in alcohol and freely soluble in water and has pKa's of 4.43 and 10.75. The injectable product has its pH adjusted to approximately 6.8.

Aminocaproic acid may also be known as: acidum aminocaproicum, CL-10304 CY-116, EACA, epsilon aminocaproic acid, JD-177, NSC-26154, *Amicar*®, *Capracid*®, *Capramol*®, *Caproamin*®, *Caprolisin*®, *Epsicaprom*®, *Hemocaprol*®, *Hemocid*®, *Hexalense*®, or *Ipsilon*®.

### Storage/Stability

Products should be stored at room temperature. Avoid freezing liquid preparations. Discoloration will occur if aldehydes or aldehydic sugars are present.

### Compatibility/Compounding Considerations

When given as an intravenous infusion, normal saline, D5W and Ringer's Injection have been recommended for use as the infusion diluent.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Aminocaproic Acid Oral Tablets: 500 mg & 1000 mg; *Amicar*® (Xanodyne); generic (VersaPharm); (Rx)

Aminocaproic Oral Solution: 250 mg/mL in 237 mL & 473 mL; Aminocaproic Acid (VersaPharm); *Amicar*® (Xanodyne); generic; (Rx)

Aminocaproic Acid Injection: 250 mg/mL in 20 mL vials; generic; (Rx)

## AMINOPENTAMIDE HYDROGEN SULFATE

(a-mee-noe-pent-a-mide) *Centrine*®

ANTICHOLINERGIC/ANTISPASMODIC

### Prescriber Highlights

- Anticholinergic/antispasmodic for GI indications in small animals
- Typical adverse effect profile (“dry, hot, red”); potentially could cause tachycardia
- Contraindicated in glaucoma; relatively contraindicated in tachycardias, heart disease, GI obstruction, etc.

## Uses/Indications

The manufacturer states that the drug is indicated “in the treatment of acute abdominal visceral spasm, pylorospasm or hypertrophic gastritis and associated nausea, vomiting and/or diarrhea” for use in dogs and cats.

## Pharmacology/Actions

Aminopentamide is an anticholinergic agent that when compared to atropine has been described as having a greater effect on reducing colonic contractions and less mydriatic and salivary effects. It reportedly may also reduce gastric acid secretion.

## Pharmacokinetics

No information was located.

## Contraindications/Precautions/Warnings

The manufacturer lists glaucoma as an absolute contraindication to therapy and to use the drug cautiously, if at all, in patients with pyloric obstruction. Additionally, aminopentamide should not be used if the patient has a history of hypersensitivity to anticholinergic drugs, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy or myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy).

Antimuscarinic agents should be avoided or used with extreme caution in patients with known or suspected GI infections (*e.g.*, parvovirus enteritis), or with autonomic neuropathy. Atropine or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged clinical signs.

Antimuscarinic agents should be used with caution in patients with hepatic disease, renal disease, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, esophageal reflux, and in geriatric or pediatric patients.

## Adverse Effects

Adverse effects resulting from aminopentamide therapy may include dry mouth, dry eyes, blurred vision, and urinary hesitancy. Urinary retention is a symptom of too high a dose and the drug should be withdrawn until resolved.

## Overdosage/Acute Toxicity

No specific information was located regarding acute overdosage clinical signs or treatment for this agent. The following discussion is from the Atropine monograph that could be used as a guideline for treating overdoses:

If a recent oral ingestion, emptying of gut contents and administration of activated charcoal and saline cathartics may be warranted. Treat clinical signs supportively and symptomatically. Do not use phenothiazines as they may contribute to the anticholinergic effects. Fluid therapy and standard treatments for shock may be instituted.

The use of physostigmine is controversial and should probably be reserved for cases where the patient exhibits either extreme agitation and is at risk for injuring themselves or others, or for cases where supraventricular tachycardias and sinus tachycardias are severe or life threatening. The usual dose for physostigmine (human) is: 2 mg IV slowly (for average sized adult), if no response, may repeat every 20 minutes until reversal of toxic antimuscarinic effects or cholinergic effects takes place. The human pediatric dose is 0.02 mg/kg slow IV (repeat q10 minutes as above) and may be a reasonable choice for treatment of small animals. Physostigmine adverse effects (bronchoconstriction, bradycardia, seizures) may be treated with small doses of IV atropine.

## Drug Interactions

No specific interactions were noted for this product. The following drug interactions have either been reported or are theoretical in humans or animals receiving atropine, a similar drug and may be of significance in veterinary patients:

- **ANTIHISTAMINES, PROCAINAMIDE, QUINIDINE, MEPERIDINE, BENZODIAZEPINES, PHENOTHIAZINES:** May enhance the activity of atropine and its derivatives
- **PRIMIDONE, DISOPYRAMIDE, NITRATES:** May potentiate the adverse effects of atropine and its derivatives
- **CORTICOSTEROIDS (long-term use):** May increase intraocular pressure
- **NITROFURANTOIN, THIAZIDE DIURETICS, SYMPATHOMIMETICS:** Atropine and its derivatives may enhance actions
- **METOCLOPRAMIDE:** Atropine and its derivatives may antagonize metoclopramide actions

## Doses

### ■ DOGS:

a) May be administered every 8–12 hours via IM, SC or oral routes. If the desired effect is not attained, the dosage may be gradually increased up to 5 times those listed below: Animals weighing: 10 lbs or less: 0.1 mg; 11–20 lbs: 0.2 mg; 21–50 lbs: 0.3 mg; 51–100 lbs: 0.4 mg; over 100 lbs: 0.5 mg (Package Insert; *Centrine*® —Fort Dodge)

b) To decrease tenesmus in malabsorption/maldigestion syndromes: 0.1–0.4 mg (total dose) SC, or IM twice daily–three times daily (Chiapella 1989)

### ■ CATS:

a) As in “a” above in dogs

b) As second-line adjunctive therapy for refractory IBD: 0.1–0.4 mg/kg SC two to three times daily (Washabau 2000)

## Monitoring

- Clinical efficacy
- Adverse effects (see above)

## Client Information

- Contact veterinarian if animal has difficulty urinating or if animal is bothered by dry eyes or mouth

## Chemistry/Synonyms

An antispasmodic, anticholinergic agent, aminopentamide hydrogen sulfate has a chemical name of 4-(dimethylamino)-2,2-diphenylvaleramide.

Aminopentamide hydrogen sulfate may also be known as dimevamid or *Centrine*®.

## Storage/Stability

Store aminopentamide tablets and injection at controlled room temperature (15–30°C; 59–86°F).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Aminopentamide Hydrogen Sulfate Tablets: 0.2 mg; *Centrine*® (Pfizer); (Rx). FDA-approved for use in dogs and cats only.

Aminopentamide Hydrogen Sulfate Injection: 0.5 mg/mL in 10 mL vials; *Centrine*® (Pfizer); (Rx). FDA-approved for use in dogs and cats only.

**HUMAN-LABELED PRODUCTS:** None

## AMINOPHYLLINE

### THEOPHYLLINE

(am-in-off-i-lin); (thee-off-i-lin)

PHOSPHODIESTERASE INHIBITOR BRONCHODILATOR

### Prescriber Highlights

- **Bronchodilator drug with diuretic activity; used for bronchospasm & cardiogenic pulmonary edema**
- **Narrow therapeutic index in humans, but dogs appear to be less susceptible to toxic effects at higher plasma levels**
- **Therapeutic drug monitoring recommended**
- **Many drug interactions**

---

## Uses/Indications

The theophyllines are used primarily for their bronchodilatory effects, often in patients with myocardial failure and/or pulmonary edema. While they are still routinely used, the methylxanthines must be used cautiously due to their adverse effects and toxicity.

## Pharmacology/Actions

The theophyllines competitively inhibit phosphodiesterase thereby increasing amounts of cyclic AMP that then increase the release of endogenous epinephrine. The elevated levels of cAMP may also inhibit the release of histamine and slow reacting substance of anaphylaxis (SRS-A). The myocardial and neuromuscular transmission effects that the theophyllines possess may be a result of translocating intracellular ionized calcium.

The theophyllines directly relax smooth muscles in the bronchi and pulmonary vasculature, induce diuresis, increase gastric acid secretion and inhibit uterine contractions. They have weak chronotropic and inotropic action, stimulate the CNS and can cause respiratory stimulation (centrally-mediated).

## Pharmacokinetics

The pharmacokinetics of theophylline have been studied in several domestic species. After oral administration, the rate of absorption of the theophyllines is limited primarily by the dissolution of the dosage form in the gut. In studies in cats, dogs, and horses, bioavailabilities after oral administration are nearly 100% when non-sustained release products are used. One study in dogs that compared various sustained-release products (Koritz, Neff-Davis, and Munsiff 1986), found bioavailabilities ranging from approximately 30–76% depending on the product used.

Theophylline is distributed throughout the extracellular fluids and body tissues. It crosses the placenta and is distributed into milk (70% of serum levels). In dogs, at therapeutic serum levels only about 7–14% is bound to plasma proteins. The volume of distribution of theophylline for dogs has been reported to be 0.82 L/kg. The volume of distribution in cats is reported to be 0.46 L/kg, and in horses, 0.85–1.02 L/kg. Because of the low volumes of distribution and theophylline's low lipid solubility, obese patients should be dosed on a lean body weight basis.

Theophylline is metabolized primarily in the liver (in humans) to 3-methylxanthine which has weak bronchodilatory activity. Renal clearance contributes only about 10% to the overall plasma clearance of theophylline. The reported elimination half-lives (mean values) in various species are: dogs ≈ 5.7 hours; cats ≈ 7.8 hours, pigs ≈ 11 hours; and horses ≈ 11.9 to 17 hours. In humans, there are very wide interpatient variations in serum half-lives and resultant serum levels. It could be expected that similar variability exists in veterinary patients, particularly those with concurrent illnesses.

## Contraindications/Precautions/Warnings

The theophyllines are contraindicated in patients who are hypersensitive to any of the xanthines, including theobromine or caffeine. Patients who are hypersensitive to ethylenediamine should not take aminophylline.

The theophyllines should be administered with caution in patients with severe cardiac disease, seizure disorders, gastric ulcers, hyperthyroidism, renal or hepatic disease, severe hypoxia, or severe hypertension. Because it may cause an arrhythmia, patients with cardiac arrhythmias should receive theophyllines with caution.

disease, severe hypoxia, or severe hypertension. Because it may cause or worsen preexisting arrhythmias, patients with cardiac arrhythmias should receive theophylline only with caution and enhanced monitoring. Neonatal and geriatric patients may have decreased clearances of theophylline and be more sensitive to its toxic effects. Patients with CHF may have prolonged serum half-lives of theophylline.

### Adverse Effects

The theophyllins can produce CNS stimulation and gastrointestinal irritation after administration by any route. Most adverse effects are related to the serum level of the drug and may be symptomatic of toxic blood levels; dogs appear to tolerate levels that may be very toxic to humans. Some mild CNS excitement and GI disturbances are not uncommon when starting therapy and generally resolve with chronic administration in conjunction with monitoring and dosage adjustments.

Dogs and cats can exhibit clinical signs of nausea and vomiting, insomnia, increased gastric acid secretion, diarrhea, polyphagia, polydipsia, and polyuria. Side effects in horses are generally dose related and may include: nervousness, excitability (auditory, tactile, and visual), tremors, diaphoresis, tachycardia, and ataxia. Seizures or cardiac dysrhythmias may occur in severe intoxications.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

Clinical signs of toxicity (see above) are usually associated with levels greater than 20 micrograms/mL in humans and become more severe as the serum level exceeds that value. Tachycardias, arrhythmias, and CNS effects (seizures, hyperthermia) are considered the most life-threatening aspects of toxicity. Dogs appear to tolerate serum levels higher than 20 micrograms/mL.

Treatment of theophylline toxicity is supportive. After an oral ingestion, the gut should be emptied, charcoal and a cathartic administered using the standardized methods and cautions associated with these practices. Patients suffering from seizures should have an adequate airway maintained and treated with IV diazepam. The patient should be constantly monitored for cardiac arrhythmias and tachycardia. Fluid and electrolytes should be monitored and corrected as necessary. Hyperthermia may be treated with phenothiazines and tachycardia treated with propranolol if either condition is considered life threatening.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aminophylline or theophylline and may be of significance in veterinary patients:

The following drugs can *decrease* theophylline levels:

- **BARBITURATES (phenobarbital)**
- **CARBAMAZEPINE** (may increase or decrease levels)
- **CHARCOAL**
- **HYDANTOINS (phenytoin)**
- **ISONIAZID** (may increase or decrease levels)
- **KETOCONAZOLE**
- **LOOP DIURETICS (furosemide)**; (may increase or decrease levels)
- **RIFAMPIN**
- **SYMPATHOMIMETICS (beta-agonists)**

The following drugs can *increase* theophylline levels:

- **ALLOPURINOL**
- **BETA-BLOCKERS (non-selective such as propranolol)**
- **CALCIUM CHANNEL BLOCKERS (e.g., diltiazem, verapamil)**
- **CIMETIDINE**
- **CORTICOSTEROIDS**
- **FLUOROQUINOLONES (enrofloxacin, ciprofloxacin)**: If adding either, consider reducing the dose of theophylline by 30%. Monitor for toxicity/efficacy. Marbofloxacin reduces clearance of theophylline in dogs, but not with clinical significance. In animals with renal impairment, marbofloxacin may interfere with theophylline metabolism in a clinically relevant manner.
- **MACROLIDES (e.g., erythromycin; clindamycin, lincomycin)**
- **THIABENDAZOLE**
- **THYROID HORMONES** (in hypothyroid patients)

Theophylline may decrease the effects of following drugs:

- **BENZODIAZEPINES**
- **LITHIUM**
- **PANCURONIUM**
- **PROPOFOL**
- **EPHEDRINE, ISOPROTERENOL**: Toxic synergism (arrhythmias) can occur if theophylline is used concurrently with sympathomimetics (especially ephedrine) or possibly isoproterenol
- **HALOTHANE**: Theophylline with halothane may cause increased incidence of cardiac dysrhythmias
- **KETAMINE**: Theophylline with ketamine can cause an increased incidence of seizures

### Laboratory Considerations

- Theophylline can cause falsely elevated values of serum **uric acid** if measured by the Bittner or colorimetric methods. Values are not affected if using the uricase method.
- Theophylline serum levels can be falsely elevated by **furosemide, phenylbutazone, probenecid, theobromine, caffeine, sulfathiazole, chocolate, or acetaminophen** if using a spectrophotometric method of assay.

## Doses

**Note:** Theophyllines have a relatively low therapeutic index; determine dosage carefully. Because of aminophylline/theophylline's pharmacokinetic characteristics, it should be dosed on a lean body weight basis in obese patients. Dosage conversions between aminophylline and theophylline can be easily performed using the information found in the Chemistry section below. Aminophylline causes intense local pain when administered IM and is rarely used or recommended via this route.

### ■DOGS:

- Using *Theochron*® Extended-Release Tablets or *Theo-Cap*® Extended-Release Capsules: Give 10 mg/kg PO every 12 hours initially, if no adverse effects are observed and the desired clinical effect is not achieved, give 15 mg/kg PO q12h while monitoring for adverse effects. (Bach *et al.* 2004)
- For adjunctive medical therapy for mild clinical signs associated with tracheal collapse (<50% collapse): aminophylline: 11 mg/kg PO, IM or IV three times daily. (Fossom 2005)
- For adjunctive therapy of severe, acute pulmonary edema and bronchoconstriction: Aminophylline 4–8 mg/kg IV or IM, or 6–10 mg/kg PO every 8 hours. Long-term use is not recommended. (Ware 2003)
- For cough: Aminophylline: 10 mg/kg PO, IV three times daily (Anderson-Westberg 2005)
- As a bronchodilator for collapsing trachea: 11 mg/kg PO or IV q6–12h (Ettinger & Kantrowitz 2005)

### ■CATS:

- Using *Theo-Dur*®: 20 mg/kg PO once daily in the PM; using *Slo-Bid*®: 25 mg/kg PO once daily in the PM (Johnson 2000) [**Note:** The products *Theo-Dur*® and *Slo-Bid*® mentioned in this reference are no longer available in the USA. Although hard data is not presently available to support their use in cats, a reasonable alternative would be to cautiously use the dog dose and products mentioned above in the reference by Bach *et al.*—Plumb]
- Using aminophylline tablets: 6.6 mg/kg PO twice daily; using sustained release tablets (*Theo-Dur*®): 25–50 mg (total dose) per cat PO in the evening (Noone 1999)
- For adjunctive medical therapy for mild clinical signs associated with tracheal collapse (<50% collapse): aminophylline: 5 mg/kg PO, two times daily. (Fossom 2005)
- For adjunctive therapy for bronchoconstriction associated with fulminant CHF: Aminophylline 4–8 mg/kg SC, IM, IV q8–12h. (Ware 2003)
- For cough: Aminophylline: 5 mg/kg PO twice daily (Anderson-Westberg 2005)

### ■FERRETS:

- 4.25 mg/kg PO 2–3 times a day (Williams 2000)

### ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

**Note:** Intravenous aminophylline should be diluted in at least 100 mL of D5W or normal saline and administered slowly (not >25 mg/min).

For adjunctive treatment of pulmonary edema:

- Aminophylline 2–7 mg/kg IV q6–12h; Theophylline 5–15 mg/kg PO q12h (Mogg 1999)
- 11 mg/kg PO or IV q8–12h. To “load” may either double the initial dose or give both the oral and IV dose at the same time. IV infusion should be in approximately 1 liter of IV fluids and given over 20–60 minutes. Recommend monitoring serum levels. (Foreman 1999)

For adjunctive treatment for heaves (RAO):

- Aminophylline: 5–10 mg/kg PO or IV twice daily. (Lavoie 2003)
- Aminophylline: 4–6 mg/kg PO three times a day. (Ainsworth & Hackett 2004)

## Monitoring

- Therapeutic efficacy and clinical signs of toxicity
- Serum levels at steady state. The therapeutic serum levels of theophylline in humans are generally described to be between 10–20 micrograms/mL. In small animals, one recommendation for monitoring serum levels is to measure trough concentration; level should be at least above 8–10 micrograms/mL (**Note:** Some recommend not exceeding 15 micrograms/mL in horses).

## Client Information

- Give dosage as prescribed by veterinarian to maximize the drug's benefit

## Chemistry/Synonyms

Xanthine derivatives, aminophylline and theophylline are considered to be respiratory smooth muscle relaxants but, they also have other pharmacologic actions. Aminophylline differs from theophylline only by the addition of ethylenediamine to its structure and may have different amounts of molecules of water of hydration. 100 mg of aminophylline (hydrous) contains approximately 79 mg of theophylline (anhydrous); 100 mg of aminophylline (anhydrous) contains approximately 86 mg theophylline (anhydrous). Conversely, 100 mg of theophylline (anhydrous) is equivalent to 116 mg of aminophylline (anhydrous) and 127 mg aminophylline (hydrous).

Aminophylline occurs as bitter-tasting, white or slightly yellow granules or powder with a slight ammoniacal odor and a pKa of 5. Aminophylline is soluble in water and insoluble in alcohol.

Theophylline occurs as bitter-tasting, odorless, white, crystalline powder with a melting point between 270–274°C. It is sparingly soluble in alcohol and only slightly soluble in water at a pH of 7, but solubility increases with increasing pH.

Aminophylline may also be known as: aminofilina, aminophyllinum, euphyllinum, metaphyllin, theophyllaminum, theophylline and ethylenediamine, theophylline

ethylenediamine compound, and theophyllinum ethylenediaminum; many trade names are available.

Theophylline may also be known as: anhydrous theophylline, teofillina, or theophyllinum; many trade names are available.

## Storage/Stability

Unless otherwise specified by the manufacturer, store aminophylline and theophylline oral products in tight, light-resistant containers at room temperature. Do not crush or split sustained-release oral products unless label states it is permissible.

Aminophylline for injection should be stored in single-use containers in which carbon dioxide has been removed. It should also be stored at temperatures below 30°C and protected from freezing and light. Upon exposure to air (carbon dioxide), aminophylline will absorb carbon dioxide, lose ethylenediamine and liberate free theophylline that can precipitate out of solution. Do not inject aminophylline solutions that contain either a precipitate or visible crystals.

## Compatibility/Compounding Considerations

Aminophylline for injection is reportedly **compatible** when mixed with all commonly used IV solutions, but may be **incompatible** with 10% fructose or invert sugar solutions.

Aminophylline is reportedly **compatible** when mixed with the following drugs: amobarbital sodium, bretylium tosylate, calcium gluconate, chloramphenicol sodium succinate, dexamethasone sodium phosphate, dopamine HCl, erythromycin lactobionate, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, mephentermine sulfate, methicillin sodium, methylodopate HCl, metronidazole with sodium bicarbonate, pentobarbital sodium, phenobarbital sodium, potassium chloride, secobarbital sodium, sodium bicarbonate, sodium iodide, terbutaline sulfate, thiopental sodium, and verapamil HCl.

Aminophylline is reportedly **incompatible** (or data conflicts) with the following drugs: amikacin sulfate, ascorbic acid injection, bleomycin sulfate, cephalothin sodium, cephapirin sodium, clindamycin phosphate, codeine phosphate, corticotropin, dimenhydrinate, dobutamine HCl, doxorubicin HCl, epinephrine HCl, erythromycin gluceptate, hydralazine HCl, hydroxyzine HCl, insulin (regular), isoproterenol HCl, levorphanol bitartrate, meperidine HCl, methadone HCl, methylprednisolone sodium succinate, morphine sulfate, nafcillin sodium, norepinephrine bitartrate, oxytetracycline, penicillin G potassium, pentazocine lactate, procaine HCl, prochlorperazine edisylate or mesylate, promazine HCl, promethazine HCl, sulfisoxazole diolamine, tetracycline HCl, vancomycin HCl, and vitamin B complex with C. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used and it is suggested to consult specialized references for more specific information.

**Compounded preparation stability:** Aminophylline oral suspension compounded from commercially available injectable solution has been published (Chong *et al.* 2000). Diluting 40 mL of aminophylline 25 mg/mL injection with 2.7 mL of *Ora-Plus*® and *qs ad* to 45.4 mL with *Ora-Sweet*® yields a 22 mg/mL oral suspension that retains >90% potency for 91 days stored at 25°C. Compounded preparations of aminophylline should be protected from light and should not be refrigerated due to development of crystalline precipitation and >20% loss of potency after 7 days.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

The listing below is a sampling of products and sizes available; consult specialized references for a more complete listing.

Aminophylline Tablets: 100 mg (79 mg theophylline) & 200 mg (158 mg theophylline); generic; (Rx)

Aminophylline Injection: 250 mg (equiv. to 197 mg theophylline) mL in 10 mL & 20 mL vials, amps and syringes; generic; (Rx)

Theophylline Time Released Capsules and Tablets: 100 mg, 125 mg, 200 mg, 300 mg, 400 mg, 450 mg, & 600 mg. (**Note:** Different products have different claimed release rates which may or may not correspond to actual times in veterinary patients; Theophylline Extended-Release (Dey); *Theo-24*® (UCB Pharma); *Theophylline SR* (various); *Theochron*® (Forest, various); Theophylline (Able); *Theocron*® (Inwood); *Uniphyl*® (Purdue Frederick); generic; (Rx)

Theophylline Tablets and Capsules: 100 mg, 200 mg, & 300 mg; *Bronkodyl*® (Winthrop); *Elixophyllin*® (Forest); generic; (Rx)

Theophylline Elixir: 80 mg/15 mL (26.7 mg/5 mL) in pt, gal, UD 15 mL and 30 mL, *Asmalix*® (Century); *Elixophyllin*® (Forest); *Lanophyllin*® (Lannett); generic; (Rx)

Theophylline & Dextrose Injection: 200 mg/container in 50 mL (4 mg/mL) & 100 mL (2 mg/mL); 400 mg/container in 100 mL (4 mg/mL), 250 mL (1.6 mg/mL), 500 mL (0.8 mg/mL) & 1000 mL (0.4 mg/mL); 800 mg/container in 250 mL (3.2 mg/mL), 500 mL (1.6 mg/mL) & 1000 mL (0.8 mg/mL); Theophylline & 5% Dextrose (Abbott & Baxter); (Rx)

## AMIODARONE HCL

(a-mee-oh-da-rone) Cordarone®, Pacerone®

CLASS III ANTIARRHYTHMIC

## Prescriber Highlights

- **Antidysrhythmic agent that can be used in dogs for arrhythmias associated with left ventricular dysfunction or to convert atrial fib into sinus rhythm; very limited experience warrants cautious use**

- May be useful in horses to convert atrial fib or V tach into sinus rhythm
  - Contraindicated in 2nd, 3rd degree heart block, bradyarrhythmias
  - In Dogs: GI disturbances (vomiting, anorexia) most likely adverse effect, but corneal deposits, neutropenia, thrombocytopenia, bradycardia, hepatotoxicity, positive Coombs' test reported
  - In Horses: Limited use, accurate adverse effect profile to be determined; Hind limb weakness, increased bilirubin reported when used IV to convert atrial fib
  - Many drug interactions
- 

### Uses/Indications

Because of its potential toxicity and lack of experience with use in canine and equine patients, amiodarone is usually used when other less toxic or commonly used drugs are ineffective. It may be useful in dogs and horses to convert atrial fib into sinus rhythm and in dogs for arrhythmias associated with left ventricular dysfunction. In horses, one horse with ventricular tachycardia was converted into sinus rhythm using amiodarone.

As the risk of sudden death is high in Doberman pinschers exhibiting rapid, wide-complex ventricular tachycardia or syncope with recurrent VPC's, amiodarone may be useful when other drug therapies are ineffective.

### Pharmacology/Actions

Amiodarone's mechanism of action is not fully understood; it apparently is a potassium channel blocker that possesses unique pharmacology from other antiarrhythmic agents. It can be best classified a Class III antiarrhythmic agent that also blocks sodium and calcium channels, and beta-adrenergic receptors. Major properties include prolongation of myocardial cell action-potential duration and refractory period.

### Pharmacokinetics

Amiodarone may be administered parenterally or orally. Amiodarone is widely distributed throughout the body and can accumulate in adipose tissue. Amiodarone is metabolized by the liver into the active metabolite desethylamiodarone. After oral administration of a single dose in normal dogs, amiodarone's plasma half-life averaged 7.5 hours, but repeated dosing increased its half-life from 11 hours to 3.2 days.

In horses, amiodarone has a low oral bioavailability (range from 6–34%) and peak levels of amiodarone and desethylamiodarone occur about 7–8 hours after an oral dose. After IV administration amiodarone is rapidly distributed with a high apparent volume of distribution of 31 L/kg. In horses, amiodarone is relatively highly bound to plasma proteins (96%). Clearance was 0.35 L/kg/hr and median elimination half-lives for amiodarone and desethylamiodarone were approximately 51 and 75 hours, respectively (De Clercq, Baert *et al.* 2006).

In humans, oral absorption is slow and variable, with bioavailabilities ranging from 22–86%. Elimination half-lives for amiodarone and desethylamiodarone range from 2.5–10 days after a single dose, but with chronic dosing, average 53 days and 60 days, respectively.

### Contraindications/Precautions/Warnings

Amiodarone is considered contraindicated in patients (humans) hypersensitive to it, having severe sinus-node dysfunction with severe sinus bradycardia, 2nd or 3rd degree heart block, or bradycardial syncope.

Clinical experience in veterinary patients is limited. Consider use only when other less toxic and more commonly used drugs are ineffective.

### Adverse Effects

Gastrointestinal effects (*e.g.*, anorexia, vomiting) are apparently the most likely adverse effects seen in the limited number of canine patients treated. Hepatopathy (bilirubinemia, increased hepatic enzymes) has been reported in dogs on amiodarone. Because hepatic effects can occur before clinical signs are noted, routine serial evaluation of liver enzymes and bilirubin is recommended. Other adverse effects reported in dogs include bradycardia, neutropenia, thrombocytopenia, or positive Coombs' test. During IV infusion, pain at injection site, and facial pruritus and hyperemia have been noted. Corneal deposits may be seen in dogs treated with amiodarone, but this affect apparently occurs less frequently in dogs than in humans.

Horses treated with IV amiodarone for 36 hours or longer have developed short-term hind limb weakness and diarrhea.

In human patients, adverse effects are very common while on amiodarone therapy. Those that most commonly cause discontinuation of the drug include: pulmonary infiltrates or pulmonary fibrosis (sometimes fatal), liver enzyme elevations, congestive heart failure, paroxysmal ventricular tachycardia, and thyroid dysfunction (hypo- or hyperthyroidism). An odd effect seen in some individuals is a bluish cast to their skin. Reversible corneal deposits are seen in a majority of humans treated with amiodarone.

Clinical experience in dogs is limited; the adverse effect profile of this drug in people warrants its use in veterinary patients only when other less toxic agents are ineffective and treatment is deemed necessary.

### Reproductive/Nursing Safety

In laboratory animals, amiodarone has been embryotoxic at high doses and congenital thyroid abnormalities have been detected in offspring. Use during pregnancy only when the potential benefits outweigh the risks of the drug. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

### Overdosage/Acute Toxicity

Clinical overdosage experience is limited; most likely adverse effects seen are hypotension, bradycardia, cardiogenic shock, AV block, and hepatotoxicity. Treatment is supportive. Bradycardia may be managed with a pacemaker or beta-1 agonists (*e.g.*, isoproterenol); hypotension managed with positive inotropic agents or vasopressors. Neither amiodarone nor its active metabolite are dialyzable.

### Drug Interactions

Several potentially significant interactions may occur with amiodarone. The following is a partial list of interactions that have either been reported or are theoretical in humans or animals receiving amiodarone and may be of significance in veterinary patients:

Amiodarone may significantly **increase** the serum levels and/or pharmacologic or toxic effects of:

Amiodarone may significantly increase the serum levels of several or pharmacologic or toxic effects of:

- **ANTICOAGULANTS (warfarin)**
- **DIGOXIN**
- **CYCLOSPORINE**
- **LIDOCAINE**
- **METHOTREXATE (with prolonged amiodarone administration)**
- **PHENYTOIN**
- **PROCAINAMIDE**
- **QUINIDINE**

Amiodarone may have **additive effects on QTc interval**; possible serious arrhythmias may result:

- **AZOLE ANTIFUNGALS (ketoconazole, itraconazole, etc.)**
- **CISAPRIDE**
- **DISOPYRAMIDE**
- **DOLASETRON**
- **FLUOROQUINOLONE ANTIBIOTICS (some, such as moxifloxacin, not enrofloxacin, marbofloxacin, etc.)**
- **MACROLIDE ANTIBIOTICS (e.g., erythromycin)**
- **ONDANSETRON**

Other amiodarone drug interactions:

- **ANESTHETICS, GENERAL:** Increased risks for hypotension or arrhythmias
- **BETA-ADRENERGIC BLOCKERS:** Possible potentiation of bradycardia, AV block or sinus arrest
- **CALCIUM-CHANNEL BLOCKERS (e.g., diltiazem, verapamil):** Possible potentiation of bradycardia, AV block or sinus arrest
- **CIMETIDINE:** Increased amiodarone levels
- **CYCLOSPORINE:** Increased cyclosporine levels; may increase creatinine
- **FENTANYL:** Possible hypotension, bradycardia
- **RIFAMPIN:** Decreased amiodarone levels

### Laboratory Considerations

- While most human patients remain euthyroid while receiving amiodarone, it may cause an increase in **serum T<sub>4</sub>** and serum reverse T<sub>3</sub> levels, and a reduction in **serum T<sub>3</sub>** levels
- The human therapeutic serum concentrations of 1–2.5 micrograms/mL are believed to apply to dogs as well
- Amiodarone may cause a **positive Coombs'** test result

### Doses

**Note:** Some human references state that because of the potential for drug interactions with previous drug therapies, the life-threatening nature of the arrhythmias being treated, and the unpredictability of response from amiodarone, the drug should be initially given (loaded) over several days in an inpatient setting where adequate monitoring can occur.

#### ■ DOGS:

- For atrial fibrillation or ventricular arrhythmias primarily in ambulatory patients: 8–10 mg/kg PO every 12 hours. Use caution if patient has bradycardia, AV blocks, or thyroid disorders. (Mucha 2009)
- For ventricular arrhythmias secondary to occult cardiomyopathy in Doberman pinschers: 10 mg/kg PO twice daily for one week and then 8 mg/kg PO once daily. After 6 months reduce to 5 mg/kg PO once daily. For severe V-Tach, mexiletine is added at 5–8 mg/kg three times daily for one week. Once efficacy confirmed, patient weaned off mexiletine. (Meurs 2005)
- For ventricular tachycardia when other first line drugs (Class I antiarrhythmics ± beta-blockers) are ineffective: 10 mg/kg PO q12h for one week and then 5 mg/kg PO q12h for maintenance. (Smith 2009)
- For SVTs or Vtach: 10–20 mg/kg PO once daily (q24h) loading for 5-7 days; 5–10 mg/kg PO once daily thereafter. (Saunders, A. *et al.* 2006), (Saunders, A.B. 2008)

#### ■ HORSES:

For conversion of atrial fibrillation or ventricular tachycardia:

- 5 mg/kg/hr for one hour, followed by 0.83 mg/kg/hr for 23 hours and then 1.9 mg/kg/hour for the following 30 hours. In the study (A fib), infusion was discontinued when conversion occurred or when any side effects were noted. 4 of 6 horses converted from A fib; one horse from V tach. In order to increase success rate and decrease adverse effects, regimen should be further adapted based upon PK/PD studies in horses. (De Clercq, van Loon *et al.* 2006a), (De Clercq, van Loon *et al.* 2006b)

### Monitoring

- Efficacy (ECG)
- Toxicity (GI effects; CBC, serial liver enzymes; thyroid function tests; blood pressure; pulmonary radiographs if clinical signs such as dyspnea/cough occur)

## Client Information

- Because relatively few canine/equine patients have received this agent and the drug's potential for toxicity, clients should give informed consent before the drug is prescribed or administered.

## Chemistry/Synonyms

An iodinated benzofuran, amiodarone is unique structurally and pharmacologically from other antiarrhythmic agents. It occurs as a white to cream colored lipophilic powder having a pKa of approximately 6.6. Amiodarone 200 mg tablets each contain approximately 75 mg of iodine.

Amiodarone HCl may also be known as: amiodaroni hydrochloridum, L-3428, 51087N, or SKF-33134-A; many trade names are available.

## Storage/Stability

Tablets should be stored in tight containers, at room temperature and protected from light. A 3-year expiration date is assigned from the date of manufacture.

Injection should be stored at room temperature and protected from light or excessive heat. While administering, light protection is not necessary.

## Compatibility/Compounding Considerations

Use D5W as the IV diluent. Amiodarone is reportedly compatible with dobutamine, lidocaine, potassium chloride, procainamide, propafenone, and verapamil. Variable compatibility is reported with furosemide and quinidine gluconate.

**Compounded preparation stability:** Amiodarone oral suspension compounded from commercially available tablets has been published (Nahata, 1997). Triturating one (1) tablet of amiodarone 200 mg with 20 mL of *Ora-Plus*® and *qs ad* to 40 mL with *Ora-Sweet*® (or *Ora-Sweet*®*SF*) yields a 5 mg/mL oral suspension that retains >90% potency for 91 days stored at 5°C. Compounded preparations of amiodarone should be protected from light. Amiodarone suspensions may be stored at room temperature during short periods (such as travel).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Amiodarone Oral Tablets: 100 mg, 200 mg & 400 mg; *Cordarone*® (Wyeth-Ayerst); *Pacerone*® (Upsher Smith); generic; (Rx)

Amiodarone Injection Solution: 50 mg/mL in 3 mL, 10 mL & 30 mL single-dose vials, 18 mL multiple-dose vials & 3 mL prefilled syringes; *Nexterone*® (Prism); generic; (Rx)

## AMITRIPTYLINE HCL

(a-mih-*trip*-ti-leen) Elavil®

TRICYCLIC BEHAVIOR MODIFIER; ANTIPRURITIC; NEUROPATHIC PAIN MODIFIER

### Prescriber Highlights

- Tricyclic “antidepressant” used primarily for behavior disorders & neuropathic pain/pruritus in small animals
  - May reduce seizure thresholds in epileptic animals
  - Sedation & anticholinergic effects most likely adverse effects
  - Overdoses can be very serious in both animals & humans
- 

## Uses/Indications

Amitriptyline has been used for behavioral conditions such as separation anxiety or generalized anxiety in dogs, and excessive grooming, spraying and anxiety in cats. Currently clomipramine is often chosen over amitriptyline for use in dogs when a tricyclic is to be tried for behavioral indications. Amitriptyline may be useful for adjunctive treatment of pruritus, or chronic pain of neuropathic origin in dogs and cats. In cats, it potentially could be useful for adjunctive treatment of lower urinary tract disease. Amitriptyline has been tried to reduce feather plucking in birds.

## Pharmacology/Actions

Amitriptyline (and its active metabolite, nortriptyline) has a complicated pharmacologic profile. From a slightly oversimplified viewpoint, it has 3 main characteristics: blockage of the amine pump, thereby increasing neurotransmitter levels (principally serotonin, but also norepinephrine), sedation, and central and peripheral anticholinergic activity. Other pharmacologic effects include stabilizing mast cells via H-1 receptor antagonism, and antagonism of glutamate receptors and sodium channels. In animals, tricyclic antidepressants are similar to the actions of phenothiazines in altering avoidance behaviors.

## Pharmacokinetics

Amitriptyline is rapidly absorbed from both the GI tract and from parenteral injection sites, but transdermal (PLO-gel based) absorption in cats is poor (Mealey *et al.* 2004). Peak levels occur in 1–2 hours after oral administration in cats and other species within 2–12 hours. Amitriptyline is highly bound to plasma proteins, enters the CNS, and enters maternal milk in levels at, or greater than those found in maternal serum. The drug is metabolized in the liver to several metabolites, including nortriptyline, which is active. In humans, the terminal half-life is approximately 30 hours. Half-life in dogs has been reported to be 6–8 hours.

## Contraindications/Precautions/Warnings

These agents are contraindicated if prior sensitivity has been noted with any other tricyclic. Concomitant use with monoamine oxidase inhibitors is generally contraindicated. Use with extreme caution in patients with seizure disorders as tricyclic agents may reduce seizure thresholds. Use with caution in patients with thyroid disorders, hepatic disorders, KCS, glaucoma, cardiac rhythm disorders, diabetes, or adrenal tumors.

## Adverse Effects

The most predominant adverse effects seen with the tricyclics are related to their sedating and anticholinergic (constipation, urinary retention) properties. Occasionally, dogs exhibit hyperexcitability and, rarely, develop seizures. However, adverse effects can run the entire gamut of systems, including cardiac (dysrhythmias), hematologic (bone marrow suppression), GI (diarrhea, vomiting), endocrine, etc. Cats may demonstrate the following adverse effects: sedation, hypersalivation, urinary retention, anorexia, thrombocytopenia, neutropenia, unkempt hair coat, vomiting, ataxia, disorientation and cardiac conductivity disturbances.

## Reproductive/Nursing Safety

Isolated reports of limb reduction abnormalities have been noted; restrict use to pregnant animals only when the benefits clearly outweigh the risks. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

## Overdosage/Acute Toxicity

Overdosage with tricyclics can be life-threatening (arrhythmias, cardiorespiratory collapse). Because the toxicities and therapies for treatment are complicated and controversial, it is recommended to contact an animal poison control center for further information in any potential overdose situation.

There were 178 exposures to amitriptyline reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 113 were dogs with 21 showing clinical signs. The remaining 65 cases were cats with 39 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy and tachycardia. Common findings in cats recorded in decreased frequency included vocalization, ataxia, mydriasis, tachycardia, disorientation, lethargy, and agitation.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amitriptyline and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Increased effects; hyperthermia and ileus possible
- **CIMETIDINE:** May inhibit tricyclic antidepressant metabolism and increase the risk of toxicity
- **CISAPRIDE:** May have additive effects on QTc interval; possible serious arrhythmias may result
- **CNS DEPRESSANTS:** Increased effects
- **DIAZEPAM:** Possible increased amitriptyline levels
- **MONOAMINE OXIDASE INHIBITORS** (including **selegiline, amitraz**): Potential life threatening serotonin syndrome; use together not recommended
- **QUINIDINE:** Increased risk for QTc interval prolongation and tricyclic adverse effects
- **SELECTIVE-SEROTONIN RE-UPTAKE INHIBITORS** (SSRIs, **fluoxetine**, etc.): Potential increased amitriptyline levels, increased risk for serotonin syndrome; **Note:** SSRI's and TCA's etc. amitriptyline are often used together in veterinary behavior medicine, but enhanced monitoring for adverse effects is suggested)
- **SYMPATHOMIMETIC AGENTS:** May increase the risk of cardiac effects (arrhythmias, hypertension, hyperpyrexia)
- **THYROID AGENTS:** Increased risk for arrhythmias; monitor

## Laboratory Considerations

- Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on **ECG**
- The response to **metapyrone** may be decreased by amitriptyline
- Tricyclics may alter (increase or decrease) **blood glucose** levels

## Doses

### ■ DOGS:

For adjunctive treatment of pruritus:

- a) 1–2 mg/kg PO q12h (Paradis & Scott 1992)
- b) For acral pruritic dermatitis: 2.2 mg/kg PO twice daily; only occasionally effective. A 2–4 week trial is recommended (Rosychuck 1991)

For behavior disorders amenable to tricyclics:

- a) For separation anxiety or generalized anxiety: 1–2 mg/kg PO q12h; with behavior modification (Shanley & Overall 1992); (Line 2000); (Overall 2000)
- b) 1–4 mg/kg PO q12h. Begin at 1–2 mg/kg PO q12h for 2 weeks, increase by 1 mg/kg up to maximum dosage (4 mg/kg) as necessary. If no clinical response, decrease by 1 mg/kg PO q12h for 2 weeks until at initial dosage. (Virga 2002)
- c) 2.2–4.4 mg/kg PO q12h (Reisner & Houpt 2000)
- d) 0.25–1.5 mg/kg PO every 12–24h (Crowell-Davis 1999)

For neuropathic pain:

a) 1–2 mg/kg PO q12–24h (Hardie 2000)

b) For adjunctive treatment of pain associated with appendicular osteosarcoma: 1–2 mg/kg PO q12–24h (Liptak & Ehrhart 2005)

#### ■CATS:

For adjunctive treatment of behavior disorders amenable to tricyclics:

a) 5–10 mg per cat PO once daily (Miller 1989), (Marder 1991), (Reisner & Houpt 2000)

b) 0.5–2 mg/kg PO q12–24h; start at 0.5 mg/kg PO q12h (Overall 2000)

c) 0.5–1 mg/kg PO q12–24h (Crowell-Davis 1999)

d) 0.5–1 mg/kg PO q12–24h. Allow 3–4 weeks for initial trial. (Virga 2002)

For self-mutilation behaviors associated with anxiety:

a) 5–10 mg per cat PO once to twice daily; with behavior modification (Shanley & Overall 1992)

b) 1–2 mg/kg PO q12h (Line 2000)

For pruritus (after other more conventional therapies have failed):

a) 5–10 mg per cat PO once daily or 2.5–7.5 mg/cat once to twice daily. When discontinuing, taper dose over 1–3 weeks. (Messinger 2000)

For symptomatic therapy of idiopathic feline lower urinary tract disease (FLUTD):

a) 2.5–12.5 mg (total dose) PO once daily at night (Bartges 2006)

b) 5–10 mg (total dose) PO once daily at night; the drug is in popular use at present and further studies are needed (Senior 2006)

c) Reserved for cases with severe, recurrent signs; 2.5–12.5 mg (total dose) PO at the time the owner retires for the night. Dosage is adjusted to produce a barely perceptible calming effect on the cat. If no improvement is seen within 2 months, the medication may be gradually tapered and then stopped. (Buffington 2006)

For neuropathic pain:

a) 2.5–12.5 mg/cat PO once daily (Hardie 2000)

b) 0.5–2 mg/kg PO once daily; may be a useful addition to NSAIDs for chronic pain. (Lascelles *et al.* 2003)

#### ■BIRDS:

For adjunctive treatment of feather plucking:

a) 1–2 mg/kg PO q12–24 hours. Anecdotal reports indicate some usefulness. Barring side-effects, may be worth a more prolonged course of therapy to determine efficacy. (Lightfoot 2001)

## Monitoring

#### ■ Efficacy

■ Adverse effects; it is recommended to perform a cardiac evaluation, CBC and serum chemistry panel prior to therapy

■ For cats, some clinicians recommend that liver enzymes be measured prior to therapy, one month after initial therapy, and yearly, thereafter

#### Client Information

■ All tricyclics should be dispensed in child-resistant packaging and kept well away from children or pets.

■ Several weeks may be required before efficacy is noted and to continue dosing as prescribed. Do not abruptly stop giving medication without veterinarian's advice.

#### Chemistry/Synonyms

A tricyclic dibenzocycloheptene-derivative antidepressant, amitriptyline HCl occurs as a white or practically white, odorless or practically odorless crystalline powder that is freely soluble in water or alcohol. It has a bitter, burning taste and a pKa of 9.4.

Amitriptyline may also be known as amitriptylini hydrochloridum; many trade names are available.

#### Storage/Stability

Amitriptyline tablets should be stored at room temperature. The injection should be kept from freezing and protected from light.

#### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

Amitriptyline HCl Tablets: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, & 150 mg; generic; (Rx)

There are also fixed dose oral combination products containing amitriptyline and chlordiazepoxide, and amitriptyline and perphenazine.

## AMLODIPINE BESYLATE

(am-loe-di-peen) Norvasc®

CALCIUM CHANNEL BLOCKER

### Prescriber Highlights

- Calcium channel blocker used most often for treating hypertension, especially in cats
  - Slight negative inotrope; use with caution in patients with heart disease, hepatic dysfunction
  - Potentially may cause anorexia & hypotension in cats early in therapy; gingival hyperplasia seen in some dogs
  - Hypertension may rapidly reoccur if dosages are missed
- 

### Uses/Indications

Oral amlodipine appears to be a useful agent in the treatment of hypertension in cats and many consider it the drug of choice for this indication. In pharmacokinetic studies, amlodipine has decreased blood pressure in dogs with chronic renal disease, but its efficacy in treating hypertensive dogs has been disappointing. When used alone in healthy dogs in higher dosages, amlodipine has been shown to activate the renin-angiotensin-aldosterone system (RAAS). Use with an ACE inhibitor (enalapril) at least partially blocks this effect (Atkins *et al.* 2007).

Hypertension in cats is usually secondary to other diseases (often renal failure or cardiac causes such as thyrotoxic cardiomyopathy or primary hypertrophic cardiomyopathy, etc.) and is most often seen in middle-aged or geriatric cats. These animals often present with acute clinical signs such as blindness, seizures, collapse or paresis. A cat is generally considered hypertensive if systolic blood pressure is >160 mmHg. Early reports indicate that if antihypertensive therapy is begun acutely, some vision may be restored in about 50% of cases of blindness secondary to hypertension.

### Pharmacology/Actions

Amlodipine inhibits calcium influx across cell membranes in both cardiac and vascular smooth muscle. It has a greater effect on vascular smooth muscle, thereby acting as a peripheral arteriolar vasodilator and reducing afterload. Amlodipine also depresses impulse formation (automaticity) and conduction velocity in cardiac muscle. After an initial dose in dogs, amlodipine has a mild diuretic action.

### Pharmacokinetics

No feline-specific data on the drug's pharmacokinetics was located. In humans, amlodipine's bioavailability does not appear to be altered by the presence of food in the gut. The drug is slowly but almost completely absorbed after oral administration and is reported to be absorbed after rectal administration. In humans, peak plasma concentrations occur between 6–9 hours post-dose and effects on blood pressure are correspondingly delayed. In cats, effects on systemic blood pressure are usually seen within 4 hours of dosing and may persist for approximately 30 hours post dose (Brown 2009). The drug has very high plasma protein binding characteristics (approximately 93%). However, drug interactions associated with potential displacement from these sites have not been elucidated. Amlodipine is slowly, but extensively metabolized to inactive compounds in the liver. Terminal plasma half-life is approximately 30 hours in dogs and 35 hours in healthy humans, but is prolonged in the elderly and in those patients with hypertension or hepatic dysfunction.

### Contraindications/Precautions/Warnings

Because amlodipine may have slight negative inotropic effects, it should be used cautiously in patients with heart failure or cardiogenic shock. It should also be used cautiously in patients with hepatic disease or at risk for developing hypotension. A relative contraindication for amlodipine exists for humans with advanced aortic stenosis.

There is concern that using amlodipine alone for treating hypertension in cats with renal disease may expose glomeruli to higher pressures secondary to efferent arteriolar constriction. This is caused by localized increases in renin-angiotensin-aldosterone (RAAS) axis activity thereby allowing progressive damage to glomeruli. It is postulated that using an ACE inhibitor with amlodipine may help prevent this occurrence (Stepien 2006). Whether routine use of ACE inhibitors with amlodipine is necessary and beneficial in animals with chronic kidney disease and hypertension is somewhat controversial, particularly in cats.

### Adverse Effects

Because of amlodipine's relatively slow onset of action, hypotension and inappetence is usually absent in cats. Infrequently, cats may develop azotemia, lethargy, hypokalemia, reflex tachycardia and weight loss. In humans taking amlodipine, headache (7.3% incidence) is the most frequent problem reported.

In dogs, gingival hyperplasia has been reported when used long term (Thomason *et al.* 2009).

### Reproductive/Nursing Safety

While no evidence of impaired fertility was noted in rats given 8X overdoses, amlodipine has been shown to be fetotoxic (intrauterine death rates increased 5 fold) in laboratory animals (rats, rabbits) at very high dosages. No evidence of teratogenicity or mutagenicity was observed in lab animal studies. In rats, amlodipine prolonged labor. It is unknown whether amlodipine enters maternal milk. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

Limited experience with other calcium channel blockers in humans has shown that profound hypotension and bradycardia may result. There were 35 exposures to amlodipine reported to the ASPCA Animal Poison Control Center (APCC) during 2006 - 2009. In these cases, 15 were dogs with 7 showing clinical signs and the remaining 20 cases were cats with 4 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy. Common findings in cats recorded in decreasing frequency included lethargy and vomiting.

Risk in animals with overdoses is for hypotension and reflex tachycardia (possible to see bradycardia). When possible, massive overdoses should be managed with gut emptying and supportive treatment. Beta agonists, intravenous lipid therapy, and intravenous calcium may be beneficial.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amlodipine and may be of significance in veterinary patients:

No clinically significant drug-drug interactions have been noted specifically with amlodipine at this time. However, concomitant use of **diuretics, beta-blockers, other vasodilators or other agents that may reduce blood pressure** (e.g., **fentanyl**) may cause hypotension if used with amlodipine. **Grapefruit juice/powder** may alter bioavailability.

## Laboratory Considerations

- No specific concerns were noted

## Doses

### ■CATS:

For treatment of systemic hypertension:

a) As a first step drug when systolic BP >160 mmHg, diastolic >120 mmHg: **1**) amlodipine (0.625 mg per cat q24h, if cat greater than 6 kg, 1.25 mg/cat q24h), add ACE inhibitor if proteinuric; **2**) ACE inhibitor (benazepril/enalapril 0.5 mg/kg q12h); **3**) spironolactone (1–2 mg/kg twice daily); **4**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1-2 weeks systolic BP > 160 mmHg. (Henik 2007)

b) 0.625–1.25 mg (total dose) PO once daily. Drug of choice; often successful as a single agent. Can be combined with an ACEI, beta-blocker or diuretic if needed. Maximum effect seen within 7 days of therapy. (Sparkes 2003)

### ■DOGS:

For adjunctive therapy for refractory heart failure:

a) For treatment of advanced mitral valve degeneration as an afterload reducer after ACE inhibitor maintenance therapy has been established: 0.2–0.4 mg/kg PO twice daily. Initiate therapy at 0.1 mg/kg PO twice daily and up-titrate weekly while monitoring blood pressure. (Kraus 2003)

b) As an arterial vasodilator particularly in dogs moderately refractory, or recurrent CHF secondary to mitral regurgitation and maintained blood pressures: 0.1 mg/kg q12–24h initially; titrate up as needed to 0.25 mg/kg PO q12–24h; monitor blood pressure. (DeFrancesco 2006)

For treatment of systemic hypertension: in dogs with chronic renal disease:

a) In dogs with chronic renal disease: 0.1–0.5 mg/kg PO once daily (q24h), most often combined with an ACE inhibitor. Dogs may require weeks to months of therapy to achieve satisfactory blood pressure control. (Polzin 2009)

b) As a 2nd step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after **1**) enalapril/benazepril (0.5 mg/kg q12h); **2**) amlodipine (0.1 mg/kg q24h); **3**) amlodipine (0.2 mg/kg q24h); **4**) spironolactone (1–2 mg/kg twice daily); **5**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1-2 weeks systolic BP > 160 mmHg. (Henik 2007)

## Monitoring

- Blood pressure;
- Ophthalmic exam
- Adverse effects

## Client Information

- May give with food
- Missing dosages can cause rapid redevelopment of symptoms and damage secondary to hypertension

## Chemistry/Synonyms

Amlodipine besylate, a dihydropyridine calcium channel-blocking agent, occurs as a white crystalline powder that is slightly soluble in water and sparingly soluble in alcohol.

Amlodipine Besylate may also as: amlodipini besilas, UK-48340-26, or UK-48340-11 (amlodipine maleate); many trade names are available.

## Storage/Stability

Store amlodipine tablets at room temperature, in tight, light resistant containers.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Amlodipine oral suspension compounded from commercially available tablets has been published (Nahata et al. 1999). Triturating six (6) amlodipine 5 mg tablets with 15 mL of *Ora-Plus*® and *qs ad* to 30 mL with *Ora-Sweet*® yields a 1 mg/mL oral suspension that retains >90% potency for 91 days stored at both 5°C and 25°C. Compounded preparations of amlodipine should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Amlodipine Oral Tablets: 2.5 mg, 5 mg, & 10 mg; *Norvasc*® (Pfizer); generic; (Rx)

Fixed-dose combination products with benazepril (*Lotrel*®) or atorvastatin (*Caduet*®) are available.

## AMMONIUM CHLORIDE

(ah-moe-nee-um) Uroze®

ACIDIFYING AGENT

### Prescriber Highlights

- **Urinary acidifier; treatment of metabolic alkalosis**
  - **Contraindicated in patients with hepatic failure or uremia**
  - **Potential adverse effects are primarily GI distress; IV use may lead to metabolic acidosis**
  - **Very unpalatable; addition of sugar (not molasses) may improve palatability to goats and sheep**
  - **May increase excretion of quinidine; decrease efficacy of erythromycin or aminoglycosides in urine**
- 

### Uses/Indications

The veterinary indications for ammonium chloride are as a urinary acidifying agent to help prevent and dissolve certain types of uroliths (e.g., struvite), to enhance renal excretion of some types of toxins (e.g., strontium, strychnine) or drugs (e.g., quinidine), or to enhance the efficacy of certain antimicrobials (e.g., chlortetracycline, methenamine mandelate, nitrofurantoin, oxytetracycline, penicillin G or tetracycline) when treating urinary tract infections. Ammonium chloride has also been used intravenously for the rapid correction of metabolic alkalosis.

Because of changes in feline diets to restrict struvite and as struvite therapeutic diets (e.g., s/d) cause aciduria, ammonium chloride is not commonly recommended for struvite uroliths in cats.

Ammonium chloride is still recommended to help prevent uroliths in small ruminants, but dietary changes can significantly affect its efficacy for this purpose.

### Pharmacology/Actions

The acidification properties of ammonium chloride are caused by its dissociation into chloride and ammonium ions *in vivo*. The ammonium cation is converted by the liver to urea with the release of a hydrogen ion. This ion combines with bicarbonate to form water and carbon dioxide. In the extracellular fluid, chloride ions combine with fixed bases and decrease the alkaline reserves in the body. The net effects are decreased serum bicarbonate levels and a decrease in blood and urine pH.

Excess chloride ions presented to the kidney are not completely reabsorbed by the tubules and are excreted with cations (principally sodium) and water. This diuretic effect is usually compensated for in the kidneys after a few days of therapy.

### Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, ammonium chloride is rapidly absorbed from the GI.

### Contraindications/Precautions/Warnings

Ammonium chloride is contraindicated in patients with severe hepatic disease as ammonia may accumulate and cause toxicity. In general, ammonium chloride should not be administered to uremic patients since it can intensify the metabolic acidosis already existing in some of these patients. As sodium depletion can occur, ammonium chloride should not be used alone in patients with severe renal insufficiency and metabolic alkalosis secondary to vomiting hydrochloric acid. In these cases, sodium chloride repletion with or without ammonium chloride administration should be performed to correct both sodium and chloride deficits. Ammonium chloride is contraindicated in patients with urate calculi or respiratory acidosis and high total CO<sub>2</sub> and buffer base. Ammonium chloride alone cannot correct hypochloremia with secondary metabolic alkalosis due to intracellular potassium chloride depletion; potassium chloride must be administered to these patients.

Do not administer subcutaneously, rectally or intraperitoneally.

Use ammonium chloride with caution in patients with pulmonary insufficiency or cardiac edema.

A high roughage/concentrate ratio diet can decrease the urine pH lowering effect of ammonium chloride in horses (Kienzle *et al.* 2006).

### Adverse Effects

Development of metabolic acidosis (sometimes severe) can occur unless adequate monitoring is performed. When used intravenously, pain at the injection site can develop; slow administration lessens this effect. Gastric irritation, nausea and vomiting may be associated with oral dosing of the drug. Urinary acidification is associated with an increased risk for calcium oxalate urolith formation in cats.

### Overdosage/Acute Toxicity

Clinical signs of overdosage may include: nausea, vomiting, excessive thirst, hyperventilation, bradycardias or other arrhythmias, and progressive CNS depression. Profound acidosis and hypokalemia may be noted on laboratory results.

Treatment should consist of correcting the acidosis by administering sodium bicarbonate or sodium acetate intravenously. Hypokalemia should be treated by using a suitable oral (if possible) potassium product. Intense acid-base and electrolyte monitoring should be performed on an ongoing basis until the patient is stable.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in terms of reproduction or development of the fetus*). In humans, it is not known whether this drug can cause fetal harm when administered to a pregnant woman or if it can affect lactation.

enus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.)

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ammonium chloride or other urinary acidifying agents and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (e.g., **gentamicin**) and **ERYTHROMYCIN**: Are more effective in an alkaline medium; urine acidification may diminish these drugs effectiveness in treating bacterial urinary tract infections
- **QUINIDINE**: Urine acidification may increase renal excretion

## Doses

### ■ DOGS:

For urine acidification:

- As adjunctive therapy for struvite uroliths: 20 mg/kg PO three times daily (Labato 2002)
- To enhance the renal elimination of certain toxins/drugs: 200 mg/kg/day divided four times daily (Grauer & Hjelle 1988)
- To enhance elimination of strontium: 0.2–0.5 grams PO 3–4 times a day (used with calcium salts) (Bailey 1986)

For ATT (ammonia tolerance testing):

- 2 mL/kg of a 5% solution of ammonium chloride deep in the rectum, blood sampled at 20 minutes and 40 minutes; or oral challenge with ammonium chloride 100 mg/kg (maximum dose = 3 grams) either in solution: dissolved in 20–50 mL warm water or in gelatin capsules, blood sampled at 30 and 60 minutes. Test may also be done by comparing fasting and 6-hour postprandial samples without giving exogenous ammonium chloride. (Center 2004)

### ■ CATS:

For urine acidification:

- In struvite dissolution therapy if diet and antimicrobials do not result in acid urine or to help prevent idiopathic FUS in a non-obstructed cat: 20 mg/kg PO twice daily (Lage *et al.* 1988)
- As adjunctive therapy for struvite uroliths: 20 mg/kg PO twice daily (Labato 2002)

### ■ HORSES:

- 4–15 grams PO (Swinyard 1975)
- Ammonium chloride as a urinary acidifier: 60–520 mg/kg PO daily. Ammonium salts are unpalatable and will have to be dosed via stomach tube or dosing syringe. Alternatively, ammonium sulfate at 165 mg/kg PO per day is more palatable and may be accepted when mixed with grain or hay. (Jose-Cunilleras and Hinchcliff 1999)
- As a urinary acidifier to enhance renal excretion of strychnine: 132 mg/kg PO (Schmitz 2004)

### ■ CATTLE:

For urolithiasis prevention:

- 200 mg/kg PO (Howard 1986)
- 15–30 grams PO (Swinyard 1975)

### ■ SHEEP & GOATS:

For urolithiasis prevention:

- 300 mg/kg PO (Edmondson 2009)
- 0.5–1% of the daily dry matter will acidify urine, but can be very unpalatable. Table sugar may improve palatability. (Snyder 2009), (Van Metre 2009).

## Monitoring

- Urine pH (Urine pH's of  $\leq 6.5$  are recommended as goals of therapy)
- Blood pH if there are clinical signs of toxicity or treating metabolic alkalosis
- Serum electrolytes, if using chronically or if treating metabolic acidosis
- Prior to IV use, it is recommended that the carbon dioxide combining power of the patient's serum be measured to insure that serious acidosis is prevented

## Client Information

- Contact veterinarian if animal exhibits signs of nausea, vomiting, excessive thirst, hyperventilation or progressive lethargy
- Powders may have a bitter taste and patients may not accept their food after mixing

## Chemistry/Synonyms

An acid-forming salt, ammonium chloride occurs as colorless crystals or as white, fine or coarse, crystalline powder. It is somewhat hygroscopic, and has a cool, saline taste. When dissolved in water, the temperature of the solution is decreased. One gram is soluble in approximately 3 mL of water at room temperature; 1.4 mL at 100°C. One gram is soluble in approximately 100 mL of alcohol.

One gram of ammonium chloride contains 18.7 mEq of ammonium and chloride ions. The commercially available concentrate for injection (26.75%) contains 5 mEq of each ion per mL and contains disodium edetate as a stabilizing agent. The pH of the concentrate for injection is approximately 5.

Ammonium chloride may also be known as muriate of ammonia and sal ammoniac.

## Storage/Stability

Ammonium chloride for injection should be stored at room temperature; avoid freezing. At low temperatures, crystallization may occur; it may be resolubilized by

warming to room temperature in a water bath.

### Compatibility/Compounding Considerations

Ammonium chloride should not be titrated with strong oxidizing agents (e.g., potassium chlorate) as explosive compounds may result.

Ammonium chloride is reported to be physically **compatible** with all commonly used IV replacement fluids and potassium chloride. It is **incompatible** with codeine phosphate, dimenhydrinate, methadone HCl, nitrofurantoin sodium, sulfisoxazole diolamine, and warfarin sodium. It is also reportedly **incompatible** with alkalis and their hydroxides.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

**Note:** The following may not be FDA-approved products as they are not located in the “Green Book”.

Ammonium Chloride Tablets: 200 mg, 400 mg; *UriKare® 200, 400 Tablets* (Neogen); (Rx). Labeled for use in cats and dogs.

Ammonium Chloride Granules: 200 mg per ¼ teaspoonful powder; *Uroze® 200* (Virbac), *UriKare® 200* (Neogen); (Rx). Labeled for cats and dogs.

Ammonium Chloride Granules: 400 mg per ¼ teaspoonful powder; *Uroze®* (Virbac), *UriKare® 400* (Neogen); (Rx). Labeled for cats and dogs.

Ammonium chloride is also found in some veterinary labeled cough preparations e.g., *Spect-Aid® Expectorant Granules* (7% guaifenesin, 75% ammonium chloride, potassium iodide 2%) and in some cough syrups (also containing guaifenesin, pyrrolamine and phenylephrine).

When used in large animals, feed grade ammonium chloride can be obtained from feed mills.

#### HUMAN-LABELED PRODUCTS:

Ammonium Chloride Injection: 26.75% (5 mEq/mL) in 20 mL (100 mEq) vials; generic (Hospira); (Rx). Preparation of solution for IV administration: Dilute 1 or 2 vials (100–200 mEq) in either 500 or 1000 mL of sodium chloride 0.9% for injection. Do not administer at a rate greater than 5 mL/min (human adult).

## AMMONIUM MOLYBDATE

### AMMONIUM TETRATHIOMOLYBDATE

(ah-moe-nee-um moe-lib-date; tet-ra-thye-oh-moe-lib-date) Molyphen®

#### COPPER POISONING TREATMENT

#### Prescriber Highlights

- Used primarily to treat copper poisoning in food animals (esp. sheep)
- Consider contacting FDA for guidance in treating food animals

---

### Uses/Indications

Ammonium molybdate and ammonium tetrathiomolybdate (TTM) are used for the investigational or compassionate treatment of copper poisoning in food animals, primarily sheep.

### Adverse Effects

After apparent successful treatment for copper poisoning with ammonium tetrathiomolybdate (TTM), a flock of sheep became infertile, progressively unthrifty, and died 2–3 years later. The authors concluded the TTM was retained in the CNS, pituitary and adrenal glands and caused a toxic endocrinopathy (Haywood *et al.* 2004).

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Doses

**Note:** In food animals, FARAD recommends a minimum 10 day preslaughter withdrawal time and a minimum 5 day milk withholding interval. (Haskell *et al.* 2005)

Ammonium tetrathiomolybdate does not go into solution readily and ammonium molybdate administered orally is often preferred.

#### ■SHEEP:

For treatment of copper poisoning:

- a) Food animals: Ammonium molybdate: 200 mg per head PO once daily for 3 weeks. Ammonium tetrathiomolybdate: 1.7–3.4 mg per head IV or SC every other day for 3 treatments (Post & Keller 2000)

- b) 100 mg with 1-gram sodium sulfate by mouth daily (Debuf 1991)
- c) 200 mg ammonium or sodium molybdate plus 500 mg of sodium thiosulfate given daily PO for up to 3 weeks (Thompson & Buck 1993)
- d) Ammonium tetrathiomolybdate: 1.7 mg/kg IV or 3.4 mg/kg SC every other day for 3 treatments. Alternatively, ammonium molybdate 50–500 mg PO once daily and sodium thiosulfate 300–1000 mg PO once daily for 3 weeks. (Plumlee 1996)
- e) Ammonium tetrathiomolybdate: 2–15 mg/kg IV q24h (once daily) for 3-6 days. (Boileau 2009)

## Dosage Forms/Regulatory Status/Synonyms

**VETERINARY-LABELED PRODUCTS:** None.

**Note:** Ammonium Molybdate or ammonium tetrathiomolybdate can be obtained from various chemical supply houses, but it is recommended to contact the FDA before treating for guidance when contemplating using molybdate.

**HUMAN-LABELED PRODUCTS:**

Ammonium Molybdate Injection: 25 micrograms/mL (as 46 micrograms/mL ammonium molybdate tetrahydrate) in 10 mL vial; *Molyphen*® (American Pharmaceutical Partners); generic; (Rx)

Ammonium molybdate may also be known as: *Molybdene Injectable*®, or *Molyphen*®. Ammonium tetrathiomolybdate may also be known as TTM.

## AMOXICILLIN

(a-mox-i-sill-in) Amoxil®, Amoxi-Tabs®

AMINOPENICILLIN

### Prescriber Highlights

- **Bactericidal aminopenicillin with same spectrum as ampicillin (ineffective against bacteria that produce beta-lactamase)**
  - **Most likely adverse effects are GI-related, but hypersensitivity & other adverse effects rarely occur**
  - **Available in oral & parenteral dosage forms in USA**
- 

## Uses/Indications

The aminopenicillins have been used for a wide range of infections in various species. FDA-approved indications/species, as well as non-approved uses, are listed in the Dosages section below. According to one reference (Trepanier 2009), amoxicillin (alone) is a reasonable first choice for empiric treatment (before culture and susceptibility results are back) of abscesses in cats.

## Pharmacology/Actions

Like other penicillins, amoxicillin is a time-dependent, bactericidal (usually) agent that acts by inhibiting cell wall synthesis. Although there may be some slight differences in activity against certain organisms, amoxicillin generally shares the same spectrum of activity and uses as ampicillin. Because it is better absorbed orally (in non-ruminants), higher serum levels may be attained than with ampicillin.

Penicillins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity the drugs have that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, penicillins are generally considered more effective against actively growing bacteria.

The aminopenicillins, also called the “broad-spectrum” or ampicillin penicillins, have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *E. coli*, Klebsiella, and Haemophilus. Like the natural penicillins, they are susceptible to inactivation by beta-lactamase-producing bacteria (*e.g.*, *Staph aureus*). Although not as active as the natural penicillins, they do have activity against many anaerobic bacteria, including Clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa*, Serratia, Indole-positive Proteus (*Proteus mirabilis* is susceptible), Enterobacter, Citrobacter, and Acinetobacter. The aminopenicillins also are inactive against Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

In order to reduce the inactivation of penicillins by beta-lactamases, potassium clavulanate and sulbactam have been developed to inactivate these enzymes and thus extend the spectrum of those penicillins. When used with a penicillin, these combinations are often effective against many beta-lactamase-producing strains of otherwise resistant *E. coli*, *Pasturella* spp., *Staphylococcus* spp., Klebsiella, and Proteus. Type I beta-lactamases that are often associated with *E. coli*, Enterobacter, and Pseudomonas are not generally inhibited by clavulanic acid.

## Pharmacokinetics

Amoxicillin trihydrate is relatively stable in the presence of gastric acid. After oral administration, it is about 74–92% absorbed in humans and monogastric animals. Food will decrease the rate, but not the extent of oral absorption and many clinicians suggest giving the drug with food, particularly if there is concomitant associated GI distress. Amoxicillin trihydrate is also available as a suspension. However, 25% of the drug is excreted in the urine as unchanged drug, 50% is excreted as the inactive metabolite, amoxicillin acid, and 25% is excreted as the inactive metabolite, amoxicillin acid.

GI distress. Amoxicillin serum levels will generally be 1.5–3 times greater than those of ampicillin after equivalent oral doses.

After absorption, the volume of distribution for amoxicillin is approximately 0.3 L/kg in humans and 0.2 L/kg in dogs. The drug is widely distributed to many tissues, including liver, lungs, prostate (human), muscle, bile, and ascitic, pleural and synovial fluids. Amoxicillin will cross into the CSF when meninges are inflamed in concentrations that may range from 10–60% of those found in serum. Very low levels of the drug are found in the aqueous humor, and low levels found in tears, sweat and saliva. Amoxicillin crosses the placenta, but it is thought to be relatively safe to use during pregnancy. It is approximately 17–20% bound to human plasma proteins, primarily albumin. Protein binding in dogs is approximately 13%. Milk levels of amoxicillin are considered low.

Amoxicillin is eliminated primarily through renal mechanisms, principally by tubular secretion, but some of the drug is metabolized by hydrolysis to penicilloic acids (inactive) and then excreted in the urine. Elimination half-lives of amoxicillin have been reported as 45–90 minutes in dogs and cats, and 90 minutes in cattle. Clearance is reportedly 1.9 mL/kg/min in dogs.

### Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, cephalosporins, cefamycins, carbapenems).

Do not administer penicillins, cephalosporins, or macrolides to rabbits, guinea pigs, chinchillas, hamsters, etc. or serious enteritis and clostridial enterotoxemia may occur.

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases.

### Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections). Healthy dogs given oral amoxicillin had their gut flora altered with a shift in balance toward gram-negative bacteria that included resistant *Enterobacteriaceae* species (Gronvold *et al.* 2010).

High doses or very prolonged use have been associated with neurotoxicity (*e.g.*, ataxia in dogs). Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

### Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta; safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

### Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress but other effects are possible (see Adverse Effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amoxicillin and may be of significance in veterinary patients:

- **BACTERIOSTATIC ANTIMICROBIALS** (*e.g.*, chloramphenicol, erythromycin and other macrolides, tetracyclines, sulfonamides, etc.): Because there is evidence of *in vitro* antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has been generally not recommended in the past, but actual clinical importance is not clear and in doubt.
- **METHOTREXATE**: Amoxicillin may decrease the renal excretion of MTX causing increased levels and potential toxic effects.
- **PROBENECID**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives.

### Laboratory Considerations

- Amoxicillin may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by amoxicillin.
- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

### Doses

#### ■ DOGS:

For susceptible infections:

a) For Gram-positive infections: 10 mg/kg PO, IM, SC twice daily for at least 2 days after symptoms subside.

For Gram-negative infections: 20 mg/kg PO three times daily or IM, SC twice daily for at least 2 days after symptoms subside (Aucoin 2000)

b) For susceptible UTI's: 10–20 mg/kg PO q12h for 5–7 days.

For susceptible systemic infections (bacteremia/sepsis): 22–30 mg/kg IV, IM, SC q8h for 7 days.

For susceptible orthopedic infections: 22–30 mg/kg IV, IM, SC, or PO q6–8h for 7–10 days. (Greene *et al.* 2006)

c) For Lyme disease: 22 mg/kg PO q12h for 21–28 days (Appel & Jacobson 1995)

d) For susceptible urinary tract infections: 11 mg/kg PO q8h. For preventative therapy for repeated (>2 per 6 months) urinary tract Gram-positive bacterial

d) For susceptible urinary tract infections: 11 mg/kg PO q8h. For preventative therapy for repeated (>2 per 6 months) urinary tract Gram-positive bacterial infections: 20 mg/kg PO once daily before bedtime after the dog has urinated. Use only after effective treatment completed using full therapeutic doses. (Adams 2009)

#### ■CATS:

For susceptible infections:

a) For Gram-positive infections: 10 mg/kg PO, IM, SC twice daily for at least 2 days after symptoms subside.

For Gram-negative infections: 20 mg/kg PO three times daily or IM, SC twice daily for at least 2 days after symptoms subside) (Aucoin 2000)

b) For susceptible UTI's and soft tissue infections: 50 mg (total dose per cat) or 11–22 mg/kg PO once daily for 5–7 days.

For sepsis: 10–20 mg/kg IV, SC, or PO q12h for as long as necessary. **Note:** Duration of treatment are general guidelines, generally treat for at least 2 days after all signs of infection are gone. (Greene *et al.* 2006)

c) *C. perfringens*, bacterial overgrowth (GI): 22 mg/kg PO once daily for 5 days (Lappin 2000)

d) *C. perfringens* enterotoxigenesis: 11–22 mg/kg PO two to three times daily for 7 days (Leib 2004)

e) For treating *H. pylori* infections using triple therapy: amoxicillin 20 mg/kg PO twice daily for 14 days; metronidazole 10–15 mg/kg PO twice daily; clarithromycin 7.5 mg/kg PO twice daily (Simpson 2003)

#### ■FERRETS:

For eliminating *Helicobacter* gastritis infections:

a) Using triple therapy: Metronidazole 22 mg/kg, amoxicillin 22 mg/kg and bismuth subsalicylate (original *Pepto-Bismol*®) 17.6 mg/kg PO. Give each 3 times daily for 3–4 weeks. (Hall & Simpson 2000)

b) Using triple therapy: Metronidazole 20 mg/kg PO q12h, amoxicillin 20 mg/kg PO q12h and bismuth subsalicylate 17.5 mg/kg PO q8h. Give 21 days. Sucralfate (25 mg/kg PO q8h) and famotidine (0.5 mg/kg PO once daily) are also used. Fluids and assisted feeding should be continued while the primary cause of disease is investigated. (Johnson 2006)

For susceptible infections:

a) 10–35 mg/kg PO or SC twice daily (Williams 2000)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

**Note:** See warning above in Contraindications

a) Hedgehogs: 15 mg/kg IM or PO q12h (Smith 2000)

#### ■CATTLE:

For susceptible infections:

a) 6–10 mg/kg SC or IM q24h (Withdrawal time = 30 days) (Jenkins 1986)

b) For respiratory infections: 11 mg/kg IM or SC q12h (Hjerpe 1986), (Beech 1987b)

c) Calves: Amoxicillin trihydrate: 7 mg/kg PO q8–12h (Baggot 1983)

#### ■HORSES:

For susceptible infections:

a) For respiratory infections: 20–30 mg/kg PO q6h (Beech 1987a)

b) Foals: Amoxicillin Sodium: 15–30 mg/kg IV or IM q6–8h; amoxicillin trihydrate suspension: 25–40 mg/kg PO q8h; amoxicillin/clavulanate 15–25 mg/kg IV q6–8h (Brumbaugh 1999)

#### ■BIRDS:

For susceptible infections:

a) 125 mg/kg q12h PO. Mix oral solution to double strength to a final concentration of 125 mg/mL. (Antinoff 2009)

b) 100 mg/kg q8h, IM, SC, PO (Hoeffler 1995)

c) Ratites: 15–22 mg/kg PO twice daily; in drinking water: 250 mg/gallon for 3–5 days (Jenson 1998)

#### ■REPTILES:

For susceptible infections:

a) For all species: 22 mg/kg PO q12–24h; not very useful unless used in combination with aminoglycosides (Gauvin 1993)

### Monitoring

■ Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

### Client Information

■ The oral suspension should preferably be refrigerated, but refrigeration is not absolutely necessary; any unused oral suspension should be discarded after 14 days

■ Amoxicillin may be administered orally without regard to feeding status

■ If the animal develops gastrointestinal symptoms (*e.g.*, vomiting, anorexia), giving with food may be of benefit

### Chemistry/Synonyms

An aminocillin, amoxicillin is commercially available as the trihydrate. It occurs as a practically odorless, white, crystalline powder that is sparingly soluble in water. Amoxicillin differs structurally from ampicillin only by having an additional hydroxyl group on the phenyl ring.

Amoxicillin may also be known as: amoxycillin, p-hydroxyampicillin, or BRL 2333; many trade names are available.

## Storage/Labeling

Amoxicillin capsules, tablets, and powder for oral suspension should be stored at room temperature (15–30°C) in tight containers. After reconstitution, the oral suspension should preferably be refrigerated (refrigeration not absolutely necessary) and any unused product discarded after 14 days.

## Dosage Forms/Regulatory Status/Withdrawal Times

### VETERINARY-LABELED PRODUCTS:

Amoxicillin Oral Tablets: 50 mg, 100 mg, 150 mg, 200 mg, & 400 mg; *Amoxi-Tabs*® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Amoxicillin Powder for Oral Suspension 50 mg/mL (after reconstitution) in 15 mL or 30 mL bottles; *Amoxi-Drop*® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

Amoxicillin Intramammary Infusion 62.5 mg/syringe in 10 mL syringes; *Amoxi-Mast*® (Schering-Plough); (Rx). FDA-approved for use in lactating dairy cattle. Slaughter withdrawal (when administered as labeled) = 12 days; Milk withdrawal (when administered as labeled) = 60 hours.

### HUMAN-LABELED PRODUCTS:

Amoxicillin Oral Tablets (chewable): 125 mg, 200 mg, 250 mg, & 400 mg; *Amoxil*® (GlaxoSmithKline); generic; (Rx)

Amoxicillin Oral Tablets: 500 mg & 875 mg; *Amoxil*® (GlaxoSmithKline); generic; (Rx)

Amoxicillin Oral Capsules: 250 mg, & 500 mg; *Amoxil*® (GlaxoSmithKline); generic; (Rx)

Amoxicillin Powder for Oral Suspension: 200 mg/5 mL in 50 mL, 75 mL & 100 mL; 250 mg/5 mL in 80 mL, 100 mL & 150 mL; 400 mg/5 mL in 50 mL, 75 mL & 100 mL; *Amoxil*® (GlaxoSmithKline); *Trimox*® (Sandoz); generic; (Rx)

Amoxicillin Oral Extended-Release Tablets: 775 mg in 30s & UD 10s; *Moxatag*® (Middlebrook) (Rx)

## AMOXICILLIN/CLAVULANATE POTASSIUM

### AMOXICILLIN/CLAVULANIC ACID

(a-mox-i-sill-in clav-yue-lan-ate) Clavamox®, Augmentin®

#### POTENTIATED AMINOPENICILLIN

### Prescriber Highlights

- **Bactericidal aminopenicillin with beta-lactamase inhibitor that expands its spectrum. Not effective against Pseudomonas or Enterobacter**
- **Most likely adverse effects are GI related, but hypersensitivity & other adverse effects rarely occur**

---

## Uses/Indications

Amoxicillin/potassium clavulanate tablets and oral suspension products are FDA-approved for use in dogs and cats for the treatment of urinary tract, skin and soft tissue infections caused by susceptible organisms. It is also indicated for canine periodontal disease due to susceptible strains of bacteria. According to one reference (Trepanier 2009), amoxicillin + clavulanate is a reasonable first choice for empiric treatment (before culture and susceptibility results are back) of bacterial cystitis in female dogs, and hepatobiliary infections (with a fluoroquinolone) in dogs or cats.

## Pharmacology/Actions

For information on the pharmacology/actions of amoxicillin, refer that monograph.

Clavulanic acid has only weak antibacterial activity when used alone and presently it is only available in fixed-dose combinations with either amoxicillin (oral) or ticarcillin (parenteral). Clavulanic acid acts by competitively and irreversibly binding to beta-lactamases, including types II, III, IV, and V, and penicillinases produced by Staphylococcus. Staphylococci that are resistant to penicillinase-resistant penicillins (e.g., oxacillin) are considered resistant to amoxicillin/potassium clavulanate, although susceptibility testing may indicate otherwise. Amoxicillin/potassium clavulanate is usually ineffective against type I cephalosporinases. These plasmid-mediated cephalosporinases are often produced by members of the family Enterobacteriaceae, particularly *Pseudomonas aeruginosa*. When combined with amoxicillin, there is little if any synergistic activity against organisms already susceptible to amoxicillin, but amoxicillin-resistant strains (due to beta-lactamase inactivation) may be covered.

When performing Kirby-Bauer susceptibility testing, the *Augmentin*® (human-product trade name) disk is often used. Because the amoxicillin:clavulanic acid ratio of 2:1 in the susceptibility tests may not correspond to *in vivo* drug levels, susceptibility testing may not always accurately predict efficacy for this combination.

## Pharmacokinetics

The pharmacokinetics of amoxicillin are presented in that drug's monograph. There is no evidence to suggest that the addition of clavulanic acid significantly alters amoxicillin pharmacokinetics.

Clavulanate potassium is relatively stable in the presence of gastric acid and is readily absorbed. In dogs, the absorption half-life is reportedly 0.39 hours with peak levels occurring about 1 hour after dosing. Specific bioavailability data for dogs or cats was not located.

Clavulanic acid has an apparent volume of distribution of 0.32 L/kg in dogs and is distributed (with amoxicillin) into the lungs, pleural fluid and peritoneal fluid. Low concentrations of both drugs are found in the saliva, sputum and CSF (uninflamed meninges). Higher concentrations in the CSF are expected when meninges are inflamed, but it is questionable whether therapeutic levels are attainable. Clavulanic acid is 13% bound to proteins in dog serum. The drug readily crosses the placenta but is not believed to be teratogenic. Clavulanic acid and amoxicillin are both found in milk in low concentrations.

Clavulanic acid is apparently extensively metabolized in the dog (and rat) primarily to 1-amino-4-hydroxybutan-2-one. It is not known if this compound possesses any beta-lactamase inhibiting activity. The drug is also excreted unchanged in the urine via glomerular filtration. In dogs, 34–52% of a dose is excreted in the urine as unchanged drug and metabolites, 25–27% eliminated in the feces, and 16–33% into respired air. Urine levels of active drug are considered high, but may be only 1/5th of those of amoxicillin.

## Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished.

Do not administer penicillins, cephalosporins, or macrolides to rabbits, guinea pigs, chinchillas, hamsters, etc. or serious enteritis and clostridial enterotoxemia may occur.

## Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (*e.g.*, ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

## Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amoxicillin-clavulanate and may be of significance in veterinary patients:

- **BACTERIOSTATIC ANTIMICROBIALS** (*e.g.*, chloramphenicol, erythromycin and other macrolides, tetracyclines, sulfonamides, etc.): Because there is evidence of *in vitro* antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has been generally not recommended in the past, but actual clinical importance is not clear and currently in doubt.
- **METHOTREXATE**: Amoxicillin may decrease the renal excretion of MTX causing increased levels and potential toxic effects
- **PROBENECID**: Competitively blocks the tubular secretion of most penicillins, thereby increasing serum levels and serum half-lives

## Laboratory Considerations

- Amoxicillin may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by amoxicillin.
- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

## Doses

**Note:** All doses are for combined quantities of both drugs (unless noted otherwise).

### ■ DOGS:

For susceptible infections:

- 13.75 mg/kg PO twice daily; do not exceed 30 days of therapy (Package insert; *Clavamox*®—Pfizer)
- For susceptible UTI's: 12.5 mg/kg PO q12h for 5–7 days

For susceptible skin, soft tissue infections: 12.5 mg/kg PO q12h for 5–7 days (may need to extend to 21 days; do not exceed past 30 days). Much higher

doses have been recommended for resistant skin infections.

For susceptible deep pyodermas: 12.5 mg/kg PO q12h for 14–120 days

For systemic bacteremia: 22 mg/kg PO q8–12h for 7 days

**Note:** Duration of treatments are general guidelines; generally treat for at least 2 days after all signs of infection are gone. (Greene *et al.* 2006)

c) For Gram-positive infections: 10 mg/kg PO twice daily

For Gram-negative infections: 20 mg/kg PO three times daily (Aucoin 2000)

d) For non-superficial pyoderma: 10–25 mg/kg PO twice daily for 3–6 weeks. Maximum dose is 650 mg twice daily. Increase to three times daily if no response in 1 week. If no response by the 2nd week, discontinue. (Aucoin 2002)

e) For recurrent pyoderma: 13.75–22 mg/kg PO q8–12h (Hillier 2006)

f) For pyoderma: 22 mg/kg PO twice daily or 13.75 mg/kg PO q8h (Rosenkrantz 2009)

g) For susceptible urinary tract infections: 12.5 mg/kg PO q8h (Adams 2009)

#### ■CATS:

For susceptible infections:

a) 62.5 mg/cat PO twice daily; do not exceed 30 days of therapy (Package insert; *Clavamox*®—Pfizer)

b) For Gram-positive infections: 10 mg/kg PO twice daily;

For Gram-negative infections: 20 mg/kg PO three times daily (Aucoin 2000)

c) For susceptible UTI's: 62.5 mg/cat (total dose) PO q12h for 10–30 days;

For susceptible skin, soft tissue infections: 62.5 mg/cat (total dose) or 10–20 mg/kg PO q12h for 5–7 days;

For susceptible sepsis, pneumonia: 10–20 mg/kg PO q8h for 7–10 days

**Note:** Duration of treatment are general guidelines, generally treat for at least 2 days after all signs of infection are gone. (Greene *et al.* 2006)

#### ■FERRETS:

For susceptible infections:

a) 10–20 mg/kg PO 2–3 times daily (Williams 2000)

#### ■BIRDS:

For susceptible infections:

a) 50–100 mg/kg PO q6–8h (Hoeffler 1995)

b) Ratites: 10–15 mg/kg PO twice daily (Jenson 1998)

### Client Information

- The oral suspension should preferably be refrigerated, but refrigeration is not absolutely necessary; any unused oral suspension should be discarded after 10 days
- Amoxicillin/clavulanate may be administered orally without regard to feeding status
- If the animal develops gastrointestinal symptoms (*e.g.*, vomiting, anorexia), giving with food may be of benefit

### Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs or symptoms develop. Serum levels and therapeutic drug monitoring are not routinely performed with these agents.

### Chemistry/Synonyms

A beta-lactamase inhibitor, clavulanate potassium occurs as an off-white, crystalline powder that has a pKa of 2.7 (as the acid) and is very soluble in water and slightly soluble in alcohol at room temperatures. Although available in commercially available preparations as the potassium salt, potency is expressed in terms of clavulanic acid.

Amoxicillin may also be known as: amoxycillin, p-hydroxyampicillin, or BRL 2333; many trade names are available. Clavulanate potassium may also be known as: clavulanic acid, BRL-14151K, or kalii clavulanas.

### Storage/Stability

Clavulanate products should be stored at temperatures less than 24°C (75°F) in tight containers. Potassium clavulanate is reportedly very susceptible to moisture and should be protected from excessive humidity.

After reconstitution, oral suspensions are stable for 10 days when refrigerated. Unused portions should be discarded after that time. If kept at room temperature, suspensions are reportedly stable for 48 hours. The veterinary oral suspension should be reconstituted by adding 14 mL of water and shaking vigorously; refrigerate and discard any unused portion after 10 days.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

*Oral Tablets (4:1 ratio):*

62.5 mg: Amoxicillin 50 mg/12.5 mg clavulanic acid (as the potassium salt)

125 mg: Amoxicillin 100 mg/25 mg clavulanic acid (as the potassium salt)

250 mg: Amoxicillin 200 mg/50 mg clavulanic acid (as the potassium salt)

375 mg: Amoxicillin 300 mg/75 mg clavulanic acid (as the potassium salt); *Clavamox Tablets*® (Pfizer); (Rx). FDA-approved for use in dogs and cats.

*Powder for Oral Suspension:*

Amoxicillin 50 mg/12.5 mg clavulanic acid (as the potassium salt) per mL in 15 mL dropper bottles; *Clavamox® Drops* (Pfizer); (Rx). FDA-approved for use in dogs and cats.

## HUMAN-LABELED PRODUCTS:

**Note:** Human-labeled amoxicillin/clavulanate products have varying ratios of amoxicillin: clavulanate ranging from 2:1 to 7:1.

Amoxicillin (as trihydrate)/Clavulanic Acid (as potassium salt) Tablets: Amoxicillin 250 mg/125 mg clavulanic acid; Amoxicillin 500 mg/125 mg clavulanic acid; Amoxicillin 875 mg/125 mg clavulanic acid; *Augmentin®* (GlaxoSmithKline); generic (Rx)

Chewable Tablets: Amoxicillin 125 mg/31.25 mg clavulanic acid; Amoxicillin 200 mg/28.5 mg clavulanic acid; 250 mg/62.5 mg clavulanic acid & 400 mg/57 mg clavulanic acid; *Augmentin®* (GlaxoSmithKline); generic; (Rx)

Powder for Oral Suspension—Amoxicillin/Clavulanic Acid (as potassium salt) after reconstitution: Amoxicillin 125 mg/31.25 mg clavulanic acid per 5 mL in 75 mL, 100 mL & 150 mL; Amoxicillin 200 mg/28.5 mg clavulanic acid per 5 mL in 50 mL, 75 mL & 100 mL; Amoxicillin 250 mg/62.5 mg clavulanic acid per 5 mL in 75 mL, 100 mL & 150 mL; Amoxicillin 400 mg/57 mg clavulanic acid per 5 mL in 50 mL, 75 mL & 100 mL; 600 mg/42.9 mg clavulanic acid per 5 mL in 75 mL, 100 mL, 125 mL & 200 mL; *Augmentin®* & *Augmentin ES-600®* (GlaxoSmithKline); *Amoclan®* (West-ward); generic; (Rx)

## AMPHOTERICIN B DESOXYCHOLATE

### AMPHOTERICIN B LIPID-BASED

(*am-foc-ter-i-sin bee*) *Abelcet®*, *Fungizone®*

#### ANTIFUNGAL

#### Prescriber Highlights

- Systemic antifungal used for serious mycotic infections
- Must be administered IV
- Nephrotoxicity is biggest concern (not in birds), particularly with the desoxycholate form; newer lipid based products are less nephrotoxic & penetrate into tissues better, but are more expensive
- Renal function monitoring essential
- Drug interactions

---

## Uses/Indications

Because the potential exists for severe toxicity associated with this drug, it should only be used for progressive, potentially fatal fungal infections. Veterinary use of amphotericin has been primarily in dogs, but other species have been treated successfully. For further information on fungal diseases treated, see the Pharmacology and Dosage sections.

The liposomal form of amphotericin B can be used to treat Leishmaniasis.

## Pharmacology/Actions

Amphotericin B is usually fungistatic, but can be fungicidal against some organisms depending on drug concentration. It acts by binding to sterols (primarily ergosterol) in the cell membrane and alters the permeability of the membrane allowing intracellular potassium and other cellular constituents to “leak out.” Because bacteria and rickettsia do not contain sterols, amphotericin B has no activity against those organisms. Mammalian cell membranes do contain sterols (primarily cholesterol) and the drug’s toxicity may be a result of a similar mechanism of action, although amphotericin binds less strongly to cholesterol than ergosterol.

Amphotericin B has *in vitro* activity against a variety of fungal organisms, including Blastomyces, Aspergillus, Paracoccidioides, Coccidioides, Histoplasma, Cryptococcus, Mucor, and Sporothrix. Zygomycetes is reportedly variable in its response to amphotericin. Aspergillosis in dogs and cats does not tend to respond satisfactorily to amphotericin therapy. Additionally, amphotericin B has *in vivo* activity against some protozoa species, including *Leishmania* spp. and *Naegleria* spp.

It has been reported that amphotericin B has immunoadjuvant properties but further work is necessary to confirm the clinical significance of this effect.

## Pharmacokinetics

Pharmacokinetic data on veterinary species is apparently unavailable. In humans (and presumably animals), amphotericin B is poorly absorbed from the GI tract and must be given parenterally to achieve sufficient concentrations to treat systemic fungal infections. After intravenous injection, the drug reportedly penetrates well into most tissues but does not penetrate well into the pancreas, muscle, bone, aqueous humor, or pleural, pericardial, synovial, and peritoneal fluids. The drug does enter the pleural cavity and joints when inflamed. CSF levels are approximately 3% of those found in the serum. Approximately 90–95% of amphotericin in the vascular compartment is bound to serum proteins. The newer “lipid” forms of amphotericin B have higher penetration into the lungs, liver and spleen than the conventional form.

The metabolic pathways of amphotericin are not known, but it exhibits biphasic elimination. An initial serum half-life of 24–48 hours, and a longer terminal half-life of about 15 days have been described. Seven weeks after therapy has stopped, amphotericin can still be detected in the urine. Approximately 2–5% of the drug is

covered in the urine in unchanged in unchanged (biologically active) form.

### Contraindications/Precautions/Warnings

Amphotericin is contraindicated in patients who are hypersensitive to it, unless the infection is life-threatening and no other alternative therapies are available.

Because of the serious nature of the diseases treated with systemic amphotericin, it is not contraindicated in patients with renal disease, but it should be used cautiously with adequate monitoring.

### Adverse Effects

Amphotericin B is notorious for its nephrotoxic effects; most canine patients will show some degree of renal toxicity after receiving the drug. The proposed mechanism of nephrotoxicity is via renal vasoconstriction with a subsequent reduction in glomerular filtration rate. The drug may directly act as a toxin to renal epithelial cells. Renal damage may be more common, irreversible and severe in patients who receive higher individual doses or have preexisting renal disease. Usually, renal function will return to normal after treatment is halted, but may require several months to do so.

Newer forms of lipid-complexed and liposome-encapsulated amphotericin B significantly reduce the nephrotoxic qualities of the drug. Because higher dosages may be used, these forms may also have enhanced effectiveness. A study in dogs showed that amphotericin B lipid complex was 8–10 times less nephrotoxic than the conventional form.

The patient's renal function should be aggressively monitored during therapy. A pre-treatment serum creatinine, BUN (serum urea nitrogen/SUN), serum electrolytes (including magnesium if possible), total plasma protein (TPP), packed cell volume (PCV), body weight, and urinalysis should be done prior to starting therapy. BUN, creatinine, PCV, TPP, and body weight are rechecked before each dose is administered. Electrolytes and urinalysis should be monitored at least weekly during the course of treatment. Several different recommendations regarding the stoppage of therapy when a certain BUN is reached have been made. Most clinicians recommend stopping, at least temporarily, amphotericin treatment if the BUN reaches 30–40 mg/dL, serum creatinine >3 mg/dL or if other clinical signs of systemic toxicity develop such as serious depression or vomiting.

At least two regimens have been used in the attempt to reduce nephrotoxicity in dogs treated with amphotericin desoxycholate. Mannitol (12.5 grams or 0.5–1 g/kg) given concurrently with amphotericin B (slow IV infusion) to dogs may reduce nephrotoxicity, but may also reduce the efficacy of the therapy, particularly in blastomycosis. Mannitol treatment also increases the total cost of therapy. Sodium loading prior to treating has garnered considerable support in recent years. A tubuloglomerular feedback mechanism that induces vasoconstriction and decreased GFR has been postulated for amphotericin B toxicity; increased sodium load at the glomerulus may help prevent that feedback. One clinician (Foil 1986), uses 5 mL/kg of normal saline given in two portions, before and after amphotericin B dosing and states that is has been "... helpful in averting renal insufficiency...."

Cats are apparently more sensitive to the nephrotoxic aspects of amphotericin B, and many clinicians recommend using reduced dosages in this species (see Dosage section).

Adverse effects reported in horses include: tachycardia, tachypnea, lethargy, fever, restlessness, anorexia, anemia, phlebitis, polyuria and collapse.

Other adverse effects that have been reported in mammals with amphotericin B include: anorexia, vomiting, hypokalemia, distal renal tubular acidosis, hypomagnesemia, phlebitis, cardiac arrhythmias, non-regenerative anemia and fever (may be reduced with pretreatment with NSAIDs or a low dosage of steroids). Calcinosis cutis has been reported in dogs treated with amphotericin B. Amphotericin B can increase creatine kinase levels.

In birds, nephrotoxicity does not appear to be an issue with amphotericin B use. It has been postulated that the shorter half-life of the drug noted in birds may be responsible for the lack of nephrotoxicity.

### Reproductive/Nursing Safety

The safety of amphotericin B during pregnancy has not been established, but there are apparently no reports of teratogenicity associated with the drug. The risks of therapy should be weighed against the potential benefits. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

### Overdosage/Acute Toxicity

No case reports were located regarding acute intravenous overdose of amphotericin B. Because of the toxicity of the drug, dosage calculations and solution preparation procedures should be double-checked. If an accidental overdose is administered, renal toxicity may be minimized by administering fluids and mannitol as outlined above in the Adverse Effects section.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving amphotericin B and may be of significance in veterinary patients:

- **CORTICOSTEROIDS:** May exacerbate the potassium-losing effects of amphotericin
- **DIGOXIN:** Amphotericin B-induced hypokalemia may exacerbate digoxin toxicity
- **FLUCYTOSINE:** Synergy (*in vitro*) between amphotericin and flucytosine may occur against strains of *Cryptococcus* and *Candida*, but increased flucytosine toxicity may also occur
- **NEPHROTOXIC DRUGS (aminoglycosides, polymyxin B, colistin, cisplatin, cyclosporine, methoxyflurane or vancomycin):** Since the renal effects of other nephrotoxic drugs may be additive with amphotericin B, avoid, if possible the concurrent or sequential use of these AGENTS
- **POTASSIUM-DEPLETING DRUGS (e.g., thiazide or loop diuretics)**
- **SALINE SOLUTIONS OR WITH SOLUTIONS CONTAINING A PRESERVATIVE:** Reconstituting amphotericin B with these solutions may cause precipitation
- **SKELETAL MUSCLE RELAXANTS (tubocurarine):** Amphotericin B-induced hypokalemia may enhance curariform effects

### Doses

All dosages are for amphotericin B desoxycholate (regular amphotericin B) unless specifically noted for the lipid-based products.

**Note:** Some clinicians have recommended administering a 1 mg test dose (less in small dogs or cats) IV over anywhere from 20 minutes to 4 hours and monitoring pulse, respiration rates, temperature, and if possible, blood pressure. If a febrile reaction occurs some clinicians recommend adding a glucocorticoid to the IV infusion

solution or using an antipyretic prior to treating, but these practices are controversial.

A published study (Rubin et al. 1989) demonstrated less renal impairment and systemic adverse effects in dogs who received amphotericin B IV slowly over 5 hours in 1 L of D5W than in dogs who received the drug IV in 25 mL of D5W over 3 minutes.

## ■DOGS:

For treatment of susceptible systemic fungal infections:

a) Two regimens can be used; after diluting vial (as outlined below in preparation of solution section), either:

1) Rapid-Infusion Technique: Dilute quantity of stock solution to equal 0.25 mg/kg in 30 mL of 5% dextrose. Using butterfly catheter, flush with 10 mL of D5W. Infuse amphotericin B solution IV over 5 minutes. Flush catheter with 10 mL of D5W and remove catheter. Repeat above steps using 0.5 mg/kg 3 times a week until 9–12 mg/kg accumulated dosage is given.

2) Slow IV Infusion Technique: Dilute quantity of stock solution to equal 0.25 mg/kg in 250–500 mL of D5W. Place indwelling catheter in peripheral vein and give total volume over 4–6 hours. Flush catheter with 10 mL of D5W and remove catheter. Repeat above steps using 0.5 mg/kg 3 times a week until 9–12 mg/kg accumulated dosage is given. (Noxon 1989)

b) In dehydrated, sodium-depleted animals, must rehydrate before administration. Dosage is 0.5 mg/kg diluted in D5W. In dogs with normal renal function, may dilute in 60–120 mL of D5W and give by slow IV over 15 minutes. In dogs with compromised renal function, dilute in 500 mL or 1 liter of D5W and give over slowly IV over 3–6 hours. Re-administer every other day if BUN remains below 50 mg/dL. If BUN exceeds 50 mg/dL, discontinue until BUN decreases to at least 35 mg/dL. Cumulative dose of 8–10 mg/kg is required to cure blastomycosis or histoplasmosis. Coccidioidomycosis, aspergillosis and other fungal diseases require a greater cumulative dosage.) (Legendre, A. 1995)

c) For treating systemic mycoses using the lipid-based products: *AmBisome*®, *Amphocil*® or *Abelcet*®: Give test dose of 0.5 mg/kg; then 1–2.5 mg/kg IV q48h (or Monday, Wednesday, Friday) for 4 weeks or until the total cumulative dose is reached. Use 1 mg/kg dose for susceptible yeast and dimorphic fungi until a cumulative dose of 12 mg/kg is reached; for more resistant filamentous fungal infections (e.g., pythiosis) use the higher dose 2–2.5 mg/kg until a cumulative dose of 24–30 mg/kg is reached. (Greene, C. & Watson 1998)

d) For treating systemic mycoses using the amphotericin B lipid complex (ABLC; *Abelcet*®) product: 2–3 mg/kg IV three days per week for a total of 9–12 treatments (cumulative dose of 24–27 mg). Dilute to a concentration of 1 mg/mL in dextrose 5% (D5W) and infuse over 1–2 hours. (Grooters 1999)

e) For systemic mycoses using amphotericin B lipid complex (*Abelcet*®): Dilute in 5% dextrose to a final concentration of 1 mg/mL and administer at a dosage of 2–3 mg/kg three times per week for 9–12 treatments or a cumulative dosage of 24–27 mg/kg. (Schulman & Marks 2005)

For blastomycosis (see general dosage guidelines above):

a) Amphotericin B 0.5 mg/kg 3 times weekly until a total dose of 6 mg/kg is given, with ketoconazole at 10–20 mg/kg (30 mg/kg for CNS, bone or eye involvement) divided for 3–6 months. (Foil 1986)

b) Amphotericin B 0.15–0.5 mg/kg IV 3 times a week with ketoconazole 20 mg/day PO once daily or divided twice daily; 40 mg/kg divided twice daily for ocular or CNS involvement (for at least 2–3 months or until remission then start maintenance). When a total dose of amphotericin B reaches 4–6 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or ketoconazole at 2.5–5 mg/kg PO once daily. If CNS/ocular involvement use ketoconazole at 20–40 mg/kg PO divided twice daily. (Greene, C.E. et al. 1984)

c) For severe cases, using amphotericin B lipid complex (*Abelcet*®): 1–2 mg/kg IV three times a week (or every other day) to a cumulative dose of 12–24 mg/kg. (Taboada 2000)

For cryptococcosis (see general dosage guidelines above):

a) Amphotericin B 0.5–0.8 mg/kg SC 2–3 times per week. Dose is diluted in 0.45% NaCl with 2.5% dextrose (400 mL for cats, 500 mL for dogs less than 20 kg and 1000 mL for dogs greater than 20 kg). Concentrations greater than 20 mg/L result in local irritation and sterile abscess formation. May combine with flucytosine or the azole antifungals. (Taboada 2000)

For histoplasmosis (see general dosage guidelines above):

a) Amphotericin B 0.15–0.5 mg/kg IV 3 times a week with ketoconazole 10–20 mg/day PO once daily or divided twice daily (for at least 2–3 months or until remission then start maintenance). When a total dose of amphotericin B reaches 2–4 mg/kg, start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or at 2.5–5 mg/kg PO once daily. (Greene, C.E. et al. 1984)

b) As an alternative to ketoconazole treatment: 0.5 mg/kg IV given over 6–8 hours. If dose is tolerated, increase to 1 mg/kg given on alternate days until total dose of 7.5–8.5 mg/kg cumulative dose is achieved. (Macy 1987)

For Leishmaniasis:

a) Using the liposomal form of Amphotericin B: 3–3.3 mg/kg IV 3 times weekly for 3–5 treatments. (Lappin 2000)

b) Using *AmBisome*® (lipid-based product): Give initial test dose of 0.5 mg/kg, then 3–3.3 mg/kg IV every 72–96 hours until a cumulative dose of 15 mg/kg is reached. May be possible to give the same cumulative dose with a lower level every 48 hours. (Greene, C. et al. 2006)

For gastrointestinal pythiosis:

a) Resect lesions that are surgically removable to obtain 5–6 cm margins. Follow-up medical therapy using the amphotericin B lipid complex (ABLC; *Abelcet*®) product: 1–2 mg/kg IV three times weekly for 4 weeks (cumulative dose 12–24 mg). May alternatively use itraconazole at 10 mg/kg PO once daily for 4–6 months. (Taboada 1999)

## ■CATS:

For treatment of susceptible systemic fungal infections:

a) Rapid-Infusion Technique: After diluting vial (as outlined below in preparation of solution section), dilute quantity of stock solution to equal 0.25 mg/kg in 30 mL of 5% dextrose. Using butterfly catheter, flush with 10 mL of D5W. Infuse amphotericin B solution IV over 5 minutes. Flush catheter with 10 mL of D5W and remove catheter. Repeat above steps using 0.25 mg/kg 3 times a week until 9–12 mg/kg accumulated dosage is given. (Noxon 1989)

For cryptococcosis (see general dosage guidelines above):

a) As an alternative therapy to ketoconazole: Amphotericin B: 0.25 mg/kg in 30 mL D5W IV over 15 minutes q48h with flucytosine at 200 mg/kg/day divided q6h PO. Continue therapy for 3–4 weeks after clinical signs have resolved or until BUN >50 mg/dL. (Legendre, A. 1995)

b) Amphotericin B 0.15–0.4 mg/kg IV 3 times a week with flucytosine 125–250 mg/day PO divided two to four times a day. When a total dose of amphotericin

B reaches 4–6 mg/kg, start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month with flucytosine at dosage above or with ketoconazole at 10 mg/kg PO once daily or divided twice daily. (Greene, C.E. *et al.* 1984)

c) Amphotericin B 0.5–0.8 mg/kg SC 2–3 times per week. Dose is diluted in 0.45% NaCl with 2.5% dextrose (400 mL for cats, 500 mL for dogs less than 20 kg and 1000 mL for dogs greater than 20 kg). Concentrations greater than 20 mg/L result in local irritation and sterile abscess formation. May combine with flucytosine or the azole antifungals. (Taboada 2000)

d) For treating systemic mycoses using the amphotericin B lipid complex (ABLC; *Abelcet*®) product: 1 mg/kg IV three days per week for a total of 12 treatments (cumulative dose of 12 mg). Dilute to a concentration of 1 mg/mL in dextrose 5% (D5W) and infuse over 1–2 hours. (Grooters 1999)

For histoplasmosis (see general dosage guidelines above):

a) Amphotericin B: 0.25 mg/kg in 30 mL D5W IV over 15 minutes q48h with ketoconazole at 10 mg/kg q12h PO. Continue therapy for 4–8 weeks or until BUN >50 mg/dL. If BUN increases greater than 50 mg/dL, continue ketoconazole alone. Ketoconazole is used long-term (at least 6 months of duration). (Legendre, A.M. 1989)

b) Amphotericin B 0.15–0.5 mg/kg IV 3 times a week with ketoconazole 10 mg/day PO once daily or divided twice daily (for at least 2–3 months or until remission, then start maintenance). When a total dose of amphotericin B reaches 2–4 mg/kg, start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or at 2.5–5 mg/kg PO once daily. (Greene et al, 1984)

For blastomycosis (see general dosage guidelines above):

a) Amphotericin B: 0.25 mg/kg in 30 mL D5W IV over 15 minutes q48h with ketoconazole: 10 mg/kg q12h PO (for at least 60 days). Continue amphotericin B therapy until a cumulative dose of 4 mg/kg is given or until BUN >50 mg/dL. If renal toxicity does not develop, may increase dose to 0.5 mg/kg of amphotericin B. (Legendre, 1989)

b) Amphotericin B 0.15–0.5 mg/kg IV 3 times a week with ketoconazole 10 mg/day PO once daily or divided twice daily (for at least 2–3 months or until remission then start maintenance). When a total dose of amphotericin B reaches 4–6 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or ketoconazole at 2.5–5 mg/kg PO once daily. If CNS/ocular involvement, use ketoconazole at 20–40 mg/kg PO divided twice daily. (Greene, O’Neal, and Barsanti 1984)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** 1 mg/kg/day IV (Ivey & Morrissey, 2000)

#### ■ HORSES:

For treatment of susceptible systemic fungal infections:

a) For fungal pneumonia: Day 1: 0.3 mg/kg IV; Day 2: 0.4 mg/kg IV; Day 3: 0.6 mg/kg IV; days 4–7: no treatment; then every other day until a total cumulative dose of 6.75 mg/kg has been administered (Foreman 1999)

b) For phycomycoses and pulmonary mycoses: After reconstitution (see below) transfer appropriate amount of drug to 1L of D5W and administer using a 16 g needle IV at a rate of 1 L/hr. Dosage schedule follows: Day 1: 0.3 mg/kg IV; Day 2: 0.45 mg/kg IV; Day 3: 0.6 mg/kg IV; then every other day for 3 days per week (MWF or TTHSa) until clinical signs of either improvement or toxicity occur. If toxicity occurs, a dose may be skipped, dosage reduced or dosage interval lengthened. Administration may extend from 10–80 days.) (Brumbaugh 1987)

c) For intrauterine infusion: 200–250 mg. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

#### ■ LLAMAS:

For treatment of susceptible systemic fungal infections:

a) A single case report. Llama received 1 mg test dose, then initially at 0.3 mg/kg IV over 4 hours, followed by 3 L of LRS with 1.5 mL of B-Complex and 20 mEq of KCl added. Subsequent doses were increased by 10 mg and given every 48 hours until reaching 1 mg/kg q48h IV for 6 weeks. Animal tolerated therapy well, but treatment was ultimately unsuccessful (Coccidioidomycosis). (Fowler 1989)

#### ■ BIRDS:

For treatment of susceptible systemic fungal infections:

a) For raptors and psittacines with aspergillosis: 1.5 mg/kg IV three times daily for 3 days with flucytosine or follow with flucytosine. May also use intratracheally at 1 mg/kg diluted in sterile water once to 3 times daily for 3 days in conjunction with flucytosine or nebulized (1 mg/mL of saline) for 15 minutes twice daily. Potentially nephrotoxic and may cause bone marrow suppression. (Clubb 1986)

b) 1.5 mg/kg IV q12h for 3–5 days; topically in the trachea at 1 mg/kg q12h; 0.3–1 mg/mL nebulized for 15 minutes 2–4 times daily. (Flammer 2003)

c) For treatment of *Macrorhabdiosis* (*Microrhabdus ornithogaster*): amphotericin B at 100–150 mg/kg PO q12h for 30 days; treatment failures are common especially with shorter durations of treatment. (Flammer 2008)

#### ■ REPTILES:

For susceptible fungal respiratory infections:

a) For most species: 1 mg/kg diluted in saline and given intra-tracheally once daily for 14–28 treatments. (Gauvin 1993)

#### Monitoring

Also see Adverse Effects section

■ BUN and serum creatinine every other day while dosage is being increased, and at least weekly thereafter during therapy

■ Serum electrolytes (sodium, potassium and magnesium) weekly

■ Liver function tests weekly

■ CBC weekly

■ Urinalysis weekly

■ TPP at least weekly

■ Animal’s weight

## Client Information

- Clients should be informed of the potential seriousness of toxic effects that can occur with amphotericin B therapy
- The costs associated with therapy

## Chemistry/Synonyms

A polyene macrolide antifungal agent produced by *Streptomyces nodosus*, amphotericin B occurs as a yellow to orange, odorless or practically odorless powder. It is insoluble in water and anhydrous alcohol. Amphotericin B is amphoteric and can form salts in acidic or basic media. These salts are more water soluble but possess less antifungal activity than the parent compound. Each mg of amphotericin B must contain not less than 750 micrograms of anhydrous drug. Amphotericin A may be found as a contaminant in concentrations not exceeding 5%. The commercially available powder for injection contains sodium desoxycholate as a solubilizing agent.

Newer lipid-based amphotericin B products are available that have less toxicity than the conventional desoxycholate form. These include amphotericin B cholesteryl sulfate complex (amphotericin B colloidal dispersion, ABCD, *Amphotec*®), amphotericin B lipid complex (ABLC, *Abelcet*®), and amphotericin B liposomal (ABL, L-AMB, *Ambisome*®).

Amphotericin B may also be known as: amphotericin; amphotericin B cholesteryl sulfate complex, amphotericin B lipid complex, amphotericin B liposome, amphotericin B phospholipid complex, amphotericin B-Sodium cholesteryl sulfate complex, anfotericina B, or liposomal amphotericin B; many trade names are available.

## Storage/Stability

Vials of amphotericin B powder for injection should be stored in the refrigerator (2–8°C), protected from light and moisture. Reconstitution of the powder must be done with sterile water for injection (no preservatives—see directions for preparation in the Dosage Form section below).

After reconstitution, if protected from light, the solution is stable for 24 hours at room temperature and for 1 week if kept refrigerated. After diluting with D5W (must have pH >4.3) for IV use, the manufacturer recommends continuing to protect the solution from light during administration. Additional studies however, have shown that potency remains largely unaffected if the solution is exposed to light for 8–24 hours.

One reference (Orosz 2000) states that for avian use, the conventional amphotericin B (amphotericin B deoxycholate) can be diluted with sterile water, divided into 10 ml aliquots using aseptic technique, and stored at -20°C for approximately 1 month. However, no published data was located documenting the stability of the drug for this practice.

## Compatibility/Compounding Considerations

Amphotericin B deoxycholate is reportedly **compatible** with the following solutions and drugs: D5W, D5W in sodium chloride 0.2%, heparin sodium, heparin sodium with hydrocortisone sodium phosphate, hydrocortisone sodium phosphate/succinate and sodium bicarbonate.

Amphotericin B deoxycholate is reportedly **incompatible** with the following solutions and drugs: **normal saline, lactated Ringer's**, D5-normal saline, D5-lactated Ringer's, amino acids 4.25%–dextrose 25%, amikacin, calcium chloride/gluconate, carbenicillin disodium, chlorpromazine HCl, cimetidine HCl, diphenhydramine HCl, dopamine HCl, edetate calcium disodium (Ca EDTA), gentamicin sulfate, kanamycin sulfate, lidocaine HCl, metaraminol bitartrate, methyldopate HCl, nitrofurantoin sodium, oxytetracycline HCl, penicillin G potassium/sodium, polymyxin B sulfate, potassium chloride, prochlorperazine mesylate, streptomycin sulfate, tetracycline HCl, and verapamil HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Amphotericin B Desoxycholate Powder for Injection: 50 mg in vials; generic (Pharma-Tek); (Rx)

Directions for reconstitution/administration: Using strict aseptic technique and a 20 gauge or larger needle, rapidly inject 10 mL of sterile water for injection (without a bacteriostatic agent) directly into the lyophilized cake; immediately shake well until solution is clear. A 5 mg/mL colloidal solution results. Further dilute (1:50) for administration to a concentration of 0.1 mg/mL with 5% dextrose in water (pH >4.2). An in-line filter may be used during administration, but must have a pore diameter >1 micron.

Amphotericin B Lipid-Based Suspension for Injection: 100 mg/20 mL (as lipid complex) in 10 mL & 20 mL vials with 5 micron filter needles: *Abelcet*® (Enzon); (Rx)

Amphotericin B Lipid-Based Powder for Injection: 50 mg (as cholesteryl) in 20 mL single-use vials; 100 mg (as cholesteryl) in 50 mL single-use vials; *Amphotec*® (Sequus Pharmaceuticals); 50 mg (as liposomal) in single-dose vials with 5-micron filter; *Ambisome*® (Astellas); (Rx)

Amphotericin B is also available in topical formulations: *Fungizone*® (Apothecon); (Rx)

---

**AMPICILLIN**  
**AMPICILLIN SODIUM**  
**AMPICILLIN TRIHYDRATE**

(am-pi-sill-in; sul-bak-tam) Polyflex®

**AMINOPENICILLIN**

**Prescriber Highlights**

- **Bactericidal aminopenicillin with same spectrum as amoxicillin (ineffective against bacteria that produce beta-lactamase)**
  - **Most likely adverse effects are GI-related, but hypersensitivity & other adverse effects rarely occur; may cause more GI effects than amoxicillin when used orally**
  - **More susceptible than amoxicillin to food reducing oral absorption**
  - **Available in both parenteral & oral forms**
- 

**Uses/Indications**

In dogs and cats, ampicillin is not as well absorbed after oral administration as amoxicillin and its oral use has largely been supplanted by amoxicillin. It is used commonly in parenteral dosage forms when an aminopenicillin is indicated in all species. Ampicillin at high dosages, is still an effective drug for treating penicillin-sensitive enterococci, particularly *E. faecium*. An aminoglycoside (e.g., gentamicin) is often added to treat serious enterococcus infections caused by penicillin-sensitive organisms.

The aminopenicillins, also called the “broad-spectrum” or ampicillin penicillins, have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *E. coli*, Klebsiella, and Haemophilus.

**Pharmacology/Actions**

Like other penicillins, ampicillin is a time-dependent, bactericidal (usually) agent that acts via inhibiting cell wall synthesis. Ampicillin and the other aminopenicillins have increased activity against many strains of gram-negative aerobes not covered by either the natural penicillins or penicillinase-resistant penicillins, including some strains of *E. coli*, Klebsiella and Haemophilus. Like the natural penicillins, they are susceptible to inactivation by beta-lactamase-producing bacteria (e.g., Staph aureus). Although not as active as the natural penicillins, they do have activity against many anaerobic bacteria, including Clostridial organisms. Organisms that are generally not susceptible include *Pseudomonas aeruginosa*, Serratia, Indole-positive Proteus (*Proteus mirabilis* is susceptible), Enterobacter, Citrobacter, and Acinetobacter. The aminopenicillins also are inactive against Rickettsia, mycobacteria, fungi, Mycoplasma, and viruses.

In order to reduce the inactivation of penicillins by beta-lactamases, potassium clavulanate and sulbactam have been developed to inactivate these enzymes and extend the spectrum of those penicillins. See the ampicillin/sulbactam or amoxicillin/clavulanate monographs for more information.

**Pharmacokinetics**

Ampicillin anhydrous and trihydrate are relatively stable in the presence of gastric acid. After oral administration, ampicillin is about 30–55% absorbed in humans (empty stomach) and monogastric animals. Food will decrease the rate and extent of oral absorption.

When administered parenterally (IM, SC) the trihydrate salt will achieve serum levels of approximately 1/2 those of a comparable dose of the sodium salt. The trihydrate parenteral dosage form should not be used where higher MIC’s are required for treating systemic infections.

After absorption, the volume of distribution for ampicillin is approximately 0.3 L/kg in humans and dogs, 0.167 L/kg in cats, and 0.16–0.5 L/kg in cattle. The drug is widely distributed to many tissues, including liver, lungs, prostate (human), muscle, bile, and ascitic, pleural and synovial fluids. Ampicillin will cross into the CSF when meninges are inflamed in concentrations that may range from 10–60% those found in serum. Very low levels of the drug are found in the aqueous humor; low levels are found in tears, sweat and saliva. Ampicillin crosses the placenta, but is thought to be relatively safe to use during pregnancy. Ampicillin is approximately 20% bound to plasma proteins, primarily albumin. Milk levels of ampicillin are considered low. In lactating dairy cattle, the milk to plasma ratio is about 0.3.

Ampicillin is eliminated primarily through renal mechanisms, principally by tubular secretion, but some of the drug is metabolized by hydrolysis to penicilloic acids (inactive) and then excreted in the urine. Elimination half-lives of ampicillin have been reported as 45–80 minutes in dogs and cats, and 60 minutes in swine.

**Contraindications/Precautions/Warnings**

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases.

Do not administer penicillins, cephalosporins, or macrolides to rabbits, guinea pigs, chinchillas, hamsters, etc., or serious enteritis and clostridial enterotoxemia may occur.

**Adverse Effects**

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that up to 15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

**Reproductive/Nursing Safety**

## Leptoreproductive/Nursing Safety

Penicillins have been shown to cross the placenta; safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes ampicillin as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

## Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects). In humans, very high dosages of parenteral penicillins, particularly in patients with renal disease, have induced CNS effects.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ampicillin and may be of significance in veterinary patients:

- **BACTERIOSTATIC ANTIMICROBIALS** (e.g., chloramphenicol, erythromycin and other macrolides, tetracyclines, sulfonamides, etc.): Because there is evidence of *in vitro* antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has not been generally recommended in the past, but actual clinical importance is not clear and currently in doubt.
- **METHOTREXATE**: Ampicillin may decrease the renal excretion of MTX causing increased levels and potential toxic effects
- **PROBENECID**: Competitively blocks the tubular secretion of most penicillins thereby increasing serum levels and serum half-lives

## Laboratory Considerations

- Ampicillin may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by ampicillin.
- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of aminoglycosides may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

## Doses

### ■ DOGS:

For susceptible infections:

- For Gram-positive infections: 10–20 mg/kg PO twice daily; 5 mg/kg IM, SC twice daily; 5 mg/kg IV three times daily.  
For Gram-negative infections: 20–30 mg/kg PO three times daily; 10 mg/kg IM, SC three times daily; 10 mg/kg IV four times daily (Aucoin 2000)
- For susceptible UTI's: 12.5 mg/kg PO q12h for 3–7 days, 6.6 mg/kg IM or SC q12h for 3–7 days;  
For susceptible soft tissue infections: 10–20 mg/kg PO, IM or SC q8h for 7 days;  
For pneumonia, systemic: 22 mg/kg PO, IV or SC q8h for 7–14 days;  
For meningitis, orthopedic infections: 22 mg/kg PO, IV, IM, SC q6–8h as long as necessary;  
For susceptible sepsis, bacteremia: 20–40 mg/kg IV, IM or SC q6–8h for as long as necessary;  
For neonatal sepsis: 50 mg/kg IV or intraosseous q4–6h as long as necessary;  
For susceptible orthopedic infections or meningitis: 22 mg/kg IV, IM, SC, or PO q6–8h for as long as necessary (Greene *et al.* 2006)
- For sepsis: 20–40 mg/kg IV q6–8h (Hardie 2000)
- For susceptible UTI's: 25 mg/kg PO q8h (Polzin 2005)
- To eliminate the leptospiremic phase of leptospirosis: 22 mg/kg q6–8h IV during the acute illness until patient is eating, then amoxicillin 22 mg/kg PO q8h (Lunn 2006)

### ■ CATS:

For susceptible infections:

- For Gram-positive infections: 10–20 mg/kg PO twice daily; 5 mg/kg IM, SC twice daily; 5 mg/kg IV three times daily;  
For Gram-negative infections: 20–30 mg/kg PO three times daily; 10 mg/kg IM, SC three times daily; 10 mg/kg IV four times daily (Aucoin 2000)
- For susceptible UTI's: 20 mg/kg PO q8–12h for 7–14 days;  
For soft tissue infections 20–40 mg/kg PO q8–12h for 14 days;  
For systemic infections: 7–11 mg/kg IV, IM or SC q8–12h for as long as necessary; (Greene *et al.* 2006)
- For sepsis: 20–40 mg/kg IV q6–8h (Hardie 2000)

### ■ CATTLE:

For susceptible infections:

- For respiratory infections: Ampicillin trihydrate (*Polyflex*®): 22 mg/kg SC q12h (60 day slaughter withdrawal suggested) (Hjerpe 1986)
- For respiratory infections: Ampicillin sodium 22 mg/kg SC q12h; Ampicillin trihydrate: 11 mg/kg IM q24h (Beech 1987b)

### ■ HORSES:

For susceptible infections:

- Ampicillin sodium: 10–50 mg/kg IV or IM three times daily  
Ampicillin trihydrate: 5–20 mg/kg IM twice daily (Robinson 1987)

Ampicillin sodium: 11–15 mg/kg IM or IV three to four times daily (Beech 198/a)

b) **Foals:** Ampicillin sodium 11 mg/kg q6h IM or IV (Furr 1999)

c) **Foals:** Ampicillin sodium 15–30 mg/kg IV or IM q 6–8h (Brumbaugh 1999)

d) For intrauterine infusion: 1–3 grams. Little science is available for recommending doses, volume infused, frequency diluents, etc. Most treatments are commonly performed every day or every other day for 3–7 days.) (Perkins 1999)

#### ■ **FERRETS:**

For susceptible infections: 5–10 mg/kg IM, SC or IV twice daily (Williams 2000)

#### ■ **RABBITS/RODENTS/SMALL MAMMALS:**

a) **Rabbits:** Not recommended as it can cause a fatal enteritis (Ivey & Morrisey 2000)

b) **Gerbils, Mice, Rats:** 20–100 mg/kg PO, SC, IM q8–12h

c) **Guinea pigs, Chinchillas, Hamsters:** Do NOT use as it may cause enterocolitis (Adamcak & Otten 2000)

d) **Hedgehogs:** 10 mg/kg IM or PO once daily (Smith 2000)

#### ■ **SWINE:**

For susceptible infections:

a) Ampicillin sodium: 6–8 mg/kg SC or IM q8h (Baggot 1983)

#### ■ **BIRDS:**

For susceptible infections:

a) Amazon parrots: 150–200 mg/kg PO twice daily–three times daily (poorly absorbed PO); 100 mg/kg IM (as the trihydrate/*Polyflex*®) q4h.

**Pet birds:** 250 mg capsule in 8 oz. of drinking water (poorly absorbed; rapidly excreted)

**Chickens:** 1.65 g/L drinking water (see above)

**Most birds:** 250 mg/kg via feed for 5–10 days. Sprinkle on favorite food, or add to mash or corn mix. (Clubb 1986)

b) 100 mg/kg IM or IM q8h (Hoeffler 1995)

c) **Ratites:** 11–15 mg/kg PO or IV 3 times daily; 15–20 mg/kg IM twice daily (Jenson 1998)

#### ■ **REPTILES:**

For susceptible infections:

a) All species: 3–6 mg/kg PO, SC or IM every 12–24 hours for 2 weeks; not very useful unless used in combination with aminoglycosides (Gauvin 1993)

b) For Chelonians (turtles et al): 50 mg/kg IM q12h (Jacobson 2000)

### Monitoring

■ Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs or symptoms develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

### Client Information

■ Unless otherwise instructed by the veterinarian, this drug should be given orally on an empty stomach, at least 1 hour before feeding or 2 hours after.

■ Keep oral suspension in the refrigerator and discard any unused suspension after 14 days. If stored at room temperature, discard unused suspension after 7 days.

### Chemistry/Synonyms

A semi-synthetic aminopenicillin, ampicillin anhydrous and trihydrate occur as practically odorless, white, crystalline powders that are slightly soluble in water. At usual temperatures (<42°C), ampicillin anhydrous is more soluble in water than the trihydrate (13 mg/mL vs. 6 mg/mL at 20°C). Ampicillin anhydrous or trihydrate oral suspensions have a pH of 5–7.5 after reconstitution with water.

Ampicillin sodium occurs as an odorless or practically odorless, white to off-white, crystalline hygroscopic powder. It is very soluble in water or other aqueous solutions. After reconstitution, ampicillin sodium has a pH of 8–10 at a concentration of 10 mg/mL. Commercially available ampicillin sodium for injection has approximately 3 mEq of sodium per gram of ampicillin.

Potency of the ampicillin salts is expressed in terms of ampicillin anhydrous.

Ampicillin may also be known as: aminobenzylpenicillin, ampicillinum, ampicillinum anhydricum, anhydrous ampicillin, AY-6108, BRL-1341, NSC-528986, or P-50; many trade names are available.

### Storage/Stability

Ampicillin anhydrous or trihydrate capsules and powder for oral suspension should be stored at room temperature (15–30°C). After reconstitution, the oral suspension is stable for 14 days if refrigerated (2–8°C); 7 days when kept at room temperature.

Ampicillin trihydrate for injection (*Polyflex*®) was labeled as stable for 12 months when refrigerated (2–8°C and 3 months when kept at room temperature. Its new labeling states that it is stable for 3 months when refrigerated. It is not clear if this change is a result of more recent scientific stability studies.

Ampicillin sodium for injection is relatively unstable after reconstitution and should generally be used within 1 hour of reconstitution. As the concentration of the drug in solution increases, the stability of the drug decreases. Dextrose may also speed the destruction of the drug by acting as a catalyst in the hydrolysis of ampicillin.

While most sources recommend using solutions of ampicillin sodium immediately, studies have demonstrated that at concentrations of 30 mg/mL, ampicillin sodium solutions are stable up to 48 hours at 4°C in sterile water for injection or 0.9% sodium chloride (72 hours if concentrations are 20 mg/mL or less). Solutions with a concentration of 30 mg/mL or less have been shown to be stable up to 24 hours in solutions of lactated Ringer's solution if kept at 4°C. Solutions of 20 mg/mL or less are reportedly stable up to 4 hours in D5W if refrigerated.

### Compatibility/Compounding Considerations

Ampicillin sodium is reportedly **compatible** with the following additives (see the above paragraph for more information): heparin sodium, chloramphenicol sodium

succinate, procaine HCl and verapamil HCl.

Ampicillin sodium is reportedly **incompatible** with the following additives: amikacin sulfate, chlorpromazine HCl, dopamine HCl, erythromycin lactobionate, gentamicin HCl, hydralazine HCl, hydrocortisone sodium succinate, kanamycin sulfate, lincomycin HCl, oxytetracycline HCl, polymyxin B sulfate, prochlorperazine edisylate, sodium bicarbonate and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Ampicillin Trihydrate Injection Powder for Suspension: 10 g and 25 g (of ampicillin) vials; *Polyflex*® (Fort Dodge); (Rx). FDA-approved for use in dogs, cats, and cattle. Withdrawal times at labeled doses (cattle; do not treat for more than 7 days): Milk = 48 hours; Slaughter = 6 days (144 hours).

### HUMAN-LABELED PRODUCTS:

Ampicillin Sodium Powder for Injection: 250 mg & 500 mg, 1 g & 2 g in vials; generic; (Rx)

Ampicillin Oral Capsules (as trihydrate): 250 mg & 500 mg; *Principen*® (Geneva); generic; (Rx)

Ampicillin (as trihydrate) Powder for Oral Suspension: 125 mg/5 mL (as trihydrate) when reconstituted in 100 mL, 150 mL & 200 mL; 250 mg/5 mL (as trihydrate) when reconstituted in 100 mL & 200 mL; *Principen*® (Geneva); (Rx)

## AMPICILLIN SODIUM + SULBACTAM SODIUM

(am-pi-sill-in; sul-bak-tam) Unasyn®

### INJECTABLE POTENTIATED AMINOPENICILLIN

#### Prescriber Highlights

- Parenteral potentiated aminopenicillin that may be used for infections where amoxicillin/clavulanate would be appropriate but when an injectable antibiotic is required
- Hypersensitivity reactions possible; contraindicated in patients with documented severe hypersensitivity to penicillins
- Usually dosed IM or IV q6–8h

---

## Uses/Indications

Ampicillin sodium/sulbactam sodium in a 2:1 ratio is effective when used parenterally for several types of infections caused by many beta-lactamase-producing bacterial strains of otherwise resistant *E. coli*, *Pasturella* spp., *Staphylococcus* spp., *Klebsiella*, and *Proteus*. Other aerobic bacteria commonly susceptible to this combination include *Streptococcus*, *Listeria monocytogenes*, *Bacillus anthracis*, *Salmonella*, *Pasturella*, and *Acinetobacter*. Anaerobic bacterial infections caused by *Clostridium*, *Bacteroides*, *Fusobacterium*, *Peptostreptococcus* or *Propionibacterium* may be effectively treated with ampicillin/ sulbactam.

Type I beta-lactamases that may be associated with *Citrobacter*, *Enterobacter*, *Serratia* and *Pseudomonas* are not generally inhibited by sulbactam or clavulanic acid. Ampicillin/sulbactam is ineffective against practically all strains of *Pseudomonas aeruginosa*.

In dogs and cats, ampicillin/sulbactam therapy may be considered when oral amoxicillin/clavulanate treatment is not viable (patient NPO, critically ill) or when large parenteral doses would be desirable (sepsis, pneumonia, other severe infections) for treating susceptible bacterial infections or prophylaxis.

Ampicillin/sulbactam has been used successfully to treat experimentally induced *Klebsiella* pneumonia in foals.

## Pharmacology/Actions

When sulbactam is combined with ampicillin it extends its spectrum of activity to those bacteria that produce beta-lactamases of Richmond-Sykes types II-VI that would otherwise render ampicillin ineffective. Sulbactam binds to beta-lactamases thereby “protecting” the beta-lactam ring of ampicillin from hydrolysis.

Sulbactam has some intrinsic antibacterial activity against some bacteria (*Neisseria*, *Moraxella*, *Bacteroides*) at achievable levels. Sulbactam binding to certain penicillin-binding proteins (PBPs) may explain its activity. For most bacteria, sulbactam alone does not achieve levels sufficient to act alone as an antibacterial but when used in combination with ampicillin, synergistic effects may result.

On a mg for mg basis, clavulanic acid is a more potent beta-lactamase inhibitor than is sulbactam, but sulbactam has advantages of reduced likelihood of inducing chromosomal beta-lactamases, greater tissue penetration and greater stability.

For further information on the pharmacology of ampicillin, refer to that monograph.

## Pharmacokinetics

As sulbactam sodium is not appreciably absorbed from the GI tract, this medication must be given parenterally. A covalently linked double ester form of ampicillin/sulbactam (sultamicillin) is orally absorbed, but this combination is not commercially available in the USA. When administered parenterally (IV/IM), sulbactam's pharmacokinetic profile closely mirrors that of ampicillin in most species studied. During the elimination phase in calves, plasma concentrations of sulbactam were consistently higher than those of ampicillin, leading the authors of the study to propose using a higher ratio (than 2:1 ampicillin/sulbactam) if the combination is used in calves.

## Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of severe hypersensitivity (*e.g.*, anaphylaxis) to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, cephalosporins, cefamandole, carbapenems).

Patients with severe renal dysfunction may require increased periods of time between doses.

## Adverse Effects

Intramuscular injections may be painful. Intravenous injections may cause thrombophlebitis. Hypersensitivity reactions to penicillins occur infrequently in animals, but can be severe (anaphylaxis), particularly after IV administration.

High doses or very prolonged use of penicillins have been associated with neurotoxicity (*e.g.*, ataxia in dogs). Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema and tachycardia.

## Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes ampicillin as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), ampicillin is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

It is unknown if sulbactam crosses the placenta and safe use during pregnancy has not been established.

Both ampicillin and sulbactam are distributed into human breast milk in low concentrations. For humans, the World Health Organization (WHO) rates ampicillin as being **compatible** with breastfeeding and the American Academy of Pediatrics lists sulbactam as **compatible** with breastfeeding.

## Overdosage/Acute Toxicity

Neurological effects (ataxia) have rarely been reported in dogs receiving very high dosages of penicillins; should these develop, weigh the risks of continued use versus those of dosage reduction or using a different antibiotic. In humans, very high dosages of parenteral penicillins, especially in those with renal disease, have induced CNS effects.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ampicillin/sulbactam and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES (amikacin, gentamicin, tobramycin):** *In vitro* studies have demonstrated that penicillins can have synergistic or additive activity against certain bacteria when used with aminoglycosides. However, beta-lactam antibiotics can inactivate aminoglycosides *in vitro* and *in vivo* in patients in renal failure or when penicillins are used in massive dosages. Amikacin is considered the most resistant aminoglycoside to this inactivation.
- **BACTERIOSTATIC ANTIMICROBIALS (e.g., chloramphenicol, erythromycin and other macrolides, tetracyclines, sulfonamides, etc.):** Because there is evidence of *in vitro* antagonism between beta-lactam antibiotics and bacteriostatic antibiotics, use together has been generally not recommended in the past, but actual clinical importance is not clear and in doubt.
- **PROBENECID:** Can reduce the renal tubular secretion of both ampicillin and sulbactam, thereby maintaining higher systemic levels for a longer period of time. This potential "beneficial" interaction requires further investigation before dosing recommendations can be made for veterinary patients.

## Laboratory Considerations

- Ampicillin may cause false-positive **urine glucose** determinations when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Test-Tape*®, *Clinistix*®) are not affected by ampicillin.
- As penicillins and other beta-lactams can inactivate **aminoglycosides** *in vitro* (and *in vivo* in patients in renal failure or when penicillins are used in massive dosages), serum concentrations of aminoglycosides may be falsely decreased particularly when the serum is stored prior to analysis. It is recommended that if the aminoglycoside assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

## Doses

### ■ DOGS:

For susceptible infections:

- a) For respiratory infections: 50 mg/kg (combined) IV q8h (Hawkins 2003)
- b) For respiratory infections: 20 mg/kg IV or IM q6–8h (Greene & Reinero 2006)
- c) As adjunctive treatment of serious bite wounds: 30–50 mg/kg q8h IV (Bateman 2005)
- d) For intra-abdominal infections: 20 mg/kg IV or IM q6–8h (Extrapolation of human dose with limited studies in dogs and cats) (Greene 2006)

### ■ CATS:

For susceptible infections:

- a) For respiratory infections using ampicillin/sulbactam (*Unasyn*®): 50 mg/kg (combined) IV q8h (Hawkins 2003)
- b) As adjunctive treatment of serious bite wounds: 30–50 mg/kg q8h IV (Bateman 2005)

b) AS adjunctive treatment of serious bite wounds: 30–50 mg/kg q8h IV (Bateman 2005)

c) For intra-abdominal infections: 20 mg/kg IV or IM q6–8h (Extrapolation of human dose with limited studies in dogs and cats) (Greene 2006)

## Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs or symptoms develop
- Serum levels and therapeutic drug monitoring are not routinely performed with these agents

## Client Information

- Because of the dosing intervals required this drug is best administered to inpatients only

## Chemistry/Synonyms

Ampicillin sodium and sulbactam sodium for injection occurs as a white to off-white powder that is freely soluble in water or other aqueous solutions.

Ampicillin/Sulbactam may also be known as: *Ampibactan*®, *Bacimex*®, *Begalin-P*®, *Bethacil*®, *Comabactan*®, *Galotam*®, *Loricin*®, *Sulam*®, *Sulperazon*®, *Synergistin*®, *Unacid*®, *Unacim*®, *Unasyn*® or *Unasyna*®.

## Storage/Stability

The unconstituted powder should be stored at temperatures at, or below, 30°C.

## Compatibility/Compounding Considerations

Diluents for reconstituting the powder for injection for IV use that are reported **compatible** with ampicillin/sulbactam include sterile water for injection, and 0.9% sodium chloride. If reconstituted to a concentration of 45 mg/mL (30/15), the resulting solution is stable for 8 hours at room temperature and for 48 hours at 4°C. If reconstituted to a concentration of 30 mg/mL (20/10), the resulting solution is stable for 72 hours at 4°C. After reconstitution and before administering, the solution should be further diluted into a 50 or 100 mL bag of 0.9% sodium chloride and administered IV over 15–30 minutes. Diluted solutions for IV administration are stable at room temperature for 8 hours.

When reconstituting for IM use, sterile water for injection or 0.5% or 2% lidocaine HCl injection may be used. 3.2 mL of diluent is added to the 1.5 g vial; 6.4 mL of diluent to the 3 g vial. After reconstituting, the solution should be administered within 1 hour.

Ampicillin/sulbactam injection is **not compatible** with aminoglycoside antibiotics (*e.g.*, gentamicin, amikacin) and should not be mixed with these agents.

Ampicillin/sulbactam is **compatible** with vancomycin when mixed at concentrations of 50/25 mg/mL of ampicillin/sulbactam and 20 mg/mL or less of vancomycin.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Ampicillin Sodium/Sulbactam Sodium Powder (injection): 1.5 g (1 g ampicillin sodium/0.5 g sulbactam sodium), 3 g (2 g ampicillin sodium/1 g sulbactam sodium) in vials, piggyback bottles and ADD-Vantage vials, and 15 g (10 g ampicillin sodium/5 g sulbactam sodium) in bulk; *Unasyn*® (Roerig); generic; (Rx)

## AMPROLIUM HYDROCHLORIDE

(*am-proc-lee-um*) Amprovine®, Corid®

ANTICOCCIDIAL

### Prescriber Highlights

- **Thiamine analog antiprotozoal (coccidia)**
  - **Prolonged high dosages may cause thiamine deficiency; treatment is usually no longer than 14 days**
  - **Occasionally may cause GI or neurologic effects**
  - **May be unpalatable**
- 

## Uses/Indications

Amprolium has good activity against *Eimeria tenella* and *E. acervulina* in poultry and can be used as a therapeutic agent for these organisms. It only has marginal activity or weak activity against *E. maxima*, *E. mivati*, *E. necatrix*, or *E. brunetti*. It is often used in combination with other agents (*e.g.*, ethopabate) to improve control against those organisms.

In cattle, amprolium has FDA-approval for the treatment and prevention of *E. bovis* and *E. zurnii* in cattle and calves.

Amprolium has been used in dogs, swine, sheep, and goats for the control of coccidiosis, although there are no FDA-approved products in the USA for these species.

## Pharmacology/Actions

By mimicking its structure, amprolium competitively inhibits thiamine utilization by the parasite. Prolonged high dosages can cause thiamine deficiency in the host.

by mimicking its structure; amprolium competitively inhibits thiamine utilization by the parasite. Prolonged high dosages can cause thiamine deficiency in the host, excessive thiamine in the diet can reduce or reverse the anticoccidial activity of the drug.

Amprolium is thought to act primarily upon the first generation schizont in the cells of the intestinal wall, preventing differentiation of the merozoites. It may suppress the sexual stages and sporulation of the oocysts.

### Pharmacokinetics

No information was located for this agent.

### Contraindications/Precautions/Warnings

Not recommended to be used for more than 12 days in puppies.

### Adverse Effects

In dogs, neurologic disturbances, depression, anorexia, and diarrhea have been reported but are rare and are probably dose-related. See Overdosage section below for treatment recommendations. The undiluted liquid or pastes are reportedly unpalatable.

### Overdosage/Acute Toxicity

Amprolium has induced polioencephalomalacia (PEM) in sheep when administered at 880 mg/kg PO for 4–6 weeks and at 1 gram/kg for 3–5 weeks. Erythrocyte production also ceased in lambs receiving these high dosages.

It is reported that overdoses of amprolium will produce neurologic clinical signs in dogs. Treatment should consist of stopping amprolium therapy and administering parenteral thiamine (1–10 mg/day IM or IV).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving amprolium and may be of significance in veterinary patients:

■**THIAMINE:** Exogenously administered thiamine in high doses may reverse or reduce the efficacy of amprolium

### Doses

#### ■**DOGS:**

For coccidiosis:

a) Small Pups (< 10 kg adult weight): 100 mg (total dose) (using the 20% powder) in a gelatin capsule PO once daily for 7–12 days. Large pups (>10 kg adult weight): 200 mg (total dose) (using the 20% powder) in a gelatin capsule PO once daily for 7–12 days. *In food*, for pups or bitches: 250–300 mg total dose using the 20% powder on food once daily for 7–12 days. *In water*, for pups or bitches: 30 mL of the 9.6% solution in one gallon of water (no other water provided) for 7–10 days (Greene *et al.* 2006)

b) Prophylaxis: 0.075% solution as drinking water (Matz 1995)

c) 150 mg/kg of amprolium and 25 mg/kg of sulfadimethoxine for 14 days (Blagburn 2003)

d) For control of coccidiosis: 1.5 tablespoonsful (22.5 mL) of the 9.6% solution per one gallon of water to be used as the sole drinking water source, not to exceed 10 days. Monitor water consumption both for treatment and hydration assurance; rarely some dogs may not drink the amprolium water due to its bitter taste. In situations where dogs are co-habitants, it is necessary to place enough water for all to have access. (Blagburn 2005), (Blagburn 2007)

#### ■**CATS:**

For coccidiosis:

a) For *Cystoisospora* spp.: 60–100 mg total dose PO once daily for 7 days (Lappin 2000)

b) *On food*: 300–400 mg/kg on food once daily for 5 days or 110–220 mg/kg on food once daily for 7–12 days. *In water*: 1.5 teaspoonsful (7.5 mL) of the 9.6% solution in one gallon of water per day for 10 days.

In combination: amprolium at 150 mg/kg PO once daily with sulfadimethoxine (25 mg/kg PO once daily) for 14 days (Greene *et al.* 2006)

#### ■**FERRETS:**

For coccidiosis:

a) 19 mg/kg PO once daily (Lennox 2006)

#### ■**RABBITS/RODENTS/SMALL MAMMALS:**

a) Rabbits for coccidiosis: Using 9.6% solution: 1 mL/7 kg BW PO once daily for 5 days; in drinking water: 0.5 mL/500 mL for 10 days (Ivey & Morrisey 2000)

b) Gerbils, Mice, Rats, Hamsters: 10–20 mg/kg total daily dose divided q8–24h SC or IM. Chinchillas: 10–15 mg/kg per day divided q8–24h SC, IM or IV (Adamcak & Otten 2000)

#### ■**CATTLE:**

For coccidiosis:

a) Treatment: 10 mg/kg PO for 5 days; 5 mg/kg for 21 days for prophylaxis (Todd *et al.* 1986)

#### ■**SWINE:**

For coccidiosis:

a) Treatment: 25–65 mg/kg PO once or twice daily for 3–4 days (Todd *et al.* 1986)

b) 100 mg/kg/day in food or water (Howard 1986)

#### ■**SHEEP & GOATS:**

For coccidiosis:

a) Lambs: 55 mg/kg daily PO for 19 days (Todd *et al.* 1986)

#### ■**CAMELIDS (NEW WORLD):**

For *Eimeria macusaniensis* (E. mac):

For *Eimeria maculatumensis* (E.mac).

a) 10 mg/kg PO once daily for 5 days (Wolff 2009)

b) 10 mg/kg PO as a 1.5% solution PO once daily. Treat for 10-15 days and give thiamine at 10 mg/kg SC once daily every 5 days during treatment. (Cebra *et al.* 2007)

#### ■ BIRDS:

a) For coccidiosis in pet birds: 2 mL (using the 9.6% solution)/gallon of water for 5 days or longer. Cages should be steam cleaned to prevent reinfection. Supplement diet with B vitamins. Some strains resistant in Toucans and Mynahs. (Clubb 1986)

b) For chickens (broilers or layers), turkeys, and pheasants: Refer to individual product instructions.

#### Monitoring

■ Clinical efficacy

#### Chemistry/Synonyms

A structural analogue of thiamine (vitamin B1), amprolium hydrochloride occurs as a white or almost white, odorless or nearly odorless powder. One gram is soluble in 2 mL of water and is slightly soluble in alcohol.

Amprolium may also be known as amprocidi, *Amprol*®, *Corid*®, *Coxoid*®, *Coxiprol*® or *Nemapro*®.

#### Storage/Stability

Unless otherwise instructed by the manufacturer, amprolium products should be stored at room temperature (15–30°C).

#### Dosage Forms/Regulatory Status/Withdrawal Times

##### VETERINARY-LABELED PRODUCTS:

Amprolium 9.6% (96 mg/mL) Oral Solution in 1 gal jugs; *Amprovine*® or *Corid*® 9.6% Oral Solution (Huvepharma); (OTC). FDA-approved for use in calves (not veal calves). Slaughter withdrawal (when used as labeled) = 24 hours; a withdrawal period has not been established for pre-ruminating calves.

Amprolium 20% Soluble Powder; *Corid*® 20% Soluble Powder (Huvepharma); (OTC). FDA-approved for use in calves (not veal calves). Slaughter withdrawal (when used as labeled) = 24 hours. A withdrawal period has not been established for pre-ruminating calves.

There are also available medicated feeds (amprolium alone) and combination products (medicated feeds, feed additives) containing amprolium with other therapeutic agents. These products may be labeled for use in calves, chickens and/or turkeys.

**HUMAN-LABELED PRODUCTS:** None

#### ANTIVENIN (CROTALIDAE) POLYVALENT (EQUINE ORIGIN)

#### ANTIVENIN (CROTALIDAE) POLYVALENT IMMUNE FAB (OVINE ORIGIN)

(an-tie-ven-nin) Pit Viper Antivenin; CroFab®

#### ANTIDOTE

**Note:** The location of antivenins for rare species and the telephone numbers for envenomation experts are available from the Arizona Poison and Drug Information Center (800-222-1222). The National Animal Poison Control Center (888-426-4435) is another source for up-to-date snakebite treatment recommendations.

#### Prescriber Highlights

- May cause hypersensitivity reactions
  - Treatment can be very expensive
- 

#### Uses/Indications

The equine-derived product is indicated for the treatment of envenomation from most venomous snake bites (pit vipers) in North America and those caused by several species found in Central and South America (fer-de-lance, Central and South American Rattlesnake). The ovine-derived product is indicated for North American Crotalid snake envenomation in humans, but has been used in dogs. There is a fair amount of controversy with regard to use of these products in domestic animals. The risks of administration (*e.g.*, anaphylaxis—see below) may outweigh their potential benefits in certain circumstances. However, these agents can be life saving

when given early in select situations. Many factors contribute to the potential for toxicity (victim's size and general health, bite site(s), number of bites, age, species and size of snake, etc.).

### Pharmacology/Actions

Antivenins act by neutralizing the venoms (complex proteins) in patients via passive immunization of globulins obtained from horses immunized with the venom. Antivenin is very effective in reversing venom-related coagulation abnormalities, but Timber Rattlesnake venom-induced thrombocytopenia may be resistant to treatment.

### Contraindications/Precautions/Warnings

Because there is a risk of anaphylaxis occurring secondary to equine-origin proteins, some recommend performing sensitivity testing before administration, but evaluation of results may be difficult and a test-dose is not provided with the veterinary-labeled product. Up to 50% of the veterinary-labeled product contains equine albumin and other equine proteins.

### Adverse Effects

The most significant adverse effect associated with the use of the equine origin product is anaphylaxis secondary to its equine serum source; an incidence rate of less than 2% has been reported. A 1:10 dilution of the antivenin given intracutaneously at a dose of 0.02–0.03 mL has been suggested as a test for hypersensitivity. Wheal formation and erythema indicate a positive reaction and are generally seen within 30 minutes of administration. However, a negative response does not insure that anaphylaxis will be avoided and slow intravenous administration is usually sufficient to identify animals that will react to the product. A pre-treatment dose of diphenhydramine is often recommended before administering antivenin primarily to sedate the patient and, theoretically, reduce any possible allergic reactions to the antivenin. Should an anaphylactoid reaction be detected (nausea, pruritus, hyperemia of the inner pinna), stopping the infusion, giving an additional dose of diphenhydramine and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.

One case of a dog developing antivenin-associated serum sickness has been reported after treatment using Crotilidae antivenin (Berdoulay *et al.* 2005).

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

Safety during nursing has not been established but it would unlikely pose much risk.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving antivenin and may be of significance in veterinary patients:

- **ANALGESICS/SEDATIVES:** Although reducing excessive movement and other supportive therapy are important parts of treating envenomation, drugs that can mask the clinical signs associated with the venom (*e.g.*, analgesics and sedatives) should initially be used with caution.
- **ANTIHISTAMINES:** It has been stated that antihistamines may potentiate the venom; however, documentation of this interaction was not located and diphenhydramine is routinely used by many clinicians treating snakebite in dogs.
- **BETA-BLOCKERS:** May mask the early signs associated with anaphylaxis
- **CORTICOSTEROID** use has fallen out of favor in the treatment of snakebite envenomation and is usually not employed, but controversy remains regarding their use. Corticosteroids may be useful to treat anaphylaxis, however.
- **HEPARIN:** Is reportedly not effective in treating the thrombin-like enzymes found in rattlesnake venom.

### Doses

**Note:** The treatment of pit viper snakebite involves significant treatment (aggressive IV fluids, antibiotics) and monitoring beyond administration of antivenin. It is highly recommended to refer to specialized references *e.g.*, (Peterson 2006) or to contact an animal poison control center for guidance beyond what is listed below.

#### ■ DOGS/CATS:

Crotilidae antivenin (equine origin):

a) Dogs/Cats: Dose necessary is calculated relative to the amount of venom injected, body mass of patient and the bite site. Average dose required for dogs or cats is 1–2 vials of antivenin. The earlier the antivenin is administered the more effective it is. Intravascular bites or bites to the torso or tongue are serious and require prompt, aggressive antivenin administration. Smaller patients may require higher doses (as venom amount/kg body weight is higher), and multiple vials may be necessary. Initially, give one vial, by diluting to 100–250 mL of crystalloid fluids and initially administer by slow IV (if there are no problems, may increase rate and administer volume over 30 minutes). In smaller patients, adjust infusion volume to prevent fluid overload. (Peterson 2006)

b) Dogs: Administer 1–5 rehydrated vials (10–50 mL) IV depending on severity of symptoms, duration of time after the bite, snake size, patient size (the smaller the victim, the larger the dose). Additional doses may be given every 2 hours as required. If unable to give IV, may administer IM as close to bite as practical. Give supportive therapy (*e.g.*, corticosteroids, antibiotics, fluid therapy, blood products, and tetanus prophylaxis) as required. (Package Insert; *Antivenin*®—Fort Dodge)

#### ■ HORSES:

a) Crotilidae Antivenin: Use only if necessary to treat systemic effects, otherwise avoid use. Administer 1–2 vials slowly IV diluted in 250–500 mL saline or lactated Ringer's. Administer antihistamines; corticosteroids are contraindicated. (Bailey & Garland 1992)

### Monitoring

- Signs associated with an allergic response to the antivenin (anaphylaxis, anaphylactoid-reactions, serum sickness)
- CBC with platelets; coagulation parameters
- Biochem profile; hydration status
- ECG

### Client Information

Clients must be made aware of the potential for anaphylaxis as well as the expenses associated with treatment, monitoring and hospitalization.

Clients must be made aware of the potential for anaphylaxis as well as the expenses associated with treatment, monitoring and hospitalization.

## Chemistry

Antivenin products are concentrated serum globulins obtained from horses immunized with the venoms of several types of snakes. They are provided as refined, lyophilized product with a suitable diluent. Up to 50% of the proteins contained in the veterinary product may be equine-specific proteins.

## Storage/Stability

Do not store above 98°F (37°C); avoid freezing and excessive heat. Reconstitute the vial with the diluent provided; gently swirl the vial (may require several minutes; do not shake) to prevent excessive foaming. Warming the vial to body temperature may speed up reconstitution. Once reconstituted the vial contents are often added to a crystalloid intravenous solution (D5W, normal saline often recommended) for infusion. Depending on dog size, one vial in 100–250 mL has been suggested for infusion (Peterson 2006).

The package insert for the veterinary-labeled product states that after rehydration the vial should be used immediately. One reference (anon 2007a) states that the human-labeled equine origin product can be used within 4 hours of reconstitution if refrigerated, but another (anon 2007b) states that it can be used within 48 hours after reconstitution and within 12 hours after further dilution into IV fluids.

The polyvalent immune fab (ovine) product should be stored in the refrigerator and used within 4 hours of reconstitution.

## Dosage Forms/Regulatory Status

**Note:** The availability status of antivenins in the USA is in flux. It is highly recommended to contact a poison control center (see sample phone numbers at the top of this monograph) to get current recommendations on availability and treatment options.

### VETERINARY-LABELED PRODUCTS:

Antivenin (Crotalidae) Polyvalent Equine Origin single dose vial lyophilized; 10 mL vials with diluent. *Antivenin*® (Fort Dodge); (Rx). Approved for use in dogs.

### HUMAN-LABELED PRODUCTS:

Antivenin (Crotalidae) Polyvalent Powder for Injection (lyophilized): combo packs with 1 mL vial of normal horse serum (for testing) and 10 mL Bacteriostatic water for injection USP; *Antivenin (Crotalidae) Polyvalent*® (Wyeth); (Rx)

Antivenin (Crotalidae) Polyvalent Immune Fab (Ovine Origin) Powder for Injection (lyophilized): 1 g total protein per single use vial; *CroFab*® (Altana); (Rx)

## ANTIVENIN (MICRURUS FULVIAS) EASTERN AND TEXAS CORAL SNAKE

(an-tie-ven-nin) North American Coral Snake Antivenin

### ANTIDOTE

**Note:** The location of antivenins for rare species and the telephone numbers for envenomation experts are available from the Arizona Poison and Drug Recommendation Center (800-222-1222). The National Animal Poison Control Center (888-426-4435) is another source for up-to-date snakebite treatment recommendations.

### Prescriber Highlights

- May cause hypersensitivity reactions
  - Treatment can be very expensive
- 

## Uses/Indications

This product is indicated for the treatment of envenomation from the Eastern coral snake (*Micrurus fulvius fulvius*) and the Texas coral snake (*Micrurus fulvius tener*). It will not neutralize the venom from the Sonoran or Arizona coral snake (*Micruroides euryxanthus*) or the Brazilian giant coral snake (*Micrurus frontalis*). Coral snake envenomation is quite rare in the United States and approximately 60% of coral snake bites do not result in envenomation. Unlike pit viper venom, coral snake venom primarily causes neurotoxicity and clinical signs may be delayed. It has been recommended that animals suspected of a coral snake envenomation be hospitalized with close observation for 24–48 hours post-bite.

## Pharmacology/Actions

Antivenins act by neutralizing the venoms (complex proteins) in patients via passive immunization of globulins obtained from horses immunized with the venom. Each vial of antivenin will neutralize approximately 2 mg of *M. fulvius fulvius* venom.

## Contraindications/Precautions/Warnings

The coral snake antivenin will not neutralize *M. euryxanthus* (Sonoran or Arizona Coral Snake) venom. Because there is a risk of anaphylaxis occurring secondary to the horse serum, many recommend performing sensitivity testing before administration.

## Adverse Effects

The most significant adverse effect associated with the use of these products is anaphylaxis secondary to the equine serum source of this product. An incidence rate of less than 2% has been reported. A 1:10 dilution of the antivenin given intracutaneously at a dose of 0.02–0.03 mL may be useful as a test for hypersensitivity. Wheal formation and erythema indicate a positive reaction and are generally seen within 30 minutes of administration. A negative response does not insure that anaphylaxis

will not occur, however. A pre-treatment dose of diphenhydramine is often recommended before administering antivenin. Should an anaphylactoid reaction be detected, stopping the infusion, giving an additional dose of diphenhydramine and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving antivenin and may be of significance in veterinary patients:

- **ANALGESICS/SEDATIVES:** Although reducing excessive movement and other supportive therapy are important parts of treating envenomation, drugs that can mask the clinical signs associated with the venom (*e.g.*, analgesics and sedatives) should initially be used with caution
- **ANTI-HISTAMINES:** It has been stated that antihistamines may potentiate the venom; however, documentation of this interaction was not located and diphenhydramine is routinely used by many clinicians treating snakebite in dogs.
- **BETA-BLOCKERS:** May mask the early signs associated with anaphylaxis.
- **CORTICOSTEROID** use has fallen out of favor in the treatment of snakebite envenomation and is usually considered contraindicated. Corticosteroids may be useful to treat anaphylaxis, however.

## Doses

**Note:** The treatment of Coral snakebite involves significant treatment and monitoring beyond administration of antivenin. It is highly recommended to refer to specialized references *e.g.*, (Peterson 2006a) or to contact an animal poison control center for guidance beyond what is listed below.

### ■ DOGS/CATS:

Coral Snake antivenin (not Sonoran or Arizona variety):

- a) Dogs: After testing for hypersensitivity give 1–2 vials initially, and more in 4–6 hours if necessary. Therapy is best started within 4 hours after envenomation. Supportive care includes broad-spectrum antibiotics, fluid therapy and mechanical ventilation if necessary. Corticosteroids are not recommended. (Marks, Mannella et al. 1990)
- b) Dogs/Cats: Dose necessary is calculated relative to the amount of venom injected and the body mass of patient. Average dose required for dogs or cats is 1–2 vials of antivenin. The earlier the antivenin is administered the more effective it is. Smaller patients may require higher doses (as venom amount/kg body weight is higher), and multiple vials may be necessary. Initially give one vial, by diluting to 100–250 mL of crystalloid fluids and initially administering by slow IV. In smaller patients, adjust infusion volume to prevent fluid overload. Give additional vials as indicated by the progression of the syndrome. (Peterson 2006b)

### ■ HORSES:

Coral Snake Antivenin:

- a) Use only if necessary to treat systemic effects, otherwise avoid use. Administer 1–2 vials slowly IV diluted in 250–500 mL saline or lactated Ringer's. Administer antihistamines; corticosteroids are contraindicated. May be used with Crotilidae antivenin. (Bailey and Garland 1992)

## Monitoring

- Signs associated with an allergic response to the antivenin (anaphylaxis, anaphylactoid-reactions, serum sickness)
- Cardiorespiratory monitoring; mechanical ventilation may be necessary
- Pulse oximetry

## Client Information

- Clients must be made aware of the potential for anaphylaxis as well as the expenses associated with treatment, monitoring and hospitalization.

## Chemistry

These products are concentrated serum globulins obtained from horses immunized with the venoms of several types of snakes. They are provided as refined, lyophilized product with a suitable diluent.

## Storage/Stability

Product should be stored in the refrigerator. Avoid freezing and excessive heat. Reconstitute vial with 10 mL of the supplied diluent. Gentle agitation may be used to hasten dissolution of the lyophilized powder. Reconstituted vials should be used within 48 hours (keep refrigerated) and within 12 hours once added to IV solutions.

## Dosage Forms/Regulatory Status

**Note:** The availability status of antivenins in the USA is in flux. It is highly recommended to contact a poison control center (see sample phone numbers at the top of this monograph) to get current recommendations on availability and treatment options.

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Antivenin (*Micrurus fulvius*) Powder for Injection lyophilized: in single-use vials with 1 vial diluent (10 mL water for injection); *Antivenin (Micrurus fulvius)*; (Ayerst); (Rx). **Note:** The manufacturer has discontinued producing this product, but has enough antivenin on hand to satisfy demand for several years.

## ANTIVENIN (LATRODECTUS MACTANS) BLACK WIDOW SPIDER

(an-tie-ven-nin) Black Widow Spider Antivenin

### ANTIDOTE

**Note:** The location of antivenins for rare species and the telephone numbers for envenomation experts are available from the Arizona Poison and Drug Information Center (800-222-1222). The National Animal Poison Control Center (888-426-4435) is another source for up-to-date envenomation treatment recommendations.

### Prescriber Highlights

- May cause hypersensitivity reactions
  - May be difficult for veterinarians to obtain
- 

### Uses/Indications

Black widow spider antivenin is used to treat envenomation caused by this spider. Cats, camels and horses are considered to be extremely sensitive to the venom. Primary toxic signs are due to neurotoxins in the venom.

### Pharmacology/Actions

Antivenins act by neutralizing the venoms (complex proteins) in patients via passive immunization of globulins obtained from horses immunized with the venom. In humans, symptoms begin to subside in 1-2 hours after administration.

### Contraindications/Precautions/Warnings

Because there is a risk of anaphylaxis occurring secondary to the horse serum, many recommend performing sensitivity testing before administration.

### Adverse Effects

The most significant adverse effect associated with the use of the equine origin product is anaphylaxis secondary to its equine serum source; an incidence rate of less than 2% has been reported. A 1:10 dilution of the antivenin given intracutaneously at a dose of 0.02–0.03 mL has been suggested as a test for hypersensitivity. Wheal formation and erythema indicate a positive reaction and are generally seen within 30 minutes of administration. However, a negative response does not insure that anaphylaxis will be avoided and slow intravenous administration is usually sufficient to identify animals that will react to the product. A pre-treatment dose of diphenhydramine is often recommended before administering antivenin primarily to sedate the patient and, theoretically, to reduce any possible allergic reactions to the antivenin. Should an anaphylactoid reaction be detected (nausea, pruritus, hyperemia of the inner pinna), stopping the infusion, giving an additional dose of diphenhydramine and restarting the infusion 5 minutes later at a slower rate may allow the dose to be administered without further problems.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving black widow spider antivenin and may be of significance in veterinary patients:

- **BETA-BLOCKERS:** May mask the early signs associated with anaphylaxis

### Doses

#### ■ DOGS/CATS:

- After reconstituting the antivenin, add to 100 mL of normal saline and administer via slow IV over 30 minutes. Pretreatment with 2–4 mg/kg of diphenhydramine SC may help calm the patient and may possibly protect against allergic reactions from the antivenin. Monitor inner pinna during infusion for signs of anaphylaxis (hyperemia). If hyperemia occurs, discontinue infusion and give a second dose of diphenhydramine. If allergic reactions abate, may restart infusion at a slower rate; if they recur, stop infusion and seek consultation. Use care with administration of IV fluids as envenomation can cause significant hypertension. Benzodiazepines may alleviate muscle cramping. (Peterson & McNalley 2006)
- Dissolve contents of one vial and add to 100–200 mL of warm 0.9% NaCl and infuse over 2–6 hours. Administer diphenhydramine at 0.5–1 mg/kg prior to infusion. (Atkins 2006)

### Client Information

- Clients must be made aware of the potential for anaphylaxis as well as the expenses associated with treatment, monitoring and hospitalization.

### Monitoring

- Signs associated with an allergic response to the antivenin (anaphylaxis, anaphylactoid-reactions, serum sickness)
- Respiratory/cardiac rate
- Blood pressure
- Serum chemistry (blood glucose mandatory)
- CBC
- Urine output: urinalysis

## Chemistry

This product is concentrated serum globulins obtained from horses immunized with the venom of the black widow spider. It is provided as refined, lyophilized product with a suitable diluent.

## Storage/Stability

Product should be stored in the refrigerator (2–8°C). It is reconstituted by adding 2.5 mL of the diluent provided; shake the vial to completely dissolve the contents. Do not freeze the reconstituted solution. For IV use, further dilute the solution in 10–100 mL of normal saline injection.

## Dosage Forms/Regulatory Status

Note: The availability status of antivenins in the USA is in flux. It is highly recommended to contact a poison control center (see sample phone numbers at the top of this monograph) to get current recommendations on availability and treatment options.

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Antivenin (*Latrodectus mactans*) Powder for Injection: greater than or equal to 6000 antivenin Units/vial in single-use vials with 1 vial diluent (2.5 mL vial of sterile water for injection) and 1 mL vial of normal horse serum (1:10 dilution) for sensitivity testing; Antivenin (*Latrodectus mactans*); (Merck); (Rx)

## APOMORPHINE HCL

(a-poe-mor-feen) Apokyn®

EMETIC

### Prescriber Highlights

- **Rapid acting, centrally-mediated emetic used in dogs & sometimes in cats**
- **Contraindicated in certain species (e.g., rodents, rabbits) & when vomiting may be deleterious (e.g., impending coma, aspiration)**
- **May cause protracted vomiting; naloxone should reverse CNS effects or cardio-respiratory depression, but not vomiting**
- **Availability & expense may be an issue**

## Uses/Indications

Apomorphine is used primarily as an emetic in dogs, and is considered the emetic of choice for dogs by many clinicians. It is sometimes used in cats, but its use in this species is somewhat controversial.

## Pharmacology/Actions

Apomorphine stimulates dopamine receptors in the chemoreceptor trigger zone, thus inducing vomiting. It can cause both CNS depression and stimulation, but tends to cause more stimulatory effects. Medullary centers can be depressed with resultant respiratory depression.

## Pharmacokinetics

Apomorphine is slowly absorbed after oral administration and has unpredictable efficacy when given by this route, therefore, it is usually administered parenterally or topically to the eye. When given intravenously in dogs, emesis occurs very rapidly; after IM use, vomiting occurs generally within 5 minutes but may be more prolonged. Topical administration to the conjunctival sac is usually effective but less so than either IV or IM administration.

Apomorphine is primarily conjugated in the liver and then excreted in the urine.

## Contraindications/Precautions/Warnings

Emetics can be an important aspect in the treatment of orally ingested toxins, but must not be used injudiciously. Emetics should not be used in rodents or rabbits, because they are either unable to vomit or do not have stomach walls strong enough to tolerate the act of emesis. Emetics are also contraindicated in patients that are: hypoxic, dyspneic, in shock, lack normal pharyngeal reflexes, seizing, comatose, severely CNS depressed or where CNS function is deteriorating, or extremely physically weak. Emetics should also be withheld in patients who have previously vomited repeatedly. Because of the risk for additional esophageal or gastric injury with emesis, emetics are contraindicated in patients who have ingested strong acids, alkalis, or other caustic agents. Because of the risks of aspiration, emetics are usually contraindicated after petroleum distillate ingestion, but may be employed when the risks of toxicity of the compound are greater than the risks of aspiration. Use of emetics after ingestion of strychnine or other CNS stimulants may precipitate seizures.

Emetics generally do not remove more than 80% of the material in the stomach (usually 40–60%) and successful induction of emesis does not signal the end of appropriate monitoring or therapy. In addition to the contraindications outlined in the general statement, apomorphine should not be used in cases of oral opiate or other CNS depressant (e.g., barbiturates) toxicity, or in patients hypersensitive to morphine.

The use of apomorphine in cats is controversial, and several clinicians state that it should not be used in this species as it is much less effective than either xylazine or ipecac syrup and possibly, less safe.

If vomiting does not occur within the expected time after apomorphine administration, repeated doses are unlikely to induce emesis and may cause clinical signs of toxicity.

## Adverse Effects

At usual doses, the principal adverse effect that may be seen with apomorphine is protracted vomiting. Protracted vomiting after ophthalmic administration may be averted by washing the conjunctival sac with sterile saline or ophthalmic rinsing solution. Excitement, restlessness, CNS depression or respiratory depression are usually only associated with overdoses of the drug. Anecdotal reports of corneal ulcers have been noted after conjunctival administration.

## Reproductive/Nursing Safety

The reproductive safety of this drug has not been established; weigh the risks of use versus the potential benefits.

## Overdosage/Acute Toxicity

Excessive doses of apomorphine may result in respiratory and/or cardiac depression, CNS stimulation (excitement, seizures) or depression and protracted vomiting. Naloxone may reverse the CNS and respiratory effects of the drug but cannot be expected to halt the vomiting. Atropine has been suggested to treat severe bradycardias.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving apomorphine and may be of significance in veterinary patients:

- **ANTIDOPAMINERGIC DRUGS** (e.g., **phenothiazines**) may negate the emetic effects of apomorphine
- **ONDANSETRON**: A human patient that received ondansetron and apomorphine developed severe hypotension. In humans, use together is contraindicated.
- **OPIATES OR OTHER CNS OR RESPIRATORY DEPRESSANTS** (e.g., **barbiturates**): Additive CNS, or respiratory depression may occur when apomorphine is used with these agents

## Doses

### ■ DOGS:

For induction of emesis:

- a) 0.03 mg/kg IV or 0.04 mg/kg IM (IV route preferred); alternatively a portion of tablet may be crushed in a syringe, dissolved with few drops of water and administered into the conjunctival sac. After sufficient vomiting occurs, rinse conjunctival sac free of unabsorbed apomorphine. (Beasley & Dorman 1990)
- b) 0.04 mg/kg IV or 0.08 mg/kg IM or SC (Bailey 1989), (Riviere 1985), (Mount 1989)
- c) 0.04 mg/kg IV, 0.07 mg/kg IM, or 0.25 mg/kg into the conjunctival sac (Jenkins 1988)

### ■ CATS:

**Note:** Use of apomorphine in cats is controversial and many recommend not using in this species.

- a) For induction of emesis: 0.04 mg/kg IV or 0.08 mg/kg IM or SC (Bailey 1989), (Reid & Oehme 1989)

## Monitoring

- CNS, respiratory, and cardiac systems should be monitored
- Vomitus should be quantified, examined for contents and saved for possible later analysis

## Client Information

- This agent must be used in a professionally supervised setting only

## Chemistry/Synonyms

A centrally-acting emetic, apomorphine occurs as a white powder or minute, white or grayish-white crystals and is sparingly soluble in water or alcohol.

Apomorphine HCl may also be known as: apomorphini hydrochloridum, *APO-go*®, *APO-go Pen*®, *Apofin*®, *Apokinon*®, *Apokyn*®, *Apomine*®, *Britaject*®, *Ixense*®, *Taluvian*®, or *Uprima*®.

## Storage/Stability

Apomorphine soluble tablets should be stored in tight containers at room temperature (15–30°C) and protected from light.

Upon exposure to light and air, apomorphine gradually darkens in color. Discolored tablets or discolored solutions (green to turquoise) should not be used. Apomorphine solutions are more stable in acidic than in alkaline solutions. A 0.3% solution of apomorphine has a pH of about 3–4.

## Compatibility/Compounding Considerations

Solutions of apomorphine can be made by solubilizing tablets in at least 1–2 mL of either sterile water for injection or 0.9% sodium chloride for injection. After being sterilized by filtration, the solution is stable for 2 days if protected from light and air and stored in the refrigerator. Do not use solutions that are discolored or form a precipitate after filtering.

**Compounded preparation stability:** Apomorphine injectable solution compounded from the active pharmaceutical ingredient (API) has been published (Jaeger, 1976). Dissolving 10 mg apomorphine to a final volume of 10 mL with 0.1% sodium metabisulfite in sterile water and filtering through a 0.22micron sterilizing filter yields a 2.5 mg/mL sterile solution that retains potency for two months stored at 25°C. Compounded preparations of apomorphine should be protected from light. Solutions of apomorphine should be cold sterilized and not be autoclaved as autoclaving results in the development of a green color.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Pharmaceutical dosage forms of apomorphine have been occasionally difficult to obtain and compounding pharmacies may be required to obtain the drug.

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

## APRAMYCIN SULFATE

(a-pra-mye-sin) Apralan®

AMINOGLYCOSIDE ANTIBIOTIC

### Prescriber Highlights

- Orally administered aminocyclitol antibiotic for porcine *E. coli* bacillosis in swine (sometimes used in calves—not FDA-approved)
  - Products no longer available in USA
  - May be partially absorbed in neonates; potentially nephro- & ototoxic if absorbed systemically
- 

## Uses/Indications

Apramycin is no longer commercially available in the USA, but it is used in some countries for the treatment of bacterial enteritis, colibacillosis, salmonellosis, etc. in pigs, calves and poultry.

## Pharmacology/Actions

Apramycin is an aminoglycoside that is bactericidal against many gram-negative bacteria (*E. coli*, *Pseudomonas*, *Salmonella*, *Klebsiella*, *Proteus*, *Pasturella*, *Treponema hyodysenteriae*, *Bordetella bronchiseptica*), *Staphylococcus* and *Mycoplasma*. It prevents protein synthesis by susceptible bacteria, presumably by binding to the 30S ribosomal subunit.

## Pharmacokinetics

After oral administration, apramycin is partially absorbed, particularly in neonates. Absorption is dose related and decreases substantially with the age of the animal. Absorbed drug is eliminated via the kidneys unchanged.

## Contraindications/Precautions/Warnings

Do not use in known cases of apramycin hypersensitivity. The drug apparently has a wide margin of safety when used orally and is safe to use in breeding swine. Apramycin is contraindicated in cats and in patients with myasthenia gravis.

## Adverse Effects

When used as labeled, the manufacturer does not list any adverse reactions. Should substantial amounts of the drug be absorbed, both ototoxicity and nephrotoxicity are a distinct possibility.

## Drug Interactions/Laboratory Considerations

None were noted. May have similar interaction potential as neomycin; refer to that monograph for more information.

## Doses

### ■SWINE:

For bacterial enteritis caused by susceptible organisms:

- a) Treated pigs should consume enough water to receive 12.5 mg/kg body weight per day for 7 days. Add to drinking water at a rate of 375 mg per gallon. After adding to water, stir and allow to stand for 15 minutes, then stir again. (Label directions; *Apralan*® Soluble Powder—SKB)
- b) 20–40 mg/kg PO daily in drinking water (Huber 1988)
- c) Pigs: To be administered via the drinking water. Add 1 small measure (4.4 mL) or 1 sachet of soluble powder per 20 L of drinking water. (Label information; *Apralan Soluble Powder*®—Elanco U.K.)

### ■CATTLE:

- a) For bacterial enteritis caused by susceptible organisms: 20–40 mg/kg PO daily in drinking water (Huber 1988)
- b) **Calves:** For the treatment of colibacillosis or salmonellosis: 1–2 sachets to be administered in the drinking water, milk, or milk replacer to provide 20–40 mg of apramycin activity per kg of bodyweight daily according to the severity of the disease. Continue treatment for 5 days. (Label information; *Apralan Soluble Powder*®—Elanco U.K.)

### ■POULTRY:

- a) For bacterial enteritis caused by susceptible organisms: To be administered via drinking water to provide 250–500 mg of apramycin activity per liter for 5 days. This may be achieved by adding 50 g apramycin per 100–200 liters of water. (Label information; *Apralan Soluble Powder*®—Elanco U.K.)

## Monitoring

– Clinical efficacy

**Chemistry/Synonyms**

Apramycin is an aminocyclitol antibiotic produced from *Streptomyces tenebrarius*; it is soluble in water.

Apramycin may also be known as nebramycin factor 2, nebramycin II, apramycine, apramicina, AIDS166733, *Apralan*® or *Abylan*®.

**Storage/Stability**

Apramycin powder should be stored in a cool dry place, in tightly closed containers, protected from moisture. Store at temperatures less than 25°C. If exposed to rust, as in a rusty waterer, the drug can be inactivated. The manufacturer recommends preparing fresh water daily. Shelf life of the powder is 24 months.

**Dosage Forms/Regulatory Status****VETERINARY-LABELED PRODUCTS:**

None at present in the USA. A swine product: Apramycin Sulfate Soluble Powder 37.5 & 48 g (base) bottle; *Apralan*® (Elanco); (OTC), was formerly marketed in the USA and is still available in several countries.

In the UK: Apramycin Soluble Powder: 1 gram sachets and 50 g (apramycin activity) in 220 mL; *Apralan Soluble Powder*® (Elanco); (POM-V). In the UK when used as labeled: Slaughter withdrawal: Pigs = 14 days, Calves = 28 days, Poultry = 7 days. Not for use in laying hens where eggs are for human consumption.

**HUMAN-LABELED PRODUCTS:** None

**References**

Häber, WG (1988). Aminoglycosides, Macrolides, Lincosamides, Polymyxins, Chloramphenicol, and other Antibacterial Drugs. *Veterinary Pharmacology and Therapeutics*. NH Booth and LE McDonald Eds. Ames, Iowa State University Press: 822-848.

**ASA**—see [Aspirin](#)

**ASCORBIC ACID****VITAMIN C**

(a-*skor*-bik)

**Prescriber Highlights**

- **Prevention/treatment of scurvy in Guinea pigs most accepted use**
- **At usual dosages, little downside to use; may exacerbate liver injury in copper toxicosis**
- **Some drug interactions, primarily due to its urinary acidification qualities**
- **May alter some lab results (urine glucose, occult blood in stool, serum bilirubin)**

**Uses/Indications**

Ascorbic acid is used to prevent and treat scurvy in guinea pigs. It has been used as a urinary acidifier in small animals, but its efficacy is in question. Sodium ascorbate does not acidify the urine. In the past, it was used to treat copper-induced hepatopathy in dogs but this use has fallen into disfavor (see Contraindications below).

**Pharmacology/Actions**

Exogenously supplied ascorbic acid is a dietary requirement in some exotic species (including rainbow trout, Coho salmon), guinea pigs, and in primates. The other domestic species are able to synthesize *in vivo* enough Vitamin C to meet their nutritional needs. Vitamin C is used for tissue repair and collagen formation. It may be involved with some oxidation-reduction reactions, and with the metabolism of many substances (iron, folic acid, norepinephrine, histamine, phenylalanine, tyrosine, some drug enzyme systems). Vitamin C is believed to play a role in protein, lipid and carnitine synthesis, maintaining blood vessel integrity and immune function.

**Pharmacokinetics**

Vitamin C is generally well absorbed in the jejunum (human data) after oral administration, but absorption may be reduced with high doses as an active process is involved with absorption. Ascorbic acid is widely distributed and only about 25% is bound to plasma proteins. Vitamin C is biotransformed in the liver. When the body is saturated with vitamin C and blood concentrations exceed the renal threshold, the drug is more readily excreted unchanged into the urine.

**Contraindications/Precautions/Warnings**

Vitamin C (high doses) should be used with caution in patients with diabetes mellitus due to the laboratory interactions (see below), or in patients susceptible to urolithiasis as it can promote hyperoxaluria.

Because there is some evidence that it may increase copper's oxidative damage to the liver, avoid vitamin C's use in animals with copper-associated hepatopathy.

**Adverse Effects**

At usual doses vitamin C has minimal adverse effects. Occasionally GI disturbances have been noted in humans. At higher dosages there is an increased potential for urate, oxalate or cystine stone formation, particularly in susceptible patients.

**Reproductive/Nursing Safety**

The reproductive safety of vitamin C has not been studied, but it is generally considered safe at moderate dosages. In humans, the FDA categorizes this drug as category **A** for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) But in dosages greater than the RDA, the FDA categorizes vitamin C as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in*

There is no adverse effect on the fetus, but there are no adequate studies in humans, or there are no animal reproduction studies and no adequate studies in humans.)

### Overdosage/Acute Toxicity

Very large doses may result in diarrhea and potentially urolithiasis. Generally, treatment should consist of monitoring and keeping the patient well hydrated.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ascorbic acid (high dosages) and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** (*e.g.*, **gentamicin**) and **ERYTHROMYCIN:** Are more effective in an alkaline medium; urine acidification may diminish these drugs' effectiveness in treating bacterial urinary tract infections
- **QUINIDINE:** Urine acidification may increase renal excretion
- **DEFEROXAMINE:** While vitamin C may be synergistic with deferoxamine in removing iron, it may lead to increased iron tissue toxicity, especially in cardiac muscle. It should be used with caution, particularly in patients with preexisting cardiac disease.
- **IRON SALTS:** Presence of vitamin C may enhance the oral absorption of iron salts

### Laboratory Considerations

- **URINE GLUCOSE:** Large doses of vitamin C may cause false-negative values
- **STOOL OCCULT BLOOD:** False-negative results may occur if vitamin C is administered within 48–72 hours of an amine-dependent test
- **BILIRUBIN, SERUM:** Vitamin C may decrease concentrations

### Doses

#### ■ CATS:

- a) For adjunctive treatment of FIP: 125 mg (total dose) PO q12h (Weiss 1994)
- b) For adjunctive treatment of toxic (*e.g.*, acetaminophen) methemoglobinemia (with oxygen, acetylcysteine): 30 mg/kg PO q6h (Macintire 2006)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

- a) **Rabbits:** For soft stools (may reduce cecal absorption of clostridial endotoxins): 100 mg/kg PO q12h (Ivey & Morrisey 2000)

#### ■ GUINEA PIGS:

For treatment of scurvy:

- a) During pregnancy: 30 mg/kg either parenterally or PO (in feed or water) (Fish & Besch-Williford 1992)
- b) 25–50 mg (total dose) parenterally once daily until improvement is noted, then give oral supplemental vitamin C (daily requirement is 15 mg/day) (Wilson 2005)
- c) 10 mg/kg daily, by injection if necessary, plus supportive care. Recovery is relatively rapid, usually within a week. Prevention is adequate daily intake of vitamin C. (Burke 1999)
- d) 50 mg/kg PO, IM or SC (Adamcak & Otten 2000)

For prevention of scurvy:

- a) Add 200 mg vitamin C to one liter of dechlorinated water and add to water bottle. 10–30 mg/kg PO, SC or IM (Adamcak & Otten 2000)

#### ■ HORSES:

- a) For replacement therapy after stress (*e.g.*, strenuous exercise): 20 grams PO daily (Ferrante & Kronfeld 1992)
- b) For adjunctive treatment of erythrocyte oxidative injury (*e.g.*, red maple toxicity): 10–20 grams PO once daily (Davis & Wilkerson 2003); 30–50 mg/kg IV twice daily diluted in 5–10 L of crystalloid fluids (Alward 2008).
- c) As a urinary acidifier: 1–2 g/kg PO daily (Jose-Cunilleras & Hinchcliff 1999)
- d) As adjunctive therapy for perinatal asphyxia syndrome in foals: 100 mg/kg per day IV (Slovic 2003)

#### ■ CATTLE:

- a) For vitamin C-responsive dermatitis in calves: 3 grams SC once or twice (Miller 1993)

### Chemistry/Synonyms

A water-soluble vitamin, ascorbic acid occurs as white to slightly yellow crystal or powder. It is freely soluble in water and sparingly soluble in alcohol. The parenteral solution has a pH of 5.5–7.

Ascorbic acid may also be known as: acidum ascorbicum, L-ascorbic acid, cevitamic acid, E300, or vitamin C; many trade names are available.

### Storage/Stability

Protect from air and light. Ascorbic acid will slowly darken upon light exposure; slight discoloration does not affect potency. Because with time ascorbic acid will decompose with the production of CO<sub>2</sub>, open ampules and multidose vials carefully. To reduce the potential for excessive pressure within ampules, store in refrigerator and open while still cold.

### Compatibility/Compounding Considerations

Ascorbic acid for injection is **compatible** with most commonly used IV solutions, but is **incompatible** with many drugs when mixed in syringes or IV bags. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

## VETERINARY-LABELED PRODUCTS:

Parenteral Injection: 250 mg/mL (as sodium ascorbate) in 100 and 250 mL vials; generic; (Rx or OTC depending on labeling)

Ascorbic Acid Powder: 442.25 g/lb *Vita-Flex Pure C®* (Vita-Flex); 50 grams/lb *Mega-C Powder®* (AHC); 146 g/pack *Stabilized C®* (Alpharma); (OTC)

## HUMAN-LABELED PRODUCTS:

As Ascorbic Acid Oral Tablets & Capsules: 250mg, 500 mg, 1000 mg & 1500 mg; *Cevi-Bid®* (Lee); generic; (OTC);

Ascorbic Acid Oral Extended-release Tablets: 500 mg & 1000 mg; generic; (OTC)

Ascorbic Acid Oral Crystals: 1000 mg per ¼ tsp. in 120 g and 1 lb; *Vita-C®* (Freeda); (OTC)

Ascorbic Acid Oral Powder: 1060 mg per ¼ tsp. in 120 g and 1 lb; 60 mg per ¼ tsp. in 454 g; *Dull-C®* (Freeda); Ascorbic Acid (Humco); (OTC)

Ascorbic Acid Oral Liquid/Solution: 100 mg/mL in 50 mL & 500 mg/5 mL in 120 mL & 480 mL; *Cecon®* (Abbott); generic; (OTC)

Ascorbic Acid Injection: 500 mg/mL in 50 mL vials; *Ascor L 500®* (McGuff) (0.025% EDTA, preservative-free); generic; (Rx)

---

## ASPARAGINASE

(*a-spar-a-gin-ase*) L-Asparaginase, Elspar®

ANTINEOPLASTIC

### Prescriber Highlights

- Antineoplastic useful in treating lymphomas and leukemias in dogs/cats
- Two primary adverse effects: hypersensitivity & effects on protein synthesis (usually manifested by: GI effects, hemorrhagic pancreatitis, hepatotoxicity or coagulation disorders);
- Bone marrow suppression is rare and it does not have significant GI mucosal toxicity
- Usually given IM or SC as IV administration may increase for anaphylaxis

---

## Uses/Indications

Asparaginase has been useful in combination with other agents in the treatment of lymphoid malignancies. The drug is most useful in inducing remission of disease but is also used in maintenance or rescue protocols. It may also have benefit in treating leukemia, particularly ALL.

Use of asparaginase as part of an initial treatment lymphosarcoma protocol is now somewhat controversial, as one study (MacDonald *et al.* 2005) in dogs showed no statistical difference for response rates, remission or survival rate, remission or survival duration, or prevalence of toxicity and treatment delay in dogs treated with or without asparaginase as part of a standard CHOP protocol.

## Pharmacology/Actions

Some malignant cells are unable to synthesize asparagine and are dependent on exogenous asparagine for DNA and protein synthesis. Asparaginase catalyzes asparagine into ammonia and aspartic acid. The antineoplastic activity of asparaginase is greatest during the post mitotic (G1) cell phase. While normal cells are able to synthesize asparagine intracellularly, some normal cells having a high rate of protein synthesis, require some exogenous asparagine and may be adversely affected by asparaginase.

Resistance to asparaginase can develop rapidly, but apparently, there is no cross-resistance between asparaginase and other antineoplastic agents.

Asparaginase possesses antiviral activity, but its toxicity prevents it from being clinically useful in this regard.

## Pharmacokinetics

Asparaginase is not absorbed from the GI tract and must be given either IV or IM. After IM injection, serum levels of asparaginase are approximately 1/2 of those after IV injection. Because of its high molecular weight, asparaginase does not diffuse readily out of the capillaries and about 80% of the drug remains within the intravascular space.

In humans after IV dosing, serum levels of asparagine fall almost immediately to zero and remain that way as long as therapy continues. Once therapy is halted, serum levels of asparagine do not recover for at least 23 days.

The metabolic fate of asparaginase is not known. In humans, the plasma half-life is highly variable and ranges from 8–30 hours.

## Contraindications/Precautions/Warnings

Asparaginase is contraindicated in patients who have exhibited anaphylaxis to it, or those with pancreatitis or a history of pancreatitis. Asparaginase should be used with caution in patients with preexisting hepatic, renal, hematologic, gastrointestinal, or CNS dysfunction.

No special precautions are required for handling asparaginase, but any inadvertent skin contact should be washed off, as the drug can be a contact irritant.

## Adverse Effects

Asparaginase adverse reactions are classified in two main categories, hypersensitivity reactions and effects on protein synthesis. Hypersensitivity reactions can occur with clinical signs of vomiting, diarrhea, urticaria, pruritus, dyspnea, restlessness, hypotension and collapse. The likelihood of hypersensitivity reactions occurring increases with subsequent doses and intravenous administration. Some clinicians recommend giving a test dose before the full dose to test for local hypersensitivity. Most oncologists now recommend administering antihistamines (*e.g.*, diphenhydramine (at 2 mg/kg in dogs and 1 mg/kg in cats SC 30 minutes prior to administration) prior to dosing. If a hypersensitivity reaction occurs, diphenhydramine (0.2–0.5 mg/kg slow IV), dexamethasone sodium phosphate (1–2 mg/kg IV), intravenous fluids and, if severe, epinephrine (0.1–0.3 mL of a 1:1000 solution IV) have been suggested (O’Keefe & Harris 1990).

The other broad category of toxicity is associated with asparaginase’s effects on protein synthesis. Hemorrhagic pancreatitis or other gastrointestinal disturbances, hepatotoxicity and coagulation defects may be noted. Large doses may be associated with hyperglycemia secondary to altered insulin synthesis. Bone marrow depression is an uncommon consequence of asparaginase therapy, but leukopenia has been reported.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Little information was located regarding overdosages with this agent. It would be expected that toxicity secondary to the protein synthesis altering effects of the drug would be encountered. In dogs, it has been reported that the maximally tolerated dose of asparaginase is 10,000 IU/kg and the lethal dose is 50,000 IU/kg.

It is recommended to treat supportively if an overdose occurs.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving asparaginase and may be of significance in veterinary patients:

- **METHOTREXATE:** Asparaginase may reduce methotrexate effectiveness against tumor cells until serum asparagine levels return to normal
- **PREDNISONE:** Use with asparaginase may increase risk for hyperglycemia; in humans, asparaginase is usually administered after prednisone
- **VINCRIStINE:** In humans, increased toxicity (neuropathy and erythropoiesis disruption) may occur when asparaginase (IV) is given concurrently with or before vincristine. Myelosuppression reportedly occurs in a minority of dogs treated with vincristine/asparaginase; some veterinary oncologists separate the dosing by a few days to a week, but others do not feel this is beneficial.

## Laboratory Considerations

- **Serum ammonia and urea nitrogen:** levels may be increased by the action of the drug
- **Thyroxine-binding globulin:** Asparaginase may cause rapid (within 2 days) and profound decreases in circulating TBG, which may alter interpretation of thyroid function studies; values may return to normal after approximately 4 weeks

## Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

### ■ DOGS/CATS:

The following is a usual dose or dose range for asparaginase and should be used only as a general guide: Asparaginase is usually dosed in dogs and cats at 400 Units/kg or 10,000 Units/m<sup>2</sup> (NOT Units/kg) IM or SC, with a maximum dose of 10,000 Units per patient. **Note:** Many oncologists recommend administering antihistamines such as diphenhydramine at 2 mg/kg for dogs and 1 mg/kg for cats SC 30 minutes prior to administration.

## Monitoring

- Animals should have hepatic, renal, pancreatic (blood glucose, amylase) and hematopoietic function determined prior to initiating therapy and regularly monitored during therapy.

## Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Clients should contact the veterinarian if the patient exhibits any symptoms of profound depression, severe diarrhea, abnormal bleeding (including bloody diarrhea) and/or bruising

## Chemistry/Synonyms

Asparaginase is an enzyme derived from *E. coli* and occurs as a white or almost white, slightly hygroscopic powder that is soluble in water. The commercially available product is a lyophilized powder that also contains mannitol that after reconstituting has a pH of about 7.4. Activity of asparaginase is expressed in terms of International Units (I.U.), or Units.

Asparaginase may also be known as: coloaspase, A-ase, ASN-ase, L-asparaginase, L-asparagine amidohydrolase, MK-965 NSC-109229, Re-82-TAD-15, *Crasnitin*®, *Crasnitine*®, *Elspar*®, *Erwinase*®, *Kidrolase*®, *L-Asp*®, *Laspar*®, *Leucogen*®, *Leunase*®, *Paronal*®, or *Serasa*®.

## Storage/Stability

Asparaginase powder for injection should be stored at temperatures less than 8°C, but it is stable for at least 48 hours at room temperature. After reconstituting, the manufacturer states that the drug is stable when refrigerated for up to 8 hours, but other sources state that it is stable for up to 14 days.

Solutions should be used only if clear; turbid solutions should be discarded. Upon standing, gelatinous fibers may be noted in the solution occasionally. These may be removed without loss of potency with a 5 micron filter. Some loss of potency may occur if a 0.2 micron filter is used.

The solution may be gently shaken while reconstituting, but vigorous shaking should be avoided as the solution may become foamy and difficult to withdraw from

The solution may be gently shaken while reconstituting, but vigorous shaking should be avoided as the solution may become foamy and difficult to withdraw from the vial and some loss of potency can occur. Recommended intravenous diluents for asparaginase include D5W and sodium chloride 0.9%.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Asparaginase Powder for Injection, lyophilized: 10,000 Units in 10 mL vials (with 80 mg mannitol, preservative-free); Reconstitute vial with 5 mL Sodium Chloride Injection or Sterile Water for Injection for IV use. For IM use, add 2 mL Sodium Chloride Injection. See Storage/Stability section for more information. *Elspar*® (Merck); (Rx)

## ASPIRIN

(*ass-pir-in*) ASA, Acetylsalicylic Acid

ANALGESIC; ANTIPIRETTIC; PLATELET AGGREGATION REDUCER; ANTIINFLAMMATORY

### Prescriber Highlights

- NSAID used for analgesic, antiinflammatory & antiplatelet effects in a variety of species
- Contraindicated in patients hypersensitive to it or with active GI bleeds; Relatively contraindicated in patients with bleeding disorders, asthma, or renal insufficiency (but has been used to treat glomerular disease)
- Aspirin has a very long half life in cats (approx. 30 hours; dose carefully); dogs are relatively sensitive to GI effects (bleeding)
- Low grade teratogen & may delay labor; avoid use in pregnancy
- Many drug & lab interactions

---

## Uses/Indications

Aspirin is used in all species for its analgesic and antipyretic effects. It is one of the few nonsteroidal antiinflammatory agents that is relatively safe to use in both dogs and cats, although it can cause significant GI bleeding in dogs. Besides its analgesic, antiinflammatory and antipyretic effects, aspirin is used therapeutically for its effects on platelet aggregation in the treatment of DIC and pulmonary artery disease secondary to heartworm infestation in dogs. It is also used in cats with cardiomyopathy. Aspirin (at low doses) may be of benefit in the adjunctive treatment of glomerular disease due to its antiplatelet and antiinflammatory activity.

## Pharmacology/Actions

Aspirin inhibits cyclooxygenase (COX-1, prostaglandin synthetase) thereby reducing the synthesis of prostaglandins and thromboxanes (TXA<sub>2</sub>). These effects are thought to be how aspirin produces analgesia, antipyrexia, and reduces platelet aggregation and inflammation.

Most cells can synthesize new cyclooxygenase, but platelets cannot. Therefore, aspirin can cause an irreversible effect on platelet aggregation. A study in dogs investigating the platelet function effects of various aspirin doses, showed that doses less than 1 mg/kg/day or at 10 mg/kg/day PO did not have any statistically significant effect on platelet aggregation. Doses of 1 and 2 mg/kg/day inhibited platelet function and aggregation. (Shearer *et al.* 2009)

Aspirin has been shown to decrease the clinical signs of experimentally induced anaphylaxis in calves and ponies.

While aspirin does not directly inhibit COX-2, it can modify it to produce, with lipoyxygenase (LOX), a compound known as aspirin-triggered lipoxin (ATL), which appears to have gastric mucosal protective actions. This may explain why aspirin tends to have reduced gastric damaging effects when used over time.

## Pharmacokinetics

Aspirin is rapidly absorbed from the stomach and proximal small intestine in monogastric animals. The rate of absorption is dependent upon factors as stomach content, gastric emptying times, tablet disintegration rates and gastric pH. Absorption is slow from the GI tract in cattle, but approximately 70% of an oral dose will be absorbed.

During absorption, aspirin is partially hydrolyzed to salicylic acid where it is distributed widely throughout the body. Highest levels may be found in the liver, heart, lungs, renal cortex, and plasma. The amount of plasma protein binding is variable depending on species, serum salicylate and albumin concentrations. At lower salicylate concentrations it is 90% protein bound, but only 70% protein bound at higher concentrations. Salicylate is excreted into milk but levels appear to be very low. Salicylate will cross the placenta and fetal levels may actually exceed those found in the mother.

Salicylate is metabolized in the liver primarily by conjugation with glycine and glucuronic acid via glucuronyl transferase. Because cats are deficient in this enzymatic pathway, they have prolonged half-lives (27-45 hours) and are susceptible to accumulating the drug. Minor metabolites formed include gentisic acid, 2,3-dihydroxybenzoic acid, and 2,3,5-trihydroxybenzoic acid. Gentisic acid appears to be the only active metabolite, but because of its low concentrations appears to play an insignificant role therapeutically. The rate of metabolism is determined by both first order kinetics and dose-dependent kinetics depending on the metabolic pathway. Serum half life in dogs is approximately 8 hours, while in humans it averages 1.5 hours. Generally, steady-state serum levels will increase to levels higher (proportionally) than expected with dosage increases. These effects have not been well studied in domestic animals, however.

Salicylate and its metabolites are rapidly excreted by the kidneys by both filtration and renal tubular secretion. Significant tubular reabsorption occurs which is highly pH dependent. Salicylate excretion can be significantly increased by raising urine pH to 5-8. Salicylate and metabolites may be removed using peritoneal

alysis or more rapidly using hemodialysis.

### Contraindications/Precautions/Warnings

Aspirin is contraindicated in patients demonstrating previous hypersensitivity reactions to it or in patients with bleeding ulcers. It is relatively contraindicated in patients with hemorrhagic disorders, asthma, or renal insufficiency.

Because aspirin is highly protein bound to plasma albumin, patients with hypoalbuminemia may require lower dosages to prevent clinical signs of toxicity. Aspirin should be used cautiously with enhanced monitoring in patients with severe hepatic failure or diminished renal function. Because of its effects on platelets, aspirin therapy should be halted, if possible, one week prior to surgical procedures.

Aspirin must be used cautiously in cats because of their inability to rapidly metabolize and excrete salicylates. Clinical signs of toxicity may occur if dosed recklessly or without stringent monitoring. Aspirin should be used cautiously in neonatal animals; adult doses may lead to toxicity.

### Adverse Effects

The most common adverse effect of aspirin at therapeutic doses is gastric (nausea, anorexia, vomiting) or intestinal irritation with varying degrees of occult GI blood loss occurring. The resultant irritation may result in vomiting and/or anorexia. Severe blood loss may result in a secondary anemia or hypoproteinemia. In dogs, plain uncoated aspirin may be more irritating to the gastric mucosa than either buffered aspirin or enteric-coated tablets. Hypersensitivity reactions have been reported in dogs although they are thought to occur rarely. Cats may develop acidosis from aspirin therapy.

### Reproductive/Nursing Safety

Salicylates are possible teratogens and have been shown to delay parturition; their use should be avoided during pregnancy, particularly during the later stages. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

### Overdosage/Acute Toxicity

Clinical signs of acute overdosage in dogs and cats include: depression, vomiting (may be blood tinged), anorexia, hyperthermia, and increased respiratory rate. Initially, a respiratory alkalosis occurs with a compensatory hyperventilation response. A profound metabolic acidosis follows. If treatment is not provided, muscular weakness, pulmonary and cerebral edema, hypernatremia, hypokalemia, ataxia, and seizures may all develop with eventual coma and death.

There were 538 exposures to aspirin reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 481 were dogs with 240 showing clinical signs and 54 cases were cats with 14 showing clinical signs. The remaining 3 cases were made up of 2 birds, and 1 lagomorph that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, panting, hyperthermia, diarrhea, bloody vomitus, and polydipsia. Common findings in cats recorded in decreasing frequency included vomiting. Treatment of acute overdosage initially consists of emptying the gut if ingestion has occurred within 12 hours, giving activated charcoal and an oral cathartic, placing an intravenous line, beginning fluids and drawing appropriate lab work (*e.g.*, blood gases). Some clinicians suggest performing gastric lavage with a 3–5% solution of sodium bicarbonate to delay the absorption of aspirin. A reasonable choice for an intravenous solution to correct dehydration would be dextrose 5% in water. Acidosis treatment and forced alkaline diuresis with sodium bicarbonate should be performed for serious ingestions, but should only be attempted if acid-base status can be monitored. Diuresis may be enhanced by the administration of mannitol (1–2 grams/kg/hr). GI protectant medications should also be administered. Seizures may be controlled with IV diazepam. Treatment of hypoprothrombinemia may be attempted by using phytonadione (2.5 mg/kg divided q8–12h) and ascorbic acid (25 mg parenterally) but ascorbic acid may negate some of the urinary alkalization effects of bicarbonate. Peritoneal dialysis or exchange transfusions may be attempted in very severe ingestions when heroic measures are desired.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aspirin and may be of significance in veterinary patients:

- **DRUGS THAT ALKALINIZE THE URINE** (*e.g.*, acetazolamide, sodium bicarbonate) significantly increase the renal excretion of salicylates; because carbonic anhydrase inhibitors (*e.g.*, acetazolamide, dichlorphenamide) may cause systemic acidosis and increase CNS levels of salicylates, toxicity may occur.
- **AMINOGLYCOSIDES**: Some clinicians feel that aspirin should not be given concomitantly with aminoglycoside antibiotics because of an increased likelihood of nephrotoxicity developing. The actual clinical significance of this interaction is not clear, and the risk versus benefits should be weighed when contemplating therapy.
- **CORTICOSTEROIDS**: May increase the clearance of salicylates, decrease serum levels and increase the risks for GI bleeding. One dog study showed no significant difference in gastric mucosal injury when ultra-low dose (0.5 mg/kg/day) aspirin was added to prednisone therapy. Addition of aspirin did increase the incidence of mild, self-limiting diarrhea (Graham & Leib 2009).
- **DIGOXIN**: In dogs, aspirin has been demonstrated to increase plasma levels of digoxin by decreasing the clearance of the drug.
- **FUROSEMIDE**: May compete with the renal excretion of aspirin and delay its excretion; this may cause clinical signs of toxicity in animals receiving high aspirin doses.
- **HEPARIN or ORAL ANTICOAGULANTS**: Aspirin may increase the risks for bleeding.
- **METHOTREXATE**: Aspirin may displace MTX from plasma proteins increasing the risk for toxicity.
- **NSAIDS**: Increased chances of developing GI ulceration exist. Animals that have been on aspirin therapy that will be replaced with a COX-2 NSAID, should probably have a “wash out” period of 3–10 days between stopping aspirin and starting the NSAID (Bill 2008).
- **PHENOBARBITAL**: May increase the rate of metabolism of aspirin by inducing hepatic enzymes.
- **PROBENECID, SULFINPYRAZONE**: At usual doses, aspirin may antagonize the uricosuric effects of probenecid or sulfinpyrazone
- **SPIRONOLACTONE**: Aspirin may inhibit the diuretic activity of spironolactone
- **TETRACYCLINE**: The antacids in buffered aspirin may chelate tetracycline products if given simultaneously; space doses apart by at least one hour
- **URINARY ACIDIFYING DRUGS (methionine, ammonium chloride, ascorbic acid)**: Can decrease the urinary excretion of salicylates

### Laboratory Considerations

■ At high doses, aspirin may cause false positive results for **urinary glucose** if using the cupric sulfate method (*Cliniast*® Benedict's solution) and false negative

At high doses, aspirin may cause false-positive results for **urinary glucose** if using the cupric sulfate method (*Cumlix®*, Benedict's solution) and false-negative results if using the glucose oxidase method (*Clinistix®* or *Tes-Tape®*).

■ **Urinary ketones** measured by the ferric chloride method (Gerhardt) may be affected if salicylates are in the urine (reddish-color produced). **5-HIAA** determinations by fluorescent methods may be interfered by salicylates in the urine. Falsely elevated **VMA** (vanillylmandelic acid) may be seen with most methods used if salicylates are in the urine. Falsely lowered **VMA** levels may be seen if using the Pisano method.

■ Urinary excretion of **xylose** may be decreased if aspirin is given concurrently. Falsely elevated **serum uric acid** values may be measured if using colorimetric methods.

■ Aspirin can decrease serum concentrations of **total T<sub>4</sub>**.

## Doses

### ■ DOGS:

**Note:** Recommend using buffered varieties of aspirin in dogs

a) For analgesia: 10 mg/kg PO q12h (Lascelles 2003)

b) As an antiinflammatory/antirheumatic: 25 mg/kg PO q8h (Holland & Chastain 1995)

c) For antipyrexia: 10 mg/kg PO twice daily (Holland & Chastain 1995)

d) Post-Adulticide therapy for heartworm disease: 7–10 mg/kg PO once a day (Calvert 1987)

To decrease platelet aggregation; as an antithrombotic:

a) For adjunctive therapy in IMHA: 0.5 mg/kg PO twice daily. At this low dose risk for gastric ulceration is low, but adding misoprostol (2–5 micrograms/kg PO three times) may reduce the risk. (Noonan 2009)

b) For adjunctive therapy of glomerular disease: 0.5 mg/kg PO q24h (DiBartola & Chew 2006)

c) For adjunctive therapy with azathioprine and glucocorticoids for immune-mediated hemolytic anemia: 0.5 mg/kg PO once daily (Weinkle *et al.* 2004)

As an analgesic/antiinflammatory prior to elective intraocular surgery:

a) 6.5 mg/kg two to three times daily (Wyman 1986)

### ■ CATS:

For analgesia/antipyrexia/antiinflammatory:

a) One “baby” aspirin (81 mg) PO every 2–3 days (Bill 2008)

b) 10 mg/kg PO every other day (Holland & Chastain, 1995)

c) 10 mg/kg PO q48–72h in food (Hardie, 2000)

As an antithrombotic agent:

a) For prophylaxis of arterial thromboembolism (ATE): 5 mg (total dose) per cat PO q72hours (every 3rd day) (Smith *et al.* 2003), (Smith 2009)

b) For prophylaxis of arterial thromboembolism: 81 mg (total dose; one “baby” aspirin) q72hours (every 3rd day). Likely a weaker, but less expensive option than clopidogrel/LMWH. Generally, aspirin therapy is recommended in all cats with atrial enlargement and cardiomyopathy. (Meurs 2006)

c) For prevention of thromboembolism: High dose: 40 mg per cat PO q72h, or Low dose: 5 mg per cat PO q72h. (Fuentes 2009)

### ■ FERRETS:

a) 10–20 mg/kg PO once daily (has short duration of activity) (Williams 2000)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** 5–20 mg/kg PO once daily for low grade analgesia (Ivey & Morrisey 2000)

b) **Mice, Rats, Gerbils, Hamsters:** 100–150 mg/kg PO q4h. **Guinea pigs:** 87 mg/kg PO (Adamcak & Otten 2000)

### ■ CATTLE:

For analgesia/antipyrexia:

a) 100 mg/kg PO q12h (Walz 2006)

b) Mature Cattle: two to four 240 grain boluses PO; Calves: one to two 240 grain boluses, allow animals to drink water after administration (Label directions; Vedco Brand)

### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

For analgesia:

a) Mature Horses: two to four 240 grain boluses PO; Foals: one to two 240 grain boluses; allow animals to drink water after administration (Label directions–Vedco Brand)

b) 25 mg/kg PO q12h initially, then 10 mg/kg once daily (Jenkins 1987)

c) 15–100 mg/kg PO once daily (Robinson 1987)

For anti-platelet activity as an adjunctive treatment of laminitis:

a) 5–10 mg/kg PO q24–48 hours or 20 mg/kg PO every 4–5 days (Brumbaugh *et al.* 1999)

### ■ SWINE:

For analgesia:

a) 10 mg/kg q4h PO (Jenkins 1987), (Koritz 1986)

b) 10 mg/kg q6h PO (Davis 1979)

### ■ AVIAN:

a) 5 grams in 250 mL of water as sole water source (Clubb 1986) **Note:** Because of the significant hydrolysis that will occur, this solution should be freshly prepared every 12 hours if stored at room temperature or every 4 days if kept refrigerated at 5° C.

## Monitoring

- Analgesic effect &/or antipyretic effect
- Bleeding times if indicated
- PCV and stool guaiac tests if indicated

## Client Information

- Contact veterinarian if symptoms of GI bleeding or distress occur (black, tarry feces; anorexia or vomiting, etc.).
- Because aspirin is a very old drug, formal approvals from the FDA for its use in animals have not been required. There is no listed meat or milk withdrawal times listed for food-producing animals but because there are salicylate-sensitive people, in the interest of public health, this author suggests a minimum of 1 day withdrawal time for either milk or meat.

## Chemistry/Synonyms

Aspirin, sometimes known as acetylsalicylic acid or ASA, is the salicylate ester of acetic acid. The compound occurs as a white, crystalline powder or tabular or needle-like crystals. It is a weak acid with a pKa of 3.5. Aspirin is slightly soluble in water and is freely soluble in alcohol. Each gram of aspirin contains approximately 760 mg of salicylate.

Aspirin may also be known as: ASA, acetylsal acid, acetylsalicylic acid, acidum acetylsalicylicum, polopiryna, or salicylic acid acetate; many trade names are available.

## Storage/Stability

Aspirin tablets should be stored in tight, moisture resistant containers. Do not use products past the expiration date or if a strong vinegar-like odor is noted emitting from the bottle.

Aspirin is stable in dry air, but readily hydrolyzes to acetate and salicylate when exposed to water or moist air; it will then exude a strong vinegar-like odor. The addition of heat will speed the rate of hydrolysis. In aqueous solutions, aspirin is most stable at pH's of 2–3 and least stable at pH's below 2 or greater than 8. Should an aqueous solution be desirable as a dosage form, the commercial product *Alka-Seltzer*® will remain stable for 10 hours at room temperature in solution.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Aspirin is hydrolyzed by water to degradative byproducts, acetic acid and salicylic acid.

Effervescent buffered aspirin tablets (*Alka-Seltzer*®) dissolved in water are demonstrated to be stable for 10 hours at room temperature and for 90 hours if refrigerated. Although pharmacists compound aspirin suspensions in fixed oils, the long term stability of these preparations has not been determined.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

**Note:** Aspirin products may not be FDA-approved.

Aspirin Tablets (Enteric-Coated): 81 mg; (Hartz); (OTC). Labeled for use in dogs.

Aspirin Tablets (Buffered, Microencapsulated, Chewable for dogs): 150 mg & 450 mg; *Canine Aspirin Chewable Tablets for Small & Medium* (150 mg) or *Large Dogs*® (450 mg) (Pala-Tech); (OTC). Labeled for use in dogs.

Aspirin Tablets 60 grain (3.9 g): Aspirin 60 Grain (Butler); (OTC) and (Vedco); (Rx); Rx is labeled for use in horses, cattle, sheep and swine; not for use in horses intended for food or in lactating dairy animals.

Aspirin Boluses 240 grain (15.6 g): Labeled for use in horses, foals, cattle and calves; not for use in lactating animals. Aspirin 240 Grain Boluses, Aspirin Bolus (various); (OTC)

Aspirin Boluses 480 grain (31.2 g). Labeled for use in mature horses, & cattle. Aspirin 480 Grain Boluses (various); (OTC)

Oral Aspirin Gel: 250 mg/mL in 30 mL: *Aspir-Flex*® *Aspirin Gel for Small and Medium Dogs* (Durvet); 500 mg/1 mL in 30 mL: *Aspir-Flex*® *Aspirin Gel for Large Dogs* (Durvet); (OTC). Labeled for use in dogs.

Aspirin Powder: 1 lb. (various); (OTC); Aspirin Powder Molasses-Flavored 50% acetylsalicylic acid in base (Butler); Aspirin USP 204 g/lb (apple flavored) (Neogen); Acetylsalicylic acid; (OTC)

Aspirin Granules: 2.5 gram per 39 mL scoop (apple and molasses flavor); *Arthri-Eze Aspirin Granules*® (Durvet); (OTC); Labeled for use in horses

Aspirin Liquid Concentrate (equiv to 12% aspirin) for Dilution in Drinking Water in 32 oz btl. (AgriPharm, First Priority); (OTC). Labeled for addition to drinking water for swine, poultry, beef and dairy cattle

There are no listed meat or milk withdrawal times listed for food-producing animals, but because there are salicylate-sensitive people, in the interest of public health, this author suggests a minimum of 1 day withdrawal time for either milk or meat. For further guidance with determining use and withdrawal times, contact FARAD (see Phone Numbers & Websites in the appendix for contact information).

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

**Note:** Many dosage forms and brand names are commercially available; the following is an abbreviated list of some products that have been used for veterinary indications:

Aspirin, Chewable Tablets: 81 mg (1.25 grains); *Bayer*® *Children's Aspirin* (Bayer); *St. Joseph*® *Adult Chewable Aspirin* (Schering-Plough); (OTC)

Aspirin, Tablets; plain uncoated; 325 mg (5 grain), & 500 mg (7.8 grain); *Genuine* and *Maximum Bayer*® *Aspirin Tablets* and *Caplets* (Bayer); *Empirin*® (GlaxoWellcome); *Arthritis Foundation*® *Pain Reliever* (McNeil-CPC); *Norwich*® *Regular Strength* (Lee); *Norwich Extra-Strength*® (Procter & Gamble); generic; (OTC)

(OTC)

Aspirin Tablets, enteric coated: 81 mg, 165 mg, 325 mg, 500 mg, 650 mg, & 800 mg; *Ecotrin® Adult Low Strength* (GlaxoSmithKline Consumer Healthcare); *Halfprin 81®* and *1/2 Halfprin®* (Kramer), *Heartline®* (BDI), *Ecotrin® Tablets & Caplets* and *Ecotrin® Maximum Strength Caplets* (SmithKline Beecham); *Extra Strength Bayer® Enteric 500 Aspirin* (Bayer); generic; (OTC)

Aspirin Extended-controlled Release Tablets: 81 mg, 650 mg, 800 mg & 975 mg; *Extended Release Bayer® 8-hour Caplets* (Bayer); (OTC), *ZORprin®* (PAR); (Rx), *Bayer® Low Adult Strength* (Bayer); generic; (OTC)

Aspirin, Tablets; buffered uncoated; 325 mg (5 grain), with aluminum &/or magnesium salts; *Tri-Buffered Bufferin Tablets* and *Caplets®* (Bristol-Myers Squibb); *Bayer® Buffered Aspirin* (Bayer); *Asprimox®* and *Asprimox® Extra Protection for Arthritis* (Invamed); 500 mg with calcium carbonate, magnesium carbonate, & magnesium oxide; *Extra Strength Bayer® Plus Caplets* (Bayer); *Bufferin®* (Bristol-Myers); 500 mg with 237 mg calcium carbonate, 33 mg magnesium hydroxide, 33 mg aluminum hydroxide; *Ascriptin® Maximum Strength* (Novartis); 500 mg with 100 mg magnesium hydroxide and 27 mg aluminum hydroxide; *Arthritis Pain Formula®* (Whitehall); 325 mg with 75 mg aluminum hydroxide, 75 mg magnesium hydroxide and calcium carbonate; *Asprimox Extra Protection for Arthritis Pain®* (Invamed); generic; (OTC)

Aspirin Tablets: buffered coated: 325 mg & 500 mg. *Adprin-B®* (Pfeiffer); *Asprimox®* (Invamed); *Magnaprin®* and *Magnaprin® Arthritis Strength Captabs®* (Rugby); *Ascriptin®* and *Ascriptin® Extra Strength* (Rhône-Poulenc Rorer), *Bufferin®* (Bristol Myers); generic; (OTC)

Rectal suppositories, chewing gum and effervescent oral dosage forms are also available commercially for human use.

## ATENOLOL

(a-ten-oh-lol) **Tenormin®**

**BETA-ADRENERGIC BLOCKER**

### Prescriber Highlights

- **Beta-blocker that is used primarily for hypertension & tachyarrhythmias in small animals**
- **Has minimal beta-2 activity at usual doses; comparatively safe to use in asthmatic patients**
- **Contraindicated in patients with bradycardic arrhythmias, or hypersensitivity to it**
- **Negative inotrope so must be used with caution in patients with CHF; use with caution in renal failure patients & those with sinus node dysfunction**
- **Higher dosages may mask clinical signs of hyperthyroidism or hypoglycemia; may cause hyper- or hypoglycemia—use with caution in brittle diabetics**
- **Primary adverse effects are lethargy, hypotension, or diarrhea**
- **If discontinuing, recommend withdrawing gradually**

---

## Uses/Indications

Atenolol may be useful in the treatment of supraventricular tachyarrhythmias, premature ventricular contractions (PVC's, VPC's), systemic hypertension and in treating cats with hypertrophic cardiomyopathy without accompanying pulmonary edema. Atenolol is relatively safe to use in animals with bronchospastic disease.

## Pharmacology/Actions

Atenolol is a relatively specific Beta1-blocker. At higher dosages, this specificity may be lost and Beta2 blockade can occur. Atenolol does not possess any intrinsic sympathomimetic activity like pindolol nor does it possess membrane-stabilizing activity like pindolol or propranolol. Cardiovascular effects secondary to atenolol's negative inotropic and chronotropic actions include: decreased sinus heart rate, slowed AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia.

## Pharmacokinetics

Only about 50–60% of an oral dose is absorbed in humans, but is absorbed rapidly. In cats, it is reported to have a bioavailability of approximately 90%. The drug has very low protein binding characteristics (5–15%) and is distributed well into most tissues. Atenolol has low lipid solubility and unlike propranolol, only small amounts of atenolol are distributed into the CNS. Atenolol crosses the placenta and levels in milk are higher than those found in plasma. Atenolol is minimally biotransformed in the liver; 40–50% is excreted unchanged in the urine and the bulk of the remainder is excreted in the feces unchanged (unabsorbed drug). Reported half-lives: dogs

### Contraindications/Precautions/Warnings

Atenolol is contraindicated in patients with overt heart failure, hypersensitivity to this class of agents, greater than first-degree heart block, or sinus bradycardia. Non-specific beta-blockers are generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blocker therapy. They are also relatively contraindicated in patients with bronchospastic lung disease. Atenolol may reduce survival or cause increased morbidity in cats with hypertrophic cardiomyopathy, particularly those with accompanying pulmonary edema.

Atenolol should be used cautiously in patients with significant renal insufficiency or sinus node dysfunction.

Atenolol (at high dosages) can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients.

Atenolol can mask the clinical signs associated with thyrotoxicosis, however, it may be used clinically to treat the clinical signs associated with this condition.

### Adverse Effects

It is reported that adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Adverse effects considered clinically relevant include: bradycardia, inappetence, lethargy and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction (less so with Beta1 specific drugs like atenolol). Syncope and diarrhea have also been reported in canine patients with beta-blockers. Lethargy and hypotension may be noted within 1 hour of administration.

Exacerbation of symptoms has been reported following abrupt cessation of beta-blockers in humans. It is recommended to withdraw therapy gradually in patients who have been receiving the drug chronically.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

There were 219 exposures to atenolol reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 159 were dogs with 19 showing clinical signs, and the remaining 60 cases were cats with 9 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy and vomiting. Common findings in cats recorded in decreasing frequency included lethargy and vomiting.

Humans have apparently survived dosages of up to 5 grams. The most predominant clinical signs expected would be extensions of the drug's pharmacologic effects: hypotension, bradycardia, bronchospasm, cardiac failure, hypoglycemia, and hyperkalemia.

If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered. Monitor: ECG, blood glucose, potassium and, if possible, blood pressure. Treatment of the cardiovascular effects is symptomatic. Use fluids and pressor agents (dopamine or norepinephrine) to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol given cautiously has been recommended. Insulin and dextrose may be needed for hyperkalemia and hypoglycemia. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with a digitalis glycoside, diuretics and oxygen. Glucagon (5–10 mg IV; human dose) may increase heart rate and blood pressure and reduce the cardiodepressant effects of atenolol.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atenolol and may be of significance in veterinary patients:

- **ANESTHETICS (myocardial depressant):** Additive myocardial depression may occur with the concurrent use of atenolol and myocardial depressant anesthetic agents
- **CALCIUM-CHANNEL BLOCKERS** (*e.g.*, **diltiazem, verapamil, amlodipine**): Concurrent use of beta-blockers with calcium channel blockers (or other negative inotropics) should be done with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **CLONIDINE:** Atenolol may exacerbate rebound hypertension after stopping clonidine therapy
- **FUROSEMIDE, HYDRALAZINE OR OTHER HYPOTENSIVE PRODUCING DRUGS:** May increase the hypotensive effects of atenolol
- **PHENOTHIAZINES:** With atenolol may exhibit enhanced hypotensive effects
- **RESERPINE:** Potential for additive effects (hypotension, bradycardia)
- **SYMPATHOMIMETICS (metaproterenol, terbutaline, beta-effects of epinephrine, phenylpropanolamine, etc.):** May have their actions blocked by atenolol and they may, in turn, reduce the efficacy of atenolol

### Doses

#### ■ DOGS:

For indications where beta-blockade may be indicated (cardiac arrhythmias, obstructive heart disease, hypertension, myocardial infarction, etc.):

- a) 0.3–0.6 mg/kg PO q12h; for refractory VTach combine with mexiletine (5–8 mg/kg PO q8h) (Smith 2009)
- b) For moderate to severe sub-valvular aortic stenosis (SAS): 0.5–1 mg/kg PO twice a day (Meurs 2006)
- c) To attempt to decrease syncopal episodes associated with pulmonic stenosis: 0.25–1 mg/kg PO twice a day (Meurs 2006)
- d) For hypertension: 0.25–1 mg/kg PO q12h (Stepien 2006)

#### ■ CATS:

For treatment of hypertension or cardiac conditions (*e.g.*, hypertrophic cardiomyopathy) where beta blockade may be indicated:

- a) 3 mg/kg PO q12h (or 6.25–12.5 mg total dose) PO q12h (Stepien 2006)
- b) 6.25–12.5 mg (total dose per cat) q12h (Kittleson 2009)
- c) 6.25–12.5 mg (total dose) PO q12–24h. Treatment of choice for hyperthyroid, hypertensive cats. Beta-blockers are rarely sufficient alone to treat hypertension due to other causes. (Waddell 2005)

#### ■ FERRETS:

For hypertrophic cardiomyopathy:

For hypertrophic cardiomyopathy.

- a) 6.25 mg (total dose) PO once daily (Williams 2000)
- b) 3.13–6.25 mg (total dose) PO once daily (Johnson-Delaney 2005)

## Monitoring

- Cardiac function, pulse rate, ECG if necessary, BP if indicated
- Toxicity (see Adverse Effects/Overdosage)

## Client Information

- To be effective, the animal must receive all doses as prescribed. Notify veterinarian if animal becomes lethargic or becomes exercise intolerant; develops shortness of breath or cough; or develops a change in behavior or attitude. Do not stop therapy without first conferring with veterinarian.

## Chemistry/Synonyms

A beta1-adrenergic blocking agent, atenolol occurs as a white, crystalline powder. At 37°C, 26.5 mg are soluble in 1 mL of water. The pH of the commercially available injection is adjusted to 5.5–6.5.

Atenolol may also be known as atenololum, or ICI-66082; many trade names are available.

## Storage/Stability

Tablets should be stored at room temperature and protected from heat, light and moisture.

## Compatibility/Compounding Considerations

Atenolol tablets may be crushed or split/cut into ¼s or ½s for appropriate dosing.

**Compounded preparation stability:** Atenolol oral suspensions should not be compounded with sugar-containing vehicles. Atenolol oral suspension compounded from either active pharmaceutical ingredient (API) or commercially available tablets has been published (Patel, 1997). Triturating an appropriate amount of API or tablets with equal volumes of *Ora-Plus*® and *Ora-Sweet*® SF yields a 2 mg/mL oral suspension that retains >90% potency for 90 days stored at both 5°C and 25°C. This investigation also reveals that the presence of sugars (*Ora-Sweet*® and simple syrup) reduces the potency of compounded atenolol suspensions to <90% in 7–14 days after compounding. Atenolol preparations are most stable at pH 4. Atenolol should be stored protected from light as exposure to ultraviolet light results in drug decomposition at all pH ranges.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Atenolol Oral Tablets: 25 mg, 50 mg, & 100 mg; *Tenormin*® (AstraZeneca); generic; (Rx)

Also available in an oral fixed dose combination product with chlorthalidone.

---

## ATIPAMEZOLE HCL

(at-i-pam-a-zole) Antisedan®

ALPHA-2 ADRENERGIC ANTAGONIST

### Prescriber Highlights

- **Alpha2 adrenergic antagonist; antagonizes agonists such as medetomidine or xylazine**
  - **No safety data on use in pregnant or lactating animals**
  - **May reverse effects rapidly, including analgesia; animals should be observed & protected from self-harm or causing harm to others**
  - **Adverse Effects may include vomiting, diarrhea, hypersalivation, tremors, or excitation**
- 

## Uses/Indications

Atipamezole is labeled for use as a reversal agent for medetomidine and dexmedetomidine. It potentially could be useful for reversal of other alpha2-adrenergic agonists as well (*e.g.*, amitraz, xylazine, clonidine, tizanidine, brimonidine).

## Pharmacology/Actions

Atipamezole competitively inhibits alpha2-adrenergic receptors, thereby acting as a reversal agent for alpha2-adrenergic agonists (*e.g.*, medetomidine). Net pharmacologic effects are to reduce sedation, decrease blood pressure, increase heart and respiratory rates, and reduce the analgesic effects of alpha2-adrenergic

agonists. Atipamezole may antagonize the diuretic action of xylazine in dogs (Talukder *et al.* 2009).

## Pharmacokinetics

After IM administration in the dog, peak plasma levels occur in about 10 minutes. Atipamezole is apparently metabolized in the liver to compounds that are eliminated in the urine. The drug has an average plasma elimination half-life of about 2–3 hours.

## Contraindications/Precautions/Warnings

While the manufacturer lists no absolute contraindications to the use of atipamezole, the drug is not recommended in pregnant or lactating animals due to the lack of data establishing safety. Caution should be used in administration of anesthetic agents to elderly or debilitated animals.

When used as a reversal agent (antidote) for alpha<sub>2</sub>-agonist toxicity, atipamezole's effects may subside before non-toxic levels of the offending agent are reached; repeat dosing may be necessary.

Do not give IV to reptiles as profound hypotension can occur.

## Adverse Effects

Potential adverse effects include occasional vomiting, diarrhea, hypersalivation, tremors, and brief excitation or apprehensiveness.

Because reversal can occur rapidly, care should be exercised as animals emerging from sedation and analgesia may exhibit apprehensive or aggressive behaviors. After reversal, animals should be protected from falling. Additional analgesia (*e.g.*, butorphanol) should be considered, particularly after painful procedures.

In reptiles, intravenous administration reportedly can cause profound hypotension.

## Reproductive/Nursing Safety

The manufacturer states that the drug is not recommended in pregnant or lactating animals, or in animals intended for breeding due to lack of data establishing safety in these animals. No other data was noted.

## Overdosage/Acute Toxicity

Dogs receiving up to 10X the listed dosage apparently tolerated the drug without major effects. When overdosed, dose related effects seen included panting, excitement, trembling, vomiting, soft or liquid feces, vasodilatation of sclera and some muscle injury at the IM injection site. Specific overdose therapy should generally not be necessary.

## Drug Interactions

The manufacturer states that information on the use of atipamezole with other drugs is lacking, therefore, caution should be taken when using with other drugs (other than medetomidine). The following drug interactions have either been reported or are theoretical in humans or animals receiving atipamezole and may be of significance in veterinary patients:

■ **ALPHA<sub>1</sub>-ADRENERGIC BLOCKERS** (*e.g.*, prazosin): Atipamezole is a relatively specific alpha<sub>2</sub> blocker it can also partially block alpha<sub>1</sub> receptors and reduce the effects of prazosin

■ **ALPHA<sub>2</sub>-ADRENERGICS AGONISTS** (*e.g.*, detomidine, clonidine, brimonidine, xylazine, amitraz, etc.): Atipamezole can reduce the effects (toxic or therapeutic) of these agents

## Doses

### ■ DOGS:

For reversal of medetomidine:

a) Give IM an equal volume of *Antisedan*® and *Domitor*® is administered (mL per mL). The actual concentration of *Antisedan*® will be 5X that of *Domitor*®, as *Antisedan*® is 5 mg/mL versus *Domitor*®'s 1 mg/mL. (Package Insert; *Antisedan*®—Pfizer)

b) As above, but may give IV as well as IM. If it has been at least 45 minutes since medetomidine was given, may give atipamezole at half the volume of medetomidine if administered IV. If after 10–15 minutes an IM dose of atipamezole has not seemed to reverse the effects of medetomidine, an additional dose of atipamezole at 1/2 the volume of the medetomidine dose may be given. (McGrath & Ko 1997)

For reversal of dexmedetomidine:

a) 0.2 mg/kg IM or IV (Teixereia Neto 2009)

For treatment of amitraz toxicity:

a) 50 micrograms/kg IM; doses may need to be repeated every 4-6 hours as the half life of amitraz is longer than atipamezole in dogs. (Hugnet, Buronrosse *et al.* 1996), (Papich 2009)

### ■ CATS:

a) For reversal of medetomidine as part of a medetomidine/butorphanol or buprenorphine/ketamine/carprofen or meloxicam anesthesia/analgesia injectable combination: Use an equal volume IM of atipamezole as medetomidine was used in the combination. (Ko 2005)

b) For reversal of dexmedetomidine: 0.2 mg/kg IM or IV (Teixereia Neto 2009)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** For medetomidine reversal: 0.5 mg/kg IM or SC; 0.25 mg/kg IV (Vella 2009)

b) **Mice, Rats, Gerbils, Hamsters, Guinea pigs:** To reverse xylazine or medetomidine: 0.1–1 mg/kg IM, IP, IV or SC (Adamcak & Otten 2000)

### ■ RUMINANTS:

a) For reversal of alpha<sub>2</sub>-adrenergic agonists in bovine, new world camelids, ovine and caprine species: 0.02–0.1 mg/kg IV to effect (Haskell 2005)

b) Small ruminants, camelids: 0.1–0.2 mg/kg slow IV or IM; as a rule of thumb, if induction included ketamine or Telazol do not reverse alpha<sub>2</sub> sooner than 30 and ideally 60 minutes after induction. This will allow enough of the ketamine or tiletamine to be metabolized. (Snyder 2009), (Wolff 2009)

### ■ BIRDS:

a) As a reversal agent for alpha<sub>2</sub>-adrenergic agonists (*e.g.*, xylazine, detomidine, etc.): 0.5 mg/kg IM (Clyde & Paul-Murphy 2000)

## ■ REPTILES:

a) Reversal of all dosages ketamine/medetomidine combination (see ketamine or medetomidine monographs) with atipamezole is 4–5 times the medetomidine dose (Heard 1999). Reversal may take longer (up to one hour) in reptiles than in other species; Do NOT give IV as profound hypotension can occur (Mehler 2009).

## ■ ZOO, EXOTIC, WILDLIFE SPECIES:

For use of atipamezole in zoo, exotic and wildlife medicine refer to specific references, including:

- Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.
- Handbook of Wildlife Chemical Immobilization, 3rd Ed*. Kreeger, T.J. and J.M. Arnemo. 2007.
- Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995
- Exotic Animal Formulary, 3rd Ed*. Carpenter, J.W., Saunders. 2005
- The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

## Monitoring

- Level of sedation and analgesia
- Heart rate
- Body temperature

## Client Information

- Atipamezole should be administered by veterinary professionals only. Clients should be informed that occasionally vomiting, diarrhea, hypersalivation, excitation and tremors may be seen after atipamezole administration. Should these be severe or persist after leaving the clinic, clients should contact the veterinarian.

## Chemistry/Synonyms

Atipamezole is an imidazole alpha2-adrenergic antagonist. The injection is a clear, colorless solution.

Atipamezole HCl may also be known as MPV-1248 or *Antisedan*®.

## Storage/Stability

Atipamezole HCl injection should be stored at room temperature (15°–30°C) and protected from light.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Atipamezole HCl for Injection: 5 mg/mL in 10 mL multidose vials; *Antisedan*® (Pfizer); (Rx). FDA-approved for use in dogs.

**HUMAN-LABELED PRODUCTS:** None

---

## ATOVAQUONE

(ah-toe-va-kwone) *Mepron*®

ORAL ANTIPROTOZOAL AGENT

### Prescriber Highlights

- **Atovaquone (with azithromycin) appears effective in treating dogs with *Babesia gibsoni* infections. Alone, it is a second-line agent (after trimethoprim/sulfa) for pneumocystosis in dogs.**
- **In combination with azithromycin, used to treat cytauxzoonosis in cats**
- **Limited use thus far; appears well-tolerated by dogs**
- **Treatment may be quite expensive**

---

## Uses/Indications

Atovaquone (with azithromycin) appears effective in treating dogs with *Babesia gibsoni* (Asian genotype) infections, particularly in dogs not immunosuppressed or splenectomized. Atovaquone may be of benefit for treating pneumocystosis in dogs, but it is considered second line therapy after potentiated sulfonamides.

Atovaquone (with azithromycin) may be of benefit in treating *Cytauxzoon felis* infections in cats

Atovaquone (with azithromycin) may be of benefit in treating *Cytauxzoon* infections in cats.

## Pharmacology/Actions

Atovaquone's antiprotozoal mechanism of action is not completely understood. It is believed that the hydroxynaphthoquinones, like atovaquone, selectively inhibit protozoan mitochondrial electron transport causing inhibition of *de novo* pyrimidine synthesis. Unlike mammalian cells, certain protozoa cannot salvage preformed pyrimidines.

## Pharmacokinetics

Pharmacokinetic data for dogs or cats was not located. In humans after oral administration, bioavailability ranges from 23–47%. The presence of food, particularly high in fat, can increase bioavailability significantly (2+ fold over fasted administration). The drug is highly bound to human plasma proteins (99.9%) and levels in the CSF are approximately 1% of those found in plasma. Elimination half-life in people is about 70 hours presumably due to enterohepatic recycling. There may be limited hepatic metabolism, but the bulk of absorbed drug is eventually eliminated unchanged in the feces.

## Contraindications/Precautions/Warnings

No absolute contraindications for using atovaquone in dogs or cats have been documented. Animals with malabsorption syndromes or that cannot take the drug with food should have alternate therapies considered.

The drug is contraindicated in human patients that develop or have a prior history of hypersensitivity reactions to the drug.

## Reproductive/Nursing Safety

Studies in pregnant rats with atovaquone plasma levels approximately 2–3 times those found in humans receiving therapeutic dosages revealed no increase in teratogenicity. Similar studies in rabbits showed increased maternal and fetal toxicity (decreased fetal growth and increased early fetal resorption). In humans, the FDA categorizes atovaquone as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Little information is available on the safety of this drug during lactation. In rats, milk levels were approximately  $\frac{1}{3}$  those found in maternal plasma. It is unlikely atovaquone in milk poses much risk to nursing puppies.

## Adverse Effects

Atovaquone use in dogs and cats has been limited and the adverse effect profile is not well known. One study (Birkenheuer, AJ *et al.* 2004) using atovaquone and azithromycin for treating *Babesia gibsoni* infections in 10 dogs reported that no adverse effects were noted. The combination product containing atovaquone and proguanil (*Malarone*®) reportedly causes severe gastrointestinal effects in dogs.

In humans treated with atovaquone, rashes (up to 39% of treated patients) and gastrointestinal effects (nausea, vomiting, diarrhea) are the most frequently reported adverse effects. Rashes or diarrhea may necessitate discontinuation of therapy. Other adverse effects reported in humans include hypersensitivity reactions, increased liver enzymes, CNS effects (headache, dizziness, insomnia), hyperglycemia, hyponatremia, fever, neutropenia, and anemia.

## Overdosage/Acute Toxicity

Limited information is available for any species. Minimum toxic doses have not been established; laboratory animals have tolerated doses up to 31.5 grams. The current recommendation for treating overdoses is basically symptomatic and supportive.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atovaquone and may be of significance in veterinary patients:

- **METOCLOPRAMIDE:** Can decrease atovaquone plasma concentrations
- **TETRACYCLINE:** Can decrease atovaquone plasma concentrations
- **RIFAMPIN:** Can decrease atovaquone plasma concentrations

## Laboratory Considerations

- No specific issues; see Monitoring for recommendations for testing for efficacy

## Doses

### ■ DOGS:

- a) For *Babesia gibsoni* (Asian genotype) infections: Atovaquone 13.3 mg/kg PO q8h and Azithromycin 10 mg/kg PO once daily. Give both drugs for 10 days. Reserve immunosuppressive therapy for cases that are not rapidly responding (3–5 days) to anti-protozoal therapy. (Birkenheuer, AJ *et al.* 2004), (Birkenheuer, A 2006)
- b) For Pneumocystosis: 15 mg/kg PO once daily for 3 weeks. (Greene *et al.* 2006)

### ■ CATS:

- a) For Cytauxzoonosis (*Cytauxzoon felis*): Atovaquone 15 mg/kg PO q8h with azithromycin 10 mg/kg PO q24h. All cases were treated with IV fluids and most received heparin. (Birkenheuer, A *et al.* 2008)

## Monitoring

- Monitoring for therapy for *Babesia gibsoni* in dogs should include surveillance for potential adverse effects and signs for clinical efficacy, including monitoring serial CBCs
- Severe cases may have elevated BUN or liver enzymes, and hypokalemia
- Current recommendation for determining “clearing” of the organism (*B. gibsoni*) is to perform a PCR test at 60 days and 90 days post-therapy

## Client Information

- Store medication at room temperature and away from bright light

Before using, shake bottle gently

- To increase the absorption from the GI tract, give with food high in fat (e.g., ice cream, tuna oil, butter, meat fat)
- Adverse effect profile in dogs and cats for this medication is not well known
- Report any significant effects such as rash, or severe or persistent vomiting or diarrhea, to the veterinarian

### Chemistry/Synonyms

Atovaquone is a synthetic, hydroxy-1,4-naphthoquinone antiprotozoal agent. It occurs as a yellow powder that is highly lipid soluble, insoluble in water and slightly soluble in alcohol.

Atovaquone may also be known as: BW-556C, Atovacuona, Atovakvon, Atovakvoni, Atovaquonnum, *Malani*®, *Mepron*®, or *Wellvone*®.

### Storage/Stability

The commercially available oral suspension should be stored at room temperature (15–25°C) in tight containers and protected from bright light; do not freeze.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Atovaquone Oral Suspension: 150 mg/mL in 210 mL bottles; citrus flavor; *Mepron*® (GlaxoWellcome); (Rx)

A tablet dosage form was previously available, but was discontinued when the oral suspension was approved by FDA; the suspension has much better oral bioavailability in humans. A combination tablet product containing atovaquone and proguanil HCl (*Malarone*®) is available that has labeled indications (human) for malaria prophylaxis and treatment. This combination has reportedly caused significant GI adverse effects in dogs.

---

## ATRACURIUM BESYLATE

(a-tra-cure-ee-um) Tracrium®

NONDEPOLARIZING NEUROMUSCULAR BLOCKER

### Prescriber Highlights

- **Non-depolarizing neuromuscular blocking agent; minimal cardiovascular effects; valuable in critically ill patients who cannot receive standard inhalant anesthesia concentrations**
- **Should never be given as a sole agent; has no sedative or analgesic effects**
- **More potent in horses than other species**
- **Relatively contraindicated in patients with myasthenia gravis, hypersensitivity to it**
- **Less incidence of histamine release than tubocurarine or metocurine**
- **Potential drug interactions**

---

### Uses/Indications

Atracurium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and also to facilitate endotracheal intubation. Atracurium can be used in patients with significant renal or hepatic disease. It is valuable to paralyze critically ill patients when very low settings, or no inhalant anesthesia can be used.

### Pharmacology/Actions

Atracurium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor end-plate thereby inhibiting the effects of acetylcholine. Atracurium is considered ¼ to ⅓ as potent as pancuronium. In horses, atracurium is more potent than in other species tested and more potent than other nondepolarizing muscle relaxants studied.

Atracurium does not provide any analgesia or sedation.

Neuromuscular blockade (NMB) can be variably potentiated when used with different general anesthetics. A study in dogs, demonstrated that when compared with propofol, sevoflurane prolonged atracurium-induced NMB by about 15 minutes (Kastrup *et al.* 2005).

At usual doses, atracurium exhibits minimal cardiovascular effects, unlike most other nondepolarizing neuromuscular blockers. A related compound, cisatracurium (*Nimbex*®) has even less cardiovascular effects in cats than does atracurium. While atracurium can stimulate histamine release, it is considered to cause less histamine release than either tubocurarine or metocurine. In humans, less than one percent of patients receiving atracurium exhibit clinically significant adverse reactions or histamine release.

### Pharmacokinetics

After IV injection, maximal neuromuscular blockade generally occurs within 3–5 minutes. The duration of maximal blockade increases as the dosage increases. Systemic alkalosis may diminish the degree and duration of blockade; acidosis potentiates it. In conjunction with balanced anesthesia, the duration of blockade

generally persists for 20–35 minutes. Recovery times do not appreciably change after giving maintenance doses, so predictable blocking effects can be attained when the drug is administered at regular intervals.

Atracurium is metabolized by ester hydrolysis and Hofmann elimination that occur independently of renal or hepatic function. Physiologic pH and temperature can affect elimination of atracurium. Increased body temperature can enhance the elimination of the drug. Ester hydrolysis is enhanced by decreases in pH, while Hofmann elimination is reduced by decreases in pH.

### Contraindications/Precautions/Warnings

Atracurium is contraindicated in patients who are hypersensitive to it. Because it may rarely cause significant release of histamine, it should be used with caution in patients where this would be hazardous (severe cardiovascular disease, asthma, etc.). Atracurium has minimal cardiac effects and will not counteract the bradycardia or vagal stimulation induced by other agents. Use of neuromuscular blocking agents must be done with extreme caution, or not at all, in patients suffering from myasthenia gravis. Atracurium has no analgesic or sedative/anesthetic actions. To provide amnesia in critically ill patients, when no inhalant anesthesia can be used, midazolam should be considered. Either intermittent boluses (0.1 mg/kg IV every 20–30 minutes) or a continuous IV infusion (0.1 mg/kg/hr) of midazolam has been recommended (Spelts 2009).

It is not known whether this drug is excreted in milk. Safety for use in the nursing mother has not been established.

### Adverse Effects

Clinically significant adverse effects are apparently quite rare in patients (<1% in humans) receiving recommended doses of atracurium and usually are secondary to histamine release. They can include: allergic reactions, inadequate or prolonged block, hypotension vasodilatation, bradycardia, tachycardia, dyspnea, broncho-, laryngo-spasm, rash, urticaria, and a reaction at the injection site. Patients developing hypotension usually have preexisting severe cardiovascular disease.

### Overdosage/Acute Toxicity

Overdosage possibilities can be minimized by monitoring muscle twitch responses to peripheral nerve stimulation. Increased risks of hypotension and histamine release occur with overdoses, as well as prolonged duration of muscle blockade.

Besides treating conservatively (mechanical ventilation, O<sub>2</sub>, fluids, etc.), reversal of blockade may be accomplished by administering an anticholinesterase agent such as edrophonium (0.5 mg/kg IV), or neostigmine (0.02–0.04 mg/kg IV) with an anticholinergic (atropine or glycopyrrolate). Reversal is usually attempted (in humans) approximately 20–35 minutes after the initial dose, or 10–30 minutes after the last maintenance dose. Reversal is usually complete within 8–10 minutes. Because the duration of action of atracurium may be longer than the reversal agent, careful observation and monitoring is required. Readministration of the reversal agent may be necessary.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atracurium and may be of significance in veterinary patients:

The following agents may enhance the neuromuscular blocking activity of atracurium:

■ **AMINOGLYCOSIDE ANTIBIOTICS (gentamicin, etc.)**

■ **ANESTHETICS, GENERAL (enflurane, isoflurane, halothane)**

■ **BACITRACIN, POLYMYXIN B (systemic)**

■ **PROCAINAMIDE**

■ **QUINIDINE**

■ **LITHIUM**

■ **MAGNESIUM SALTS**

■ **ANTICONSULSANTS (PHENYTOIN, CARBAMAZEPINE):** Have been reported to both decrease the effects and duration of neuromuscular blockade

■ **OTHER MUSCLE RELAXANT DRUGS:** May cause a synergistic or antagonistic effect

■ **SUCCINYLCHOLINE:** May speed the onset of action and enhance the neuromuscular blocking actions of atracurium. Do not give atracurium until succinylcholine effects have diminished.

### Doses

#### ■ DOGS:

a) For use in critically ill patients when low concentrations of, or no inhalant anesthesia can be used: 0.2 mg/kg IV initial dose; subsequent doses 0.1 mg/kg IV. Do not dose more frequently than every 20–30 minutes in critical patients unless a peripheral nerve stimulator is applied, or voluntary movement is observed. Positive pressure ventilation, preferably mechanical, is required. (Spelts 2009)

b) For neuromuscular blockade augmentation during corneal surgery: 0.15 mg/kg IV (Nasissse 2004)

c) As a muscle relaxant to facilitate intubation in patients with severe blunt trauma: IV started and acepromazine 0.01 mg/kg plus butorphanol 0.1 mg/kg plus ketamine 1 mg/kg is infused. If patient requires intubation, give atracurium at 0.25 mg/kg IV push. (Crowe 2004)

d) For induction of respiratory muscle paralysis during mechanical ventilation: Loading dose: 0.2–0.5 mg/kg IV, then a constant rate infusion 5 minutes later of 3–9 micrograms/kg/min. Use D5W or 0.9% sodium chloride for diluent; do not mix with other drugs. Respiratory and cardiovascular monitoring should be provided. (Dhupa 2005)

#### ■ CATS:

a) Induction dose: 0.22 mg/kg IV, give 1/10th to 1/6th of this dose initially as a “priming” dose, followed 4–6 minutes later with the remainder and a sedative/hypnotic agent.

Intraoperative dose: 0.11 mg/kg IV (Mandsager 1988)

b) For induction of respiratory muscle paralysis during mechanical ventilation: Loading dose: 0.2–0.5 mg/kg IV, then a constant rate infusion 5 minutes later of 0.37 micrograms/kg/min. Use D5W or 0.9% sodium chloride for diluent; do not mix with other drugs. Respiratory and cardiovascular monitoring should be provided. (Dhupa 2005)

c) For use in critically ill patients, or no inhalant anesthesia can be used: 0.2 mg/kg IV initial dose; subsequent doses 0.1 mg/kg IV. Do not dose more frequently than every 20–30 minutes in critical patients unless a peripheral nerve stimulator is applied, or voluntary movement is observed. Positive pressure ventilation, preferably mechanical, is required. (Spelts 2009)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) Rabbits: For paralysis for periophthalmic surgery: 0.1 mg/kg (Ivey & Morrissey 2000)

#### ■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

a) Intraoperative dose: 0.055 mg/kg IV (Mandsager 1988)

#### Monitoring

- Level of neuromuscular blockade; recommend use of a peripheral nerve stimulator to evaluate “train of 4” twitches. If not available, watch for spontaneous ventilation and voluntary muscle movement.
- Cardiac rate

#### Client Information

- This drug should only be used by professionals familiar with its use.

#### Chemistry/Synonyms

A synthetic, non-depolarizing neuromuscular blocking agent, atracurium, is a bisquaternary, non-choline diester structurally similar to metocurine and tubocurarine. It occurs as white to pale yellow powder; 50 mg are soluble in 1 mL of water, 200 mg are soluble in 1 mL of alcohol, and 35 mg are soluble in 1 mL of normal saline.

Atracurium besylate may also be known as: 33A74, atracurium besilate, BW-33A, *Abbottracurium*®, *Atracur*®, *Faulcurium*®, *Ifacur*®, *Laurak*®, *Mycurium*®, *Relatrac*®, *Sitrac*®, *Trablok*®, *Tracrium*®, or *Tracur*®.

#### Storage/Stability

The commercially available injection occurs as clear, colorless solution and is a sterile solution of the drug in sterile water for injection. The pH of this solution is 3.25–3.65. Atracurium injection should be stored in the refrigerator and protected against freezing. At room temperature, approximately 5% potency loss occurs each month; when refrigerated, a 6% potency loss occurs over a year’s time.

#### Compatibility/Compounding Considerations

Atracurium is **compatible** with the standard IV solutions, but while stable in lactated Ringer’s for 8 hours, degradation occurs more rapidly. It should not be mixed in the same IV bag or syringe, or given through the same needle with alkaline drugs (*e.g.*, barbiturates) or solutions (sodium bicarbonate) as precipitation may occur. It is **incompatible** when mixed with propofol, diazepam, thiopental, aminophylline, cefazolin, heparin, ranitidine, and sodium nitroprusside.

#### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

Atracurium Besylate Injection: 10 mg/mL in 5 mL single-use & 10 mL multi-use vials; *Tracrium*® (GlaxoWellcome); generic (Bedford Labs); (Rx)

## ATROPINE SULFATE

(*α*-troe-peen)

ANTICHOLINERGIC

### Prescriber Highlights

- **Prototype antimuscarinic agent used for a variety of indications (bradycardia, premed, antidote, etc.)**
- **Contraindicated in conditions where anticholinergic effects would be detrimental (*e.g.*, narrow angle glaucoma, tachycardias, ileus, urinary obstruction, etc.)**
- **Adverse effects are dose related & anticholinergic in nature: 1) dry secretions, 2) initial bradycardia, then tachycardia, 3) slow gut & urinary tract, 4) mydriasis/cycloplegia**
- **Drug interactions**

---

#### Uses/Indications

The principal veterinary indications for systemic atropine include:

Preanesthetic to prevent or reduce secretions of the respiratory tract

- Treat sinus bradycardia, sinoatrial arrest, and incomplete AV block
- Differentiate vagally-mediated bradycardia for other causes
- As an antidote for overdoses of cholinergic agents (*e.g.*, physostigmine, etc.)
- As an antidote for organophosphate, carbamate, muscarinic mushroom, blue-green algae intoxication
- Hypersialism
- Treatment of bronchoconstrictive disease

### Pharmacology/Actions

Atropine, like other antimuscarinic agents, competitively inhibits acetylcholine or other cholinergic stimulants at postganglionic parasympathetic neuroeffector sites. High doses may block nicotinic receptors at the autonomic ganglia and at the neuromuscular junction. Pharmacologic effects are dose related. At low doses salivation, bronchial secretions, and sweating (not horses) are inhibited. At moderate systemic doses, atropine dilates and inhibits accommodation of the pupil, and increases heart rate. High doses will decrease GI and urinary tract motility. Very high doses will inhibit gastric secretion.

### Pharmacokinetics

Atropine sulfate is well absorbed after oral administration, IM injection, inhalation, or endotracheal administration. After IV administration peak effects in heart rates occur within 3–4 minutes.

Atropine is well distributed throughout the body and crosses into the CNS, across the placenta, and can distribute into the milk in small quantities.

Atropine is metabolized in the liver and excreted into the urine. Approximately 30–50% of a dose is excreted unchanged into the urine. The plasma half-life in humans has been reported to be between 2–3 hours.

### Contraindications/Precautions/Warnings

Atropine is contraindicated in patients with narrow-angle glaucoma, synechiae (adhesions) between the iris and lens, hypersensitivity to anticholinergic drugs, tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, and myasthenia gravis (unless used to reverse adverse muscarinic effects secondary to therapy). Atropine may aggravate some signs seen with amitraz toxicity, leading to hypertension and further inhibition of peristalsis.

Antimuscarinic agents should be used with extreme caution in patients with known or suspected GI infections. Atropine or other antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged clinical signs. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Atropine reportedly is not effective in treating bradycardias in puppies before 14 days of age or kittens younger than 11 days old. It may also damage hypoxic myocardia in neonates (Trass 2009).

Glycopyrrolate is usually the anticholinergic of choice when treating rabbits as a large percentage (40%?) have endogenous atropinesterase present.

Antimuscarinic agents should be used with caution in patients with hepatic or renal disease, geriatric or pediatric patients, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, or esophageal reflux. Systemic atropine should be used cautiously in horses as it may decrease gut motility and induce colic in susceptible animals. It may also reduce the arrhythmogenic doses of epinephrine. Use of atropine in cattle may result in inappetence and rumen stasis that may persist for several days.

When used in food animals at doses up to 0.2 mg/kg, FARAD recommends a 28 day meat and 6 day milk withdrawal time. (Haskell *et al.* 2005)

### Adverse Effects

Adverse effects are basically extensions of the drug's pharmacologic effects and are generally dose related. At usual doses, effects tend to be mild in relatively healthy patients. The more severe effects listed tend to occur with high or toxic doses. GI effects can include dry mouth (xerostomia), dysphagia, constipation, vomiting, and thirst. GU effects may include urinary retention or hesitancy. CNS effects may include stimulation, drowsiness, ataxia, seizures, respiratory depression, etc. Ophthalmic effects include blurred vision, pupil dilation, cycloplegia, and photophobia. Cardiovascular effects include sinus tachycardia (at higher doses), bradycardia (initially or at very low doses), hypertension, hypotension, arrhythmias (ectopic complexes), and circulatory failure.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*) Atropine use in pregnancy may cause fetal tachycardia.

### Overdosage/Acute Toxicity

For signs and symptoms of atropine toxicity see adverse effects above. If a recent oral ingestion, emptying of gut contents and administration of activated charcoal and saline cathartics may be warranted. Treat clinical signs supportively and symptomatically. Do not use phenothiazines as they may contribute to the anticholinergic effects. Fluid therapy and standard treatments for shock may be instituted.

The use of physostigmine is controversial and should probably be reserved for cases where the patient exhibits either extreme agitation and is at risk for injuring themselves or others, or for cases where supraventricular tachycardias and sinus tachycardias are severe or life threatening. The usual dose for physostigmine (human) is: 2 mg IV slowly (for average sized adult). If no response, may repeat every 20 minutes until reversal of toxic antimuscarinic effects or cholinergic effects takes place. The human pediatric dose is 0.02 mg/kg slow IV (repeat q10 minutes as above) and may be a reasonable choice for initial treatment of small animals. Physostigmine adverse effects (bronchoconstriction, bradycardia, seizures) may be treated with small doses of IV atropine.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving atropine and may be of significance in veterinary patients:

The following drugs may enhance the activity or toxicity of atropine and its derivatives:

- AMANTADINE
- ANTICHOLINERGIC AGENTS (other)

## ■ANTICHOLINERGIC MUSCLE RELAXANTS

■**ANTI-HISTAMINES** (*e.g.*, **diphenhydramine**)

■**DISOPYRAMIDE**

■**MEPERIDINE**

■**PHENOTHIAZINES**

■**PROCAINAMIDE**

■**PRIMIDONE**

■**TRICYCLIC ANTIDEPRESSANTS** (*e.g.*, **amitriptyline**, **clomipramine**)

■**ALPHA-2 AGONISTS** (*e.g.*, **dexmedetomidine**, **medetomidine**): Use of atropine with alpha-2 blockers may significantly increase arterial blood pressure, heart rates and the incidence of arrhythmias (Congdon *et al.* 2009). Clinical use of atropine or glycopyrrolate to prevent or treat medetomidine- or dexmedetomidine-caused bradycardia is controversial and many discourage using together. This may be particularly important when using higher dosages of the alpha-2 agonist.

■**AMITRAZ**: Atropine may aggravate some signs seen with amitraz toxicity; leading to hypertension and further inhibition of peristalsis

■**ANTACIDS**: May decrease PO atropine absorption; give oral atropine at least 1 hour prior to oral antacids

■**CORTICOSTEROIDS (long-term use)**: may increase intraocular pressure

■**DIGOXIN (slow-dissolving)**: Atropine may increase serum digoxin levels; use regular digoxin tablets or oral liquid

■**KETOCONAZOLE**: Increased gastric pH may decrease GI absorption; administer oral atropine 2 hours after ketoconazole

■**METOCLOPRAMIDE**: Atropine and its derivatives may antagonize the actions of metoclopramide

## Doses

### ■DOGS:

As a preanesthetic adjuvant:

a) In geriatric patients: 0.01–0.02 mg/kg IM, IV; do not use anticholinergics indiscriminately in geriatric patients. (Carpenter *et al.* 2005)

b) 0.074 mg/kg IV, IM or SC (Package Insert; *Atropine Injectable*, S.A.—Fort Dodge)

c) 0.02–0.04 mg/kg SC, IM or IV (Morgan 1988)

For adjunctive treatment of bradycardias, Incomplete AV block, etc.

a) During cardiopulmonary cerebral resuscitation (CPCR) efforts: 0.04 mg/kg IV or IO; can repeat every 3–5 minutes for a maximum of 3 doses. For intratracheal (IT) administration: 0.08–0.1 mg/kg; dilute in 5–10 mL of sterile water before administering (Plunkett & McMichael 2008).

b) 0.02–0.04 mg/kg IV or IM (Russell & Rush 1995)

To differentiate vagally-mediated bradyarrhythmias from non-vagal bradyarrhythmias (Atropine Response Test):

*Rishniw Preference*: **1**) Record ECG at baseline; **2**) Administer 0.04 mg/kg atropine IV; **3**) Wait 15 minutes; **4**) Record ECG for at least 2 minutes (use slow paper speed). If the response is incomplete, repeat steps 2–4. Persistent sinus tachycardia at >140 bpm is expected in most dogs with vagally-mediated bradycardia.

*Kittleson Preference*: **1**) Record ECG at baseline; **2**) Administer 0.04 mg/kg atropine SQ; **3**) Wait 30 minutes; **4**) Record ECG for at least 2 minutes (use slow paper speed). Persistent sinus tachycardia at >140 bpm is expected in most dogs with vagally-mediated bradycardia. (Rishniw & Kittleson 2007)

For treatment of cholinergic toxicity:

a) 0.2–0.5 mg/kg; 1/4 of the dose IV and the remainder IM or SC (Firth 2000)

For treatment of bronchoconstriction:

a) 0.02–0.04 mg/kg for a duration of effect of 1–1.5 hours (Papich 1986)

### ■CATS:

As a preanesthetic adjuvant:

a) In geriatric patients: 0.01–0.02 mg/kg IM, IV; do not use anticholinergics indiscriminately in geriatric patients. (Carpenter *et al.* 2005)

b) 0.074 mg/kg IV, IM or SC (Package Insert; *Atropine Injectable*, S.A.—Fort Dodge)

c) 0.02–0.04 mg/kg SC, IM or IV (Morgan 1988)

For treatment of bradycardias:

a) During cardiopulmonary cerebral resuscitation (CPCR) efforts: 0.04 mg/kg IV or IO; can repeat every 3–5 minutes for a maximum of 3 doses. For intratracheal (IT) administration: 0.08–0.1 mg/kg; dilute in 5–10 mL of sterile water before administering (Plunkett & McMichael 2008).

b) 0.02–0.04 mg/kg SC, IM or IV q4–6h (Miller 1985)

For treatment of cholinergic toxicity:

a) 0.2–2 mg/kg; give 1/4th of the dose IV and the remainder SC or IM (Morgan 1988)

### ■FERRETS:

a) As a premed: 0.05 mg/kg SC or IM (Williams 2000)

### ■RABBITS/RODENTS/SMALL MAMMALS:

a) To treat organophosphate toxicity: 10 mg/kg SC q20 minutes (Ivey & Morrisey 2000)

### ■CATTLE:

**Note:** When used in food animals at doses up to 0.2 mg/kg, FARAD recommends a 28 day meat and 6 day milk withdrawal time. (Haskell *et al.* 2005)

As a preanesthetic:

a) Because of a lack of extended efficacy and potential adverse reactions, atropine is not used routinely as a preoperative agent in ruminants. If it is desired for use, a dose of 0.06–0.12 mg/kg IM has been suggested.) (Thurmon & Benson 1986)

For adjunctive treatment of bovine hypersensitivity disease:

a) 1 gram per cow once daily followed by 0.5 gram/cow in 2–3 days (method of administration not specified) (Manning & Scheidt 1986)

For treatment of cholinergic toxicity (organophosphates):

a) 0.5 mg/kg (average dose); give ¼th of the dose IV and the remainder SC or IM; may repeat q3–4h for 1–2 days (Bailey 1986)

#### ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

For treatment of bradyarrhythmias due to increased parasympathetic tone:

a) 0.01–0.02 mg/kg IV (Mogg 1999)

b) 0.045 mg/kg parenterally (Hilwig 1987)

As a bronchodilator:

a) 5 mg IV for a 400–500 kg animal (Beech 1987)

b) 5–7 mg/kg IV for a 450 kg horse can serve as a rescue medication in cases with severe airway obstruction, but it has an abbreviated duration of action (0.5–2 hours) and adverse effects (ileus, CNS toxicity, tachycardia, increased mucus secretion, and impaired mucociliary clearance) limit its use to a single rescue dose. (Rush 2006)

For organophosphate poisoning:

a) Approximately 1 mg/kg given to effect, IV (use mydriasis and absence of salivation as therapy endpoints), may repeat every 1.5–2 hours as required subcutaneously (Oehme 1987)

b) 0.22 mg/kg, ¼th of the dose administered IV and the remainder SC or IM (Package Insert; *Atropine Injectable, L.A.*— Fort Dodge)

#### ■SWINE:

The equine dose (above) may be used to initially treat organophosphate toxicity in swine.

As an adjunctive preanesthetic agent:

a) 0.04 mg/kg IM (Thurmon & Benson 1986)

#### ■SHEEP, GOATS:

For treating organophosphate toxicity:

a) Use the dose for cattle (above).

#### ■BIRDS:

For organophosphate poisoning:

a) 0.2 mg/kg IM every 3–4 hours as needed; ¼th the initial dose is administered. Use with pralidoxime (not in raptors) at 10–20 mg/kg IM q8–12h as needed. Do not use pralidoxime in carbamate poisonings.

To assist in diagnosing organophosphate poisoning (with history, clinical signs, etc.) in birds presenting with bradycardia: May administer atropine at 0.02 mg/kg IV. If bradycardia does not reverse, may consider organophosphate toxicity. (LaBonde 2006)

As a preanesthetic:

a) 0.04–0.1 mg/kg IM or SC once (Clubb 1986)

#### ■REPTILES:

For organophosphate toxicity in most species:

a) 0.1–0.2 mg/kg SC or IM as needed. (Gauvin 1993)

For ptialism in tortoises:

a) 0.05 mg/kg (50 micrograms/kg) SC or IM once daily (Gauvin 1993)

### Monitoring

Dependent on dose and indication:

- Heart rate and rhythm
- Thirst/appetite; urination/defecation capability
- Mouth/secretions dryness

### Client Information

- Parenteral atropine administration is best performed by professional staff and where adequate cardiac monitoring is available.
- If animal is receiving atropine systemically, allow animal free access to water and encourage drinking if dry mouth is a problem.

### Chemistry/Synonyms

The prototype tertiary amine antimuscarinic agent, atropine sulfate is derived from the naturally occurring atropine. It is a racemic mixture of d-hyoscyamine and l-hyoscyamine. The l- form of the drug is active, while the d- form has practically no antimuscarinic activity. Atropine sulfate occurs as colorless and odorless crystals, or white, crystalline powder. One gram of atropine sulfate is soluble in approximately 0.5 mL of water, 5 mL of alcohol, or 2.5 mL of glycerin. Aqueous solutions are practically neutral or only slightly acidic. Commercially available injections may have the pH adjusted to 3.0–6.5.

Atropine may also be known as dl-hyoscyamine. Atropine sulfate may also be known as: atrop. sulph., atropine sulphate, or atropini sulfas; many trade names are available.

## Storage/Stability

Atropine sulfate tablets or soluble tablets should be stored in well-closed containers at room temperature (15-30°C). Atropine sulfate for injection should be stored at room temperature; avoid freezing.

## Compatibility/Compounding Considerations

Atropine sulfate for injection is reportedly **compatible** with the following agents: benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, cimetidine HCl (not with pentobarbital), dimenhydrinate, diphenhydramine HCl, dobutamine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydromorphone HCl, hydroxyzine HCl (also with meperidine), meperidine HCl, morphine sulfate, nalbuphine HCl, pentazocine lactate, pentobarbital sodium (OK for 5 minutes, not 24 hours), perphenazine, prochlorperazine edisylate, promazine HCl, promethazine HCl (also with meperidine), and scopolamine HBr.

Atropine sulfate is reported physically **incompatible** with norepinephrine bitartrate, metaraminol bitartrate, methohexital sodium, and sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Atropine Sulfate for Injection: 0.54 mg/mL (1/120 grain); *Atroject*® (Vetus), *Atropine SA*® (Butler), generic, (various); (Rx)

Atropine Sulfate for Injection: 15 mg/mL (organophosphate treatment) 100 mL vial; *Atropine L.A.*® (Butler), (RXV); generic (various) (Rx)

Atropine is labeled for use in dogs, cats, horses, cattle, sheep, and swine in the USA. No withdrawal times are mandated when used in food animals in the USA, but FARAD recommends a 28 day meat and 6 day milk withdrawal time. (Haskell *et al.* 2005). In the UK, slaughter withdrawal for cattle, sheep, and pigs is 14 days when used as an antimuscarinic and 28 days when used as an antidote; milk withdrawal is 3 days when used as an antimuscarinic and 6 days when used as an antidote. For guidance with determining use associated withdrawal times, contact FARAD (see Phone Numbers & Websites in the appendix)

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

*Atropine Sulfate for Injection:*

0.05 mg/mL in 5 mL syringes; Atropine Sulfate (Hospira); (Rx)

0.1 mg/mL in 5 mL and 10 mL syringes; Atropine Sulfate (Hospira); (Rx)

0.3 mg/mL in 1 mL and 30 mL vials; generic; (Rx)

0.4 mg/mL in 1 mL amps and 1 mL, 20 mL, and 30 mL vials; generic; (Rx)

0.5mg/mL in 1mL and 30 mL vials & 5 mL syringes; generic; (Rx)

0.8 mg/mL in 0.5 mL and 1 mL amps and 0.5 mL syringes; generic; (Rx)

1 mg/mL in 1 mL amps and vials and 10 mL syringes; generic; (Rx)

0.5 mg, 1 mg & 2 mg pre-filled, auto-injectors; *AtroPen*® (Meridian Medical Technologies); (Rx)

*Atropine Sulfate Tablets:* 0.4 mg; *Sal-Tropine*® (Hope); (Rx)

See also the monograph for [atropine sulfate](#) for ophthalmic use in the appendix. Atropine sulfate ophthalmic drops have been used buccally to decrease excessive oral secretions in human patients.

## AURANOFIN

(*au-rane-oh-fin*) *Ridaura*®

ORAL GOLD IMMUNOSUPPRESSIVE

### Prescriber Highlights

- Orally administered gold; used for pemphigus & idiopathic polyarthritis in dogs or cats
- Can be quite toxic & expensive, intensive ongoing monitoring required; dosages must be compounded from 3 mg capsules
- Probably less toxic, but also less efficacy than injectable gold

- **Considered contraindicated in SLE (exacerbates)**
  - **Known teratogen & maternotoxic**
  - **Renal, hepatic & GI toxicity possible; dose dependent immune-mediated thrombocytopenia, hemolytic anemia or leukopenias have been seen**
- 

### Uses/Indications

Auranofin has been used to treat idiopathic polyarthritis and pemphigus foliaceus in dogs and cats. Several clinicians report that while auranofin may be less toxic, it also less efficacious than injectable gold (aurothioglucose).

### Pharmacology/Actions

Auranofin is an orally available gold salt. Gold has antiinflammatory, antirheumatic, immunomodulating, and antimicrobial (*in vitro*) effects. The exact mechanisms for these actions are not well understood. Gold is taken up by macrophages where it inhibits phagocytosis and may inhibit lysosomal enzyme activity. Gold also inhibits the release of histamine, and the production of prostaglandins. While gold does have antimicrobial effects *in vitro*, it is not clinically useful for this purpose. Auranofin suppresses helper T-cells, without affecting suppressor T-cell populations.

### Pharmacokinetics

Unlike other available gold salts, auranofin is absorbed when given by mouth (20–25% of the gold) primarily in the small and large intestines. In contrast to the other gold salts, auranofin is only moderately bound to plasma proteins (the others are highly bound). Auranofin crosses the placenta and is distributed into maternal milk. Tissues with the highest levels of gold are kidneys, spleen, lungs, adrenals and liver. Accumulation of gold does not appear to occur, unlike the parenteral gold salts. About 15% of an administered dose (60% of the absorbed dose) is excreted by the kidneys, the remainder in the feces.

### Contraindications/Precautions/Warnings

Auranofin should only be administered to animals where other less expensive and toxic therapies are ineffective and the veterinarian and owner are aware of the potential pitfalls of auranofin therapy and are willing to accept the associated risks and expenses. Gold salts are contraindicated in SLE as they may exacerbate the signs associated with this disease.

### Adverse Effects

A dose dependent immune-mediated thrombocytopenia, hemolytic anemia or leukopenias have been noted in dogs. Discontinuation of the drug and administration of steroids has been recommended. Auranofin has a higher incidence of dose dependent GI disturbances (particularly diarrhea) in dogs than with the injectable products. Discontinuation of the drug or a lowered dose will generally resolve the problem. Renal toxicity manifested by proteinuria is possible as is hepatotoxicity (increased liver enzymes). These effects are less likely than either the GI or hematologic effects. Dermatitis and corneal ulcers have also been associated with auranofin therapy.

### Reproductive/Nursing Safety

Auranofin has been demonstrated to be teratogenic and maternotoxic in laboratory animals; it should not be used during pregnancy unless the owner accepts the potential risks of use. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Following auranofin administration, gold is excreted in the milk of rodents. Trace amounts appear in the serum and red blood cells of nursing offspring. As this may cause adverse effects in nursing offspring, switching to milk replacer is recommended if auranofin is to be continued in the dam. Because gold is slowly excreted, persistence in milk will occur even after the drug is discontinued.

### Overdosage/Acute Toxicity

Very limited data is available. The minimum lethal oral dose in rats is 30 mg/kg. It is recommended that gut-emptying protocols be employed after an acute overdose when applicable. Chelating agents (*e.g.*, penicillamine, dimercaprol) for severe toxicities have been used, but are controversial. One human patient who took an overdose over 10 days developed various neurologic sequelae, but eventually (after 3 months) recovered completely after discontinuation of the drug and chelation therapy.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving auranofin and may be of significance in veterinary patients:

- **CYTOTOXIC AGENTS** (including **high dose corticosteroids**): Auranofin's safety when used with these agents has not been established; use with caution
- **PENICILLAMINE or ANTIMALARIAL DRUGS**: Use with gold salts is not recommended due to the increased potential for hematologic or renal toxicity

### Laboratory Considerations

- In humans, response to **tuberculin skin tests** may be enhanced; veterinary significance is unclear

### Doses

#### ■ DOGS:

- a) For immune-mediated arthropathies and dermatopathies: 0.05–0.2 mg/kg (up to 9 mg/day total dose) PO q12h (Vaden & Cohn 1994), (Kohn 2003)
- b) For treatment of pemphigus complex (with corticosteroids): 0.12–0.2 mg/kg twice daily (White 2000)

#### ■ CATS:

- a) As a rescue drug for feline pemphigus and for idiopathic dermatoses and plasma cell pododermatitis/stomatitis: 0.2–0.3 mg/kg twice daily; must be reformulated for accurate dosing. (Morris 2004)

### Monitoring

The following should be performed prior to therapy, then once monthly for 2–3 months, then every other month:

• Hematic and renal function tests (including urinalysis):

Hepatic and renal function tests (including urinalysis);

- CBC, with platelet counts. **Note:** eosinophilia may denote impending reactions

### Client Information

- Clients must understand that several months may be required before a positive response may be seen.
- Commitment to the twice daily dosing schedule, the costs associated with therapy, and the potential adverse effects should be discussed before initiating therapy.

### Chemistry/Synonyms

An orally administered gold compound, auranofin occurs as a white, odorless, crystalline powder. It is very slightly soluble in water and soluble in alcohol. Auranofin contains 29% gold.

Auranofin may also be known as: SKF-39162, SKF-D-39162, *Crisinor*®, *Crisofin*®, *Goldar*®, *Ridaura*® or *Ridauran*®.

### Storage/Stability

Store capsules in tight, light resistant containers at room temperature. After manufacture, expiration dates of 4 years are assigned to the capsules.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Auranofin Capsules: 3 mg; *Ridaura*® (SK-Beecham); (Rx)

## AZAPERONE

(a-zap-peer-ohne) Stresnil®

BUTYROPHENONE TRANQUILIZER

### Prescriber Highlights

- **A butyrophenone tranquilizer for swine; also used in wildlife**
  - **Do not give IV, allow pigs to be undisturbed for 20 minutes after injecting**
  - **No analgesic activity**
  - **May cause transient piling, salivation & shivering**
- 

### Uses/Indications

Azaperone is officially indicated for the “control of aggressiveness when mixing or regrouping weanling or feeder pigs weighing up to 36.4 kg” (Package Insert, *Stresnil*®—P/M; Mallinckrodt). It is also used clinically as a general tranquilizer for swine, to allow piglets to be accepted by aggressive sows, and as a preoperative agent prior to general anesthesia or cesarean section with local anesthesia.

Azaperone has been used as a neuroleptic in horses, but some horses develop adverse reactions (sweating, muscle tremors, panic reaction, CNS excitement) and IV administration has resulted in significant arterial hypotension. Because of these effects, most clinicians avoid the use of this drug in equines.

Azaperone, in combination with butorphanol and medetomidine (BAM), has been used as an immobilization combination in cervids, but it may not have additional benefit and may increase risk for hypoxia.

### Pharmacology/Actions

The butyrophenones as a class cause tranquilization and sedation (sedation may be less than with the phenothiazines), anti-emetic activity, reduced motor activity, and inhibition of CNS catecholamines (dopamine, norepinephrine). Azaperone appears to have minimal effects on respiration and may inhibit some of the respiratory depressant actions of general anesthetics. A slight reduction of arterial blood pressure has been measured in pigs after IM injections of azaperone, apparently due to slight alpha-adrenergic blockade. Azaperone has been demonstrated to prevent the development of halothane-induced malignant hyperthermia in susceptible pigs. Preliminary studies have suggested that the effects of butyrophenones may be antagonized by 4-aminopyridine.

### Pharmacokinetics

Minimal information was located regarding actual pharmacokinetic parameters, but the drug is considered to have a fairly rapid onset of action following IM injections in pigs (5–10 minutes) with a peak effect at approximately 30 minutes post injection. It has a duration of action of 2–3 hours in young pigs and 3–4 hours in older swine. The drug is metabolized in the liver with 13% of it excreted in the feces. At 16 hours post-dose, practically all the drug is eliminated from the body; however in the UK a 10-day slaughter withdrawal has been assigned.

### Contraindications/Precautions/Warnings

When used as directed, the manufacturer reports no contraindications (other than for slaughter withdrawal) for the drug. It should not be given IV as a significant excitatory phase may be seen in pigs. Avoid use in very cold conditions as cardiovascular collapse may occur secondary to peripheral vasodilation.

Secondary priapism may be seen in pigs. Priapism use in very cold conditions as cardiac vascular collapse may occur secondary to peripheral vasoconstriction.

Do not exceed dosing recommendation in boars as the drug may cause the penis to be extruded.

Because Vietnamese Pot Bellied pigs may have delayed absorption due to sequestration of the drug in body fat, re-dose with extreme caution; deaths have resulted after repeat dosing.

### Adverse Effects

Transient salivation, piling, panting and shivering have been reported in pigs. Pigs should be left undisturbed after injection (for approximately 20 minutes) until the drug's full effects have been expressed; disturbances during this period may trigger excitement.

Azaperone has minimal analgesic effects and is not a substitute for appropriate anesthesia or analgesia. Doses above 1 mg/kg may cause the penis to be extruded in boars.

In white-tailed deer, butorphanol, azaperone and medetomidine (BAM) caused greater hypoventilation and hypoxemia without significant reductions in immobilization times than butorphanol and medetomidine alone (Boesch *et al.* 2008).

### Overdosage/Acute Toxicity

Azaperone overdoses can cause hypotension; doses >1 mg/kg in boars may cause penis extrusion leading to damage. There is no reversal agent for azaperone; treat supportively.

### Drug Interactions

No specific drug interactions have been reported for azaperone. The following interactions have been reported for the closely related compounds, haloperidol or droperidol:

■ **CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.)** may cause additive CNS depression if used with butyrophenones

### Doses

#### ■ SWINE:

For the approved indication of mixing feeder or weanling pigs:

a) 2.2 mg/kg deeply IM (see client information below) (Package Insert; *Stresnil*®—P/M Mallinckrodt; **Note:** No longer on US market)

For labeled indications (*Stresnil*®—Janssen U.K.):

a) **Note:** all doses are to be given IM directly behind the ear using a long hypodermic needle and given as closely behind the ear as possible and perpendicular to the skin.

Aggression (prevention and cure of fighting; including regrouping of piglets, porkers, fattening pigs): 2 mg/kg (1 mL/20 kg)

Treatment of aggression in sows: 2 mg/kg (1 mL/20 kg)

Stress (restlessness, anxiety, etc.): 1–2 mg/kg (0.5–1 mL/20 kg)

Transport of boars: 1 mg/kg (0.5 mL/20 kg)

Transport of weaners: 0.4–2 mg/kg (0.4–1 mL/20 kg)

Obstetrics: 1 mg/kg (0.5 mL/20 kg)

As a premed: 1–2 mg/kg (0.5–1 mL/20 kg)

### Monitoring

■ Level of sedation

### Client Information

■ Must be injected IM deeply, either behind the ear and perpendicular to the skin or in the back of the ham. All animals in groups to be mixed must be treated.

### Chemistry/Synonyms

A butyrophenone neuroleptic, azaperone occurs as a white to yellowish-white macrocrystalline powder with a melting point between 90–95°C. It is practically insoluble in water; 1 gram is soluble in 29 mL of alcohol.

Azaperone may also be known as azaperonum, R-1929, *Stresnil*®, or *Suicalm*®.

### Storage/Stability

Azaperone injection should be stored at controlled room temperature (15–25°C) and away from light. Do not store above 25°C. Once the vial is opened it should be used within 28 days.

### Compatibility/Compounding Considerations

No published information was located regarding mixing azaperone with other compounds. A compounded product that combines butorphanol, azaperone and medetomidine (BAM) is reportedly available.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** **Note:** No FDA-approved azaperone products are currently marketed in the USA. Compounded azaperone injection and a combination injection containing butorphanol, azaperone, and medetomidine (BAM) can be obtained from zoopharm.net

In the UK: Azaperone 40 mg/mL for Injection in 100 mL vials; *Stresnil*® (Janssen—UK); (POM-V) Pigs may be slaughtered for human consumption only after 10 days from the last treatment.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

### References

---

## AZATHIOPRINE

### AZATHIOPRINE SODIUM

(ay-za-thye-oh-preen) Imuran®

IMMUNOSUPPRESSANT

#### Prescriber Highlights

- **Purine antagonist immunosuppressive used for a variety of autoimmune diseases**
  - **May take several weeks for immunosuppression to occur**
  - **Often used in combination with corticosteroids to reduce doses and dosing frequency of each drug**
  - **Known mutagen & teratogen; use with caution in patients with hepatic disease**
  - **Bone marrow depression principal adverse effect; GI effects (including GI distress, anorexia, pancreatitis & hepatotoxicity) also seen**
  - **Usually not used in cats as they are very sensitive to bone marrow effects**
- 

#### Uses/Indications

In veterinary medicine, azathioprine is used primarily as an immunosuppressive agent in the treatment of immune-mediated diseases in dogs. See Doses below for more information. For auto-agglutinating immune mediated hemolytic anemia, azathioprine is generally recommended to start at the time of diagnosis. When used in combination with cyclosporine, azathioprine has been used to prevent rejection of MHC-matched renal allografts in dogs.

Azathioprine is often used in combination with corticosteroids, such as prednisolone, primarily to reduce the incidence of adverse effects of each drug by allowing dosage reductions and eventually, every other day dosing of each drug.

Although the drug can be very toxic to bone marrow in cats, it is sometimes used to treat feline autoimmune skin diseases.

#### Pharmacology/Actions

While the exact mechanism how azathioprine exerts its immunosuppressive action has not been determined, it is probably dependent on several factors. Azathioprine antagonizes purine metabolism thereby inhibiting RNA, DNA synthesis and mitosis. It may also cause chromosome breaks secondary to incorporation into nucleic acids and cellular metabolism may become disrupted by the drug's ability to inhibit coenzyme formation. Azathioprine has greater activity on delayed hypersensitivity and cellular immunity than on humoral antibody responses. Clinical response to azathioprine may require up to 6 weeks.

#### Pharmacokinetics

Azathioprine is poorly absorbed from the GI tract and is rapidly metabolized to mercaptopurine. Mercaptopurine is rapidly taken up by lymphocytes and erythrocytes. Mercaptopurine remaining in the plasma is then further metabolized to several other compounds that are excreted by the kidneys. Only minimal amounts of either azathioprine or mercaptopurine are excreted unchanged. Cats have low activity of thiopurine methyltransferase (TPMT), one of the routes used to metabolize azathioprine. Approximately 11% of humans have low thiopurine methyltransferase activity, and these individuals have a greater incidence of bone marrow suppression, but also greater azathioprine efficacy. Dogs have variable TPMT activity levels similar to that seen in humans, which may explain why some canine patients respond better and/or develop more myelotoxicity than others. However, one study (Rodriguez *et al.* 2004) in dogs did not show significant correlation between TPMT activity in red blood cells and drug toxicity.

#### Contraindications/Precautions/Warnings

Azathioprine is contraindicated in patients hypersensitive to it. The drug should be used cautiously in patients with hepatic dysfunction. Use of azathioprine in cats is controversial; they seem to be more susceptible to azathioprine's bone marrow suppressive effects.

#### Adverse Effects

The principal adverse effect associated with azathioprine is bone marrow suppression. Cats are more prone to develop these effects and the drug is generally not recommended for use in this species. Leukopenia is the most prevalent consequence, but anemias and thrombocytopenia may also be seen. GI upset/anorexia, poor hair growth, acute pancreatitis and hepatotoxicity have been associated with azathioprine therapy in dogs.

Because azathioprine depresses the immune system, animals may be susceptible to infections or neoplastic illnesses with long-term use.

In recovering dogs with immune-mediated hemolytic anemia, taper the withdrawal of the drug slowly over several months and monitor for early signs of relapse. Rapid withdrawal can lead to a rebound hyperimmune response.

#### Reproductive/Nursing Safety

Azathioprine is mutagenic and teratogenic in lab animals. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Azathioprine is distributed into milk; it is recommended to use milk replacer while the dam is receiving azathioprine.

#### Overdosage/Acute Toxicity

No specific information was located regarding acute overdose of azathioprine. It is suggested to use standard protocols to empty the GI tract if ingestion was recent and to treat supportively. Contact an animal poison control center for more information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving azathioprine and may be of significance in veterinary patients:

- **ACE INHIBITORS (benazepril, enalapril, etc.):** Increased potential for hematologic toxicity
- **ALLOPURINOL:** The hepatic metabolism of azathioprine may be decreased by concomitant administration of allopurinol; in humans, it is recommended to reduce the azathioprine dose to  $\frac{1}{4}$ – $\frac{1}{3}$  usual if both drugs are to be used together
- **AMINOSALICYLATES (sulfasalazine, mesalamine, olsalazine):** Increased risk for azathioprine toxicity
- **NON-DEPOLARIZING MUSCLE RELAXANTS (e.g., pancuronium, tubocurarine):** The neuromuscular blocking activity of these drugs may be inhibited or reversed by azathioprine
- **CORTICOSTEROIDS:** Although azathioprine is often used with corticosteroids, there is greater potential risk for toxicity development
- **DRUGS AFFECTING MYELOPOIESIS (e.g., trimethoprim/sulfa, cyclophosphamide, etc.):** Increased potential for hematologic toxicity
- **WARFARIN:** Potential for reduced anticoagulant effect

## Doses

### ■ DOGS:

As an immunosuppressive:

- a) For inflammatory bowel disease: Initially 2 mg/kg PO once daily for 2 weeks, then tapered to 2 mg/kg PO every other day for 2–4 weeks, then 1 mg/kg PO every other day. May take 2–6 weeks before beneficial effects are seen. (Moore 2004)
- b) For immune-mediated anemia, colitis, immune-mediated skin disease, and acquired myasthenia gravis: 2 mg/kg PO once daily (q24h); long-term therapy 0.5–1 mg/kg PO every other day, with prednisolone administered on the alternate days (Papich 2001)
- c) For adjunctive therapy in myasthenia gravis in non-responsive patients: Initially, 1 mg/kg PO once daily. CBC is evaluated every 1–2 weeks. If neutrophil and platelet counts are normal after 2 weeks, dose is increased to 2 mg/kg PO once daily. CBC is repeated every week for the first month and then monthly thereafter. Recommend to discontinue azathioprine if WBC falls below 4,000 cells/mcL or neutrophil count is less than 1,000 cells/mcL. Serum ACHR antibody concentrations reevaluated q4–6 weeks. Azathioprine dose is tapered to every other day when clinical remission occurs and serum ACHR antibody concentrations are normalized. (Coates 2000)
- d) For lymphoplasmacytic enteritis if clinical response to prednisolone is poor or the adverse effects (of prednisolone) predominate: azathioprine 2 mg/kg PO once daily for 5 days, then on alternate days to prednisolone (Simpson 2003)
- e) For severe cases (autoagglutination, hemolytic crisis with rapid decline of hematocrit, intravascular hemolysis, Cocker Spaniels) of immune-mediated hemolytic anemia: 2.2 mg/kg PO once daily (q24h) in addition to prednisone (initially at 2.2 mg/kg PO q12h until hematocrit reaches 25–30%; then dose is gradually tapered by approximately 25% q2–3 weeks until a dose of 0.5 mg/kg PO q48h is reached). (Macintire 2006)
- f) For use with glucocorticoids in acute immune-mediated hemolytic anemia (IMHA): Author starts all patients with IMHA with adjunctive immunosuppressants (usually azathioprine) at 1–2 mg/kg PO once daily. Often used for long-term maintenance as steroid side effects quickly become intolerable to many pet owners. Generally well tolerated in dogs but may cause bone marrow suppression and hepatotoxicity. (Noonan 2009)
- g) For severe and refractory inflammatory bowel disease: 2.2 mg/kg PO once daily; a lag time of 3–5 weeks is expected before clinical improvement is noted (Jergens & Willard 2000)
- h) For adjunctive treatment of ocular fibrous histiocytomas: 2 mg/kg PO daily for 2 weeks, reevaluate, and reduce to 1 mg/kg every other day for 2 weeks, then 1 mg/kg once weekly for 1 month (Riis 1986)
- i) In combination with cyclosporine, to prevent rejection of MHC-matched renal allografts in dogs: 1–5 mg/kg PO every other day (Gregory 2000)
- j) For perianal fistulas (anal furunculosis): In the study, initially 2 mg/kg PO once daily (q24h) until a reduction in the size, number or inflammation of the fistulas was seen or total WBC <5000 cells/mcL or neutrophil count was <3500 cells/mcL or platelet count <160,000 cells/mcL. Then reduce to 2 mg/kg PO every other day (q48h) and continued for 12 weeks as long as myelosuppression doesn't develop. After 12 weeks, reduce dose to 1 mg/kg PO every other day (q48h) with a planned therapy duration of 12 months. Prednisone was given at 2 mg/kg PO once daily for the first two weeks of therapy; then at 1 mg/kg PO once daily for another 2 weeks and then discontinued. All dogs were placed on a limited antigen diet. No correlation with efficacy and lymphocyte blastogenesis effect. Complete or partial remission in 64% of treated dogs, which is less than systemic cyclosporine or topical tacrolimus treatment, but azathioprine treatment is less expensive. (Harkin *et al.* 2007)
- k) For treatment of glomerulonephritis: 2 mg/kg PO once daily. Immunosuppressive treatment is controversial. (Labato 2006)
- l) To reduce inflammation in dogs with chronic hepatitis: 2.2 mg/kg PO once daily in combination with corticosteroids (Prednis(ol)one initially at 1–2 mg/kg/day PO; dose is gradually tapered with clinical improvement). Azathioprine dose is given every other day after 1–2 weeks. (Twedt 2010b), (Twedt 2010a)

### ■ CATS:

**Note:** Most do not recommend azathioprine for use in cats because of the potential for development of fatal toxicity and the difficulty in accurately dosing.

As an immunosuppressive:

- a) For severe and refractory inflammatory bowel disease: Must be used with caution; myelotoxicity with severe neutropenia is possible. Azathioprine at 0.3 mg/kg PO once every other day; may take 3–5 weeks before any beneficial effects. Administration can be enhanced by crushing one 50 mg tablet and suspending it in 15 mL of syrup resulting in a concentration of 3.3 mg/mL. Must be shaken well before each use. If cat becomes ill, rectal temperature and WBC should be determined immediately. (Willard 2002)

### ■ FERRETS:

As an immunosuppressive:

- a) For treating inflammatory bowel disease: Treatments include prednisone (1 mg/kg PO q12–24h), azathioprine (0.9 mg/kg PO q24–72h), and dietary management. (Johnson 2006)

### ■ HORSES:

As an immunosuppressive:

- a) 3 mg/kg PO q24h. Although clinical experiences are still limited, azathioprine appears to be a relatively safe immunosuppressive treatment in the horse and its cost is relatively low. (Divers 2010)
- b) For various autoimmune skin diseases (e.g., pemphigus foliaceus): 1–3 mg/kg PO q24h for 1 month, then every other day (q48h). May cause thrombocytopenia. Azathioprine used as a steroid-sparing drug; used with corticosteroids in an attempt to eventually decrease the amount of steroid needed. (White 2006)

## Monitoring

- Hemograms (including platelets) should be monitored closely; initially every 1–2 weeks and every 1–2 months (some recommend q2 weeks) once on maintenance therapy. It is recommended by some clinicians that if the WBC count drops to between 5,000–7,000 cells/mm<sup>3</sup> the dose be reduced by 25%. If WBC count drops below 5,000 cells/mm<sup>3</sup> treatment should be discontinued until leukopenia resolves.
- Liver function tests; serum amylase, if indicated
- Efficacy

## Client Information

- There is the possibility of severe toxicity developing from this drug including drug-related neoplasms or mortality; routine testing to detect toxic effects are necessary
- Contact veterinarian should the animal exhibit symptoms of abnormal bleeding, bruising, lack of appetite, vomiting or infection
- Although, no special precautions are necessary with handling intact tablets, wash hands after administering the drug; if using a compounded formulation, wear protective gloves or wash hands immediately after administration

## Chemistry/Synonyms

Related structurally to adenine, guanine and hypoxanthine, azathioprine is a purine antagonist antimetabolite that is used primarily for its immunosuppressive properties. Azathioprine occurs as an odorless, pale yellow powder that is insoluble in water and slightly soluble in alcohol. Azathioprine sodium powder for injection occurs as a bright yellow, amorphous mass. After reconstituting with sterile water for injection to a concentration of 10 mg/mL, it has an approximate pH of 9.6.

Azathioprine/Azathioprine sodium may also be known as: azathioprinum, BW-57322, or NSC-39084; many trade names are available.

## Storage/Stability

The azathioprine tablets should be stored at room temperature in well-closed containers and protected from light.

The sodium powder for injection should be stored at room temperature and protected from light. It is reportedly stable at neutral or acidic pH, but will hydrolyze to mercaptopurine in alkaline solutions. This conversion is enhanced upon warming or in the presence of sulfhydryl-containing compounds (e.g., cysteine). After reconstituting, the injection should be used within 24-hours as no preservative is present.

## Compatibility/Compounding Considerations

Azathioprine sodium is reportedly **compatible** with the following intravenous solutions: dextrose 5% in water, and sodium chloride 0.45% or 0.9%. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Compounded preparation stability:** Azathioprine oral suspension compounded from commercially available tablets has been published (Allen, 1996). Triturating one-hundred twenty (120) azathioprine 50 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® SF) yields a 50 mg/mL suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. The stability of azathioprine aqueous liquids decreases in the presence of alkaline pH. The optimal stability is reported to be between 5.5 and 6.5. Compounded preparations of azathioprine should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Azathioprine Tablets: 50 mg, 75 mg & 100 mg; *Azasan*® (aaiPharma); *Imuran*® (Prometheus); generic (aaiPharma); (Rx)

Azathioprine Sodium Injection: 100 mg (as sodium)/vial in 20 mL vials; generic; (Rx)

## AZITHROMYCIN

(ay-zith-roe-my-sin) Zithromax®

MACROLIDE ANTIBIOTIC

## Prescriber Highlights

- **Oral & parenteral human macrolide antibiotic; potentially useful for a variety of infections in veterinary patients; not effective for clearing *Chlamydomytila felis* or *Mycoplasma Haemofelis* in cats.**
  - **Very long tissue half-lives in dogs & cats**
  - **Contraindications: Hypersensitivity to macrolides**
  - **Caution: Hepatic disease**
  - **Adverse Effects: Potentially GI distress, but less so than with erythromycin**
  - **Relatively expensive, but prices are dropping secondary to the availability of generic products**
- 

### Uses/Indications

Azithromycin with its relative broad spectrum and favorable pharmacokinetic profile may be useful for a variety of infections in veterinary species, including *Bordetella pneumoniae* in dogs.

Azithromycin has been shown to be ineffective in the treatment of *Mycoplasma haemofelis* or eliminating *Chlamydomytila felis* in cats.

Azithromycin may be potentially useful for treating *Rhodococcus* infections in foals.

### Pharmacology/Actions

Like other macrolide antibiotics, azithromycin inhibits protein synthesis by penetrating the cell wall and binding to the 50S ribosomal subunits in susceptible bacteria. It is considered a bacteriostatic antibiotic.

Azithromycin has a relatively broad spectrum. It has *in vitro* activity (does not necessarily indicate clinical efficacy) against gram-positive organisms such as *Streptococcus pneumoniae*, *Staph aureus*; gram-negative organisms such as *Haemophilus influenzae*; *Bartonella* spp., *Bordetella* spp.; and *Mycoplasma pneumoniae*, *Borrelia burgdorferi* and *Toxoplasma* spp.

### Pharmacokinetics

The pharmacokinetics of azithromycin have been described in cats and dogs. In dogs, the drug has excellent bioavailability after oral administration (97%). Tissue concentrations apparently do not mirror those in the serum after multiple doses and tissue half-lives in the dogs may be up to 90 hours. Greater than 50% of an oral dose is excreted unchanged in the bile. In cats, oral bioavailability is 58%. Tissue half-lives are less than in dogs, and range from 13 hours in adipose tissue to 72 hours in cardiac muscle. As with dogs, cats excrete the majority of a given dose in the bile.

In foals, azithromycin is variably absorbed after oral administration with a mean systemic bioavailability ranging from 40–60%. It has a very high volume of distribution (11.6–18.6 L/kg). Elimination half-life is approximately 20–26 hours. The drug concentrates in bronchoalveolar cells and pulmonary epithelial fluid. Elimination half-life in PMN's is about 2 days. In adult horses, oral bioavailability is low (1–7%).

When compared to erythromycin, azithromycin has better absorption characteristics, longer tissue half-lives, and higher concentrations in tissues and white blood cells. Azithromycin achieves high concentrations in bronchial secretions and has excellent ocular penetration.

Goats have an elimination half-life of 32.5 hours (IV), 45 hours (IM), an apparent volume of distribution (steady-state) of 34.5 L/kg and a clearance of 0.85 L/kg/hr.

Rabbits have an elimination half-life of 24.1 hours (IV), and 25.1 hours (IM). IM injection has a high bioavailability, but causes some degree of muscle damage at the injection site.

Sheep have an elimination half-life average of 48 hours (IV), 61 hours (IM), an apparent volume of distribution (steady-state) of 34.5 L/kg and a clearance of 0.52 L/kg/hr.

### Contraindications/Precautions/Warnings

Azithromycin is contraindicated in animals hypersensitive to any of the macrolides. It should be used with caution in patients with impaired hepatic function.

### Adverse Effects

Azithromycin can cause vomiting in dogs if high doses are given, but compared to erythromycin, azithromycin has fewer GI adverse effects. Other adverse effects, particularly those associated with the liver, may become apparent in dogs and cats as more experience is attained. Local IV site reactions have occurred in patients receiving IV azithromycin. Foals may develop diarrhea while receiving the drug.

### Reproductive/Nursing Safety

Safety during pregnancy has not been fully established; use only when clearly necessary. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

### Overdosage/Acute Toxicity

Acute oral overdoses are unlikely to cause significant morbidity other than vomiting, diarrhea and GI cramping.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving azithromycin and may be of significance in veterinary patients:

■ **ANTACIDS (oral; magnesium- and aluminum-containing):** May reduce the rate of absorption of azithromycin; suggest separating dosages by 2 hours

■ **CISAPRIDE:** No data on azithromycin, but other macrolides contraindicated with cisapride; use with caution

■ **CYCLOSPORINE:** Azithromycin may potentially increase cyclosporine blood levels; monitor carefully

■ **DIGOXIN:** No data on azithromycin, but other macrolides can increase digoxin levels; monitor carefully

■ **TRIMOPRIDE:** Azithromycin use is contraindicated in patients taking nimeride (unlikely to be used in vet med, used for Tourette's disorder in humans). Acute death

**PRIMOZIDE:** Azithromycin is contraindicated in patients taking pimozide (unlikely to be used in vet med—used for Tourette's disorder in humans). Acid deaths have occurred.

## Doses

### ■ DOGS:

For susceptible infections:

- 5–10 mg/kg PO once daily for 3–5 days (Trepanier 1999), (Sykes 2003)
- 5 mg/kg PO once daily for 2 days, then every 3–5 days for a total of 5 doses (Aucoin 2002)
- For “Derm” infections: 5–10 mg/kg PO once daily for 5–7 days. For animals that are difficult to pill, a dose given every 5 days (after the initial 5–7 day course of therapy) may be effective if continued treatment is necessary. (Merchant 2000)
- For canine pyoderma: 10 mg/kg PO once daily for 5–10 days (Ramadinha *et al.* 2002)
- For *Babesia gibsoni* (Asian genotype) infections: Atovaquone 13.3 mg/kg PO q8h with a fatty meal and Azithromycin 10 mg/kg PO once daily. Give both drugs for 10 days. Reserve immunosuppressive therapy for cases that are not rapidly responding (3–5 days) to anti-protozoal therapy. (Birkenheuer, AJ *et al.* 2004), (Birkenheuer, A 2006)
- For idiopathic lymphoplasmacytic (chronic) rhinitis: Long term administration of antibiotics having immunomodulatory effects combined with nonsteroidal antiinflammatory agents can be helpful in some dogs. Doxycycline 3–5 mg/kg PO q12h, or azithromycin 5 mg/kg PO q24h in combination with piroxicam 0.3 mg/kg PO q24h. (Kuehn 2010)

### ■ CATS:

For susceptible infections:

- 5–10 mg/kg PO once daily for 3–5 days (Trepanier 1999), (Sykes 2003)
- 5 mg/kg PO once daily for 2 days, then every 3–5 days for a total number of doses of 5 (Aucoin 2002)
- For “Derm” infections: 7–15 mg/kg PO q12h daily for 5–7 days. For animals that are difficult to pill, a dose given every 5 days (after the initial 5–7 day course of therapy) may be effective if continued treatment is necessary. (Merchant 2000)
- For susceptible upper respiratory infections: 5–10 mg/kg PO once daily for 5 days, then q72h (every 3rd day) long-term. If there is an initial positive response to the antibiotic, therapy should be continued for 6–8 weeks without changing the antibiotic. (Scherk 2006)
- For Bartonellosis: 10 mg/kg PO once daily for 21 days. Response to therapy is rapid; most cats with anterior uveitis will show significant improvement in less than one week. Recurrence after 21 days of treatment, followed by good flea control, is low. Failure of Bartonella positive cats to respond indicates that Bartonella is part of a polymicrobial disease syndrome. (Ketring 2009)

### ■ HORSES:

For treatment of *R. equi* infections in foals:

- 10 mg/kg PO once daily. Because of persistence of high levels in bronchoalveolar cells and pulmonary epithelial lining fluid, after 5 days of once daily treatment, every other day (q48h) dosing may be appropriate. (Jacks *et al.* 2001)

### ■ RODENTS/SMALL MAMMALS:

- Rabbits: For Staphylococcus osteomyelitis: 50 mg/kg PO once daily with 40 mg/kg of rifampin q12h PO (Ivey & Morrisey 2000)
- Rabbits: For jaw abscesses: 15–30 mg/kg PO once daily (q24h). Systemic antibiotic treatment is continued for 2–4 weeks post-operatively. Advise owners to discontinue treatment if anorexia or diarrhea occurs. (Johnson 2006b)
- Guinea pigs: For Pneumonia: 15–30 mg/kg PO once daily (q24h). Advise owners to discontinue treatment if soft stools develop. (Johnson 2006a)

### ■ BIRDS:

- For Chlamydiosis; study done in experimentally infected cockatiels: Azithromycin 40 mg/kg PO once every other day (q48h) for 21 days (as effective as a 21 or 45 day treatment with doxycycline). Birds were dosed via metallic feeding tube into crop using the commercially available (*Zithromax*®) human oral suspension. (Guzman *et al.* 2010)

## Monitoring

- Clinical efficacy
- Adverse effects

## Client Information

- Give medication as prescribed. Do not refrigerate oral suspension and shake well before each use. If using the suspension, preferably give to an animal with an empty stomach. Discard any unused oral suspension after 14 days.
- Contact veterinarian if animal develops severe diarrhea or vomiting, or if condition deteriorates after beginning therapy.

## Chemistry/Synonyms

A semisynthetic azalide macrolide antibiotic, azithromycin dihydrate occurs as a white crystalline powder. In one mL of water at neutral pH and at 37° C, 39 mg are soluble. Although commercial preparations are available as the dihydrate, potency is noted as the anhydrous form.

Azithromycin may also be known as: azithromycinum, acitromicina, CP-62993, or XZ-450; many trade names are available.

## Storage/Stability

The commercially available tablets should be stored at temperatures less than 30°C. Products for reconstitution for oral suspension should be stored between 5–30°C before reconstitution with water. After reconstitution the multiple dose product may be stored between 5–30°C for up to ten days and then discarded. The single dose packets should be given immediately after reconstitution.

The injectable product should be stored below 30°C. After reconstitution with sterile water for injection, solutions containing 100 mg/mL are stable for 24 hours if stored below 30°C.

## Compatibility/Compounding Considerations

Azithromycin injection is physically and chemically **compatible** with several intravenous solutions, including: half-normal and normal saline, D5W, LRS, D5 with 0.3% or 0.45% sodium chloride, and D5 in LRS. When azithromycin injection is diluted into 250–500 mL of one of the above solutions, it remains physically and chemically stable for 24 hours at room temperature and up to 7 days if kept refrigerated at 5°C.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

Preparations compounded for dogs and cats may be available from compounding pharmacies.

## HUMAN-LABELED PRODUCTS:

Azithromycin Oral Tablets: 250 mg, 500 mg & 600 mg (as dihydrate); *Zithromax*® (Pfizer); generic; (Rx)

Azithromycin Powder for Oral Suspension: After reconstitution: 100 mg/5 mL in 15 mL bottles; 200 mg/5 mL in 15, 22.5 & 30 mL bottles; 1 g/packet in single-dose packets of 3's & 10's; *Zithromax*® (Pfizer); generic; and extended-release powder for oral suspension in 2 g single-dose bottles *Zmax*® (Pfizer); (Rx)

Azithromycin Powder for Injection (lyophilized): 500 mg in 10 mL vials; *Zithromax*® (Pfizer); generic; (Rx)

---

## AZTREONAM

(*az-tree-oh-nam*) Azactam®

INJECTABLE MONOBACTAM ANTIBACTERIAL

### Prescriber Highlights

- **Monobactam injectable antibiotic with good activity against a variety of gram-negative aerobic bacteria**
- **May be considered for use for treating serious infections, when aminoglycosides or fluoroquinolones are ineffective or relatively contraindicated**
- **Very limited information available regarding dosing & adverse effect profile**

---

## Uses/Indications

Aztreonam is a monobactam antibiotic that may be considered for use in small animals for treating serious infections caused by a wide variety of aerobic and facultative gram-negative bacteria, including strains of *Citrobacter*, *Enterobacter*, *E. coli*, *Klebsiella*, *Proteus*, *Pseudomonas* and *Serratia*. The drug exhibits good penetration into most tissues and low toxic potential and may be of benefit in treating infections when an aminoglycoside or a fluoroquinolone are either ineffective or are relatively contraindicated. Any consideration for using aztreonam must be tempered with the knowledge that little clinical experience or research findings have been published with regard to target species.

Aztreonam has also been used to treat pet fish (koi) infected with *Aeromonas salmonicida*.

## Pharmacology/Actions

Aztreonam is a bactericidal antibiotic that binds to penicillin-binding protein-3 thereby inhibiting bacterial cell wall synthesis resulting in cell lyses and death of susceptible bacteria. Aztreonam is relatively stable to the effects of bacterial beta-lactamases and unlike many other beta-lactam antibiotics, it does not induce the activity of beta-lactamases.

Aztreonam has activity against many species and most strains of the following gram-negative bacteria: *Aeromonas*, *Citrobacter*, *Enterobacter*, *E. coli*, *Klebsiella*, *Pasturella*, *Proteus*, *Pseudomonas* and *Serratia*. It is not clinically efficacious against gram-positive or anaerobic bacteria.

Aztreonam can be synergistic against *Pseudomonas aeruginosa* and other gram-negative bacilli when used with aminoglycosides.

## Pharmacokinetics

There is limited information published on the pharmacokinetic parameters of aztreonam in dogs and none was located for cats.

In dogs, after a 20 mg/kg dose was administered IM, peak plasma levels of approximately 40 micrograms/mL occurred in about 20 minutes. Serum protein binding is about 20–30%, compared to 65% in humans. High tissue levels are found in the kidney (approx. 2.5X that of plasma). Liver concentrations approximate those found in plasma and lower levels are found in the lung and spleen. The drug is primarily (80%) excreted unchanged in the dog. Elimination half-lives are approximately 0.7 hours after IV administration and 0.9 hours after IM administration. These values are approximately twice as short as those reported in humans (ages 1 yr to adult) with normal renal function.

## Contraindications/Precaution/Warnings

Aztreonam should not be used in patients with documented severe hypersensitivity to the compound. Patients with serious renal dysfunction may need dosage adjustment. Use cautiously in patients with serious liver dysfunction.

## Adverse Effects

Adverse effect profiles for aztreonam specific to target species were not located. Aztreonam's adverse effects in humans are similar to those of other beta-lactam antibiotics: hypersensitivity, gastrointestinal effects including GI bacterial overgrowth/Pseudomembranous colitis, pain and/or swelling after IM injection, and phlebitis after IV administration. Transient increases in liver enzymes, serum creatinine, and coagulation indices have been noted.

## Reproductive/Nursing Safety

Aztreonam crosses the placenta and can be detected in fetal circulation. However, no evidence of teratogenicity or fetal toxicity have been reported after doses of up to 5 times normal were given to pregnant rats and rabbits. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Aztreonam has been detected in human breast milk at levels approximately 1% of those found in serum. As the drug is not absorbed orally, it is likely safe to use in nursing animals though antibiotic-associated diarrhea is possible.

## Overdosage/Acute Toxicity

There is little reason for concern in patients with adequate renal function. The IV LD<sub>50</sub> for mice is 3.3 g/kg. Hemodialysis or peritoneal dialysis may be used to clear aztreonam from the circulation.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving aztreonam and may be of significance in veterinary patients:

■ **PROBENECID:** Can reduce the renal tubular secretion of aztreonam, thereby maintaining higher systemic levels for a longer period of time; this potential “beneficial” interaction requires further investigation before dosing recommendations can be made for veterinary patients

For *in vitro* interactions, see the Storage-Stability-Compatibility section.

## Laboratory Considerations

■ Aztreonam may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by aztreonam.

## Doses

### ■ DOGS:

**Note:** Dosages for this medication are not well established for use in veterinary patients. For dogs, an anecdotal dosing suggestion is to use the human pediatric dose of 30 mg/kg IM or IV q6–8h. When compared to humans, aztreonam has a shorter half-life, but is about half as bound to plasma proteins; the human pediatric dose may be a reasonable choice until more data becomes available.

### ■ FISH:

a) For treating *Aeromonas salmonicida* in koi: 100 mg/kg IM or ICe (intracoelemic) every 48 hours for 7 treatments. (Lewbart 2005)

## Monitoring

- Because monobactams usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop
- Serum levels and therapeutic drug monitoring are not routinely performed with this agent

## Client Information

- Veterinary professionals only should administer this medication
- Because of the dosing intervals required, this drug is best administered to inpatients only

## Chemistry/Synonyms

Aztreonam is a synthetic monobactam antimicrobial. It occurs as a white, odorless crystalline powder.

Aztreonam may also be known as: Aztreonamum, Azthreonom, Atstreonaami, SQ-26776, *Monobac*®, *Azactam*®, *Aztreotic*®, *Azenam*®, *Primbactam*®, *Trezam*®, or *Urobactam*®.

## Storage/Stability

Commercially available powder for reconstitution should be stored at room temperature (15°–30°C).

For IM use, add at least 3 mL of diluent (sterile water for injection, bacteriostatic sterile water for injection, NS, or bacteriostatic sodium chloride injection.) Solutions are stable for 48 hours at room temperature, 7 days if refrigerated.

For direct IV use, add 6–10 mL of sterile water for injection to each 15 or 30 mL vial. If the medication is to be given as an infusion, add at least 3 mL of sterile water for injection for each gram of aztreonam powder; then add the resulting solution to a suitable IV diluent (NS, LRS, D5W, etc.) so that the final concentration does not exceed 20 mg/mL. Inspect all solutions for visible particulate matter. Solutions may be colorless or a light, straw yellow color; upon standing, a light pink color may develop which does not affect the drug's potency. Intravenous solutions not exceeding concentrations of 20 mg/mL are stable for 48 hours at room temperature, 7 days if refrigerated. The package insert has specific directions for freezing solutions after dilution.

## Compatibility/Compounding Considerations

Intravenous admixtures containing aztreonam are **compatible** with clindamycin, amikacin, gentamicin, tobramycin, ampicillin-sulbactam, imipenem-cilastatin, morphine, propofol, piperacillin-tazobactam, ticarcillin-clavulanate, ranitidine, sodium bicarbonate, potassium chloride, butorphanol, furosemide, hydromorphone, cefotaxime, cefuroxime, ceftriaxone and cefazolin. It is **not compatible** with metronidazole, nafcillin, amphotericin B, or vancomycin.

## Dosage Forms/Regulatory Status

agens. Atropine has been suggested to improve ventilation, heart rate, BP, and body temperature. Diazepam may be useful for treating seizures. Intravenous lipids may potentially be useful as baclofen is lipid soluble. Contact an animal poison control center for further information and guidance.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving baclofen and may be of significance in veterinary patients:

- **CNS DEPRESSANTS (other):** May cause additive CNS depression

## Laboratory Considerations

- Increased **AST, alkaline phosphate** and **blood glucose** have been reported in humans

## Doses

### ■ DOGS:

To treat urinary retention by decreasing urethral resistance:

- 1–2 mg/kg PO q8h (Coates 1999), (Labato 2005), (Lulich 2004)
- 5–10 mg (total dose) PO q8h (Senior 1999)

## Monitoring

- Efficacy
- Adverse effects

## Client Information

- Do not stop therapy abruptly without veterinarian approval

## Chemistry/Synonyms

A skeletal muscle relaxant that acts at the spinal cord level, baclofen occurs as white to off-white crystals. It is slightly soluble in water and has pKa values of 5.4 and 9.5.

Baclofen may also be known as: aminomethyl chlorohydrocinnamic acid, Ba-34647, baclofenum, *Baclo*®, *Baclohexal*®, *Baclon*®, *Baclopar*®, *Baclosal*®, *Baclospas*®, *Balgifen*®, *Clinispas*®, *Clofen*®, *Kemstro*®, *Lebic*®, *Lioresal*®, *Liotec*®, *Miorel*®, *Neurospas*®, *Nu-Baclo*®, *Pacifen*®, or *Vioridon*®.

## Storage/Stability

Do not store tablets above 30°C (86°F). Intrathecal product should be stored at room temperature; do not freeze or heat sterilize.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Baclofen oral suspension compounded from commercially available tablets has been published (Allen 1996). Triturating one-hundred twenty (120) baclofen 10 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® SF) yields a 10 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of baclofen should be protected from light.

Another oral liquid compounding recipe has been described (Olin 2000): To prepare a 5 mg/mL liquid (35 day expiration date). Grind fifteen 20 mg tablets in a glass mortar to fine powder. Wet the powder with 10 mL of glycerin and form a fine paste. Slowly add 15 mL of simple syrup to the paste and transfer to a glass amber bottle. Rinse the mortar and pestle with another 15 mL of simple syrup and transfer to the bottle. Repeat until final volume is 60 mL. Shake well before each use and store in the refrigerator.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### **HUMAN-LABELED PRODUCTS:**

Baclofen Tablets: 10 mg & 20 mg; *Lioresal*® (Novartis); generic; (Rx); 10 mg & 20 mg orally disintegrating tablets: *Kemstro*® (Schwarz); (Rx)

Baclofen Intrathecal Injection: 0.05 mg/mL (50 micrograms/mL) preservative-free in single-use amps, 10 mg per 20 mL (500 micrograms/mL) preservative-free in single-use amps (1 amp refill kit) & 10 mg/5 mL (2000 micrograms/mL) preservative-free in single-use amps (2 or 4 amp refill kits); *Lioresal*® *Intrathecal* (Medtronic); (Rx)

## BARBITURATE PHARMACOLOGY

(bar-bich-yoo-rate; bar-bi-toor-ate)

Also see the monographs for [Methohexital](#), [Phenobarbital](#), [Pentobarbital](#), and [Thiopental](#).

---

While barbiturates are generally considered CNS depressants, they can invoke all levels of CNS mood alteration from paradoxical excitement to deep coma and death. While the exact mechanisms for the CNS effects caused by barbiturates are unknown, they have been shown to inhibit the release of acetylcholine, norepinephrine, and glutamate. The barbiturates also have effects on GABA and pentobarbital has been shown to be GABA-mimetic. At high anesthetic doses, barbiturates have been demonstrated to inhibit the uptake of calcium at nerve endings.

The degree of depression produced is dependent on the dosage, route of administration, pharmacokinetics of the drug, and species treated. Additionally, effects may be altered by patient age, physical condition, or concurrent use of other drugs. The barbiturates depress the sensory cortex, lessen motor activity, and produce sedation at low dosages. In humans, it has been shown that barbiturates reduce the rapid-eye movement (REM) stage of sleep. Barbiturates have no true intrinsic analgesic activity.

In most species, barbiturates cause a dose-dependent respiratory depression, but, in some species, they can cause slight respiratory stimulation. At sedative/hypnotic doses, respiratory depression is similar to that during normal physiologic sleep. As doses increase, the medullary respiratory center is progressively depressed with resultant decreases in rate, depth, and volume. Respiratory arrest may occur at doses four times lower than those will cause cardiac arrest. These drugs must be used very cautiously in cats; they are particularly sensitive to the respiratory depressant effects of barbiturates.

Besides the cardiac arresting effects of the barbiturates at euthanating dosages, the barbiturates have other cardiovascular effects. In the dog, pentobarbital has been demonstrated to cause tachycardia, decreased myocardial contractility and stroke volume, and decreased mean arterial pressure and total peripheral resistance.

The barbiturates cause reduced tone and motility of the intestinal musculature, probably secondary to its central depressant action. The thiobarbiturates (thiamylal, thiopental) may, after initial depression, cause an increase in both tone and motility of the intestinal musculature; however, these effects do not appear to have much clinical significance. Administration of barbiturates reduces the sensitivity of the motor end-plate to acetylcholine thereby slightly relaxing skeletal muscle. Because the musculature is not completely relaxed, other skeletal muscle relaxants may be necessary for surgical procedures.

There is no direct effect on the kidney by the barbiturates, but severe renal impairment may occur secondary to hypotensive effects in overdose situations. Liver function is not directly affected when used acutely, but hepatic microsomal enzyme induction is well documented with extended barbiturate (especially phenobarbital) administration. Although barbiturates reduce oxygen consumption of all tissues, no change in metabolic rate is measurable when given at sedative dosages. Basal metabolic rates may be reduced with resultant decreases in body temperature when barbiturates are given at anesthetic doses.

---

## BENAZEPRIL HCL

(ben-a-za-pril) Fortekor®, Lotensin®

ANGIOTENSIN CONVERTING ENZYME (ACE) INHIBITOR

### Prescriber Highlights

- **ACE inhibitor that may be useful for treating heart failure, hypertension, chronic renal failure & protein-losing glomerulonephropathies in dogs & cats; particularly useful in patients with hypertension and proteinuria**
  - **Caution in patients with hyponatremia, coronary or cerebrovascular insufficiency, SLE, hematologic disorders**
  - **GI disturbances most likely adverse effects, but hypotension, renal dysfunction, hyperkalemia possible**
  - **Mildly fetotoxic at high dosages**
- 

### Uses/Indications

Benazepril may be useful as a vasodilator in the treatment of heart failure and as an antihypertensive agent, particularly in dogs. Reasonable evidence exists that ACE-inhibitors increase survival (when compared to placebo) in dogs with dilated cardiomyopathy and mitral valve disease. Benazepril may be of benefit in treating the clinical signs associated with valvular heart disease and left to right shunts. ACE inhibitors may also be of benefit in the adjunctive treatment of chronic renal failure and for protein losing nephropathies.

In cats, benazepril (or enalapril) can be used for treating hypertension, adjunctive treatment of hypertrophic cardiomyopathy, and reducing protein loss associated with chronic renal failure.

### Pharmacology/Actions

Benazepril is a prodrug and has little pharmacologic activity of its own. After being hydrolyzed in the liver to benazeprilat, the drug inhibits the conversion of angiotensin-I to angiotensin-II by inhibiting angiotensin-converting enzyme (ACE). Angiotensin-II acts both as a vasoconstrictor and stimulates production of aldosterone in the adrenal cortex. By blocking angiotensin-II formation, ACE inhibitors generally reduce blood pressure in hypertensive patients and vascular resistance in patients with congestive heart failure. There is no evidence that ACE inhibitors reduce abnormal cardiac hypertrophy in cats.

When administered to dogs with heart failure at low dosages (0.1 mg/kg q12h), benazepril improved clinical signs, but did not significantly affect blood pressure (Wu & Juany 2006)

In cats with chronic renal failure, benazepril has been shown to reduce systemic arterial pressure and glomerular capillary pressure while increasing renal plasma flow and glomerular filtration rates. It may also help improve appetite.

ACE inhibitors' proteinuric reducing effects are most likely a result of reducing intraglomerular hypertension by a vasodilating effect on postglomerular arterioles.

Like enalapril and lisinopril, but not captopril, benazepril does not contain a sulfhydryl group. ACE inhibitors containing sulfhydryl groups (*e.g.*, captopril) may have a greater tendency of causing immune-mediated reactions.

### Pharmacokinetics

After oral dosing in healthy dogs, benazepril is rapidly absorbed and converted into the active metabolite benazeprilat with peak levels of benazeprilat occurring approximately 75 minutes after dosing. The elimination half-life of benazeprilat is approximately 3.5 hours in healthy dogs. Unlike enalaprilat, which is approximately 95% cleared in dogs via renal mechanisms, benazeprilat is cleared via both renal (45%) and hepatic (55%) routes.

In cats, inhibition of ACE is long-lasting (half-life of 16–23 hours), despite relatively quick elimination of free benazeprilat, due to high affinity of benazeprilat to ACE. Because enalaprilat inhibits non-linear binding of benazeprilat to ACE, doses greater than 0.25 mg/kg PO produced only small incremental increases in peak

ACE. Benazepril exhibits nonlinear binding or benazeprilat to ACE, doses greater than 0.25 mg/kg PO produced only small incremental increases in peak effect or duration of ACE inhibition. (King *et al.* 2003)

In humans, approximately 37% of an oral dose is absorbed after oral dosing and food apparently does not affect the extent of absorption. About 95% of the parent drug and active metabolite are bound to serum proteins. Benazepril and benazeprilat are primarily eliminated via the kidneys and mild to moderate renal dysfunction apparently does not significantly alter elimination as biliary clearance may compensate somewhat for reductions in renal clearances. Hepatic dysfunction or age does not appreciably alter benazeprilat levels.

### Contraindications/Precautions/Warnings

Benazepril is contraindicated in patients who have demonstrated hypersensitivity to the ACE inhibitors.

ACE inhibitors should be used with caution in patients with hyponatremia or sodium depletion, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities or a collagen vascular disease (*e.g.*, SLE). Patients with severe CHF should be monitored very closely upon initiation of therapy.

Potentially, ACE inhibitors could worsen preexisting azotemia; using a lower dose and monitoring creatinine and BUN has been recommended (Bartges 2009).

### Adverse Effects

Benazepril's adverse effect profile in dogs is not well described, but other ACE inhibitors effects in dogs usually center around GI distress (anorexia, vomiting, diarrhea). Potentially, hypotension, renal dysfunction and hyperkalemia could occur. Because it lacks a sulfhydryl group (unlike captopril), there is less likelihood that immune-mediated reactions will occur, but rashes, neutropenia and agranulocytosis have been reported in humans.

In healthy cats given mild overdoses (2 mg/kg PO once daily for 52 weeks), only increased food consumption and weight were noted.

### Reproductive/Nursing Safety

Benazepril apparently crosses the placenta. High doses of ACE inhibitors in rodents have caused decreased fetal weights and increases in fetal and maternal death rates; no teratogenic effects have been reported to date, but use during pregnancy should occur only when the potential benefits of therapy outweigh the risks to the offspring. In humans, the FDA categorizes this drug as category **C** for use during the first trimester of pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) During the second and third trimesters, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Benazepril is distributed into milk in very small amounts.

### Overdosage/Acute Toxicity

In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug's long duration of action, prolonged monitoring and treatment may be required. Recent massive overdoses should be managed using gut-emptying protocols as appropriate.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving benazepril and may be of significance in veterinary patients:

- **ASPIRIN:** Aspirin may potentially negate the decrease in systemic vascular resistance induced by ACE inhibitors; however, one study in dogs using low-dose aspirin, the hemodynamic effects of enalaprilat (active metabolite of enalapril, a related drug) were not affected
- **ANTIDIABETIC AGENTS (insulin, oral agents):** Possible increased risk for hypoglycemia; enhanced monitoring recommended
- **DIURETICS (*e.g.*, furosemide, hydrochlorothiazide):** Potential for increased hypotensive effects; some veterinary clinicians recommend reducing furosemide doses (by 25–50%) when adding enalapril or benazepril to therapy for heart failure
- **DIURETICS, POTASSIUM-SPARING (*e.g.*, spironolactone, triamterene):** Increased hyperkalemic effects, enhanced monitoring of serum potassium
- **LITHIUM:** Increased serum lithium levels possible; increased monitoring required
- **POTASSIUM SUPPLEMENTS:** Increased risk for hyperkalemia

### Laboratory Considerations

- When using **iodohippurate sodium I123/I134 or Technetium Tc99 pententate renal imaging** in patients with renal artery stenosis, ACE inhibitors may cause a reversible decrease in localization and excretion of these agents in the affected kidney which may lead to confusion in test interpretation.

### Doses

#### ■ DOGS:

For adjunctive treatment of heart failure:

- a) 0.25–0.5 mg/kg PO once daily (Miller & Tilley 1995); (Kittleston 2007)
- b) 0.25–0.5 mg/kg PO once to twice daily (Ware 1997)

For adjunctive treatment of hypertension and/or proteinuria:

- a) As a first step drug for systolic hypertension >160 mmHg, diastolic >120 mmHg; after **1**) enalapril/benazepril (0.5 mg/kg q12h); **2**) amlodipine (0.1 mg/kg q24h); **3**) amlodipine (0.2 mg/kg q24h); **4**) spironolactone (1–2 mg/kg twice daily); **5**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1-2 weeks systolic BP > 160 mmHg. (Henik 2007)
- b) 0.25–0.5 mg/kg q12–24h; Co-administration with a calcium channel antagonist may lower blood pressure when monotherapy is not sufficient. In diabetic dogs, an ACE inhibitor may block adverse effects of calcium channel antagonists. (Brown 2003)
- c) For hypertension associated with protein-losing renal disease: 0.5 mg/kg PO once daily (q24h) Response may be variable in dogs with hypertension secondary to other diseases; ACE inhibitors are usually well tolerated and can be tried in non-emergency hypertension. (Stepien 2006)
- d) For proteinuria, hypertension: 0.25–1 mg/kg PO q12-24h. Potentially, ACE inhibitors could worsen preexisting azotemia; using a lower dose and monitoring creatinine and BUN is recommended (Bartges 2009).

## CATS:

For adjunctive treatment of heart failure:

- a) 0.25–0.5 mg/kg PO once daily (Kittleson 2007)
- b) For CHF or hypertension: 0.25–0.5 mg/kg PO once to twice daily (Atkins 2003)

For adjunctive treatment of hypertension:

- a) 0.5–1 mg/kg PO once daily (Sparkes 2003), (Adams 2009)
- b) 0.25–1 mg/kg PO once to twice daily. Because of their antiproteinuric effects, ACE inhibitors are the drugs of first choice to treat hypertension in animals with proteinuria. (Langston 2003)
- c) 0.25–0.5 mg/kg PO once daily (q24h) (Stepien 2006)
- d) For proteinuria, hypertension associated with chronic kidney disease: 0.25–0.5 mg/kg PO once to twice daily (q12–24h); rarely higher (Polzin 2006)
- e) For proteinuria, hypertension: 0.25–1 mg/kg PO q12–24h. Potentially, ACE inhibitors could worsen preexisting azotemia; using a lower dose and monitoring creatinine and BUN is recommended (Bartges 2009).
- f) As a 2nd step drug when systolic BP >160 mmHg, diastolic >120 mmHg: **1**) amlodipine (0.625 mg per cat q24h, if cat greater than 6 kg, 1.25 mg/cat q24h), add ACE inhibitor if proteinuric; **2**) ACE inhibitor (benazepril/enalapril 0.5 mg/kg q12h); **3**) spironolactone (1–2 mg/kg twice daily); **4**) hydralazine 0.5 mg/kg PO twice daily. Each step added (except when increasing amlodipine dose) if after 1–2 weeks systolic BP > 160 mmHg. (Henik 2007)

## Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- Blood pressure (if treating hypertension or clinical signs associated with hypotension arise)

## Client Information

- Do not abruptly stop or reduce therapy without veterinarian's approval. Contact veterinarian if vomiting or diarrhea persist or is severe or if animal's condition deteriorates.

## Chemistry/Synonyms

Benazepril HCl, an angiotensin converting enzyme inhibitor, occurs as white to off-white crystalline powder. It is soluble in water and ethanol. Benazepril does not contain a sulfhydryl group in its structure.

Benazepril may also be known as: CGS-14824A (benazepril or benazepril hydrochloride), *Benace*®, *Boncordin*®, *Briem*®, *Cibace*®, *Cibacen*®, *Cibacen*®, *Cibacene*®, *Fortekor*®, *Labopal*®, *Lotensin*®, *Lotrel*®, *Tensanil*®, or *Zinadril*®.

## Storage/Stability

Benazepril tablets (and combination products) should be stored at temperatures less than 86°F (30°C) and protected from moisture. They should be dispensed in tight containers.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA

In the UK (and elsewhere): Benazepril Tablets: 2.5 mg, 5 mg, & 20 mg; *Fortekor*® (Novartis—UK); (POM-V) Labeled for use in cats for chronic renal insufficiency and for heart failure in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Benazepril HCl Oral Tablets: 5 mg, 10 mg, 20 mg, & 40 mg; *Lotensin*® (Novartis); generic; (Rx)

Also available in fixed dose combination products containing amlodipine (*Lotrel*®) or hydrochlorothiazide (*Lotensin HCT*®)

## BETAMETHASONE

### BETAMETHASONE ACETATE

### BETAMETHASONE SODIUM PHOSPHATE

(bet-ta-meth-a-son) Celestone®

## GLUCOCORTICOID

**Note:** For more information on the pharmacology of glucocorticoids refer to the monograph: Glucocorticoids, General information. For topical or otic use, see the Topical Dermatology & Otic sections in the appendix.

- **Injectable (long-acting) & topical glucocorticoid**
  - **Long acting; 25–40X more potent than hydrocortisone; no mineralocorticoid activity**
  - **Goal is to use as much as is required & as little as possible for as short an amount of time as possible**
  - **Primary adverse effects are “Cushingoid” in nature with sustained use**
  - **Many potential drug & lab interactions when used systemically**
- 

### Contraindications/Precautions/Warnings

For the product *Betasone*® (Schering), the manufacturer states that the drug is “contraindicated in animals with acute or chronic bacterial infections unless therapeutic doses of an effective antimicrobial agent are used.” Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with “burst” therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a “stressor” (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy.

### Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined in the Pharmacology section of the Glucocorticoids, General information monograph.

In dogs, polydipsia (PD), polyphagia (PP) and polyuria (PU), may all be seen with short-term “burst” therapy as well as with alternate-day maintenance therapy on days when given the drug. Adverse effects in dogs associated with long-term use can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to “Cushingoid” effects.

### Reproductive/Nursing Safety

In addition to the contraindications, precautions and adverse effects outlined above, betamethasone has been demonstrated to cause decreased sperm output and semen volume and increased percentages of abnormal sperm in dogs.

Use with caution in nursing dams. Corticosteroids appear in milk and could suppress growth, interfere with endogenous corticosteroid production or cause other unwanted effects in the nursing offspring. However, in humans, several studies suggest that amounts excreted in breast milk are negligible when prednisone or prednisolone doses in the mother are less than or equal to 20 mg/day or methylprednisolone doses are less than or equal to 8 mg/day. Larger doses for short periods may not harm the infant.

### Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving betamethasone systemically and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS (e.g., pyridostigmine, neostigmine, etc.):** In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness; if possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN AND OTHER SALICYLATES:** Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES:** May increase the metabolism of glucocorticoids
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each by mutually inhibiting hepatic metabolism; clinical significance is not clear
- **DIGOXIN:** When glucocorticoids are used concurrently with digitalis glycosides, an increased chance of digitalis toxicity may occur should hypokalemia develop; diligent monitoring of potassium and digitalis glycoside levels is recommended.
- **DIURETICS, POTASSIUM-DEPLETING (e.g., furosemide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ESTROGENS:** May decrease corticosteroid clearance
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids

■ **ADRENAL REQUIREMENTS:** Requirements may increase in patients receiving glucocorticoids

■ **ISONIAZID:** May have serum levels decreased by corticosteroids

■ **KETOCONAZOLE:** Corticosteroid clearance may be reduced and the AUC increased

■ **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency

■ **RIFAMPIN:** May increase the metabolism of glucocorticoids

■ **THEOPHYLLINES:** Alterations of pharmacologic effects of either drug can occur

■ **ULCEROGENIC DRUGS (e.g., NSAIDS):** Use with glucocorticoids may increase the risk of gastrointestinal ulceration

■ **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

### Laboratory Considerations

■ Glucocorticoids may increase **serum cholesterol** and **urine glucose** levels

■ Glucocorticoids may decrease **serum potassium**

■ Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T<sub>3</sub> & T<sub>4</sub>** values; thyroid gland atrophy has been reported after chronic glucocorticoid administration

■ Uptake of **I131** by the thyroid may be decreased by glucocorticoids

■ Reactions to **skin tests** may be suppressed by glucocorticoids

■ False-negative results of the **nitroblue tetrazolium test** for systemic bacterial infections may be induced by glucocorticoids

■ Betamethasone does not cross-react with the cortisol assay

### Doses

#### ■ DOGS:

For the control of pruritus:

a) *Betasone® Aqueous Suspension*: 0.25–0.5 mL per 20 pounds body weight IM. Dose dependent on severity of condition. May repeat when necessary. Relief averages 3 weeks in duration. Do not exceed more than 4 injections. (Package Insert; *Betasone®*—Schering) **Note:** Product no longer marketed in the USA.

■ **HORSES:** Source of product an issue. Alternative is [triamcinolone](#) (see that monograph for additional information). (**Note:** ARCI UCGFS Class 4 Drug)

As a relatively short-acting corticosteroid for intraarticular administration:

a) 6–15 mg per joint IA. Frequency of re-injection is limited to the minimum number needed to achieve soundness. (Frisbee 2003)

### Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

■ Weight, appetite, signs of edema

■ Serum and/or urine electrolytes

■ Total plasma proteins, albumin

■ Blood glucose

■ Growth and development in young animals

■ ACTH stimulation test if necessary

### Client Information

■ Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting veterinarian beforehand

■ Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress

### Chemistry/Synonyms

A synthetic glucocorticoid, betamethasone is available as the base and as the dipropionate, acetate and sodium phosphate salts. The base is used for oral dosage forms. The sodium phosphate and acetate salts are used in injectable preparations. The dipropionate salt is used in topical formulations and in combination with the sodium phosphate salt in a veterinary-approved injectable preparation.

Betamethasone occurs as an odorless, white to practically white, crystalline powder. It is insoluble in water and practically insoluble in alcohol. The dipropionate salt occurs as a white or creamy-white, odorless powder. It is practically insoluble in water and sparingly soluble in alcohol. The sodium phosphate salt occurs as an odorless, white to practically white, hygroscopic powder. It is freely soluble in water and slightly soluble in alcohol.

Betamethasone may also be known as flubenisolone or *Celestone®*.

### Storage/Stability

Betamethasone tablets should be stored in well-closed containers at 2–30°C. The oral solution should be stored in well-closed containers, protected from light and kept at temperatures less than 40°C. The sodium phosphate injection should be protected from light and stored at room temperature (15–30°C); protect from freezing. The combination veterinary injectable product (*Betasone®*) should be stored between 2–30°C and protected from light and freezing.

### Compatibility/Compounding Considerations

When betamethasone sodium phosphate was mixed with heparin sodium, hydrocortisone sodium succinate, potassium chloride, vitamin B-complex with C, dextrose 5% in water (D5W), D5 in Ringer's D5 in lactated Ringer's, D5 in normal saline, and 0.9% sodium chloride injection, compatibility was maintained for 14 days at room temperature.

5% in water (D5W), D5 in Ringer's, D5 in lactated Ringer's, Ringer's lactate injection or normal saline, no physical incompatibility was noted immediately or after 4 hours.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

The following product is apparently no longer marketed in the USA. Betamethasone Dipropionate Injection equivalent to 5 mg/mL of betamethasone and betamethasone sodium phosphate equivalent to 2 mg/mL betamethasone in 5 mL vials; *Betasone*® (Schering-Plough); (Rx). FDA-approved for use in dogs.

Betamethasone valerate is also found in *Gentocin*® Otic, *Gentocin*® Topical Spray and *Topagen*® Ointment, (Schering-Plough). There are several other otic and topical products containing betamethasone and gentamicin on the veterinary market. See the appendix for more information on these products.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Betamethasone Oral Solution: 0.6 mg/5 mL in 118 mL; *Celestone*® (Schering); (Rx)

Betamethasone Injection: betamethasone (as sodium phosphate) 3 mg/mL and betamethasone acetate 3 mg/mL suspension in 5 mL multi-dose vials; *Celestone Soluspan*® (Schering); (Rx)

## BETHANECHOL CHLORIDE

(beh-than-e-kole) Urecholine®

CHOLINERGIC

### Prescriber Highlights

- **Cholinergic agent used primarily to increase bladder contractility; symptomatic treatment of dysautonomia**
  - **Principle contraindications are GI or urinary tract obstructions or if bladder wall integrity is in question**
  - **Adverse Effects: "SLUD" (salivation, lacrimation, urination, defecation)**
  - **Cholinergic crisis possible if injecting IV or SC, have atropine at the ready**
- 

## Uses/Indications

In veterinary medicine, bethanechol is used primarily to stimulate bladder contractions in small animals. It also can be used as an esophageal or general GI stimulant, although metoclopramide and/or neostigmine have largely supplanted it for these uses.

## Pharmacology/Actions

Bethanechol directly stimulates cholinergic receptors. Its effects are principally muscarinic and at usual doses has negligible nicotinic activity. It is more resistant to hydrolysis than acetylcholine by cholinesterase and, therefore, has an increased duration of activity.

Pharmacologic effects include increased esophageal peristalsis and lower esophageal sphincter tone, increased tone and peristaltic activity of the stomach and intestines, increased gastric and pancreatic secretions, increased tone of the detrusor muscle of the bladder, and decreased bladder capacity. At high doses after parenteral administration, effects such as increased bronchial secretions and constriction, miosis, lacrimation, and salivation can be seen. When administered SC or orally, effects are predominantly on the GI and urinary tracts.

## Pharmacokinetics

No information was located on the pharmacokinetics of this agent in veterinary species. In humans, bethanechol is poorly absorbed from the GI tract, and the onset of action is usually within 30-90 minutes after oral dosing. After subcutaneous administration, effects begin within 5-15 minutes and usually peak within 30 minutes. The duration of action after oral dosing may persist up to 6 hours after large doses and 2 hours after SC dosing. Subcutaneous administration yields a more enhanced effect on urinary tract stimulation than does oral administration.

Bethanechol does not enter the CNS after usual doses; other distribution aspects of the drug are not known. The metabolic or excretory fate of bethanechol has not been described.

## Contraindications/Precautions/Warnings

Contraindications to bethanechol therapy include: bladder neck or other urinary outflow obstruction, when the integrity of the bladder wall is in question (*e.g.*, as after recent bladder surgery), hyperthyroidism, peptic ulcer disease or when other inflammatory GI lesions are present, recent GI surgery with resections/anastomoses, GI obstruction or peritonitis, hypersensitivity to the drug, epilepsy, asthma, coronary artery disease or occlusion, hypotension, severe bradycardia or vagotonia or vasomotor instability. If urinary outflow resistance is increased due to enhanced urethral tone (not mechanical obstruction!), bethanechol should only be used in conjunction with another agent that will sufficiently reduce outflow resistance [*e.g.*, diazepam, dantrolene (striated muscle) or phenoxybenzamine (smooth muscle).]

## Adverse Effects

When administered orally to small animals, adverse effects are usually mild with vomiting, diarrhea, salivation, and anorexia being the most likely to occur. Cardiovascular (bradycardia, arrhythmias, hypotension) and respiratory effects (asthma, dyspnea) are most likely only seen after overdosage situations or with high dose SC therapy.

In horses, salivation, lacrimation and abdominal pain are potential adverse effects.

In horses, salivation, lacrimation and abdominal pain are potential adverse effects.

IM or IV use is not recommended except in emergencies when the IV route may be used. Severe cholinergic reactions are likely if given IV. If injecting the drug (SC or IV), it is recommended that atropine be immediately available.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if bethanechol is distributed into milk.

### Overdosage/Acute Toxicity

Clinical signs of overdosage are basically cholinergic in nature. Muscarinic effects (salivation, urination, defecation, etc.) are usually seen with oral or SC administration. If given IM or IV, a full-blown cholinergic crisis can occur with circulatory collapse, bloody diarrhea, shock and cardiac arrest possible.

Treatment for bethanechol toxicity is atropine. Refer to the atropine monograph for more information on its use. Epinephrine may also be employed to treat clinical signs of bronchospasm.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bethanechol and may be of significance in veterinary patients:

■ **ANTICHOLINERGIC DRUGS** (*e.g.*, atropine, glycopyrrolate, propantheline): Can antagonize bethanechol's effects

■ **CHOLINERGIC DRUGS** (*e.g.*, neostigmine, physostigmine, pyridostigmine): Because of additional cholinergic effects, bethanechol should generally not be used concomitantly with other cholinergic drugs

■ **GANGLIONIC BLOCKING DRUGS** (*e.g.*, mecamylamine): Can produce severe GI and hypotensive effects

■ **QUINIDINE, PROCAINAMIDE**: Can antagonize the effects of bethanechol

### Doses

**Note:** The injectable product is no longer commercially marketed in the USA

#### ■ DOGS:

For urinary indications:

a) To stimulate detrusor contractility: 5–25 mg (total dose) PO 2–3 times a day (Dickinson 2010)

b) 5–15 mg (total dose) PO q8h (Lulich 2003)

c) 5–25 mg (total dose) PO q8h (Bartges 2003)

d) 2.5–25 mg (total dose) PO three times daily (Coates 2004)

For increased esophageal sphincter tone:

a) 0.5–1 mg/kg PO q8h (Jones 1985)

For symptomatic treatment of dysautonomia:

a) 2.5–7.5 mg (total dose) PO divided q8–12h; may improve gastrointestinal motility and bladder emptying (Sisson 2004)

b) 1.25–5 mg (total dose) PO once daily (Willard 2003)

c) 0.05 mg/kg SC q12h and slowly increase as necessary. While SC administration gives better results, can also use 1.25–5 mg (total dose) q12h PO. (O'Brien 2003)

#### ■ CATS:

To increase bladder contractility:

a) 1.25–7.5 mg (total dose) PO two to three times daily (Lane 2003)

b) 1.25–7.5 mg per cat PO q8h (Osborne *et al.* 2000), (Bartges 2003)

For symptomatic treatment of dysautonomia:

a) 2.5–7.5 mg (total dose) PO divided q8–12h; may improve gastrointestinal motility and bladder emptying (Sisson 2004)

b) 1.25–5 mg (total dose) PO once daily (Willard 2003)

#### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

To stimulate detrusor muscle activity:

a) 0.025–0.075 mg/kg subcutaneously q8h. Dosage is variable and should be adjusted for each patient. (Jose-Cunilleras & Hinchcliff 1999)

b) For post-surgery bladder atony in foals: 0.4 mg/kg PO 2–3 times a day in a tapering withdrawal may restore function. (McKenzie 2009)

c) If bladder is capable of weak contractions: 0.025–0.075 mg/kg SC 2–3 times; or 0.25–0.75 mg/kg PO 2–4 times a day. **Note:** Oral dose is 10X that of SC dose (Schott II & Carr 2003)

#### ■ CATTLE:

For adjunctive medical therapy (with fluids, mineral oil, and NSAIDs if needed) of cecal dilation/dislocation (CDD):

a) Only if animal is "normal" or only slightly disturbed, defecation is present, and rectal exam does not reveal torsion or retroflexion. If these criteria are not met, or no improvement within 24 hours of medical therapy, surgical therapy is recommended. Bethanechol at 0.07 mg/kg SC three times daily for 2 days. Withhold feed for 24 hours and then gradually give increasing amounts of hay if defecation is present and CDD is resolved. (Meylan 2004)

### Monitoring

■ Clinical efficacy

- Urination frequency, amount voided, bladder palpation

- Adverse effects (see above section)

## Client Information

- Give medication to animal with an empty stomach unless otherwise instructed by veterinarian
- Contact veterinarian if salivation or GI (vomiting, diarrhea, or anorexia) effects are pronounced or persist

## Chemistry/Synonyms

A synthetic cholinergic ester, bethanechol occurs as a slightly hygroscopic, white or colorless crystalline powder with a slight, amine-like or “fishy” odor. It exhibits polymorphism, with one form melting at 211° and the other form at 219°. One gram of the drug is soluble in approximately 1 mL of water or 10 mL of alcohol.

Bethanechol Chloride may also be known as: carbamylmethylcholine chloride, *Duvoid*®, *Miotonachol*®, *Muscaran*®, *Myo Hermes*®, *Myocholine*®, *Myotonine*®, *Ucholine*®, *Urecholine*®, *Urocarb*®, or *Urotonine*®.

## Storage/Stability

Bethanechol tablets should be stored at room temperature in tight containers.

**Compounded preparation stability:** Bethanechol oral suspension compounded from commercially available tablets has been published (Allen, 1998). Triturating twelve (12) bethanechol 50 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 5 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of bethanechol should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Bethanechol Chloride Oral Tablets: 5 mg, 10 mg, 25 mg & 50 mg; *Urecholine*® (Barr/Duramed); generic; (Rx)

An injectable product was formerly commercially available.

## BISACODYL

(bis-a-*koe*-dill) Dulcolax®

ORAL/RECTAL LAXATIVE

### Prescriber Highlights

- **Stimulant laxative used in dogs & cats**
  - **Contraindicated in GI obstruction**
  - **GI cramping/diarrhea possible**
  - **Don't give with milk products or antacids; do not crush or split tablets**
- 

## Uses/Indications

Bisacodyl oral and rectal products are used as stimulant cathartics in dogs and cats.

## Pharmacology/Actions

A stimulant laxative, bisacodyl's exact mechanism is unknown. It is thought to produce catharsis by increasing peristalsis by direct stimulation on the intramural nerve plexuses of intestinal smooth muscle. It has been shown to increase fluid and ion accumulation in the large intestine thereby enhancing catharsis.

## Pharmacokinetics

Bisacodyl is minimally absorbed after either oral or rectal administration. Onset of action after oral administration is generally 6–10 hours and 15 minutes to an hour after rectal administration.

## Contraindications/Precautions/Warnings

Stimulant cathartics: contraindicated in the following conditions: intestinal obstruction (not constipation), undiagnosed rectal bleeding, or when the patient is susceptible to intestinal perforation.

Bisacodyl should only be used short-term as chronic use can damage myenteric neurons.

## Adverse Effects

Bisacodyl has relatively few side effects when used occasionally; cramping, nausea, or diarrhea may be noted after use.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Bisacodyl may be distributed into milk but at quantities unlikely to cause any problems in nursing offspring.

## Overdosage/Acute Toxicity

Overdoses may result in severe cramping, diarrhea, vomiting and potentially, fluid and electrolyte imbalances. Animals should be monitored and given replacement parenteral fluids and electrolytes as necessary.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bisacodyl and may be of significance in veterinary patients:

■ **ANTACIDS/MILK:** Do not give milk or antacids within an hour of bisacodyl tablets as it may cause premature disintegration of the enteric coating.

■ **ORAL DRUGS:** Stimulant laxatives may potentially decrease GI transit time thereby affecting absorption of other oral drugs. Separate doses by two hours if possible.

## Doses

**Note:** Bisacodyl enema products and pediatric suppositories are no longer available in the USA. Human pediatric suppositories were 5 mg; the 10 mg “adult” suppositories can be cut lengthwise to approximate one pediatric suppository.

### ■ DOGS:

As a cathartic:

a) One 5 mg tablet PO for small dogs; one to two 5 mg tablets (10–15 mg) for medium to large dogs. Do not break tablets. (Willard 2003)

b) 5–20 mg (1–4 tablets) PO once daily, or 1–3 pediatric suppositories (Sherding 1994)

### ■ CATS:

As a cathartic:

a) One 5 mg tablet PO; do not break tablets. (Willard 2003)

b) 5 mg (1 tablet) PO once daily, or 1–3 pediatric suppositories (Sherding 1994)

c) One 5 mg tablet PO q24h. May be given in combination with fiber supplementation. Avoid daily use if used chronically as it may damage myenteric neurons. (Washabau 2001)

## Client Information

■ If using oral tablets, do not crush or allow animal to chew; intense cramping may occur.

■ Unless otherwise directed by veterinarian, bisacodyl should be used on an “occasional” basis only. Chronic use can damage the nerves in the colon and has led to laxative dependence in humans.

## Chemistry/Synonyms

A diphenylmethane laxative, bisacodyl occurs as white to off-white crystalline powder. It is practically insoluble in water and sparingly soluble in alcohol.

Bisacodyl may also be known as bisacodylum; many trade names are available.

## Storage/Stability

Bisacodyl suppositories and enteric-coated tablets should be stored at temperatures less than 30°C.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Bisacodyl Enteric-coated Oral Tablets: 5 mg; *Alophen*® (Numark); *Bisa-Lax*® (Bergen Brunswick); *Dulcolax*® (Boehringer Ingelheim); *Ex-Lax Ultra*® (Novartis); *Fleet*® *Laxative* (Fleet); *Modane*® (Savage Labs); *Bisac-Evac*® (G & W Labs); *Caroid*® (Mentholatum Co); *Correctol*® (Schering-Plough); *Feen-a-mint*® (Schering-Plough); generic; (OTC)

Bisacodyl Rectal Suppositories: 10 mg; *Dulcolax*® (Boehringer Ingelheim); *Bisacodyl Uniserts*® (Upsher-Smith); *Bisa-Lax*® (Bergen Brunswick); *Bisac-Evac*® (G & W Labs), *Fleet*® *Laxative* (Fleet); generic; (OTC)

Bisacodyl enema products and pediatric suppositories are no longer available in the USA. Pediatric suppositories were 5 mg and the 10 mg “adult” suppositories can be cut lengthwise to approximate a pediatric suppository.

## BISMUTH SUBSALICYLATE

(biz-mith sub-sal-iss-ih-layt) BSS, Pepto-Bismol®

### ANTIDIARRHEAL

#### Prescriber Highlights

- Used to treat diarrhea & as a component of “triple therapy” for treating *Helicobacter* GI infections
  - High doses may cause salicylism, use with caution in cats
  - Constipation/impactions may occur
  - Refrigeration may improve palatability
- 

#### Uses/Indications

In veterinary medicine, bismuth subsalicylate products are used to treat diarrhea and as a component of “triple therapy” for treating *Helicobacter* GI infections. The drug is also used in humans for other GI symptoms (indigestion, cramps, gas pains) and in the treatment and prophylaxis of traveler’s diarrhea.

#### Pharmacology/Actions

Bismuth subsalicylate is thought to possess protectant, anti-endotoxic and weak antibacterial properties. It is believed that the parent compound is cleaved in the small intestine into bismuth carbonate and salicylate. The protectant, anti-endotoxic and weak antibacterial properties are thought to be because of the bismuth. The salicylate component has antiprostaglandin activity that may contribute to its effectiveness and reduce clinical signs associated with secretory diarrheas.

#### Pharmacokinetics

No specific veterinary information was located. In humans, the amount of bismuth absorbed is negligible while the salicylate component is rapidly and completely absorbed. Salicylates are highly bound to plasma proteins and are metabolized in the liver to salicylic acid. Salicylic acid, conjugated salicylate metabolites and any absorbed bismuth are all excreted renally.

#### Contraindications/Precautions/Warnings

Salicylate absorption may occur; use with caution in patients with preexisting bleeding disorders. Because of the potential for adverse effects caused by the salicylate component, this drug should be used cautiously, if at all, in cats.

As bismuth is radiopaque, it may interfere with GI tract radiologic examinations.

#### Adverse Effects

Antidiarrheal products are not a substitute for adequate fluid and electrolyte therapy when required. May change stool color to a gray-black or greenish-black; do not confuse with melena. In human infants and debilitated individuals, use of this product may cause impactions to occur.

#### Reproductive/Nursing Safety

The FDA has not, apparently, given bismuth subsalicylate a pregnancy risk category. As it is a form of salicylate, refer to the aspirin monograph for further guidance. Use with caution in pregnant animals.

Use with caution in nursing dams.

#### Overdosage/Acute Toxicity

Bismuth subsalicylate liquid/suspension contains approximately 8.7 mg/mL salicylate. Two tablespoonsful (30 mL) is approximately equivalent to one 325 mg aspirin tablet. See the Aspirin monograph for more information.

#### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bismuth subsalicylate and may be of significance in veterinary patients:

- **TETRACYCLINE:** Bismuth containing products can decrease the absorption of orally administered tetracycline products. If both agents are to be used, separate drugs by at least 2 hours and administer tetracycline first.
- **ASPIRIN:** Because bismuth subsalicylate contains salicylate, concomitant administration with aspirin may increase salicylate serum levels; monitor appropriately.

#### Laboratory Considerations

- At high doses, salicylates may cause false-positive results for **urinary glucose** if using the cupric sulfate method (*Clinitest*®, Benedict’s solution) and false-negative results if using the glucose oxidase method (*Clinistix*® or *Tes-Tape*®).
- **Urinary ketones** measured by the ferric chloride method (Gerhardt) may be affected if salicylates are in the urine (reddish-color produced).
- **5-HIAA** determinations by the fluorometric method may be interfered by salicylates in the urine.
- Falsely elevated **VMA** (vanillylmandelic acid) may be seen with most methods used if salicylates are in the urine. Falsely lowered **VMA** levels may be seen if using the Pisano method.
- Urinary excretion of **xylose** may be decreased if salicylates are given concurrently.
- Falsely elevated **serum uric acid** values may be measured if using colorimetric methods.

**Note:** Doses of liquids below are for the 17.5 mg/mL (1.75%) liquids (veterinary suspensions; original *Pepto-Bismol*® liquid, etc.) unless otherwise specified.

#### ■ DOGS:

For acute diarrhea:

- 1 mL per 5 kg of body weight PO 3 times a day; should probably not exceed 5 days of therapy (Hall, E. & Simpson 2000)
- Pepto-Bismol*®: 0.25 mL/kg PO q4–6h, up to 2 mL/kg q 6–8h (Cote 2000)

For treating *Helicobacter* gastritis infections:

- Using triple therapy: Metronidazole 15.4 mg/kg q8h, amoxicillin 11 mg/kg q8h and bismuth subsalicylate (original *Pepto-Bismol*®) 0.22 mL/kg PO q4–6h. Give each for 3 weeks (Hall, J. 2000)
- Using triple therapy: Metronidazole 10 mg/kg PO q12h, amoxicillin 15 mg/kg q12h and bismuth subsalicylate 262 mg tablets given based upon body weight (<5kg = 0.25 tablet; 5-9.9 kg = 0.5 tablet; 10-24.9kg = 1 tablet; >25kg = 2 tablets) q12h. Give each for 2 weeks. (Leib *et al.* 2007)

As a gastroprotectant/coating agent in the adjunctive treatment of uremic gastritis:

- 2 mL/kg PO q6–8h (Bartges 2006)

#### ■ CATS:

For diarrhea:

- Pepto-Bismol*®: 0.25 mL/kg PO q4–6h; cats are sensitive to salicylates and probably should not receive frequent or high dosages (Cote 2000)
- Using “*Pepto-Bismol*® *Regular*” or equivalent strength (17.5 mg/mL) liquid: 0.5–1 mL/kg PO q12h for 3 days. (Scherk 2005)
- For diarrhea in kittens and young cats: 1–2 mL *Pepto-Bismol*® 3–4 times a day. Refrigeration may increase palatability. (Tams 1999)

For eliminating *Helicobacter* gastritis infections:

- Using triple therapy: Metronidazole 15.4 mg/kg q8h, amoxicillin 11 mg/kg q8h and bismuth subsalicylate (original *Pepto-Bismol*®) 0.22 mL/kg PO q4–6h. Give each for 3 weeks. (Hall, J. 2000)

#### ■ FERRETS:

For eliminating *Helicobacter* gastritis infections:

- Using triple therapy: Metronidazole 20 mg/kg, amoxicillin 30 mg/kg and bismuth subsalicylate 7.5 mg/kg PO. Give each q8h for 3–4 weeks. (Johnson-Delaney 2009))
- Using triple therapy: Metronidazole 20 mg/kg PO q12h, amoxicillin 20 mg/kg PO q12h and bismuth subsalicylate 17.5 mg/kg PO q8h; continue for 21 days. Used with famotidine (0.5 mg/kg PO once daily) and sucralfate (25 mg/kg PO q8h) (Johnson 2006)

#### ■ CATTLE:

For diarrhea:

- For calves: 60 mL two to four times a day for two days (Label Directions; *Corrective Mixture*®—Beecham).
- 2–3 ounces PO 2–4 times a day (Braun 1986)

#### ■ HORSES:

For diarrhea:

- For foals: 3–4 ounces per 45 kg (100 lb.) body weight PO q6–8h (Madigan 2002)
- For foals or adults: 1 ounce per 8 kg of body weight PO 3-4 times daily (Clark & Becht 1987)
- For foals: 3–4 oz. PO q6–8h (Martens & Scrutchfield 1982)
- For foals: 60 mL two to four times a day for two days (Label Directions; *Corrective Mixture*®—Beecham).

#### ■ SWINE:

For diarrhea in baby pigs:

- 2–5 mL PO two to four times a day for 2 days (Label Directions; *Corrective Mixture*®—Beecham)

### Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea

### Client Information

- Shake product well before using.
- Refrigeration of the suspension may improve palatability. Do not mix with milk before administering.
- If diarrhea persists, contact veterinarian.
- May change stool color to a gray-black or greenish-black; contact veterinarian if stool becomes “tarry” black.

### Chemistry/Synonyms

Bismuth subsalicylate occurs as white or nearly white, tasteless, odorless powder and contains about 58% bismuth. It is insoluble in water, glycerin and alcohol.

Bismuth subsalicylate may also be known as: BSS, basic bismuth salicylate, bismuth oxysalicylate, bismuth salicylate, bismuthi subsalicylas, *Bismu-kote*®, *Bismukote*®, *Bismupaste*®, *Bismatrol*®, *Bismed*®, *Bismusal*®, *Bismylate*®, *Bisval*®, *Equi-Phar*®, *Gastrocote*®, *Jatrox*®, *Kalbeten*®, *Kaopectate*®, *Katulcin-R*®, *PalaBIS*®, *Peptic Relief*®, *Pink Biscoat*®, *Pink Bismuth Rose*®, or *Ulcotind Wismut*®; many other human trade names are available.

### Storage/Stability

Bismuth subsalicylate should be stored protected from light. Unless otherwise labeled store at room temperature; do not freeze.

Bismuth subsalicylate should be stored under light. Unless otherwise labeled, store at room temperature, do not freeze.

## Compatibility/Compounding Considerations

Bismuth subsalicylate is **incompatible** with mineral acids and iron salts. When exposed to alkali bicarbonates, bismuth subsalicylate decomposes with effervescence.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

#### *Bismuth Subsalsicylate Paste:*

5% (50 mg/mL) in 15 mL tubes; *Bismukote Paste for Small Dogs*® (Vedco), (OTC). Labeled for use in small dogs.

10% (100 mg/mL) in 15 mL & 30 mL tubes; *Bismukote Paste for Medium and Large Dogs*® (Vedco), *Bismupaste D*® (Butler); (OTC). Depending on product, labeled for use in small, medium and large dogs.

20% (200 mg/mL) in 60 mL tubes; *Bismupaste E*® (Butler), *Equi-Phar*® (Vedco); (OTC). Labeled for use in horses.

#### *Bismuth Subsalsicylate Oral Suspension:*

Bismuth subsalicylate Oral Suspension 1.75% (17.5 mg/mL; 262 mg/15 mL). *Bismu-kote*® Suspension (Vedco), *Bismusal*® (Bimeda), *Bismusal*® Suspension (AgriPharm), *Bismusol*® (First Priority), *Corrective Suspension*® (Phoenix), *Gastrocote*® (Butler); generic; (OTC). Available in gallons. Labeled for use in cattle, horses, calves, foals, dogs and cats. Each mL contains about 8.7 mg salicylate.

#### *Bismuth Subsalsicylate Tablets:*

Bismuth Subsalsicylate tablets (each tablet contains 262 mg of bismuth subsalicylate). Labeled for use in dogs. *PalaBIS*® (PharmX); (OTC). One tablet contains about 102 mg salicylate.

### HUMAN-LABELED PRODUCTS:

Bismuth Subsalsicylate (BSS) Liquid/Suspension: 87 mg/5 mL; 130 mg/15 mL; 262 mg/15 mL; 524 mg/15 mL; 525 mg/15 mL; in 120 mL, 236 mL, 237 mL, 240 mL, 355 mL, 360 mL, or 480 mL; *Kaopectate*® (Pfizer); *Kaopectate*®, *Kaopectate*® Children's & Extra Strength (Pharmacia); *Pink Bismuth* (various); *Kao-Tin*® (Major); *Peptic Relief*® (Rugby); *Pepto-Bismol*® & *Maximum Strength* (Procter & Gamble *Maalox*® *Total Stomach Relief Liquid* (Novartis); (OTC). **Note:** Regular strength (262 mg/mL) contains 8.7 mg salicylate per mL; Extra-Strength (525 mg/mL) contains 15.7 mg of salicylate per mL.

Bismuth Subsalsicylate Tablets and Caplets: 262 mg (regular & chewable); *Kaopectate*® (Pfizer Consumer Health); *Bismatrol*® (Major); *Peptic Relief*® (Rugby); *Pepto-Bismol*® (Procter & Gamble)); (OTC). One tablet contains about 102 mg salicylate.

## BLEOMYCIN SULFATE

(blee-oh-mye-sin) **Blenoxane**®

ANTINEOPLASTIC

### Prescriber Highlights

- **Antibiotic antineoplastic agent infrequently used for a variety of neoplasms in dogs & cats; intralesional administration may have promise**
- **Two main toxicities: acute (fever, anorexia, vomiting, & allergic reactions) & delayed (dermatologic effects, stomatitis, pneumonitis & pulmonary fibrosis)**
- **Do not exceed total dosage recommendations**
- **Intensive adverse effect monitoring required when used systemically**

---

## Uses/Indications

Bleomycin has occasionally been used as adjunctive treatment of lymphomas, squamous cell carcinomas, teratomas, and nonfunctional thyroid tumors in both dogs and cats. Recent work has demonstrated that bleomycin may be promising for intralesional treatment for a variety of localized tumors with or without concomitant electropermeabilization.

## Pharmacology/Actions

Bleomycin is an antibiotic that has activity against a variety of gram-negative and gram-positive bacteria as well as some fungi. While its cytotoxicity prevents it from being clinically useful as an antimicrobial, it can be useful against a variety of tumors in small animals.

Bleomycin has both a DNA binding site and a site that binds to the ferrous form of iron. By accepting an electron from ferrous ion to an oxygen atom in the DNA strand, DNA is cleaved.

Resistance to bleomycin therapy is via reduced cellular uptake of the drug, reduced ability to damage DNA and increased rates of DNA repair by the cell and, probably most importantly, via the enzyme bleomycin hydrolase.

## Pharmacokinetics

Bleomycin is not appreciably absorbed from the gut and must be administered parenterally. It is mainly distributed to the lungs, kidneys, skin, lymphatics and peritoneum. In patients with normal renal function, terminal half-life is about 2 hours. In humans, 60–70% of a dose is excreted as active drug in the urine.

## Contraindications/Precautions/Warnings

Because bleomycin is a toxic drug with a low therapeutic index, it should be used only by those having the facilities to actively monitor patients and handle potential complications. Bleomycin is contraindicated in patients with prior hypersensitivity reactions from the drug, preexisting pulmonary disease, or adverse pulmonary effects from prior therapy. The drug should be used very cautiously in patients with significant renal impairment and dosage reduction may be necessary. Bleomycin can be teratogenic; it should only be used in pregnant animals when the owners accept the associated risks.

## Adverse Effects

Toxicity falls into two broad categories: acute and delayed. Acute toxicities include fever, anorexia, vomiting, and allergic reactions (including anaphylaxis). Delayed toxic effects include dermatologic effects (*e.g.*, alopecia, rashes, etc.), stomatitis, pneumonitis and pulmonary fibrosis. These latter two effects have been associated with drug-induced fatalities. Initial signs associated with pulmonary toxicity include pulmonary interstitial edema with alveolar hyaline membrane formation and hyperplasia of type II alveolar macrophages. Pulmonary toxicity is potentially reversible if treatment is stopped soon enough. Unlike many other antineoplastics, bleomycin does not usually cause bone marrow toxicity but thrombocytopenia, leukopenia and slight decreases in hemoglobin levels are possible. Renal toxicity and hepatotoxicity are potentially possible.

To reduce the likelihood of pulmonary toxicity developing, a total maximum dosage of 125–200 mg/m<sup>2</sup> should not be exceeded.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It not known if bleomycin enters milk; it is not recommended to nurse while receiving the medication.

## Overdosage/Acute Toxicity

No specific information was located. Because of the toxicity of the drug, it is important to determine dosages carefully.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bleomycin and may be of significance in veterinary patients:

- **ANESTHETICS, GENERAL:** Use of general anesthetics in patients treated previously with bleomycin should be exercised with caution. Bleomycin sensitizes lung tissue to oxygen (even to concentrations of inspired oxygen considered to be safe) and rapid deterioration of pulmonary function with post-operative pulmonary fibrosis can occur.
- **PRIOR OR CONCOMITANT CHEMOTHERAPY WITH OTHER AGENTS OR RADIATION THERAPY:** Can lead to increased hematologic, mucosal and pulmonary toxicities with bleomycin therapy.

## Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

### ■ SMALL ANIMALS:

The following is a usual dosage or dose range for bleomycin and should be used only as a general guide: 10 Units mg/m<sup>2</sup> (NOT mg/kg) or 0.3–0.5 mg/kg (Note: 1 Unit = 1 mg). Some protocols use the drug once daily for a few days and then back off to once weekly; some give the drug once weekly at the start. To reduce the likelihood of pulmonary toxicity, a total maximum dosage of 125–200 mg/m<sup>2</sup> should not be exceeded.

## Monitoring

- Efficacy
- Pulmonary Toxicity: Obtain chest films, (baseline and on a regular basis—in humans they are recommended q1–2 weeks); lung auscultation (dyspnea and fine rales may be early signs of toxicity); other initial signs associated with pulmonary toxicity include pulmonary interstitial edema with alveolar hyaline membrane formation and hyperplasia of type II alveolar macrophages
- Blood chemistry (encompassing renal and hepatic function markers) and hematologic profiles (CBC) may be useful to monitor potential renal, hepatic and hematologic toxicities
- Total dose accumulation

## Client Information

- Clients must be informed of the potential toxicities associated with therapy and urged to report any change in pulmonary function (*e.g.*, shortness of breath, wheezing) immediately

## Chemistry/Synonyms

An antibiotic antineoplastic agent, bleomycin sulfate is obtained from *Streptomyces verticillius*. It occurs as a cream colored, amorphous powder that is very soluble in water and sparingly soluble in alcohol. After reconstitution, the pH of the solution ranges from 4.5–6. Bleomycin is assayed microbiologically. One unit of bleomycin is equivalent to one mg of the reference Bleomycin A2 standard.

Bleomycin sulfate may also be known as: bleomycin sulphate, bleomycini sulfas, *Bileco*®, *Blanoxan*®, *Blenamax*®, *Blenoxane*®, *Bleo*®, *Bleo-S*®, *Bleo-cell*®, *Bleocin*®, *Bleolem*®, *Blio*®, *Blocamicina*®, *Bonar*®, *Oil Bleo*®, or *Tecnomicina*®.

## Storage/Stability

Powder for injection should be kept refrigerated. After reconstituting with sterile saline, water, or dextrose, the resulting solution is stable for 24 hours. Bleomycin is less stable in dextrose solutions than in saline. After reconstituting with normal saline, bleomycin is reportedly stable for at least two weeks at room temperature and for 4 weeks when refrigerated; however, since there are no preservatives in the resulting solution, the product is recommended for use within 24 hours.

## Compatibility/Compounding Considerations

Bleomycin sulfate is reported to be **compatible** with the following drugs: amikacin sulfate, cisplatin, cyclophosphamide, dexamethasone sodium phosphate, diphenhydramine HCl, doxorubicin, heparin sodium, metoclopramide HCl, vinblastine sulfate, and vincristine sulfate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Bleomycin Sulfate Lyophilized Powder for Injection after reconstitution: 15 Units & 30 Units per vial; generic; (Rx)

## BOLDENONE UNDECYLENATE

(*bole-di-nohn un-de-sil-en-ate*) Equipoise®

ANABOLIC STEROID

### Prescriber Highlights

- **Long-acting anabolic steroid labeled for horses; possibly useful in cats to stimulate appetite**
  - **Not recommended for use in stallions or pregnant mares**
  - **May cause androgenic effects, including aggressiveness; potentially a hepatotoxin**
  - **Potentially a drug of abuse by humans, watch for diversion scams**
- 

## Uses/Indications

Boldenone is labeled for use as adjunctive therapy "... as an aid for treating debilitated horses when an improvement in weight, haircoat, or general physical condition is desired" (Package Insert; *Equipoise*®—Fort Dodge).

Boldenone may possibly be useful to stimulate appetite in cats.

## Pharmacology/Actions

In the presence of adequate protein and calories, anabolic steroids promote body tissue building processes and can reverse catabolism. As these agents are either derived from or are closely related to testosterone, the anabolics have varying degrees of androgenic effects. Endogenous testosterone release may be suppressed by inhibiting luteinizing hormone (LH). Large doses can impede spermatogenesis by negative feedback inhibition of FSH.

Anabolic steroids can also stimulate erythropoiesis possibly by stimulation of erythropoietic stimulating factor. Anabolics can cause nitrogen, sodium, potassium and phosphorus retention and decrease the urinary excretion of calcium.

## Pharmacokinetics

No specific information was located for this agent. It is considered a long-acting anabolic, with effects persisting up to 8 weeks. It is unknown if the anabolic agents cross into milk.

## Contraindications/Precautions/Warnings

The manufacturer (Solvay) recommends not using the drug on stallions or pregnant mares. Other clinicians state that anabolic steroids should not be used in either stallions or non-pregnant mares intended for reproduction. Boldenone should not be administered to horses intended for food purposes.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, in selected patients with breast carcinoma, benign prostatic hypertrophy and during the nephrotic stage of nephritis.

## Adverse Effects

In the manufacturer's (*Equipoise*®—Solvay) package insert, only androgenic (over aggressiveness) effects are listed. However, in work reported in both stallions and mares (Squires and McKinnon 1987), boldenone caused a detrimental effect in testis size, and sperm production and quality in stallions. In mares, the drug caused fewer total and large follicles, smaller ovaries, increased clitoral size, shortened estrus duration, reduced pregnancy rates and severely altered sexual behavior.

Although not reported in horses, anabolic steroids have the potential to cause hepatic toxicity.

## Reproductive/Nursing Safety

The anabolic agents are category **X** (*Risk of use outweighs any possible benefit*) agents (used in pregnancy and are contraindicated because of possible fetal masculinization).

### Overdosage/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

### Drug Interactions

No drug interactions were located for boldenone specifically. The following drug interactions have either been reported or are theoretical in humans or animals receiving anabolic steroids and may be of significance in veterinary patients:

- **ANTICOAGULANTS (warfarin):** Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR and dosage adjustment of the anticoagulant (if necessary) are recommended
- **CORTICOSTEROIDS, ACTH:** Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN:** Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements

### Laboratory Considerations

- Concentrations of **protein bound iodine (PBI)** can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important
- Androgen/anabolic agents can decrease amounts of **thyroxine-binding globulin** and decrease **total T<sub>4</sub>** concentrations and increase **resin uptake of T<sub>3</sub> and T<sub>4</sub>**; free thyroid hormones are unaltered and, clinically, there is no evidence of dysfunction.
- Both **creatinine** and **creatinine excretion** can be decreased by anabolic steroids
- Anabolic steroids can increase the urinary excretion of **17-ketosteroids**
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress **clotting factors II, V, VII, and X**.
- Anabolic agents can affect **liver function tests** (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase)

### Doses

- **HORSES: (Note: ARCI UCGFS Class 4 Drug)**
  - a) 1.1 mg/kg IM; may repeat in 3 week intervals (most horses will respond with one or two treatments) (Package Insert; *Equipoise*®—Fort Dodge)
  - b) 1 mg/kg IM; repeated at 3 week intervals (Robinson 1987)
- **CATS:**
  - a) As an appetite stimulant: 5 mg (total dose) IM/SC every 7 days; anabolic steroids not as effective as many other appetite stimulants and may be associated with hepatotoxicity (Bartges 2003)

### Monitoring

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- Red blood cell count, indices, if indicated
- Weight, appetite

### Client Information

- Because of the potential for abuse by humans, anabolic steroids are controlled drugs. Boldenone should be kept in a secure area and out of the reach of children.
- Contact veterinarian if patient develops yellowing of whites of the eyes, or develops a decreased appetite or lethargy.

### Chemistry/Synonyms

An injectable anabolic steroid derived from testosterone, boldenone undecylenate has a chemical name of 17 beta-hydroxyandrost-1,4-dien-3-one. The commercially available product is in a sesame oil vehicle.

Boldenone undecylenate may also be known as: Ba-29038, boldenone undecenoate, *Equipoise*®, or *Vebonol*®.

### Storage/Stability

Boldenone injection should be stored at room temperature; avoid freezing.

### Compatibility/Compounding Considerations

Because boldenone injection is in an oil vehicle, it should not be physically mixed with any other medications.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Boldenone Undecylenate for Injection: 25 mg/mL in 10 mL vials; 50 mg/mL in 10 mL & 50 mL vials; *Equipoise*® (Pfizer); (Rx, C-III). FDA-approved for use in horses not to be used for food.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

## BROMIDES

### POTASSIUM BROMIDE

### SODIUM BROMIDE

(*broe-mide*)

ANTICONVULSANT

#### Prescriber Highlights

- **Primary or adjunctive therapy for seizure disorders in dogs; 3rd line agent for cats (some say contraindicated in cats)**
- **Very long half-life, must give loading dose to see therapeutic levels within a month**
- **Most prevalent adverse effect in dogs is sedation, especially when used with phenobarbital. Polyphagia with resultant weight gain is also commonly noted, particularly in the first few months of therapy. Polydipsia and polyuria can also be seen.**
- **Cats may develop adverse respiratory effects**
- **Therapeutic levels in dogs approximately 1–3 mg/mL**
- **Do not feed salty snacks; keep chloride in diet stable**
- **Toxic effects include profound sedation to stupor, ataxia, tremors, hind limb paresis, or other CNS manifestations**
- **If using sodium bromide (vs. potassium bromide), dosage adjustments must be made**

---

## Uses/Indications

Bromides are used both as primary therapy and as adjunctive therapy to control seizures in dogs that are not adequately controlled by phenobarbital (or primidone) alone (when steady state trough phenobarbital levels are >30 micrograms/mL for at least one month). While historically bromides were only recommended for use alone in patients suffering from phenobarbital (or primidone) hepatotoxicity, they have frequently been used as a drug of first choice in recent years. However, as more experience is gained in veterinary medicine with newer human anticonvulsants (*e.g.*, zonisamide, levetiracetem, gabapentin) and their transition to less expensive generically available products, bromide use in dogs may become less prevalent.

Although not frequently used, bromides are also considered suitable by some for use in cats with chronic seizure disorders, but cats may be more susceptible to the drug's adverse effects.

## Pharmacology/Actions

Bromide's anti-seizure activity is thought to be the result of its generalized depressant effects on neuronal excitability and activity. Bromide ions compete with chloride transport across cell membranes resulting in membrane hyperpolarization, thereby raising seizure threshold and limiting the spread of epileptic discharges.

## Pharmacokinetics

Bromides are well absorbed after oral administration, primarily in the small intestine. Bromides are also well absorbed after solutions are administered rectally in dogs (bioavailability of 60–100%). Bromide is distributed in the extracellular fluid and mimics the volume of distribution of chloride (0.2–0.4 L/Kg). It is not bound to plasma proteins and readily enters the CSF (in dogs: 87% of serum concentration; in humans: 37%). Bromides enter maternal milk (see Reproductive Safety below). Bromides are principally excreted by the kidneys. The half-life in dogs has been reported to be from 16–25 days; cats, 10 days; and humans, 12 days.

## Contraindications/Precautions/Warnings

Older animals and those with additional diseases, may be prone to intolerance (see Adverse Effects below) at blood levels that are easily tolerable by younger, healthier dogs. Patients with renal dysfunction may need dosage adjustments.

Because bromides have been associated with sometimes serious pulmonary effects in cats, it should be used with extreme caution. Some state that the drug should not be used in cats.

## Adverse Effects

Common (lasting up to 3 weeks) is seen in dogs receiving bromides. Serum concentrations of bromide above 15 mMol/L (150 mg/dL) are considered "toxic" by many dogs apparently tolerate levels of up to 30 mMol/L. Toxicity generally presents as profound sedation to stupor, ataxia, tremors, hind limb paresis, or other CNS manifestations. Pancreatitis has been reported in dogs receiving combination therapy of bromides with either primidone or phenobarbital; however, since this effect has been reported with both primidone and phenobarbital, its direct relationship with bromide is unknown. Additional potential adverse effects reported include: polyphagia with weight gain, polydipsia, polyuria, anorexia, vomiting, and constipation. Feeding a low calorie diet may help prevent weight gain. Pruritic dermatitis and paradoxical hyperactivity are rarely reported.

If administering an oral loading dose of potassium bromide, acute GI upset may occur if given too rapidly. Potentially, large loading doses could affect serum potassium levels in patients receiving potassium bromide.

If the patient cannot tolerate the gastrointestinal effects (vomiting) of potassium bromide and divided doses with food do not alleviate the problem, switching to sodium bromide may be tried.

Lower respiratory effects (cough, dyspnea) have been associated with bromide therapy in cats. Peribronchial infiltrates may be seen on radiographs and dyspnea may be serious or fatal. Signs appear to be reversible in most cats once bromides are discontinued. Other adverse effects in cats include polydipsia, sedation, and weight gain.

### Reproductive/Nursing Safety

Reproductive safety has not been established. Human infants have suffered bromide intoxication and growth retardation after maternal ingestion of bromides during pregnancy. Bromide intoxication has also been reported in human infants breastfeeding from mothers taking bromides. Use with caution in pregnancy or lactation.

### Overdosage/Acute Toxicity

Toxicity is more likely with chronic overdoses, but acute overdoses are a possibility. In addition to the adverse effects noted above, animals that have developed bromism (whether acute or chronic) may develop signs of muscle pain, conscious proprioceptive deficits, anisocoria, and hyporeflexia.

Standard gut removal techniques should be employed after a known acute overdose. Death after an acute oral ingestion is apparently rare as vomiting generally occurs spontaneously. Administration of parenteral (0.9% sodium chloride) or oral sodium chloride, parenteral glucose and diuretics (*e.g.*, furosemide) may be helpful in reducing bromide loads in either acutely or chronically intoxicated individuals.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bromides and may be of significance in veterinary patients:

- **CNS SEDATING DRUGS:** Because bromides can cause sedation, other CNS sedating drugs may cause additive sedation
- **DIURETICS (furosemide, thiazides):** May enhance the excretion of bromides thereby affecting seizure control and dosage requirements
- **LOW/HIGH SALT DIETS:** Bromide toxicity can occur if chloride ion ingestion is markedly reduced. Patients put on low salt diets may be at risk. Conversely, additional sodium chloride in the diet (including prescription diets high in chloride) could reduce serum bromide levels, affecting seizure control. Keep chloride content of diet relatively constant while bromides are being administered. If chloride content must be altered, monitor bromide levels more frequently.
- **DRUGS THAT CAN LOWER SEIZURE THRESHOLD (*e.g.*, xylazine):** May potentially reduce efficacy of antiseizure medications

### Laboratory Considerations

- See drug interactions above regarding chloride. Bromide may interfere with **serum chloride** determinations yielding falsely high results.
- Potassium bromide does not affect canine thyroid function test results

### Doses

**Note:** Doses are listed for potassium bromide. If using sodium bromide reduce dose by approximately 15%.

#### ■ DOGS:

Because of the extraordinarily long serum half-life in dogs, (it may take up to 4–5 months for blood levels to reach steady state concentrations), many dosing regimens include an initial oral bolus loading dose to reduce the period to attain therapeutic concentrations. An excellent review of treating idiopathic epilepsy in dogs and cats has been published (Thomas 2010). In this review, with respect to dosing bromides the author states: “Because of the variability in absorption, distribution, and speed of metabolism among patients, published dose recommendations serve as a general guide only. Because of sensitivity to side effects and lack of prior metabolic induction, most new patients are started at the lower end of the dose range. If necessary, the dose is slowly titrated upward until seizures are controlled or the maximum tolerated dose is reached. On the other hand, patients with frequent or severe seizures are often best managed by starting at the higher end of the dose range or using a loading dose. Once the seizures are controlled, the dose may need to be adjusted downward to minimize side effects.”

a) Initially, potassium bromide: 20–30 mg/kg PO once daily, with food. If sodium bromide used, decrease dose by 15% (*i.e.*, 17–26 mg/kg). The dose is subsequently adjusted based on clinical effects and therapeutic monitoring (see Monitoring below).

A loading dose may be used to obtain target serum concentrations sooner, particularly in patients with frequent seizures or if phenobarbital must be rapidly withdrawn. Several protocols published; author’s preference is: 400 mg/kg PO divided into 8 doses given over a 48-hour period (*i.e.*, 50 mg/kg every 6 hours for 2 days.) Giving entire loading dose at once will usually cause vomiting. Once loading dose given, start maintenance dose.

When bromide is added to phenobarbital to improve seizure control, the current phenobarbital dose is continued while maintenance dosing of bromide is started. After 3 months, if seizures well controlled and the serum concentration of bromide is at least 1.5 mg/mL, it may be possible to taper the phenobarbital, decreasing the dose in 25% increments every 2 to 4 weeks. If seizures become more frequent during phenobarb withdrawal, patient may require both drugs. If phenobarbital must be withdrawn quickly, a loading dose of bromide is administered and the phenobarbital is tapered over a 2-week period while maintenance doses of bromide are administered. (Thomas 2010)

b) For seizures: Loading dose: 400–600 mg/kg/day divided and given with food. May be given over 24 hours or more gradually over 5 days. Then go to initial maintenance dose: 20–30 mg/kg PO once daily (Munana 2004a)

c) A good starting dose is 35 mg/kg PO once daily, but the author often uses a loading dose: 125 mg/kg/day for 5 days PO divided q12h and then resume at 35 mg/kg PO once daily. For dogs where oral administration is not possible (*e.g.*, status epilepticus), may give rectally at 100 mg/kg body weight every 4 hours for 6 total doses. (Dewey 2005)

d) Using an intravenous *sodium bromide* loading dose to rapidly achieve minimum therapeutic concentration (1–1.5 mg/mL): Intravenous, 600–1200 mg/kg, diluted in a solution and administered over eight hours. If target serum bromide concentrations are not reached, additional intravenous sodium bromide may be administered. (USPC 2005) (**Note:** It has been anecdotally reported that a 3% solution of sodium bromide can be used intravenously. To prepare a 3% solution: add 30 grams of sodium bromide to 1000 mL of sterile water for injection; use an in-line IV filter. Use with caution—Plumb)

#### ■ CATS:

a) As third choice (after phenobarbital and diazepam) therapy of refractory seizures: 10–20 mg/kg/day PO. Follow same guideline as dogs (Quesnel 2000)

b) As second line therapy for epilepsy: 30 mg/kg PO once daily (Munana 2004b)

### Monitoring

#### ■ Efficacy/Toxicity

■ **Serum Levels:** In dogs, therapeutic bromide concentrations are generally agreed to be 1–3 mg/mL; lower range may be effective for dogs on phenobarbital therapy

therapeutic bromide concentrations are generally agreed to be 1–5 mg/mL, lower range may be effective for dogs on phenobarbital therapy and the higher range for dogs on bromide alone. Time of day (hours post-dose) for sampling is not critical. Actual monitoring recommendations vary and depend on whether the patient received a loading dose or not. One recommendation (Boothe 2004) based upon pharmacokinetic principles is: If no load was given and maintenance dose was used initially, monitor at 3–4 weeks and then at steady-state (2.5–3 months). The first sample indicates about 50% of what will be achieved at steady-state and allows adjustment of the dosage early. If a loading dose was used, an immediate level after the load (day 6 or 7 after a 5 day loading protocol), followed by a sample at 1 month and then 3 months. The immediate sample indicates what was achieved with loading; the 1 month level indicates the success of the maintenance dose, maintains what was achieved with the loading dose and allows dosage adjustment, if required; and the 3 month level establishes the new baseline.

## Client Information

- Clients must be committed to administering doses of anticonvulsant medications on a regular basis. Lack of good compliance with dosing regimens is a major cause of therapeutic failures with anti-seizure medications. If a dose is missed, give it when remembered; a dose may be doubled the next day, but should preferably be separated by several hours to reduce the chance for gastrointestinal upset.
- Clients should also understand and accept that this treatment involves using a non-approved (FDA) “drug.”
- Dose measurements of bromide solutions should be done with a needle-less syringe or other accurate measuring device. The dose may either be sprinkled on the dog’s food (assuming he/she consumes it entirely) or squirted in the side of the mouth.
- Toxic effects (*e.g.*, profound sedation, ataxia, stupor, GI effects) should be explained to the owner and if they occur, they should be reported to the veterinarian.
- Dogs that cannot tolerate the gastrointestinal effects (vomiting) of potassium chloride with single daily doses may better tolerate doses divided through the day given with food. Clients should not alter diet without first consulting with veterinarian and to avoid giving dogs salty treats (*e.g.*, pig ears).

## Chemistry

Potassium bromide occurs as white, odorless, cubical crystals or crystalline powder. One gram will dissolve in 1.5 mL of water. Potassium bromide contains 67.2% bromide. Each gram contains 8.4 mEq (mMol) of potassium and bromide.

Sodium bromide occurs as white, odorless, cubic crystals or granular powder. One gram will dissolve in 1.2 mL of water. Sodium bromide contains 77.7% bromide.

Because of the different molecular weights of sodium and potassium, with respect to actual bromide content, sodium bromide solutions of 250 mg/mL contain about 20% more bromide than potassium bromide 250 mg/mL solution. This is generally not clinically significant unless changing from one salt to another for a given patient.

## Storage/Stability

Store in tight containers. Solutions may be stored for up to one year in clear or brown, glass or plastic containers at room temperature. Refrigerating the solution may help reduce the chance for microbial growth, but may cause crystals or precipitants to form. Should precipitation occur, warming the solution should resolubilize the bromide.

## Compatibility/Compounding Considerations

Bromides can precipitate out alkaloids in solution. Mixing with strong oxidizing agents can liberate bromine. Metal salts can precipitate solutions containing bromides. Sodium bromide is hygroscopic; potassium bromide is not.

At a concentration of 250 mg/mL, 25 grams of potassium bromide are weighed and add a sufficient amount of distilled water to a final volume of 100 mL; potassium bromide dissolves easily in water, sodium bromide may take longer to dissolve. Flavoring agents are not usually necessary for patient acceptance.

## Dosage Forms/Regulatory Status

At the time of writing, neither potassium or sodium bromide are available in FDA-approved dosage forms in North America. Reagent grade or USP grade may be obtained from various chemical supply houses to compound an acceptable oral product. If purchasing a reagent grade, specify American Chemical Society (ACS) grade.

## BROMOCRIPTINE MESYLATE

(broe-moe-krip-teen) Parlodel®

DOPAMINE AGONIST/PROLACTIN INHIBITOR

### Prescriber Highlights

- Dopamine agonist & prolactin inhibitor occasionally used in dogs for pregnancy termination or pseudopregnancy; in horses for pituitary adenomas; in cats for acromegaly
  - Many adverse effects possible; GI, CNS depression & hypotension are most likely; much more likely to cause emesis in dogs than cabergoline
  - Interferes with lactation
- 

## Uses/Indications

Bromocriptine may potentially be of benefit in treating acromegaly/pituitary adenomas or pseudopregnancy in a variety of species. However, because of adverse

effects, its potential value for treating hyperadrenocorticism in dogs is low. It has been used in dogs for pregnancy termination and pseudopregnancy.

### Pharmacology/Actions

Bromocriptine exhibits multiple pharmacologic actions. It inhibits prolactin release from the anterior pituitary thereby reducing serum prolactin. The mechanism for this action is by a direct effect on the pituitary and/or stimulating postsynaptic dopamine receptors in the hypothalamus to cause release of prolactin-inhibitory factor. Bromocriptine also activates dopaminergic receptors in the neostriatum of the brain.

### Pharmacokinetics

In humans, only about 28% of a bromocriptine dose is absorbed from the gut and, due to a high first-pass effect, only about 6% reaches the systemic circulation. Distribution characteristics are not well described but in humans, it is highly bound (90–96%) to serum albumin. Bromocriptine is metabolized by the liver to inactive and non-toxic metabolites. It has a biphasic half-life; the alpha phase is about 4 hours and the terminal phase is about 15 hours, but one source says 45–50 hours.

### Contraindications/Precautions/Warnings

Bromocriptine is generally contraindicated in patients with hypertension. It should be used with caution in patients with hepatic disease as metabolism of the drug may be reduced.

### Adverse Effects

Bromocriptine may cause a plethora of adverse effects that are usually dose related and minimized with dosage reduction. Some more likely possibilities include: gastrointestinal effects (nausea, vomiting), nervous system effects (sedation, fatigue, etc.), and hypotension (particularly with the first dose, but it may persist). At dosages used in dogs, more likely to cause emesis than cabergoline.

### Reproductive/Nursing Safety

Usage during pregnancy is contraindicated in humans, although documented teratogenicity has not been established.

Because bromocriptine interferes with lactation, it should not be used in animals that are nursing.

### Overdosage/Acute Toxicity

Overdosage may cause vomiting, severe nausea, and profound hypotension. There were 20 exposures to bromocriptine reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, all 20 were dogs with 18 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, trembling, diarrhea, subdued, and tachycardia. Standardized gut removal techniques should be employed when applicable, but emesis often occurs spontaneously. Institute cardiovascular monitoring (blood pressure, heart rate) and support as needed.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving bromocriptine and may be of significance in veterinary patients:

- **ALCOHOL:** Use with alcohol may cause a disulfiram-type reaction
- **BUTYROPHENONES** (e.g., **haloperidol, azaperone**), **AMITRIPTYLINE, PHENOTHIAZINES, and RESERPINE:** May increase prolactin concentrations and bromocriptine doses may need to be increased
- **CYCLOSPORINE:** May elevate cyclosporine levels
- **ERYTHROMYCIN, CLARITHROMYCIN:** May increase bromocriptine levels
- **ESTROGENS or PROGESTINS:** May interfere with the effects of bromocriptine
- **ERGOT ALKALOIDS:** Use of bromocriptine and ergot alkaloids is not recommended; some human patients receiving both have developed severe hypertension and myocardial infarction
- **HYPOTENSIVE MEDICATIONS:** May cause additive hypotension if used with bromocriptine
- **MAO INHIBITORS** (including **amitraz**, and maybe **selegiline**): Avoid use of bromocriptine with these compounds
- **METOCLOPRAMIDE:** May cause prolactin release in dogs, thereby negating the effects of bromocriptine for treating pseudopregnancy
- **OCTREOTIDE:** May increase bromocriptine levels
- **SYMPATHOMIMETICS** (e.g., **phenylpropanolamine**): Enhanced bromocriptine effects have been reported in humans (rare), including ventricular tachycardia and cardiac dysfunction

### Doses

#### ■ DOGS:

For treatment of pseudocyesis (pseudopregnancy):

- a) 10–100 micrograms/kg PO daily in divided doses until lactation ceases. Vomiting, depression and anorexia are common side effects, usually more problematic than the lactation. (Davidson & Feldman 2005)
- b) 10–100 micrograms/kg PO twice daily for 10–14 days. Vomiting is very common; reducing dose and administering after meals may help. (Johnson 2003)
- c) 10–50 micrograms/kg PO at least twice a day (Romagnoli 2009)

For pregnancy termination after mismating:

- a) From day 35–45 after LH surge 50–100 micrograms/kg PO or IM twice daily for 4–7 days. Not uniformly effective and may cause vomiting at this dosage (a peripheral acting antiemetic 30 minutes before dose may be helpful) (Verstegen 2000)
- b) As an abortifacient 25 days after LH surge: Cloprostenol at 1 microgram/kg SC q48 hours (every other day) plus bromocriptine at 30 micrograms/kg PO q24h (every day) (Johnson 2003)

#### ■ CATS:

For adjunctive treatment of acromegaly:

a) Initial dose of 0.2 mg (total dose); may reduce insulin requirements (Jones 2004)

#### ■ **HORSES:** (Note: ARCI UCGFS Class 2 Drug)

For treatment of pituitary adenoma:

a) 0.03–0.09 mg/kg (30–90 micrograms/kg) twice daily PO or SC, but its use is limited (Toribio 2004)

b) 5 mg (total dose) IM q12h. To prepare an injectable formulation for IM use from oral dosage forms: Bromocriptine mesylate 70 mg is added to 7 mL of a solution of 80% normal saline and 20% absolute alcohol (v/v). Final concentration is 1% (10 mg/mL) (Beck 1992)

### Monitoring

■ Monitoring is dependent upon the reason for use to evaluate efficacy. However, blood pressures should be evaluated if patients have clinical signs associated with hypotension.

### Client Information

■ Have client administer drug with food to attempt to reduce GI adverse effects.

### Chemistry/Synonyms

A dopamine agonist and prolactin inhibitor, bromocriptine mesylate is a semisynthetic ergot alkaloid derivative. It occurs as a yellowish-white powder and is slightly soluble in water and sparingly soluble in alcohol.

Bromocriptine mesylate may also be known as: bromocryptine, brom-ergocryptine, 2-bromergocryptine, bromocriptine methanesulphonate, bromocriptini mesilas, 2-bromo-alpha-ergocryptine mesylate, 2-bromoergocryptine monomethanesulfonate, or CB-154 (bromocriptine); many trade names are available.

### Storage/Stability

Tablets and capsules should be protected from light and stored in tight containers at temperatures less than 25°C.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Bromocriptine Mesylate Oral Capsules: 5 mg (as base); *Parlodel*® (Novartis); generic; (Rx)

Bromocriptine Mesylate Oral Tablets: 0.8 mg (as base); *Cycloset*® (Patheon); 2.5 mg; *Parlodel*® *SnapTabs* (Novartis); generic; (Rx)

## BUDESONIDE

(bue-des-oh-nide) Entocort EC®

GLUCOCORTICOID

### Prescriber Highlights

- Orally administered glucocorticoid with limited systemic glucocorticoid effects; may be useful in treating IBD in small animals that are either refractory to, or intolerant of, systemic steroids
- Hyperadrenocorticism possible, but much less likely than with systemic steroids
- Limited veterinary experience
- Drug interactions (CYP3A inhibitors, antacids)
- Expense may be an issue; may need to be compounded to smaller dosage strengths

---

### Uses/Indications

While there are inhalational forms of the medication for treating asthma or allergic rhinitis, most veterinary interest involves its potential oral use to treat inflammatory intestinal diseases in small animals that are either refractory to, or intolerant of, systemic steroids. In humans, oral budesonide is indicated for Crohn's disease.

### Pharmacology/Actions

Budesonide is a potent glucocorticoid (15X more potent than prednisolone) with high topical activity. It has weak mineralocorticoid activity. By delaying dissolution until reaching the duodenum and subsequent controlled release of the drug, the drug can exert its topical antiinflammatory activity in the intestines. While the drug is absorbed from the gut into the portal circulation, it has a high first-pass metabolism effect through the liver that reduces systemic blood levels and resultant glucocorticoid effects of the drug. However, significant suppression of the HPA-axis does occur in patients taking the drug.

## Pharmacokinetics

Budesonide's pharmacokinetics have been reported in dogs. The drug has a bioavailability of 10–20%. When dosed at 10 micrograms/kg, half-life is about 2 hours and clearance 2.2 L/hr/kg. At 100 micrograms/kg, half-life is slightly prolonged to 2–3 hours.

Upon oral administration of the commercially available product in humans, budesonide is nearly completely absorbed from the gut, but time to achieve peak concentrations are widely variable (30–600 minutes). The presence of food in the gut may delay absorption, but does not impact the amount of drug absorbed. Because of a high first-pass effect, only about 10% of a dose is systemically bioavailable in healthy adults. In patients with Crohn's disease, oral bioavailability may be twice that initially, but with further dosing, reduces to amounts similar to healthy subjects. Budesonide's mean volume of distribution in humans ranges from 2.2–3.9 L/kg. The drug is completely metabolized and these metabolites are excreted in the feces and urine. Budesonide's terminal half-life is about 4 hours.

## Contraindications/Precautions/Warnings

Budesonide is contraindicated in patients hypersensitive to it. Because budesonide can cause systemic corticosteroid effects, it should be used with caution in any patient where glucocorticoid therapy may be problematic including those with GI ulcers, active infections, diabetes mellitus, or cataracts.

## Adverse Effects

There are limited reports of the clinical use of budesonide in small animals and the determination of the drug's adverse effect profile is ongoing. Steroid hepatopathy is possible. In humans, oral budesonide is generally well tolerated and glucocorticoid adverse effects occur infrequently when the drug is used for courses of therapy of no more than 8 weeks duration. Patients with moderate to severe hepatic dysfunction may be more likely to develop signs associated with hypercorticism.

Because budesonide does suppress the HPA-axis, animals undergoing stressful procedures such as surgery, should be considered for exogenous steroid administration.

## Reproductive/Nursing Safety

In humans, the FDA categorizes budesonide as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). Like other corticosteroids, budesonide has been demonstrated to be embryocidal and teratogenic in rats and rabbits.

Specific data on budesonide levels in maternal milk are not available and the manufacturer warns against use by nursing women; however, because of the drug's high first pass effect, the amounts are unlikely to be of clinical significance to nursing animal offspring.

## Overdosage/Acute Toxicity

Acute, oral overdoses are unlikely to be of much concern although doses of 200 mg/kg were lethal in mice. Gut evacuation should be considered for massive overdoses.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving budesonide and may be of significance in veterinary patients:

- **ERYTHROMYCIN, CIMETIDINE, KETOCONAZOLE, ITRACONAZOLE, FLUCONAZOLE, DILTIAZEM, GRAPEFRUIT JUICE POWDER,**  
etc: Because the hepatic enzyme CYP3A extensively metabolizes budesonide, drugs that inhibit this isoenzyme can significantly increase the amount of drug that enters the systemic circulation. Ketoconazole given with budesonide may increase the area under the curve (AUC) of budesonide by eight fold.
- **ORAL ANTACIDS:** Because the dissolution of the drug's coating is pH dependent, oral antacids should not be given at the same time as the drug. Other drugs that potentially would increase gastric pH (*e.g.*, omeprazole, ranitidine, etc.) apparently do not significantly impact the oral pharmacokinetics of the drug.

## Laboratory Considerations

- While no specific laboratory interactions were located, budesonide could potentially alter laboratory test results similarly to other corticosteroids.

## Doses

### ■ DOGS

For treatment of IBD:

- a) 1 mg (total dose) PO once daily for small dogs and 2 mg (total dose) PO once daily for large dogs (Mackin 2002)
- b) 3 mg/m<sup>2</sup> (NOT mg/kg) (0.5–3 mg per dog depending on body weight) PO once daily or every other day (Gaschen 2006)

### ■ CATS:

For treatment of IBD:

- a) 1 mg (total dose) PO once daily (Mackin 2002)
- b) 1 mg per cat PO once to twice daily. Main reason for use is in cats that respond to steroids, but cannot tolerate their systemic side effects. (Willard 2009)

## Monitoring

- Efficacy
- Adverse effects

## Client Information

- Do not open the capsule unless your veterinarian instructs you to do so; do not crush or allow animal to chew capsules
- This drug must be given as prescribed to be effective, do not stop therapy without contacting your veterinarian
- If animal exhibits increased thirst or appetite or their coat changes, contact your veterinarian

## Chemistry/Synonyms

Budesonide, a non-halogenated glucocorticoid, occurs as a white to off-white, odorless, tasteless powder. It is practically insoluble in water, freely soluble in chloroform and sparingly soluble in alcohol. The commercially available capsules contain a granulated micronized form of the drug that is coated to protect from

dissolution in gastric juice, but will dissolve at pH >5.5. In humans, this pH usually corresponds with the drug reaching the duodenum.

Budesonide may also be known as S 1320, *Entocord*®, *Entocort EC*®, *Pulmicort*®, and *Rhinocort*®.

### Storage/Stability

Budesonide oral capsules should be stored in tight containers at room temperature. Exposures to temperatures as low as 15°C (59°F) and as high as 30°C (86°F) are permitted.

### Compatibility/Compounding Considerations

If reformulating into smaller capsules, do not alter (damage) the micronized enteric-coated sugar spheres inside of the capsules.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None.

### HUMAN-LABELED PRODUCTS:

Budesonide Capsules: 3 mg (micronized); *Entocort EC*® (Prometheus); (Rx)

Human budesonide capsules may need to be compounded into dosage strengths suitable for dogs or cats, but the enteric-coated sugar spheres found inside the capsule should not be altered or damaged.

There are also budesonide products (powder and suspension for oral inhalation, and nasal sprays) for the treatment of asthma or allergic rhinitis. Trade names for these products include *Pulmicort*® and *Rhinocort*®.

## BUPRENORPHINE HCL

(byoo-pre-nor-feen) *Buprenex*®, *Subutex*®

OPIATE PARTIAL AGONIST

### Prescriber Highlights

- Partial *mu* opiate agonist used primarily as an injectable & buccal analgesic in small animals, especially cats; has been used in horses also
- Often used, especially in cats, as a component of short-term immobilization “cocktails” in combination with an alpha-2 agonist (*e.g.*, dexmedetomidine) with a dissociative agent (*e.g.*, ketamine)
- Buccal administration in cats well tolerated & effective
- Rarely, may cause respiratory depression
- At standard doses, naloxone may not completely reverse respiratory depressant effects in overdoses

---

### Uses/Indications

Buprenorphine is most often used as an analgesic for mild to moderate pain in small animals. In many species, it is not as an effective analgesic as pure *mu*-agonists (morphine, hydromorphone, etc.), but it generally causes fewer adverse effects. In cats, buccal (oral transmucosal) administration is often a practical, effective method for helping to control post-operative pain and it may provide better analgesia in cats than does parenteral morphine or oxymorphone. One study however, found that IV or IM buprenorphine provided better post-operative (OHE) analgesia than when the drug was administered SC or via the oral transmucosal route (Giordano *et al.* 2010). Combining opiates with short-term NSAIDs for post-op pain control is being used more commonly.

For acute pain control, buprenorphine may have the disadvantage of a longer onset of action than other opiates.

Buprenorphine has been used in horses, but its short duration of action and expense relative to other opiates limit its usefulness.

### Pharmacology/Actions

Buprenorphine has partial agonist activity at the *mu*-receptor. This is in contrast to pentazocine that acts as an antagonist at the *mu*-receptor. Buprenorphine is considered 30 times as potent as morphine and exhibits many of the same actions as the opiate agonists. It produces a dose-related analgesia but at higher dosages analgesic effects may actually decrease. Buprenorphine appears to have a high affinity for *mu*-receptors in the CNS, which may explain its relatively long duration of action. Analgesia may persist for 12 hours, but usually a 6–8 hour duration of analgesic effect is typical.

The cardiovascular effects of buprenorphine may cause a decrease in both blood pressure and cardiac rate. Rarely, human patients may exhibit increases in blood pressure and cardiac rate. Respiratory depression is a possibility, and decreased respiratory rates have been noted in horses treated with buprenorphine. Gastrointestinal effects appear to be minimal in cats treated with buprenorphine.

### Pharmacokinetics

Buprenorphine is rapidly absorbed following IM injection, with 40–90% absorbed systemically when tested in humans. The drug is also absorbed sublingually (bioavailability≈55%) in people. Oral doses appear to undergo a high first-pass effect with metabolism occurring in the GI mucosa and liver.

The distribution of the drug has not been well studied. Data from work done in rats reflects that buprenorphine concentrates in the liver, but is also found in the brain, GI tract, and placenta. It is highly bound (96%) to plasma proteins (not albumin), crosses the placenta, and it and its metabolites are found in maternal milk at concentrations equal to or greater than those found in plasma.

Buprenorphine is metabolized in the liver by N-dealkylation and glucuronidation. These metabolites are then eliminated by biliary excretion into the feces ( $\approx 70\%$ ) and urinary excretion ( $\approx 27\%$ ).

In cats, buprenorphine has a volume of distribution [Vd(ss)] of approximately 8 L/kg and a clearance of about 20 mL/kg/min. Elimination half-life is about 6–7 hours. When administered via oral mucosa (liquid placed into the side of cat's mouth), absorption was comparable to that seen with IM or IV administration. Subcutaneous administration may be less bioavailable and clinically effective than transmucosal administration. Human transdermal patch buprenorphine (*Transtac*®—Napp Pharm.; UK) applied to cats has demonstrated widely variable blood levels and without a loading dose does not appear to provide adequate analgesia.

In dogs, oral transmucosal administered buprenorphine is about 50% absorbed. The differences in oral mucosal bioavailability compared with cats may be a result of the pH differences in the oral cavity of each species; cats have a more alkaline oral pH.

In the horse, onset of action is approximately 15 minutes after IV dosing. The drug is very well absorbed after sublingual administration. The peak effect occurs in 30–45 minutes and the duration of action may last up to 8 hours. Elimination half-life after an IV dose is about 6 hours. Because acepromazine exhibits a similar onset and duration of action, many equine clinicians favor using this drug in combination with buprenorphine.

### Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and in geriatric or severely debilitated patients.

Rarely, patients may develop respiratory depression from buprenorphine; it, therefore, should be used cautiously in patients with compromised cardiopulmonary function. Like other opiates, buprenorphine must be used with extreme caution in patients with head trauma, increased CSF pressure or other CNS dysfunction (*e.g.*, coma).

Patients with severe hepatic dysfunction may eliminate the drug more slowly than normal patients. Buprenorphine may increase bile duct pressure and should be used cautiously in patients with biliary tract disease.

The drug is contraindicated in patients having known hypersensitivity to it.

### Adverse Effects

Although rare, respiratory depression appears to be the major adverse effect to monitor for with buprenorphine; other adverse effects (sedation) may be noted. The primary side effect seen in humans is sedation with an incidence of approximately 66%. May cause urine retention or difficulty voiding, particularly with high IV doses or epidural administration.

In cats, buprenorphine is usually very well tolerated with GI effects (vomiting) only rarely been reported; hyperthermia does not appear to be a problem.

In horses, buprenorphine may cause some excitement and diminished gut sounds, but colic has not been a major concern.

### Reproductive/Nursing Safety

Although no controlled studies have been performed in domestic animals or humans, the drug has exhibited no evidence of teratogenicity or causing impaired fertility in laboratory animals. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

The intraperitoneal LD<sub>50</sub> of buprenorphine has been reported to be 243 mg/kg in rats. The ratio of lethal dose to effective dose is at least 1000:1 in rodents. Because of the apparent high index of safety, life-threatening acute overdoses should be a rare event in veterinary medicine, but most overdoses will cause signs. There were 55 exposures to buprenorphine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 34 were dogs with 25 showing clinical signs, and 20 were cats with 6 showing clinical signs. The 1 remaining case was a lagomorph that showed clinical signs. Common findings in dogs recorded in decreasing frequency included vocalization, ataxia, hypersalivation, hypothermia, and lethargy.

Treatment with naloxone and doxapram have been suggested in cases of acute overdoses causing respiratory or cardiac effects. Secondary to buprenorphine's high affinity for the *mu* receptor, high doses of naloxone may be required to treat respiratory depression.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving buprenorphine and may be of significance in veterinary patients:

- **ANESTHETICS, LOCAL (mepivacaine, bupivacaine):** May be potentiated by concomitant use of buprenorphine
- **ANTICONVULSANTS (phenobarbital, phenytoin):** May decrease plasma buprenorphine levels
- **BENZODIAZEPINES:** Case reports of humans developing respiratory/cardiovascular/CNS depression; use with caution
- **CNS DEPRESSANTS (*e.g.*, anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.):** May cause increased CNS or respiratory depression when used with buprenorphine
- **ERYTHROMYCIN:** Can increase plasma buprenorphine levels
- **FENTANYL (and other pure opiate agonists):** Buprenorphine may potentially antagonize some analgesic effects (**Note: This is controversial**), but may also reverse some of the sedative and respiratory depressant effects of pure agonists
- **HALOTHANE:** Potentially can increase buprenorphine effects
- **KETOCONAZOLE, ITRACONAZOLE, FLUCONAZOLE:** Can increase plasma buprenorphine levels
- **MONAMINE OXIDASE (MAO) INHIBITORS (*e.g.*, selegiline, amitraz):** Possible additive effects or increased CNS depression
- **NALOXONE:** May reduce analgesia associated with high dose buprenorphine
- **PANCURONIUM:** If used with buprenorphine may cause increased conjunctival changes
- **RIFAMPIN:** Potentially decrease plasma buprenorphine concentrations

### Doses

#### ■ DOGS:

For analgesia:

a) 0.005–0.02 mg/kg IM, IV or SC q6–12h (Hendrix & Hansen 2000)

b) As a continuous IV infusion: 2–4 micrograms/kg/hour (Hansen 2008)

c) 0.005–0.03 mg/kg IV, IM, SC, epidural (Boothe 1999)

d) 0.006–0.02 mg/kg IV, IM, SQ; duration of effect 6–12 hours and is a relatively effective analgesic, but may be difficult to reverse with naloxone if untoward effects are seen. (Perkowski 2006)

#### ■CATS:

For analgesia:

a) 0.01–0.03 mg/kg IM, IV, Buccal. Effects may last up to 6 hours. Buccal use is well accepted by cats. (Robertson & Lascelles 2003)

b) 0.01–0.03 mg/kg PO transmucosally (squirted directly into the mouth) q8h (Lichtenberger 2006)

c) 0.01–0.03 mg/kg IM, IV, SC q6–8h; 0.01–0.03 mg/kg PO q6–12h (Hansen 2003); As a continuous IV infusion: 1–3 micrograms/kg/hour (Hansen 2008)

d) In the emergent patient: Dose rates higher than 20 micrograms/kg (0.02 mg/kg) should be used. Higher doses produce better analgesia. SC administration of 20 micrograms/kg has limited effects and transmucosal, IV or IM routes preferred. (Leece 2009)

#### ■FERRETS:

a) 0.01–0.05 mg/kg SC or IM 2–3 times daily (Williams 2000)

#### ■HORSES: (Note: ARCI UCGFS Class 2 Drug)

For neuroleptanalgesia:

a) 0.004 mg/kg IV (given with acepromazine 0.02 mg/kg) (Thurmon & Benson 1987)

b) 0.006 mg/kg IV (given with xylazine 0.07 mg/kg) (Thurmon & Benson 1987)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

As an analgesic (for control of acute or chronic visceral pain):

a) **Rabbits:** 0.01–0.05 mg/kg SC, IM or IV q6–12h; 0.5 mg/kg rectally q12h (Ivey & Morrissey 2000)

b) **Guinea pigs:** 0.05 mg/kg SC or IV q8–12h

**Mice:** 0.05–0.1 mg/kg SC q12h.

**Rats:** 0.01–0.05 mg/kg SC or IV q8–12h or 0.1–0.25 mg/kg PO q8–12h. (Adamcak & Otten 2000)

As a premedication:

a) **Rabbits:** In compromised patients: 0.05–0.1 mg/kg SC alone. (Vella 2009)

b) **Rabbits:** In healthy animals before uncomplicated elective procedures: Buprenorphine 0.02–0.06 mg/kg with midazolam (0.25–0.5 mg/kg) IM within 20 minutes of procedure along with a local or line incisional block using lidocaine and bupivacaine. Protocols are modified for ill or unstable animals. (Lennox 2009)

#### ■ZOO, EXOTIC, WILDLIFE SPECIES:

For use of buprenorphine in zoo, exotic and wildlife medicine refer to specific references, including:

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

### Monitoring

- Analgesic efficacy
- Respiratory status
- Cardiac status

### Client Information

- This agent should be used parenterally in an inpatient setting or with direct professional supervision
- Buccal/SL dosing may be performed at home, but pre-measuring dosages in syringes (if using the injection orally) should be considered

### Chemistry/Synonyms

A thebaine derivative, buprenorphine is a synthetic partial opiate agonist. It occurs as a white, crystalline powder with a solubility of 17 mg/mL in water and 42 mg/mL in alcohol. The commercially available injectable product (*Buprenex*®—Norwich Eaton) has a pH of 3.5–5 and is a sterile solution of the drug dissolved in D5W. Terms of potency are expressed in terms of buprenorphine. The commercial product contains 0.324 mg/mL of buprenorphine HCl, which is equivalent to 0.3 mg/mL of buprenorphine.

Buprenorphine HCl may also be known as: buprenorphini hydrochloridum, CL-112302, NIH-8805, UM-952; *Anorfin*®, *Buprenex*®, *Buprine*®, *Finibron*®, *Magnogen*®, *Nopan*®, *Norphin*®, *Pentorel*®, *Prefin*®, *Suboxone*®, *Subutex*®, *Temgesic*®, or *Temgesic-nX*®.

### Storage/Stability

Buprenorphine should be stored at room temperature (15–30° C). Temperatures above 40° C or below freezing should be avoided. Buprenorphine products should be stored away from bright light. Autoclaving may considerably decrease drug potency. The drug is stable between a pH of 3.5–5.

### Compatibility/Compounding Considerations

Buprenorphine is reported to be **compatible** with the following IV solutions and drugs: acepromazine, atropine, diphenhydramine, D5W, D5W and normal saline, dexmedetomidine, droperidol, glycopyrrolate, hydroxyzine, lactated Ringer's, normal saline, scopolamine, and xylazine.

Although no published data could be located to support stability for this combination, buprenorphine injection has been mixed in syringes with dexmedetomidine and ketamine.

Buprenorphine is reportedly **incompatible** with diazepam and lorazepam.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

A compounded sustained-release injectable (SC) product is reportedly available from zoopharm.net.

### HUMAN-LABELED PRODUCTS:

Buprenorphine HCl for Injection: 0.324 mg/mL (equivalent to 0.3 mg/mL buprenorphine); 1 mL amps & *Carpuject*; *Buprenex*<sup>®</sup> (Reckitt Benckiser); generic (Hospira); (Rx, C-III)

Buprenorphine HCl Sublingual Tablets: 2 & 8 mg (as base); *Subutex*<sup>®</sup> (Reckitt Benckiser); generic (Roxane Labs); (Rx, C-III)

Buprenorphine HCl Transdermal System: *Butrans*<sup>®</sup> (Purdue); (Rx, C-III)

Buprenorphine HCl Combinations: Sublingual Tablets: 2 mg buprenorphine base/0.5 mg naloxone; 8 mg buprenorphine base/2 mg naloxone; *Suboxone*<sup>®</sup> (Reckitt Benckiser); (C-III)

---

## BUSPIRONE HCL

(byoo-spye-ronc) BuSpar<sup>®</sup>

ANXIOLYTIC

### Prescriber Highlights

- **Non-benzodiazepine anxiolytic agent used in dogs & cats**
- **May take a week or more to be effective; not appropriate for acute treatment of situational anxieties**
- **Use with caution in patients with severe hepatic or renal disease**
- **Adverse Effects relatively uncommon; cats may exhibit behavior changes**
- **Human generic forms of medication relatively inexpensive**

---

## Uses/Indications

Buspirone may be effective in treating certain behavior disorders in dogs and cats, principally those that are fear/phobia related and especially those associated with social interactions. Buspirone may also be useful for urine spraying or treatment of motion sickness in cats. Approximately 50% of cats show improvement in urine marking when buspirone is given. Buspirone may be more effective in multi-cat households than in single cat households.

## Pharmacology/Actions

Buspirone is an anxiolytic agent. Unlike the benzodiazepines, buspirone does not possess any anticonvulsant or muscle relaxant activity and little sedative or psychomotor impairment activity. Buspirone does not share the same mechanisms as the benzodiazepines (does not have significant affinity for benzodiazepine receptors and does not affect GABA binding). It appears to act as a partial agonist at serotonin (5-HT<sub>1A</sub>) receptors and as an agonist/antagonist of dopamine (D<sub>2</sub>) receptors in the CNS. In neurons, buspirone slows the neuronal flow depletion of serotonin stores.

## Pharmacokinetics

In humans, buspirone is rapidly and completely absorbed but a high first pass effect limits systemic bioavailability to approximately 5%. Binding to plasma proteins is very high (95%). In rats, highest tissue concentrations are found in the lungs, kidneys, and fat. Lower levels are found in the brain, heart, skeletal muscle, plasma and liver. Both buspirone and its metabolites are distributed into maternal milk. The elimination half-life (in humans) is about 2–4 hours. Buspirone is hepatically metabolized to several metabolites (including one that is active: 1-PP). These metabolites are excreted primarily in the urine.

In a limited study done in 6 cats (Mealey *et al.* 2004), oral administration of buspirone gave peak levels in about 1.4 hours, but oral bioavailability appeared to be significantly lower than in humans. Transdermal administration of buspirone (PLO-base) did not yield detectable levels (ELISA method).

## Contraindications/Precautions/Warnings

Buspirone should be used with caution with either significant renal or hepatic disease. Because buspirone may reduce disinhibition, it should be used with caution in aggressive animals. While buspirone has far less sedating properties than many other anxiolytic drugs, it should be used with caution in working dogs.

Because buspirone often takes a week or more for effect, it should not be used as the sole therapy for situational anxieties.

## Adverse Effects

Adverse effects are usually minimal in animals treated with buspirone and it is generally well tolerated. Bradycardia, GI disturbances and stereotypic behaviors are possible. Cats may demonstrate increased affection, which may be the desired effect. In multi-cat households, cats that have previously been extremely timid in the face of repeated aggression from other cats may, after receiving buspirone begin turning on their attacker.

The most likely adverse effect profile seen with buspirone in humans includes dizziness, headache, nausea/anorexia, and restlessness; other neurologic effects (including sedation) may be noted. Rarely, tachycardias and other cardiovascular clinical signs may be present.

## Reproductive/Nursing Safety

While the drug has not been proven safe during pregnancy, doses of up to 30 times the labeled dosage in rabbits and rats demonstrated no teratogenic effects. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Buspirone and its metabolites have been detected in the milk of lactating rats; avoid use during nursing if possible.

## Overdosage/Acute Toxicity

Limited information is available. The oral LD<sub>50</sub> in dogs is 586 mg/kg. Oral overdoses may produce vomiting, dizziness, drowsiness, miosis and gastric distention. Standard overdose protocols should be followed after ingestion has been determined.

## Drug Interactions

Buspirone may be used in combination with tricyclic or SSRI agents, but dosage reductions may be necessary to minimize adverse effects.

The following drug interactions have either been reported or are theoretical in humans or animals receiving buspirone and may be of significance in veterinary patients:

- **CNS DEPRESSANTS:** Potentially could cause increased CNS depression
- **DILTIAZEM:** May cause increased buspirone plasma levels and adverse effects
- **ERYTHROMYCIN:** May cause increased buspirone plasma levels and adverse effects
- **GRAPEFRUIT JUICE (powder):** May cause increased buspirone plasma levels and adverse effects
- **KETOCONAZOLE, ITRACONAZOLE:** May cause increased buspirone plasma levels and adverse effects
- **MONOAMINE OXIDASE INHIBITORS** (*e.g.*, **selegiline, amitraz**): Use with buspirone is not recommended because dangerous hypertension may occur
- **RIFAMPIN:** May cause decreased buspirone plasma levels
- **TRAZODONE:** Use with buspirone may cause increased ALT
- **VERAPAMIL:** May cause increased buspirone plasma levels

## Doses

### ■ DOGS:

For low-grade anxieties and fears:

- a) 1 mg/kg PO q8–24h (mild anxiety); 2.5–10 mg (total dose) per dog PO q8–24h (mild anxiety); 10–15 mg per dog PO q8–12h (more severe anxiety, thunderstorm phobia) (Overall 2000)
- b) 1–2 mg/kg PO q12h; 5–15 mg (total dose) per dog PO q8–12h (Siebert 2003)
- c) 5–10 mg (total dose) PO q8–12h (Reisner & Houpt 2000)
- d) For global anxiety: 0.5–2 mg/kg PO q8–12h; may take 2–4 weeks until effect. (Horwitz 2006)
- e) 1 mg/kg PO q8–12h; most useful in social phobias; may also be useful for panic disorders (Virga 2005)

### ■ CATS:

For adjunctive treatment of low-grade anxieties/fears, spraying, overgrooming:

- a) 0.5–1 mg/kg PO q8–12h; 2.5–5 mg (total dose) per cat PO q8–12h for 6–8 weeks; some cats do well on once daily dosing (Overall 2000)
- b) 2.5–5 mg (total dose) PO once a day to 3 times a day (Seksell 2003)
- c) For urine marking: 2.5–7.5 mg (total dose) per cat PO q12h (Levine 2008)
- d) 0.5–1 mg/kg PO q12h; 2.5–7.5 mg (total dose) per cat PO q12h (Siebert 2003)
- e) 0.5–1 mg/kg PO q8–12h; most useful in social phobias; may also be useful for panic disorders (Virga 2005)

## Monitoring

- Efficacy
- Adverse effect profiles

## Chemistry/Synonyms

An arylpiperazine derivative anxiolytic agent, buspirone HCl differs structurally from the benzodiazepines. It occurs as a white, crystalline powder with solubilities at 25°C of 865 mg/mL in water and about 20 mg/mL in alcohol.

Buspirone HCl may also be known as MJ-9022; many trade names are available.

## Storage/Stability

Buspirone HCl tablets should be stored in tight, light-resistant containers at room temperature. After manufacture, buspirone tablets have an expiration date of 36 months.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Buspirone HCl Oral Tablets: 5 mg (4.6 mg as base), 7.5 mg (6.85 mg as base), 10 mg (9.1 mg as base), 15 mg (13.7 mg as base) and 30 mg (27.4 mg as base); *BuSpar*® (Bristol-Myers Squibb); generic; (Rx)

---

## BUSULFAN

(*byoo-sul-fan*) Myleran®, Busulfex®

ANTINEOPLASTIC

### Prescriber Highlights

- Antineoplastic sometimes used in treating chronic granulocytic leukemias in small animals
  - Myelosuppression; may be severe
  - May increase uric acid levels
- 

## Uses/Indications

Busulfan may be useful in the adjunctive therapy of chronic granulocytic leukemias or polycythemia vera in small animals. Not commonly used in veterinary medicine.

## Pharmacology/Actions

Busulfan is a bifunctional alkylating agent antineoplastic and is cell cycle-phase nonspecific. The exact mechanism of action has not been determined but is thought to be due to its alkylating, cross-linking of strands of DNA and myelosuppressive properties. Busulfan's primary activity is against cells of the granulocytic series.

## Pharmacokinetics

Busulfan is well absorbed after oral administration. Distribution characteristics are not well described but in humans, drug concentrations in the CSF are nearly equal to those found in plasma. It is unknown whether the drug enters maternal milk. Busulfan is rapidly, hepatically metabolized to at least 12 different metabolites that are slowly excreted into the urine. In humans, serum half-life of busulfan averages about 2.5 hours.

## Contraindications/Precautions/Warnings

Busulfan is contraindicated in patients who have shown resistance to the drug in the past or are hypersensitive to it. Only veterinarians with the experience and resources to monitor the toxicity of this agent should administer this drug. The risk versus benefits of therapy must be carefully considered in patients with preexisting bone marrow depression or concurrent infections. Additive bone marrow depression may occur in patients undergoing concomitant radiation therapy.

## Adverse Effects

The most commonly associated adverse effect seen with busulfan therapy is myelosuppression. In humans, anemia, leukopenia, and thrombocytopenia may be observed. Onset of leukopenia is generally 10–15 days after initiation of therapy and leukocyte nadirs occurring on average around 11–30 days. Severe bone marrow depression can result in pancytopenia that may take months to years for recovery. In humans, bronchopulmonary dysplasia with pulmonary fibrosis, uric acid nephropathy, and stomatitis have been reported. These effects are uncommon and generally associated with chronic, higher dose therapy.

## Reproductive/Nursing Safety

Busulfan's teratogenic potential has not been well documented, but it is mutagenic in mice and may potentially cause a variety of fetal abnormalities. It is generally recommended to avoid the drug during pregnancy, but because of the seriousness of the diseases treated with busulfan, the potential benefits to the mother must be considered. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown if busulfan enters milk; avoid nursing if the dam is receiving the drug.

## Overdosage/Acute Toxicity

There is limited experience with busulfan overdoses. The LD<sub>50</sub> in mice is 120 mg/kg. Chronic overdosage is more likely to cause serious bone marrow suppression than is an acute overdose; however, any overdose, should be treated seriously with standard gut emptying protocols used when appropriate and supportive therapy

initiated when required. There is no known specific antidote for busulfan intoxication.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving busulfan and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Use within 72 hours prior to busulfan can reduce busulfan clearance by reducing glutathione concentrations in tissues and blood
- **CYCLOPHOSPHAMIDE:** Can potentially reduce clearance of busulfan, probably by competing for available glutathione
- **ITRACONAZOLE:** Potential decreased busulfan clearance
- **MYELOSUPPRESSANT AGENTS:** Concurrent use with other bone marrow depressant medications may result in additive myelosuppression
- **PHENYTOIN:** Possible increased clearance of busulfan
- **THIOGUANINE:** Used concomitantly with busulfan may result in hepatotoxicity

### Laboratory Considerations

- Busulfan may raise serum **uric acid** levels. Drugs such as allopurinol may be required to control hyperuricemia.

### Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

#### ■ SMALL ANIMALS:

- a) Busulfan is rarely used in veterinary medicine, but when used it is usually dosed in a range of 2–4 mg/m<sup>2</sup> (NOT mg/kg) PO once daily.

### Monitoring

- CBC
- Serum uric acid
- Efficacy

### Client Information

- Clients must understand the importance of both administering busulfan as directed and reporting immediately any signs associated with toxicity (e.g., abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.).

### Chemistry/Synonyms

An alkylsulfonate antineoplastic agent, busulfan occurs as white, crystalline powder. It is slightly soluble in alcohol and very slightly soluble in water.

Busulfan may also be known as: bussulfam, busulfanum, busulphan, CB-2041, GT-41, myelosan, NSC-750, WR-19508, *Bussulfam*®, *Busulfanum*®, *Busulivex*®, *Mielucin*®, *Misulban*®, or *Myleran*®.

### Storage/Stability

Busulfan tablets should be stored in well-closed containers at room temperature.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### **HUMAN-LABELED PRODUCTS:**

Busulfan Oral Tablets: 2 mg; *Myleran*® (GlaxoSmithKline); (Rx)

Busulfan Injection Solution: 6 mg/mL in 10 mL single-use amps with syringe filters; *Busulfex*® (Otsuka America); (Rx)

---

## BUTAPHOSPHAN WITH CYANOCOBALAMIN

(byoo-ta-fos-fan; sye-an-oh-koe-bal-ah-min) Catosal®

INJECTABLE PHOSPHATE/VITAMIN B12

### Prescriber Highlights

- An injectable organic phosphorous and vitamin B-12 product
- Not an FDA-approved drug

*Because this product has not undergone FDA-approval process as a drug, there is a limited amount of information available; refer to the Cyanocobalamin and Phosphate monographs for more information*

## Uses/Indications

The combination product *Catosal*® contains butaphosphan with cyanocobalamin (Vitamin B-12). It is marketed in several countries for a variety of species (sheep, poultry, pigs, horses, goats, dogs, cattle, fur-bearing animals, and cats) when a parenteral source of phosphorous and vitamin B-12 is indicated. In the USA, the label states that it is a source of Vitamin B12 and phosphorus for prevention or treatment of deficiencies of these nutrients in cattle, swine, horses and poultry.

## Pharmacology/Actions

For more detail on pharmacology/actions, see the *Cyanocobalamin* and *Phosphate* monographs. A study (Furll *et al.* 2010) done in dairy cattle where butaphosphan/cyanocobalamin was injected daily one to two weeks before parturition either 0, 3, or 6 times (0.1 mL/kg IV; 10 mg/kg butaphosphan and 5 micrograms/kg cyanocobalamin) showed that multiple daily IV injections before parturition increased serum cyanocobalamin levels, post-partum glucose availability, and decreased peripheral fat mobilization and ketone body formation. Puerperal infection rates in the first 5 days post-partum were decreased in the group receiving 6 injections versus the cows receiving placebo.

Another study done in dairy cattle to determine the effect of butaphosphan/cyanocobalamin on the prevalence of subclinical ketosis in dairy cattle in the early postpartum period has been published (Rollin *et al.* 2010). Cows received either placebo (25 mL sterile water SC) or butaphosphan/cyanocobalamin injection (25 mL SC) on the day of, and one day after, calving. Only mature cows (3 or more lactations) receiving the drug had a lower rate of hyperketonemia than the non-treated cattle. These mature cows also showed significantly lower increases in serum concentrations of beta-hydroxybutyrate (BHBA) when measured at 3 and 10 days post-calving.

## Pharmacokinetics

No specific information located; refer to the phosphate and cyanocobalamin monographs for further information.

## Contraindications/Precautions/Warnings

This product should *not* be used in patients with hyperphosphatemia. Use with caution in patients with chronic renal failure.

Use standard aseptic procedures during administration of injections. Volumes of more than 10 mL should be split and given at separate intramuscular or subcutaneous sites.

## Adverse Effects

None noted.

## Reproductive/Nursing Safety

No specific information located.

## Overdosage/Acute Toxicity

No specific information located.

## Drug Interactions

No specific information located. Refer to the phosphate monograph for more information.

## Laboratory Considerations

No specific information located.

## Doses

### ■HORSES:

a) 1–2 mL per 100 lbs body weight SC, IM, or IV; repeat daily as needed. Use standard aseptic procedures during administration of injections. Volumes of more than 10 mL should be split and given at separate intramuscular or subcutaneous sites. (*Catosal*®; Bayer (USA) label information)

### ■CATTLE:

a) 1–2 mL per 100 lbs body weight SC, IM, or IV; repeat daily as needed. Volumes of more than 10 mL should be split and given at separate intramuscular or subcutaneous sites. Calves: 2–4 mL per 100 lbs body weight; repeat daily as needed. (*Catosal*®; Bayer (USA) label information)

### ■SWINE:

a) 2 - 5 mL per 100 lbs body weight SC, IM, or IV repeat daily as needed. Volumes of more than 10 mL should be split and given at separate intramuscular or subcutaneous sites. Piglets: 1–2.5 mL (total dose) per animal SC, IM, or IV; repeat daily as needed. (*Catosal*®; Bayer (USA) label information)

### ■BIRDS:

a) Poultry (turkeys): 1–3 mL per liter of drinking water; repeat daily as needed. (*Catosal*®; Bayer (USA) label information)

## Chemistry/Synonyms

Butaphosphan is 1-(n-Butylamino)-1-methylethyl phosphonous acid. One gram (10 mL of injection) provides 173 mg of phosphorous.

## Storage/Stability

The injectable product should be stored at temperatures below 30°C (86°F); avoiding freezing.

## Compatibility/Compounding Considerations

No specific information located. Consult the cyanocobalamin and Phosphate monographs for guidance.

## Dosage Forms/Regulatory Status

VETERINARY LABELED PRODUCTS:

## VETERINARY-LABELED PRODUCTS:

Butaphosphan 100 mg/mL and Cyanocobalamin (Vitamin B-12) 0.05 mg/mL in 100 mL & 250 mL multidose (each mL contains 30 mg of n-Butyl alcohol as a preservative); *Catosal*® (Bayer). This is not an FDA-approved drug product (not listed in Green Book). The USA labeling for the product states that federal law (USA) restricts this drug to use by or on the order of a licensed veterinarian (Rx) and that there is a zero day withdrawal period for meat, milk, and eggs.

**HUMAN-LABELED PRODUCTS:** None

## References

- Rollin, E, RD Berghaus, et al. (2010). The effect of injectable butaphosphan and cyanocobalamin on postpartum serum beta-hydroxybutyrate, calcium, and phosphorus concentrations in dairy cattle. *Journal of Dairy Science* **93**(6): 978–987.

---

## BUTORPHANOL TARTRATE

(byoo-tor-fa-nol) Stadol®, Torbutrol®, Torbugesic®

OPIATE PARTIAL AGONIST

### Prescriber Highlights

- **Partial opiate agonist/antagonist used in a variety of species as an analgesic, premed, antitussive, or antiemetic**
- **Not a good choice as an analgesic for moderate to severe pain in small animals, but a reasonably good analgesic for horses**
- **Contraindicated or caution in patients with liver disease, hypothyroidism, or renal insufficiency, Addison's, head trauma, increased CSF pressure or other CNS dysfunction (e.g., coma) & in geriatric or severely debilitated patients**
- **Reduce dose in dogs with MDR1 mutation**
- **Potential adverse effects in *Dogs/Cats*: Sedation, ataxia, anorexia or diarrhea (rarely)**
- ***Horses* (at usual doses): a transient ataxia & sedation, but CNS excitement possible**
- **Controlled substance (C-IV)**

---

## Uses/Indications

FDA-approved indication for dogs is "... for the relief of chronic non-productive cough associated with tracheobronchitis, tracheitis, tonsillitis, laryngitis and pharyngitis originating from inflammatory conditions of the upper respiratory tract" (Package Insert; *Torbutrol*®—Fort Dodge). It is also used in practice in both dogs and cats as a preanesthetic medication, analgesic, and as an antiemetic prior to cisplatin treatment (although not very effective in cats for this indication). Compared with other opiate analgesics, butorphanol is not very useful in small animals (particularly dogs) for treating pain and has to be dosed frequently. Butorphanol is a useful reversal agent for the CNS and respiratory depressant effects of *mu*-agonists. Due to its kappa effects, it can reverse CNS and respiratory depression without completely reversing the analgesic effect of the *mu* agonist drugs.

The FDA-approved indication for horses is "... for the relief of pain associated with colic in adult horses and yearlings" (Package Insert; *Torbugesic*®—Fort Dodge). It has also been used clinically as an analgesic in cattle.

## Pharmacology/Actions

Butorphanol is considered to be, on a weight basis, 4–7 times as potent an analgesic as morphine, 15–30 times as pentazocine, and 30–50 times as meperidine; however a ceiling effect is reached at higher dosages, where analgesia is no longer enhanced and may be reduced. Its agonist activity is thought to occur primarily at the kappa and sigma receptors and the analgesic actions at sites in the limbic system (sub-cortical level and spinal levels). Its use as an analgesic in small animals has been disappointing, primarily because of its very short duration of action and ability to alleviate only mild to moderate pain.

The antagonist potency of butorphanol is considered to be approximately 30 times that of pentazocine and 1/40th that of naloxone and will antagonize the effect of true agonists (e.g., morphine, meperidine, oxymorphone).

Besides the analgesic qualities of butorphanol, it possesses significant antitussive activity. In dogs, butorphanol has been shown to elevate CNS respiratory center threshold to CO<sub>2</sub> but, unlike opiate agonists, not depress respiratory center sensitivity. Butorphanol, unlike morphine, apparently does not cause histamine release in dogs. CNS depression may occur in dogs, while CNS excitation has been noted (usually at high doses) in horses and dogs.

Although possessing less cardiovascular effects than the classical opiate agonists, butorphanol can cause a decrease in cardiac rate secondary to increased parasympathetic tone and mild decreases in arterial blood pressures.

The risk of causing physical dependence seems to be minimal when butorphanol is used in veterinary patients.

## Pharmacokinetics

Butorphanol is absorbed completely in the gut when administered orally but, because of a high first-pass effect, only about 1/6th of the administered dose reaches the systemic circulation. The drug has also been shown to be completely absorbed following IM administration.

Butorphanol is well distributed, with highest levels (of the parent compound and metabolites) found in the liver, kidneys, and intestine. Concentrations in the lungs, endocrine tissues, spleen, heart, fat tissue and blood cells are also higher than those found in plasma. Approximately 80% of the drug is bound to plasma proteins (human data). Butorphanol will cross the placenta and neonatal plasma levels have been roughly equivalent to maternal levels. The drug is also distributed into maternal milk.

Butorphanol is metabolized in the liver, primarily by hydroxylation. Other methods of metabolism include N-dealkylation and conjugation. The metabolites of butorphanol do not exhibit any analgesic activity. These metabolites and the parent compound are mainly excreted into the urine (only 5% is excreted unchanged), but 11–14% of a dose is excreted into the bile and eliminated with the feces.

Following IV doses in horses, the onset of action is approximately 3 minutes with a peak analgesic effect at 15–30 minutes. The duration of action in horses may be up to 4 hours after a single dose.

## Contraindications/Precautions/Warnings

The drug is contraindicated in patients having known hypersensitivity to it. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and in geriatric or severely debilitated patients.

Like other opiates, butorphanol must be used with extreme caution in patients with head trauma, increased CSF pressure or other CNS dysfunction (e.g., coma).

Dogs with MDR1 mutations (many Collies, Australian shepherds, etc.) may develop a more pronounced sedation that persists longer than normal. The Washington State University Veterinary Clinical Pharmacology Lab recommends reducing the dose by 25% in dogs heterozygous for the MDR1 mutation and by 30-50% in dogs homozygous (mutant/mutant) for the mutation.

The manufacturer states that butorphanol "should not be used in dogs with a history of liver disease" and, because of its effects on suppressing cough, "it should not be used in conditions of the lower respiratory tract associated with copious mucous production." The drug should be used cautiously in dogs with heartworm disease, as safety for butorphanol has not been established in these cases.

Butorphanol may not be a very good analgesic and may cause respiratory depression in turtles or tortoises (Sladky *et al.* 2007).

## Adverse Effects

Adverse effects reported in dogs/cats include sedation, excitement, respiratory depression, ataxia, anorexia or diarrhea (rarely). Adverse effects may be less severe than those seen with pure agonists.

Adverse effects seen in horses (at usual doses) may include a transient ataxia and sedation, but excitement has been noted as well (see below). Although reported to have minimal effects on the GI, butorphanol has the potential to decrease intestinal motility and ileus can occur. Horses may exhibit CNS excitement (tossing and jerking of head, increased ambulation, augmented avoidance response to auditory stimuli) if given high doses (0.2 mg/kg) IV rapidly. Very high doses IV (1–2 mg/kg) may lead to the development of nystagmus, salivation, seizures, hyperthermia and decreased GI motility. These effects are considered transitory in nature.

## Reproductive/Nursing Safety

Although no controlled studies have been performed in domestic animals or humans, the drug has exhibited no evidence of teratogenicity or of causing impaired fertility in laboratory animals. The manufacturer, however, does not recommend its use in pregnant bitches, foals, weanlings (equine), and breeding horses. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats; or these drugs are safe if they are not administered when the animal is near term.*)

Butorphanol can be distributed into milk, but not in amounts that would cause concern in nursing offspring.

## Overdosage/Acute Toxicity

Acute life-threatening overdoses with butorphanol should be unlikely. The LD<sub>50</sub> in dogs is reportedly 50 mg/kg. However, because butorphanol injection is available in two dosage strengths (0.5 mg/mL and 10 mg/mL) for veterinary use, the possibility exists that inadvertent overdoses may occur in small animals. It has been suggested that animals exhibiting clinical signs of overdose (CNS effects, cardiovascular changes, and respiratory depression) be treated immediately with intravenous naloxone. Additional supportive measures (e.g., fluids, O<sub>2</sub>, vasopressor agents, and mechanical ventilation) may be required. Should seizures occur and persist, diazepam may be used for control.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving butorphanol and may be of significance in veterinary patients:

- **OTHER CNS DEPRESSANTS** (e.g., **anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol**, etc.): May cause increased CNS or respiratory depression when used with butorphanol; dosage may need to be decreased
- **ERYTHROMYCIN**: Could potentially decrease metabolism of butorphanol
- **FENTANYL** (and other **pure opiate agonists**): Butorphanol may potentially antagonize some analgesic effects (**Note**: this is controversial), but may also reverse some of the sedative and respiratory depressant effects of pure agonists
- **PANCURONIUM** If used with butorphanol may cause increased conjunctival changes
- **THEOPHYLLINE**: Could potentially decrease metabolism of butorphanol

## Doses

**Note:** All doses are expressed in mg/kg of the *base* activity. If using the human product (*Stadol*®), 1 mg of tartrate salt = 0.68 mg base.

### ■ DOGS:

As an antitussive:

- a) 0.055–0.11 mg/kg SC q6–12h; treatment should not normally be required for longer than 7 days; or 0.55 mg/kg PO q6–12h; may increase dose to 1.1 mg/kg PO q6–12h (The oral doses correspond to one 5 mg tablet per 20 lbs. and 10 lbs. of body weight, respectively); treatment should not normally be required for longer than 7 days (Package Insert; *Torbutrol*®—Fort Dodge)
- b) 0.05–1 mg/kg PO q6–12h; goal is to suppress coughing without causing excessive sedation (Johnson, L 2000)
- c) 0.55–1.1 mg/kg PO as needed (Johnson, LR 2004)

As an analgesic:

- a) 0.1–0.5 mg/kg IV, IM, SQ; provides only mild to moderate analgesia (good visceral analgesia); duration of sedative action 2–4 hours, but analgesic action may be 1 hour or less (Perkowski 2006)
- b) As a constant rate infusion: 0.1–0.4 mg/kg/hr; occasionally used for abdominal pain (Hellyer 2006)
- c) As an epidural analgesic: 0.25 mg/kg diluted with preservative-free saline (0.2 mL) or local anesthetic epidurally. Onset of action less than 30 minutes and duration is 2–4 hours. Has predominantly supraspinal effects. (Valverde 2008)

In combination as an immobilizing agent:

- a) For difficult dogs and short procedures (nail trims, X-rays, etc): butorphanol 0.2 mg/kg; medetomidine 0.001–0.01 mg/kg; midazolam 0.05–0.2 mg/kg. All

b) For difficult dogs and short procedures (nail trims, X-rays, etc): butorphanol 0.2 mg/kg; medetomidine 0.01–0.02 mg/kg; midazolam 0.05–0.2 mg/kg. All given IM.

For dogs requiring more sedation: butorphanol 0.2 mg/kg; medetomidine 0.01–0.02 mg/kg; midazolam 0.05–0.2 mg/kg; all are given IM. Consider adding Telazol 1–2 mg/kg if insufficient sedation from above. For painful procedures consider adding buprenorphine at 0.02–0.04 mg/kg or substituting butorphanol or buprenorphine with either morphine 0.5–1 mg/kg or hydromorphone 0.1–0.2 mg/kg. More information available from [www.vsag.org](http://www.vsag.org). (Moffat 2008)

As reversal agent for the sedative and respiratory depressant effects of *mu*-agonist opiates:

a) 0.05–0.1 mg/kg IV; the benefit of using butorphanol over naloxone is that it does not completely reverse analgesic effects. (Quandt 2009)

As an anti-emetic prior to cisplatin treatment:

a) 0.4 mg/kg IM 1/2 hour prior to cisplatin infusion (Klausner & Bell 1988)

#### ■CATS:

As an analgesic:

a) 0.1–0.5 mg/kg IV, IM, SQ; provides only mild to moderate analgesia (good visceral analgesia); duration of sedative action 2–4 hours, but analgesic action may be 1 hour or less (Perkowski 2006)

b) As a postoperative CRI (usually in combination with ketamine) for mild to moderate pain: Loading dose of 0.1–0.2 mg/kg IV, then a CRI of 0.1–0.2 mg/kg/hr; Ketamine is used at a loading dose of 0.1 mg/kg IV with a CRI of 0.4 mg/kg/hr. When used with an opioid CRI may allow reduction in dosage of both. (Lichtenberger 2006b)

c) As an epidural analgesic: 0.25 mg/kg diluted with preservative-free saline (0.2 mL) or local anesthetic epidurally. Onset of action less than 30 minutes and duration is 2–4 hours. Has predominantly supraspinal effects. (Valverde 2008)

As reversal agent for the sedative and respiratory depressant effects of *mu*-agonist opiates:

a) 0.05–0.1 mg/kg IV; the benefit of using butorphanol over naloxone is that it does not completely reverse analgesic effects. (Quandt 2009)

In combination as an immobilizing agent:

a) For difficult cats and short procedures (nail trims, X-rays, etc): butorphanol 0.2 mg/kg; medetomidine 0.001–0.015 mg/kg; midazolam 0.05–0.2 mg/kg. All given IM.

For cats requiring more sedation: butorphanol 0.2 mg/kg; medetomidine 0.015–0.02 mg/kg; midazolam 0.05–0.2 mg/kg; add ketamine 1–5 mg/kg when insufficient sedation from opioid, higher doses of medetomidine, and midazolam; all are given IM. For painful procedures consider adding buprenorphine at 0.02–0.04 mg/kg or substituting butorphanol or buprenorphine with either morphine 0.5 mg/kg or hydromorphone 0.1 mg/kg. More information available from [www.vsag.org](http://www.vsag.org). (Moffat 2008)

#### ■FERRETS:

a) As a sedative/analgesic:

Butorphanol alone 0.05–0.1 mg/kg IM, SC. Butorphanol/Xylazine: Butorphanol 0.2 mg/kg + Xylazine 2 mg/kg IM

For injectable anesthesia:

Butorphanol 0.1 mg/kg, Ketamine 5 mg/kg, medetomidine 80 micrograms/kg. Combine in one syringe and give IM. May need to supplement with isoflurane (0.5–1.5%) for abdominal surgery. (Finkler 1999)

b) Xylazine (2 mg/kg) plus butorphanol (0.2 mg/kg) IM;

Telazol (1.5 mg/kg) plus xylazine (1.5 mg/kg) plus butorphanol (0.2 mg/kg) IM; may reverse xylazine with yohimbine (0.05 mg/kg IM) (Williams 2000)

As an analgesic:

a) 0.05–0.5 mg/kg SC or IM q4h (Williams 2000)

b) For post-op analgesia: 0.1–0.2 mg/kg loading dose, then a constant rate infusion of 0.1–0.2 mg/kg/hr (Lichtenberger 2006a)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

For chemical restraint in rabbits:

a) 0.1–0.5 mg/kg IV (Burke 1999); (Ivey & Morrisey 2000)

For analgesia:

a) For postsurgical analgesia in rabbits: 0.1–0.5 mg/kg IV or SC q2–4h; lower dosages may be more effective due to “ceiling effect” (Ivey & Morrisey 2000)

b) **Rabbits:** As an analgesic (post-operative pain): 0.4 mg/kg SC q4–6h; for surgical procedures (in combo with xylazine/ketamine): 0.1 mg/kg once IM or SC (Huerkamp 1995)

c) **Rabbits for post-op analgesia:** 0.1–0.2 mg/kg loading dose, then a constant rate infusion of 0.1–0.2 mg/kg/hr (Lichtenberger 2006a)

#### ■BIRDS:

As an analgesic:

a) As an analgesic, sedative, preanesthetic: 1–4 mg/kg IM, IV q2–3h (Lennox 2009)

b) 1–4 mg/kg q4h IM, IV, PO (Bays 2006)

#### ■CATTLE:

As an analgesic:

a) For surgery in adult cattle: 20–30 mg IV (jugular) (may wish to pretreat with 10 mg xylazine) (Powers 1985)

b) 0.02–0.25 mg/kg IV, SQ; 20–30 mg (total dose) IV for an adult animal. Duration of effect is 4 hours. An appropriate withdrawal period is 72 hours for milk, and 4 days for meat. (Walz 2006)

#### ■HORSES: (Note: ARCI UCGFS Class 3 Drug)

As an analgesic:

The injectable product is reported to be **compatible** with the following IV fluids and drugs: acepromazine, atropine sulfate, chlorpromazine, diphenhydramine HCl, droperidol, fentanyl citrate, hydroxyzine HCl, meperidine, morphine sulfate, pentazocine lactate, perphenazine, prochlorperazine, promethazine HCl, scopolamine HBr, and xylazine.

The drug is reportedly **incompatible** with the following agents: dimenhydrinate, and pentobarbital sodium.

## Dosage Forms/Regulatory Status

**Note:** Butorphanol is a class IV controlled substance. The veterinary products (*Torbutrol*<sup>®</sup>, *Torbugesic*<sup>®</sup>) strengths are listed as base activity. The human product (*Stadol*<sup>®</sup>) strength is labeled as the tartrate salt.

## VETERINARY-LABELED PRODUCTS:

Butorphanol Tartrate Injection: 0.5 mg/mL (activity as base) in 10 mL vials; *Torbutrol*<sup>®</sup> (Fort-Dodge); (Rx, C-IV). FDA-approved for use in dogs.

Butorphanol Tartrate Injection: 2 mg/mL (activity as base) in 10 mL vials. *Torbugesic-SA*<sup>®</sup> (Fort Dodge); (Rx, C-IV). FDA-approved for use in cats.

Butorphanol Tartrate Injection: 10 mg/mL (activity as base) in 10 mL, 50 mL vials; *Torbugesic*<sup>®</sup> (Fort-Dodge), *Dolorex*<sup>®</sup> (Intervet), *Butorject*<sup>®</sup> (Phoenix), *Torphaject*<sup>®</sup> (Butler); *Equano*<sup>®</sup> (Vedco) generic; (Rx, C-IV). FDA-approved for use in horses not intended for food.

Butorphanol Tartrate Tablets: 1 mg, 5 mg, and 10 mg (activity as base) tablets; bottles of 100; *Torbutrol*<sup>®</sup> (Fort-Dodge); (Rx, C-IV). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Butorphanol Tartrate Injection: 1 mg/mL (as tartrate salt; equivalent to 0.68 mg base) in 1 & 2 mL vials; 2 mg/mL (as tartrate salt) in 1, 2 & 10 mL vials; *Stadol*<sup>®</sup> (Bristol-Myers Squibb); generic; (Rx, C-IV)

Butorphanol Nasal Spray: 10 mg/mL in 2.5 mL metered dose; generic; (Rx, C-IV)

## CABERGOLINE

(*ka-ber-go-leen*) *Dostinex*<sup>®</sup>, *Galastop*<sup>®</sup>

PROLACTIN INHIBITOR/DOPAMINE (D<sub>2</sub>) AGONIST

### Prescriber Highlights

- **Ergot derivative used for reducing prolactin levels in bitches and queens. Indications include: inducing/synchronizing estrus, inducing abortion, treating pseudopregnancy, mastitis, and pre-surgery for mammary tumors.**
- **Appears to be well tolerated in dogs & cats; vomiting has been infrequently reported, but adverse effects are much less than with bromocriptine.**
- **Potentially very expensive, particularly in large dogs, but generic tablets now available; usually must be compounded for accurate dosing.**

---

## Uses/Indications

For dogs and cats, cabergoline may be useful for inducing estrus, treatment of primary or secondary anestrus, mastitis, pseudopregnancy, as a treatment prior to mammary tumor surgery, and pregnancy termination in the second half of pregnancy. Cabergoline may be useful in treating some cases of pituitary-dependent hyperadrenocorticism (Cushing's).

Preliminary work has been done in psittacines (primarily Cockatiels) for adjunctive treatment of reproductive-related disorders, particularly persistent egg laying.

In humans, cabergoline is indicated for the treatment of disorders associated with hyperprolactinemia or the treatment of Parkinson's disease.

## Pharmacology/Actions

Cabergoline has a high affinity for dopamine<sub>2</sub> (D<sub>2</sub>) receptors and has a long duration of action. It exerts a direct inhibitory effect on the secretion of prolactin from the pituitary. When compared to bromocriptine it has greater D<sub>2</sub> specificity, a longer duration of action, and less tendency to cause vomiting.

## Pharmacokinetics

The pharmacokinetics of cabergoline have apparently not been reported for dogs or cats. In humans, the drug is absorbed after oral dosing but its absolute bioavailability is not known. Food does not appear to significantly alter absorption. The drug is only moderately bound to plasma proteins ( $\approx 50\%$ ). Cabergoline is extensively metabolized in the liver via hydrolysis; these metabolites and about 4% of unchanged drug are excreted into the urine. Half-life is estimated to be around 60 hours. Duration of pharmacologic action may persist for 48 hours or more. Renal dysfunction does not appear to significantly alter elimination characteristics of the drug.

## Contraindications/Precautions/Warnings

Cabergoline is contraindicated in dogs and cats that are pregnant unless abortion is desired (see indications). Cabergoline should not be used in patients who are hypersensitive to ergot derivatives. Patients that do not tolerate bromocriptine may or may not tolerate cabergoline. In humans, cabergoline is contraindicated in patients who have uncontrolled hypertension.

Patients with significantly impaired liver function should receive the drug with caution, and if required, possibly at a lower dosage.

When using to induce estrus, it is recommended to wait at least 4 months after the prior cycle to allow the uterus to recover.

## Adverse Effects

Cabergoline is usually well tolerated by animal patients. Vomiting has been reported, but may be alleviated by administering with food. Dogs receiving cabergoline for more than 14 days may exhibit changes in coat color.

Human patients have reported postural hypotension, dizziness, headache, nausea and vomiting while receiving cabergoline.

## Reproductive/Nursing Safety

This drug can cause spontaneous abortion in pregnant dogs or cats. In pregnant humans, cabergoline is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Because cabergoline suppresses prolactin, it should not be used in nursing mothers.

## Overdosage/Acute Toxicity

Overdose information is not available for dogs or cats, and remains very limited for humans. It is postulated that cabergoline overdoses in people could cause hypotension, nasal congestion, syncope or hallucinations. Treatment is basically supportive and primarily focuses on supporting blood pressure.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cabergoline and may be of significance in veterinary patients:

■ **HYPOTENSIVE DRUGS:** Because cabergoline may have hypotensive effects, concomitant use with other hypotensive drugs may cause additive hypotension

■ **METOCLOPRAMIDE:** Use with cabergoline may reduce the efficacy of both drugs and should be avoided

■ **PHENOTHIAZINES** (*e.g.*, **acepromazine**, **chlorpromazine**): Use of cabergoline with dopamine ( $D_2$ ) antagonists may reduce the efficacy of both drugs and should be avoided

## Laboratory Considerations

■ No particular laboratory interactions or considerations were located for this drug.

## Doses

Because of the dosage differences in animals versus human patients and the strength of the commercially available product, a compounding pharmacist must usually reformulate this medication.

### ■ DOGS:

For estrus induction:

a) 5 micrograms/kg PO once daily induces fertile proestrus in 4–25 days. (Davidson 2004)

b) 5 micrograms/kg PO once daily until an induced proestrus is pronounced for 2 days or until onset of estrus (Concannon 2005)

c) 0.6 micrograms/kg PO once daily. Make a 10 micrograms per mL solution by dissolving commercial tablets in warm distilled water (One 0.5 mg tablet (500 micrograms) per 50 mL of distilled water.) Give the appropriate dose for the patient within 15 minutes of preparation and discard the remaining solution.

Continue until day 2 after the onset of the first signs of proestrus, or until day 42 without signs of proestrus. 81% (22 of 27) of dogs treated at this low dose showed proestrus between days 4 and 48. (Cirit *et al.* 2006)

To reduce milk production:

a) For pseudocyesis (pseudopregnancy): 5 micrograms/kg once a day PO for 5–10 days. (Gobello *et al.* 2001)

b) For pseudocyesis: 5 micrograms/kg once a day or every other day SC (likely needs to be compounded). (Davidson 2004)

c) For pseudocyesis: 5 micrograms/kg PO once daily for 4–5 days; occasional failures can be handled by repeating treatment and extending duration to 8–10 days. Additional protocols for treatment failures include combining cabergoline with metergoline (500 micrograms/kg PO twice daily), or cabergoline with bromocriptine (10–30 micrograms/kg PO twice daily). (Romagnoli 2009)

d) For adjunctive treatment of mastitis after puppies weaned: 5 micrograms/kg PO daily. (Traas & O'Conner 2009)

During the diestrous period to pre-treat mammary tumors prior to surgery:

a) 5 micrograms/kg PO 5–7 days before surgery. (Fontbonne 2007)

For pregnancy termination:

a) Administer after day 40: 5 micrograms/kg PO for 5 days; approximately 50% effective (Romagnoli 2006)

b) Between days 35–45: Cabergoline 5 micrograms/kg PO once daily for 7 days in food and cloprostenol at 1 microgram/kg SC (after a tenfold dilution with physiological saline) on days 1 and 3 given at least 8 hours after food. If pregnancy not terminated by day 8, cabergoline continued (at same dose) until day 12.

For pituitary-dependent hyperadrenocorticism (Cushing's Disease):

- a) 0.1 mg/kg PO every 3 days. Effective in 70% of dogs treated. Dogs with tumor sizes greater than 5 mm did not respond. (Castillo *et al.* 2005)

#### ■CATS:

For pregnancy termination:

- a) At 30 days post-coitus, cabergoline at 5 micrograms/kg PO q24h and cloprostenol 5 micrograms/kg SC q48h in 7–13 days was used to induce abortion. (Davidson 2004)

To reduce prolactin production in queens:

- a) 5 micrograms/kg PO once daily (Romagnoli 2009)

During the diestrus period to pre-treat mammary tumors prior to surgery:

- a) 5 micrograms/kg PO 5–7 days before surgery. (Fontbonne 2007)

#### ■BIRDS:

For persistent egg laying in psittacines combination with removal of males, altered light cycle:

- a) Initially 10–20 micrograms/kg PO daily; higher dosages were also used. Further work needed to determine the dose rate, etc. (Chitty *et al.* 2006)

### Monitoring

- Efficacy
- Adverse effects

### Client Information

- Give this medication with food; contact veterinarian if vomiting persists

### Chemistry/Synonyms

Cabergoline, a synthetic, ergot-derivative, dopamine agonist similar to bromocriptine, occurs as a white powder that is insoluble in water, and soluble in ethanol or chloroform. The commercially available tablets also contain the inactive ingredients, leucine and lactose.

Cabergoline may also be known as FCE-21336, cabergolina, *Cabasar*®, *Actualene*®, *Sostilar*®, *Dostinex*® or *Galastop*®.

### Storage/Stability

The commercially available tablets should be stored at controlled room temperature (20°–25°C; 68°–77°F). The veterinary (Europe) oral liquid product *Galastop*® should be stored below 25°C and protected from light. Do not refrigerate. Once opened, it should be used within 28 days.

### Compatibility/Compounding Considerations

It has been reported that the drug is unstable or degrades in aqueous suspensions and if compounded into a liquid that will not be used immediately, should be compounded into a lipid-based product. Preparing a fresh aqueous solution for immediate use should be stable (see estrus induction for dogs dose “c” above).

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in USA.

Cabergoline is available in Europe as *Galastop*® (Ceva) 50 micrograms/mL oral liquid (miglyol base). An injectable product, *Galastop*® *Injectable* is available in some countries.

**HUMAN-LABELED PRODUCTS:**

Cabergoline Oral Tablets: 0.5 mg (500 micrograms); generic; (Rx)

## CALCITONIN SALMON

(kal-si-toe-nin sam-in) Miacalcin®, Calcimar®

OSTEOCLAST INHIBITING HORMONE

### Prescriber Highlights

- Hormone used primarily to control hypercalcemia in dogs and hypercalcemia or nutritional secondary hyperparathyroidism in reptiles
- Hypersensitivity possible
- Young animals may be extremely sensitive to effects
- May cause GI effects

## Uses/Indications

In small animals, calcitonin has been used as adjunctive therapy to control hypercalcemia. It potentially may be of use in the adjunctive treatment of pain, particularly when originating from bone. Calcitonin's use in veterinary medicine has been limited by expense, availability and resistance development to its effects after several days of treatment.

## Pharmacology/Actions

Calcitonin has a multitude of physiologic effects. It principally acts on bone inhibiting osteoclastic bone resorption. By reducing tubular reabsorption of calcium, phosphate, sodium, magnesium, potassium and chloride, it promotes their renal excretion. Calcitonin also increases jejunal secretion of water, sodium, potassium and chloride (not calcium).

## Pharmacokinetics

Calcitonin is destroyed in the gut after oral administration and therefore must be administered parenterally. In humans, the onset of effect after IV administration of calcitonin salmon is immediate. After IM or SC administration, onset occurs within 15 minutes with maximal effects occurring in about 4 hours. Duration of action is 8–14 hours after IM or SC injection. The drug is thought to be rapidly metabolized by the kidneys, in the blood and peripheral tissues.

## Contraindications/Precautions/Warnings

Calcitonin is contraindicated in animals hypersensitive to it. Patients with a history of hypersensitivity to other proteins may be at risk. Young animals are reportedly up to 100 times more sensitive to calcitonin than are older animals (adults).

## Adverse Effects

There is not a well-documented adverse effect profile for calcitonin in domestic animals. Anorexia and vomiting have been reported to occur in dogs. Overmedicating can lead to hypocalcemia. The following effects are documented in humans and potentially could be seen in animals: diarrhea, anorexia, vomiting, swelling and pain at injection site, redness and peripheral paresthesias. Rarely, allergic reactions may occur. Tachyphylaxis (resistance to drug therapy with time) may occur in some dogs treated.

## Reproductive/Nursing Safety

There is little information on the reproductive safety of calcitonin; however, it does not cross the placenta. Very high doses have decreased birth weights in laboratory animals, presumably due to the metabolic effects of the drug. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Calcitonin has been shown to inhibit lactation. Safe use during nursing has not been established.

## Overdosage/Acute Toxicity

Very limited data is available. Nausea and vomiting have been reported after accidental overdose injections. Chronic overdosing can lead to hypocalcemia.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcitonin and may be of significance in veterinary patients:

■ **VITAMIN D ANALOGS** or **CALCIUM** products: May interfere with the efficacy of calcitonin

## Doses

### ■ DOGS:

For hypervitaminosis D (toxicity)/hypercalcemia:

- 4–8 Units/kg SC two to three times a day. Effects are short-lived and multiple treatments are required. (Mooney 2008)
- 4–6 Units/kg SC q2–3 hours until serum calcium levels are normalized (Firth 2000)
- For adjunctive therapy if fluid deficit replacement, saline diuresis, furosemide and prednisone have failed to control calcium: 4 Units/kg IV, then 4–8 Units/kg SC q12–24h (Nelson & Elliott 2003)
- 4–6 Units/kg SC q8–12h (Davies 2005)

### ■ REPTILES:

For hypercalcemia:

- Green iguanas in combination with fluid therapy: 1.5 Units/kg SC q8h for several weeks if necessary (Gauvin 1993)

For nutritional secondary hyperparathyroidism (NSHP):

- If reptile is not hypocalcemic: 50 Units/kg IM once weekly for 2–3 doses. (Hernandez-Divers 2005)
- Correct husbandry problems and correct hypocalcemia with calcium and vitamin D. Once calcium level is normal and patient is on oral calcium supplementation (usually about 7 days after starting therapy) give calcitonin at 50 Units/kg IM weekly for 2–3 doses. Supportive care can be tapered off once patient becomes stable. (Johnson 2004)

## Monitoring

■ Serum Calcium

## Chemistry/Synonyms

A polypeptide hormone, calcitonin is a 32-amino acid polypeptide having a molecular weight of about 3600. Calcitonin is available commercially as either calcitonin human or calcitonin salmon, both of which are synthetically prepared. Potency of calcitonin salmon is expressed in international units (IU), in this reference this is expressed as IU/ml. Calcitonin salmon is approximately 50X more potent than calcitonin human on a per weight basis.

expressed as units. Calcitonin salmon is approximately 50% more potent than calcitonin human on a per weight basis.  
Calcitonin salmon may also be known as calcitonin-salmon, calcitoninum salmonis, salmon calcitonin, SCT-1, or *Calcimar*®; many other trade names are available internationally.

### Storage/Stability

Calcitonin salmon for injection should be stored in the refrigerator (2–8°C). The nasal solution should be stored in the refrigerator but protected from freezing. Once in use it should be stored at room temperature in an upright position; use within 35 days.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Calcitonin Salmon for Injection: 200 IU/mL in 2 mL vials; *Miacalcin*® (Novartis); (Rx)

Calcitonin Salmon Intranasal Spray: 200 Units/activation (0.09 mL/dose) in 2 mL vials (*Miacalcin*®) and 3.7 mL metered-dose (*Fortical*®) glass bottle with pump; *Miacalcin*® (Novartis); *Fortical*® (Upsher-Smith)

## CALCITRIOL

(kal-si-trye-ole) Rocaltrol®, Calcijex®, Active Vitamin D3

VITAMIN D ANALOG

### Prescriber Highlights

- **Vitamin D analog may be useful in dogs (& possibly cats) for treatment of hypocalcemia, chronic renal disease or idiopathic seborrhea.**
  - **Contraindications: Hypercalcemia, hyperphosphatemia, malabsorption syndromes**
  - **Adverse Effects: Hypercalcemia, hypercalcuria or hyperphosphatemia greatest concerns**
  - **May need to have oral dosage forms compounded**
  - **Do not confuse with calcitonin**
- 

### Uses/Indications

Calcitriol can be useful when combined with oral calcium therapy for the long-term treatment of hypocalcemia associated with hypoparathyroidism. It may be potentially beneficial in the adjunctive treatment of chronic renal disease in dogs and cats but its use is somewhat controversial, particularly the decision on how soon in the course of chronic renal insufficiency it should employed. It reportedly can improve cats' appetite and general well being. It may also be of benefit in treating some types of dermatopathies (primary idiopathic seborrhea).

### Pharmacology/Actions

Calcitriol is a vitamin D analog. Vitamin D is considered a hormone and, in conjunction with parathormone (PTH) and calcitonin, regulates calcium homeostasis in the body. Active analogues (or metabolites) of vitamin D enhance calcium absorption from the GI tract, promote reabsorption of calcium by the renal tubules, and increase the rate of accretion and resorption of minerals in bone. Calcitriol has a rapid onset of action (approximately 1 day) and a short duration of action. Unlike other forms of vitamin D, calcitriol does not require renal activation for it to be effective.

### Pharmacokinetics

If fat absorption is normal, vitamin D analogs are readily absorbed from the GI tract (small intestine). Bile is required for adequate absorption and patients with steatorrhea, liver or biliary disease will have diminished absorption. Calcitriol has a rapid onset of biologic action and has a short duration of action (<1 day to 2–3 days). Dogs and cats appear to require much smaller doses of calcitriol than do humans.

### Contraindications/Precautions/Warnings

Calcitriol is contraindicated in patients with hypercalcemia, vitamin D toxicity, malabsorption syndrome, or abnormal sensitivity to the effects of vitamin D. It should be used with extreme caution in patients with hyperphosphatemia (many clinicians believe hyperphosphatemia or a combined calcium/phosphorous product of >70 is a contraindication to the use of vitamin D analogs). Using calcitriol in patients with hyperphosphatemia can increase risks for tissue mineralization with additional renal tissue damage and dysfunction. Generally, calcium and phosphorus levels should be in the low normal range before beginning treatment.

As calcitriol can promote hypercalciuria, it should be used with caution in animals susceptible to calcium oxalate uroliths.

### Adverse Effects

While hypercalcemia is a definite concern, calcitriol administered in low dosages to dogs with chronic renal disease infrequently causes hypercalcemia, unless it is used with a calcium-containing phosphorus binder, particularly calcium carbonate. Signs of hypercalcemia include polydipsia, polyuria and anorexia. Hyperphosphatemia may also occur and patients' serum phosphate levels should be normalized before therapy is begun. Monitoring of serum calcium levels is mandatory while using this drug.

## Reproductive/Nursing Safety

Calcitriol has proven to be teratogenic in laboratory animal when given at doses several times higher than those used therapeutically. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Safe use during lactation has not been established.

## Overdosage/Acute Toxicity

Overdosage can cause hypercalcemia, hypercalciuria, and hyperphosphatemia. Intake of excessive calcium and phosphate may also cause the same effect. Acute ingestions should be managed using established protocols for removal or prevention of the drug being absorbed from the GI. Orally administered mineral oil may reduce absorption and enhance fecal elimination.

Hypercalcemia secondary to chronic dosing of the drug should be treated by first temporarily discontinuing (not dose reduction) calcitriol and exogenous calcium therapy. If the hypercalcemia is severe, furosemide, calcium-free IV fluids (*e.g.*, normal saline), urine acidification, and corticosteroids may be employed.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcitriol and may be of significance in veterinary patients:

- **CALCIUM-CONTAINING PHOSPHORUS BINDING AGENTS** (*e.g.*, calcium carbonate): Use with calcitriol may induce hypercalcemia
- **CORTICOSTEROIDS**: Can nullify the effects of vitamin D analogs
- **DIGOXIN or VERAPAMIL**: Patients on verapamil or digoxin are sensitive to the effects of hypercalcemia; intensified monitoring is required
- **PHENYTOIN, BARBITURATES or PRIMIDONE**: May induce hepatic enzyme systems and increase the metabolism of Vitamin D analogs thus decreasing their activity
- **THIAZIDE DIURETICS**: May cause hypercalcemia when given in conjunction with Vitamin D analogs

## Laboratory Considerations

- **SERUM CHOLESTEROL** levels may be falsely elevated by vitamin D analogs when using the Zlatkis-Zak reaction for determination

## Doses

### ■ DOGS:

To suppress secondary hyperparathyroidism in CRF:

- a) Decision to use calcitriol must be made with caution because hypercalcemia is potentially a serious complication that if prolonged can result in a reduction (reversible or irreversible) of GFR. Hypercalcemia is an uncommon side effect (unless used with a calcium-containing phosphorus binding agent) if calcitriol is dosed at 2.5–3.5 nanograms/kg/day PO. (Polzin *et al.* 2005)
- b) 2.5–3.5 nanograms/kg PO once daily. Dogs with refractory hyperparathyroidism may require up to 6 nanograms/kg/day. (Chew 2003)
- c) **1)** Confirm the diagnosis of chronic renal failure (serum creatinine >2 mg/dL); **2)** Reduce hyperphosphatemia to <6 mg/dL; **3)** If serum creatinine between 2–3 mg/dL and serum phosphorus <6 mg/dL, start calcitriol at 2.5–3.5 nanograms/kg/day PO (so-called “preventative” dose); if serum creatinine >3 mg/dL and serum phosphorus <6 mg/dL, obtain a baseline PTH level and start calcitriol at 3.5 nanograms/kg/day.

Monitoring of preventative dose: assess serum calcium on days 7 and 14 after starting calcitriol and then every 6 months. Serum creatinine should be measured every 1–3 months. If hypercalcemia occurs, stop calcitriol for one week to determine if the drug is causing the hypercalcemia or if it’s due to another cause (*e.g.*, too little calcitriol).

Monitoring patients with elevated PTH: monitor as above, but also determine PTH levels at 4–6 weeks after starting calcitriol. If still elevated increase dose by 1–2 nanograms/kg/day, but do not exceed 6.6 nanograms/kg/day unless monitoring ionized calcium. If higher daily doses are required (5–7 nanograms/kg/day), a pulsed-dosing strategy may be considered. This is usually about 20 nanograms/kg given twice weekly PO at bedtime on an empty stomach. (Nagode 2005)

For hypocalcemia:

- a) For subacute and chronic maintenance treatment of hypocalcemia: Initially, 20–30 nanograms/kg/day PO divided twice a day for 3–4 days, then 5–15 nanograms/kg/day divided twice a day (Chew & Nagode 2000)
- b) For long-term maintenance in animals with hypoparathyroidism: 0.03–0.06 micro-grams/kg/day. Maximal effect is in 1–4 days. Combine with oral calcium to reduce vitamin D dose requirements. Adjust dose by monitoring serum calcium. (Crystal 2007)

For primary idiopathic seborrhea (especially in spaniel breeds):

- a) 10 nanograms/kg PO once daily. Give as far away from the main meal as possible. (Kwochka 1999)

### ■ CATS:

To suppress secondary hyperparathyroidism in CRF:

- a) 1.5–3.5 nanograms/kg PO daily given separately from meals. Remove oil from capsule, dilute in corn oil, then give the appropriate volume. Store for up to 2 weeks. (Gunn-Moore 2008)
- b) 2.5–3.5 nanograms/kg PO once daily (Chew 2003)
- c) See the dog dose in “c” above (Nagode 2005)

For long-term maintenance in animals with hypoparathyroidism:

- a) 0.03–0.06 micrograms/kg/day. Maximal effect is in 1-4 days. Combine with oral calcium to reduce vitamin D dose requirements. Adjust dose by monitoring serum calcium. (Crystal 2007)

## Monitoring

- Serum calcium, phosphate, creatinine. Baseline and at one week; then every 2–4 weeks thereafter

- Serum PTH levels, especially in cats
- Clinical efficacy (e.g., improved appetite, activity level, slowed progression of disease)

## Client Information

- Clients should be briefed on the signs of hypercalcemia (polydipsia, polyuria, anorexia) and hypocalcemia (muscle tremors, twitching, tetany, weakness, stiff gait, ataxia, behavioral changes, and seizures) and instructed to report these signs to the veterinarian
- If using lower doses (<3.5 nanograms/kg/day) give with the morning meal; if using doses of >5 nanograms/kg/day; administer at bedtime on an empty stomach to reduce chance for hypercalcemia

## Chemistry/Synonyms

Calcitriol, a vitamin D analog is synthesized for pharmaceutical use. It is a white crystalline compound and is insoluble in water.

Calcitriol may also be known as: calcitriolo, calcitriolum, 1,25-dihydroxycholecalciferol, 1- $\alpha$ ,25 dihydrocholecalciferol, 1 $\alpha$ , 25-Dihydroxyvitamin D3 or 1,25-DHCC, 1,25-dihydroxyvitamin D3, Ro 21-5535, U 49562, *Acuode*®, *Alpha D3*®, *Bocatriol*®, *Calcijex*®, *Calcitriol KyraMed*®, *Calcitriol Purissimus*®, *Calcitriol-Nefro*®, *Calcitriolo*®, *Decostriol*®, *Dexiven*®, *Difix*®, *Hitrol*®, *Kalcytriol*®, *Kolkatriol*®, *Lotravel*®, *Osteotriol*®, *Renatriol*®, *Rexamat*®, *Rocaltrol*®, *Roical*®, *Rocalcal*®, *Silkis*®, *Sitriol*®, or *Tirocal*®.

## Storage/Stability

Protect from light. Store in tight, light resistant containers at room temperature. The injection does not contain preservatives and remaining drug should be discarded after opening ampule.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

**Note:** Most doses are expressed in nanograms/kg (ng/kg); to convert micrograms to nanograms: 1 microgram = 1000 ng, 0.25 micrograms = 250 ng, etc. Reformulation by a compounding pharmacy is usually required to assure accurate dosing.

Calcitriol Oral Capsules: 0.25 micrograms & 0.5 micrograms; *Rocaltrol*® (Validus); Calcitriol (Teva); (Rx)

Calcitriol Oral Solution: 1 microgram/mL in 15 mL btl, *Rocaltrol*® (Roche); & single-use graduated oral dispensers; Calcitriol (Roxane); (Rx)

Calcitriol Injection: 1 microgram/mL & 2 micrograms/mL in 1 mL amps & vials; *Calcijex*® (Abbott); Calcitriol Injection (aaiPharma); (Rx)

Topical also available

## CALCIUM ACETATE

(*kal-see-um ass-a-tate*) PhosLo®

ORAL PHOSPHATE BINDER

### Prescriber Highlights

- **Oral phosphorus binding agent for use in treating hyperphosphatemia associated with chronic renal failure**
- **Must monitor serum phosphorus & calcium**

---

## Uses/Indications

Calcium acetate can be used for oral administration to treat hyperphosphatemia in patients with chronic renal failure. Secondary to its phosphorus binding efficiency and lower concentration of elemental calcium, calcium acetate is considered the most effective and having the lowest potential for causing hypercalcemia of the calcium-based phosphorus-binding agents. When compared to calcium carbonate, calcium acetate binds approximately twice as much phosphorus per gram of elemental calcium administered. Unlike calcium citrate, calcium acetate does not promote aluminum absorption.

## Pharmacology/Actions

When calcium acetate is given with meals it binds to dietary phosphorus and forms calcium phosphate, an insoluble compound that is eliminated in the feces. Calcium acetate is soluble over a range of pH and, therefore, available for binding phosphorus in the stomach and proximal small intestine.

## Pharmacokinetics

No information was located on the pharmacokinetics of calcium acetate in dogs and cats. In humans, approximately 30% is absorbed when given with food.

## Contraindications/Precautions/Warnings

This agent should not be used when hypercalcemia is present. Because hypercalcemia can result from administering oral calcium products to animals with renal failure,

adequate monitoring of serum ionized calcium and phosphorus is required.

Use calcium containing phosphate binders with caution in patients having a serum calcium and phosphorus product greater than 60.

Using calcium-based phosphate binders and calcitriol together is controversial. Some authors state the combination is contraindicated, while others state that intensified monitoring for hypercalcemia is required.

### Adverse Effects

Hypercalcemia is the primary concern associated with using high dosages of this agent; adequate monitoring is required.

In humans, GI intolerance (nausea) has been reported.

### Reproductive/Nursing Safety

No reproductive safety studies were located and the human label states that it is not known whether the drug can cause fetal harm. However, it would be surprising if calcium acetate caused teratogenic effects. In humans, the FDA categorizes calcium acetate as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It would be expected that calcium acetate would be safe to administer during lactation.

### Overdosage/Acute Toxicity

Potentially, acute overdoses could cause hypercalcemia. Patients should be monitored and treated symptomatically. If dosage was massive and recent, consider using standard protocols to empty the gut.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcium acetate and may be of significance in veterinary patients:

- **CALCITRIOL:** If administered with calcium acetate, may lead to hypercalcemia; if calcitriol is used concomitantly, intensified monitoring for hypercalcemia is mandatory
- **DIGOXIN:** Calcium acetate is not recommended for use in human patients that are on digoxin therapy, as hypercalcemia may cause serious arrhythmias
- **FLUOROQUINOLONES, TETRACYCLINES:** Oral calcium-containing products can reduce absorption of fluoroquinolones; if both calcium acetate and one of these antibiotics are required, separate dosages by at least two hours

### Laboratory Considerations

- No specific concerns noted; see Monitoring

### Doses

#### ■ DOGS/CATS:

For hyperphosphatemia associated with chronic renal failure:

- a) In conjunction with a low-phosphorus diet: Initial therapy at 60–90 mg/kg/day, with food or mixed with food, or just prior to each meal. Individualize dose to achieve desired serum phosphorus concentrations. Perform serial serum phosphorus evaluations at 2–4 week intervals. Decrease dose if serum calcium exceeds normal limits; additional aluminum-based phosphate binders should be used if hyperphosphatemia persists. (Polzin *et al.* 2005)

### Monitoring

Initially at 10–14 day intervals; once “stable”, at 4–6 week intervals:

- Serum phosphorus (after a 12-hour fast)
- Serum ionized calcium

### Client Information

- Give with meals; either just before or mixed into food
- The veterinarian may prescribe additional doses to be administered between meals if additional calcium is required, give only with meals unless the veterinarian instructs to do so
- Use of this medication will require ongoing laboratory monitoring

### Chemistry/Synonyms

Calcium acetate is a white, odorless, hygroscopic powder that is freely soluble in water and slightly soluble in alcohol. Each gram contains approximately 254 mg of elemental calcium.

Calcium acetate may also be known as: calcii acetat, acetato de calcio, calcio acetates, kalciumacetat, or kalciumsetaatti, *PhosLo*®.

### Storage/Stability

The commercially available tablets, capsules and gelcaps should be stored at room temperature (25°C); excursions are permitted to 15–30°C.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Calcium Acetate Oral Tablets: 667 mg (169 mg elemental calcium); *Calphron*® (Nephro-Tech); *Eliphos*® (Hawthorn); (Rx)

Calcium Acetate Oral Capsules & Gelcaps: 667 mg (169 mg elemental calcium); *PhosLo*® (Fresenius); (Rx)

## CALCIUM SALTS

### CALCIUM GLUCONATE

### CALCIUM GLUCEPTATE

### CALCIUM CHLORIDE

### CALCIUM LACTATE

(kal-see-um)

ESSENTIAL CATION NUTRIENT

#### Prescriber Highlights

- **Used to treat or prevent hypocalcemia; or as an oral antacid**
  - **Contraindicated in V-fib or hypercalcemia**
  - **Must NOT give IV too rapidly**
  - **Must monitor therapy carefully depending on condition, etc.**
  - **Drug interactions & incompatibilities prevalent**
- 

#### Uses/Indications

Calcium salts are used orally for the prevention of hypocalcemia or as a phosphorus binding agent. Parenteral calcium is used for; treatment of documented ionized hypocalcemia, calcium channel blocker toxicity, or hyperkalemia

#### Pharmacology/Actions

Calcium is an essential element that is required for many functions within the body, including proper nervous and musculoskeletal system function, cell membrane and capillary permeability, and activation of enzymatic reactions.

#### Pharmacokinetics

Calcium is absorbed in the small intestine in the ionized form only. Presence of vitamin D (in active form) and an acidic pH is necessary for oral absorption. Parathormone (parathyroid hormone) increases with resultant increased calcium absorption in calcium deficiency states and decreases as serum calcium levels rise. Dietary factors (high fiber, phytates, fatty acids), age, drugs (corticosteroids, tetracyclines), disease states (steatorrhea, uremia, renal osteodystrophy, achlorhydria), or decreased serum calcitonin levels may all cause reduced amounts of calcium to be absorbed.

After absorption, ionized calcium enters the extracellular fluid and then is rapidly incorporated into skeletal tissue. Calcium administration does not necessarily stimulate bone formation. Approximately 99% of total body calcium is found in bone. Of circulating calcium, approximately 50% is bound to serum proteins or complexed with anions and 50% is in the ionized form. Total serum calcium is dependent on serum protein concentrations. Total serum calcium changes by approximately 0.8 mg/dL for every 1.09 g/dL change in serum albumin. Calcium crosses the placenta and is distributed into milk.

Calcium is eliminated primarily in the feces, contributed by both unabsorbed calcium and calcium excreted into the bile and pancreatic juice. Only small amounts of the drug are excreted in the urine as most of the cation filtered by the glomeruli is reabsorbed by the tubules and ascending loop of Henle. Vitamin D, parathormone, and thiazide diuretics decrease the amount of calcium excreted by the kidneys. Loop diuretics (*e.g.*, furosemide), calcitonin, and somatotropin increase calcium renal excretion.

#### Contraindications/Precautions/Warnings

Calcium is contraindicated in patients with ventricular fibrillation or hypercalcemia. Parenteral calcium should not be administered to patients with above normal serum calcium levels. Calcium should be used very cautiously in patients receiving digitalis glycosides, or having cardiac or renal disease. Calcium chloride, because it can be acidifying, should be used with caution in patients with respiratory failure, respiratory acidosis, or renal disease.

In dogs, calcium gluconate diluted 1:1 has been regarded as safe to administer subcutaneously for the treatment of primary hypoparathyroidism in the past, but there are now several case reports of severe tissue reactions (pyogranulomatous panniculitis, adipocyte mineralization, etc.) at the injection site; use with caution, particularly when using with calcitriol.

#### Adverse Effects

Hypercalcemia can be associated with calcium therapy, particularly in patients with cardiac or renal disease; animals should be adequately monitored. Other effects that may be seen include GI irritation and/or constipation after oral administration, mild to severe tissue reactions after IM or SC administration of calcium salts and venous irritation after IV administration. Calcium chloride may be more irritating than other parenteral salts and is more likely to cause hypotension. Too rapid intravenous injection of calcium can cause hypotension, cardiac arrhythmias and cardiac arrest.

Should calcium salts be infused perivascularly, stop the infusion; treatment then may include: infiltrating the affected area with normal saline, corticosteroids administered locally, applying heat and elevating the area, and infiltrating the affected area with 1% procaine and hyaluronidase.

#### Reproductive/Nursing Safety

Although parenteral calcium products have not been proven safe to use during pregnancy, they are often used before, during, and after parturition in cows, ewes, bitches, and queens to treat parturient paresis secondary to hypocalcemia. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Unless other drugs are given concurrently that enhance the absorption of calcium, oral overdoses of calcium containing products are unlikely to cause hypercalcemia. Hypercalcemia can occur with parenteral therapy or oral therapy in combination with vitamin D or increased parathormone levels. Hypercalcemia should be treated by withholding calcium therapy and other calcium elevating drugs (*e.g.*, vitamin D analogs). Mild hypercalcemia generally will resolve without further intervention when renal function is adequate.

More serious hypercalcemia (>12 mg/dL) should generally be treated by hydrating with IV normal saline and administering a loop diuretic (*e.g.*, furosemide) to increase both sodium and calcium excretion. Potassium and magnesium must be monitored and replaced as necessary. ECG should also be monitored during treatment. Corticosteroids, and in humans calcitonin and hemodialysis, have also been employed in treating hypercalcemia.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving calcium and may be of significance in veterinary patients:

- **CALCIUM CHANNEL BLOCKERS** (*e.g.*, **diltiazem, verapamil, etc.**): Intravenous calcium may antagonize the effects of calcium-channel blocking agents
- **DIGOXIN**: Patients on digitalis therapy are more apt to develop arrhythmias if receiving IV calcium—use with caution
- **MAGNESIUM (oral)**: With oral calcium may lead to increased serum magnesium and/or calcium, particularly in patients with renal failure.
- **MAGNESIUM SULFATE**: Parenteral calcium can neutralize the effects of hypermagnesemia or magnesium toxicity secondary to parenteral magnesium sulfate
- **NEUROMUSCULAR BLOCKERS** (*e.g.*, **tubocurarine, metubine, gallamine, pancuronium, atracurium, and vecuronium**): Parenteral calcium may reverse the effects of nondepolarizing neuromuscular blocking agents; calcium has been reported to prolong or enhance the effects of tubocurarine
- **TETRACYCLINES, FLUOROQUINOLONES (oral)**: Oral calcium can reduce the amount of tetracyclines or fluoroquinolones absorbed from the GI tract; separate dosages by two hours if possible
- **POTASSIUM SUPPLEMENTS**: Patients receiving both parenteral calcium and potassium supplementation may have an increased chance of developing cardiac arrhythmias—use cautiously
- **THIAZIDE DIURETICS**: Used in conjunction with large doses of calcium may cause hypercalcemia
- **VITAMIN A**: Excessive intake of vitamin A may stimulate calcium loss from bone and cause hypercalcemia.
- **VITAMIN D**: Concurrent use of large doses of vitamin D or its analogs may cause enhanced calcium absorption and induce hypercalcemia

## Laboratory Considerations

- **SERUM AND URINARY MAGNESIUM**: Parenteral calcium may cause false-negative results for serum and urinary magnesium when using the Titan yellow method of determination.

## Doses

### ■ DOGS

For hypocalcemia:

- a) Calcium gluconate injection: 94–140 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)
- b) For acute hypocalcemia: Calcium gluconate 10% injection: Warm to body temperature and give IV at a rate of 50–150 mg/kg (0.5–1.5 mL/kg) over 20–30 minutes. If bradycardia develops, halt infusion. Following acute crisis, infuse 10–15 mL (of a 10% solution) per kg over a 24-hour period. Long-term therapy may be accomplished by increasing dietary calcium and using vitamin D. Calcium lactate may be given orally at a rate of 0.5–2 g/day. (Seeler & Thurmon 1985)
- c) Calcium gluconate 10% 0.5–1.5 mL/kg or calcium chloride 10% 1.5–3.5 mL (total) IV slowly over 15 minutes; monitor heart rate or ECG during infusion. If ST segment elevation or Q-T interval shortening occur, temporarily discontinue infusion and reinstate at a slower rate when resolved. Maintenance therapy is dependent on cause of hypocalcemia. Hypoparathyroidism is treated with vitamin D analogs (refer to DHT monograph) with or without oral calcium supplementation. (Russo & Lees 1986)
- d) For emergency treatment of tetany and seizures secondary to hypoparathyroidism: Calcium gluconate 10%: 0.5–1.5 mL/kg (up to 20 mL) over 15–30 minutes. May repeat at 6–8 hour intervals or give as continuous infusion at 10–15 mg/kg/hour. Monitor ECG and stop infusion if S-T segment elevates, Q-T interval shortens, or arrhythmias occur. For long-term therapy (with DHT—refer to that monograph), calcium supplementation may occasionally be useful. Calcium gluconate at 500–750 mg/kg/day divided three times daily, or calcium lactate at 400–600 mg/kg/day divided three times daily, or calcium carbonate 100–150 mg/kg/day divided twice daily. Monitor serum calcium and adjust as necessary. (Kay & Richter 1988)
- e) For emergency treatment: Calcium gluconate 10% 5–15 mg/kg (0.5–1.5 mL/kg) slowly to effect over a ten minute period, or calcium chloride 10% (extremely caustic if administered extravascularly) 5–15 mg/kg (0.15–0.5 mL/kg); dose is the same but volume is 1/3 that of calcium gluconate; monitor heart rate or ECG (if possible) during infusion. If bradycardia or Q-T interval shortening occurs, temporarily discontinue infusion. Short-term treatment immediately after correction of tetany: Either give a constant rate infusion of calcium gluconate 10% at 60–90 mg/kg/day (6.5–9.75 mL/kg/day) added to the fluids or give the daily dosage SC in 3–4 divided doses per day after diluting with an equal volume of saline. (Crystal 2004)

For hyperkalemic cardiotoxicity:

- a) Secondary to uremic crisis: Correct metabolic acidosis, if present, with sodium bicarbonate (bicarbonate may also be beneficial even if acidosis not present). Calcium gluconate (10%) indicated if serum K<sup>+</sup> is >8 mEq/L. Give at an approximate dose of 0.5–1 mL/kg over 10–20 minutes; monitor ECG. Rapidly corrects arrhythmias but effects are very short (10–15 minutes). IV glucose (0.5–1 g/kg body weight with or without insulin) also beneficial in increasing intracellular K<sup>+</sup> concentrations. (Polzin & Osborne 1985)

### ■ CATS:

For hypocalcemia:

- a) Calcium gluconate injection: 94–140 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)
- b) For acute hypocalcemia secondary to hypoparathyroidism: Using 10% calcium gluconate injection, give 1–1.5 mL/kg IV slowly over 10–20 minutes. Monitor

ECG if possible. If bradycardia, or Q-T interval shortening occurs, or temporarily discontinue. Once life-threatening signs are controlled, add calcium to IV fluids and administer as a slow infusion at 60–90 mg/kg/day (of elemental calcium). This converts to 2.5 mL/kg every 6–8 hours of 10% calcium gluconate. Carefully monitor serum calcium (once to twice daily) during this period and adjust dose as required. Begin oral calcium initially at 50–100 mg/kg/day divided 3–4 times daily of elemental calcium and dihydrotachysterol once animal can tolerate oral therapy. Give DHT initially at 0.125–0.25 mg PO per day for 2–3 days, then 0.08–0.125 mg per day for 2–3 days and finally 0.05 mg PO per day until further dosage adjustments are necessary. As cat's serum calcium is stabilized, intravenous calcium may be reduced and discontinued if tolerated. Stable serum calcium levels (8.5–9.5 mg/dL) are usually achieved in about a week. Continue to monitor and adjust dosages of DHT and calcium to lowest levels to maintain normocalcemia. (Peterson & Randolph 1989) (**Note:** refer to the DHT monograph for further information.)

c) For hypocalcemia secondary to phosphate enema toxicity or puerperal tetany: follow the guidelines for use of intravenous calcium in “b” above. (Peterson & Randolph 1989)

d) For emergency treatment: Calcium gluconate 10% 5–15 mg/kg (0.5–1.5 mL/kg) slowly to effect over a ten minute period, or calcium chloride 10% (extremely caustic if administered extravascularly) 5–15 mg/kg (0.15–0.5 mL/kg); dose is the same but volume is 1/3 that of calcium gluconate; monitor heart rate or ECG (if possible) during infusion. If bradycardia or Q-T interval shortening occurs, temporarily discontinue infusion. Short-term treatment immediately after correction of tetany: Either give a constant rate infusion of calcium gluconate 10% at 60–90 mg/kg/day (6.5–9.75 mL/kg/day) added to the fluids or give the daily dosage SC in 3–4 divided doses per day after diluting with an equal volume of saline. (Crystal 2004)

## ■ CATTLE

For hypocalcemia:

a) Calcium gluconate injection: 150–250 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)

b) Calcium gluconate 23% injection: 250–500 mL IV slowly, or IM or SC (divided and given in several locations, with massage at sites of injection) (Label directions; Calcium Gluc. Injection 23%—TechAmerica)

c) 8–12 grams of calcium IV infused over a 5–10 minute period; use a product containing magnesium during the last month of pregnancy if subclinical hypomagnesemia is detected. (Allen & Sansom 1986)

## ■ HORSES

For hypocalcemia:

a) Calcium gluconate injection: 150–250 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)

b) Calcium gluconate 23% injection: 250–500 mL IV slowly, or IM or SC (divided and given in several locations, with massage at sites of injection) (Label directions; Calcium Gluconate Injection 23%—TechAmerica)

c) For lactation tetany: 250 mL per 450 kg body weight of a standard commercially available solution that also contains magnesium and phosphorous IV slowly while auscultating heart. If no improvement after 10 minutes, repeat. Intensity in heart sounds should be noted, with only an infrequent extrasystole. Stop infusion immediately if a pronounced change in rate or rhythm is detected. (Brewer 1987)

## ■ SHEEP & GOATS:

For hypocalcemia:

a) Sheep: Calcium gluconate injection: 150–250 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)

b) Sheep: Calcium gluconate 23% injection: 25–50 mL IV slowly, or IM or SC (divided and given in several locations, with massage at sites of injection) (Label directions; Calcium Gluconate Injection 23%—TechAmerica)

## ■ SWINE:

For hypocalcemia:

a) Calcium gluconate injection: 150–250 mg/kg IV slowly to effect (intraperitoneal route may also be used). Monitor respirations and cardiac rate and rhythm during administration. (USPC 1990)

b) Calcium gluconate 23% injection: 25–50 mL IV slowly, or IM or SC (divided and given in several locations, with massage at sites of injection) (Label directions; Calcium Gluconate Injection 23%—TechAmerica)

## ■ BIRDS:

For hypocalcemic tetany:

a) Calcium gluconate: 50–100 mg/kg IV slowly to effect; may be diluted and given IM if a vein cannot be located (Clubb 1986)

For egg-bound birds:

a) Initially, calcium gluconate 1% solution 0.01–0.02 mL/g IM. Provide moist heat (80–85°F) and allow 24 hours for bird to pass egg. (Nye 1986)

## ■ REPTILES:

For egg binding in combination with oxytocin (oxytocin: 1–10 Units/kg IM):

a) Calcium gluconate: 10–50 mg/kg IM as needed until calcium levels back to normal or egg binding is resolved. Use care when giving multiple injections. Calcium/oxytocin is not as effective in lizards as in other species. (Gauvin 1993)

## Monitoring

- Serum calcium
- Serum magnesium, phosphate, and potassium when indicated
- Serum PTH (parathormone) if indicated
- Renal function tests initially and as required
- ECG during intravenous calcium therapy if possible

- Urine calcium if hypercalcaemia develops

## Chemistry

Several different salts of calcium are available in various formulations. Calcium gluceptate and calcium chloride are freely soluble in water; calcium lactate is soluble in water; calcium gluconate and calcium glycerophosphate are sparingly soluble in water, and calcium phosphate and carbonate are insoluble in water. Calcium gluconate for injection has a pH of 6–8.2 and calcium chloride for injection has a pH of 5.5–7.5.

To determine calcium content per gram of various calcium salts:

- Calcium Acetate: 253 mg (12.7 mEq)
- Calcium Carbonate: 400 mg (20 mEq)
- Calcium Chloride: 270 mg (13.5 mEq)
- Calcium Citrate: 211 mg (10.6 mEq)
- Calcium Gluceptate: 82 mg (4.1 mEq)
- Calcium Gluconate: 90 mg (4.5 mEq)
- Calcium Glycerophosphate: 191 mg (9.6 mEq)
- Calcium Lactate: 130 mg (6.5 mEq)
- Calcium Phosphate Dibasic
  - Anhydrous: 290 mg (14.5 mEq)
  - Dihydrate: 230 mg (11.5 mEq)
- Calcium Phosphate Tribasic: 400 mg (20 mEq)

## Storage/Stability

Calcium gluconate tablets should be stored in well-closed containers at room temperature. Calcium lactate tablets should be stored in tight containers at room temperature. Calcium gluconate injection, calcium gluceptate injection, and calcium chloride injection should be stored at room temperature and protected from freezing.

## Compatibility/Compounding Considerations

**Calcium chloride** for injection is reportedly **compatible** with the following intravenous solutions and drugs: amikacin sulfate, ascorbic acid, bretylium tosylate, cephalirin sodium, chloramphenicol sodium succinate, dopamine HCl, hydrocortisone sodium succinate, isoproterenol HCl, lidocaine HCl, methicillin sodium, norepinephrine bitartrate, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, sodium bicarbonate, verapamil HCl, and vitamin B-complex with C.

**Calcium chloride** for injection **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: fat emulsion 10%, dobutamine HCl, oxytetracycline HCl, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used.

**Calcium chloride** for injection is reportedly **incompatible** with the following solutions or drugs: amphotericin B, cephalothin sodium, and chlorpheniramine maleate.

**Calcium gluconate** for injection is reportedly **compatible** with the following intravenous solutions and drugs: sodium chloride for injection 0.9%, lactated Ringer's injection, dextrose 5%–20%, dextrose-lactated Ringer's injection, dextrose-saline combinations, amikacin sulfate, aminophylline, ascorbic acid injection, bretylium tosylate, cephalirin sodium, chloramphenicol sodium succinate, corticotropin, dimenhydrinate, erythromycin gluceptate, heparin sodium, hydrocortisone sodium succinate, lidocaine HCl, methicillin sodium, norepinephrine bitartrate, penicillin G potassium/sodium, phenobarbital sodium, potassium chloride, tobramycin sulfate, vancomycin HCl, verapamil and vitamin B-complex with C.

**Calcium gluconate compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: phosphate salts, oxytetracycline HCl, prochlorperazine edisylate, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used.

**Calcium gluconate** is reportedly **incompatible** with the following solutions or drugs: intravenous fat emulsion, amphotericin B, cefamandole nafate, cephalothin sodium, dobutamine HCl, methylprednisolone sodium succinate, and metoclopramide HCl.

Consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

(Note: not necessarily a complete list; veterinary-labeled products are apparently not FDA-approved as they do not appear in the Green Book)

#### Parenteral Products:

Calcium Gluconate (as calcium borogluconate) 23% [230 mg/mL; 20.7 mg (1.06 mEq) calcium per mL]; in 500 mL bottles; *AmTech® Calcium Gluconate 23% Solution* (Phoenix Scientific); (OTC), *Calcium Gluconate 23%* (AgriPharm, AgriLabs, Aspen, Bimeda, Durvet, Phoenix Pharmaceutical, Vet Tek, Vetus); (OTC), *Cal-Nate 1069®* (Butler); (OTC). Depending on the product, labeled for use in cattle, horses, swine, sheep, cats, and dogs. No withdrawal times are required.

Calcium Gluconate oral 40 g–42 g calcium/300 mL tube. Supplement for use pre and post calving. *Cal Supreme Gel®* (Bimeda); (OTC)

Calcium Chloride 35% w/w or 47% w/v equivalent to 170 mg calcium/mL (127 mg per g) in 300 mL (400 g) tube. *Clearcal 50®* (Vedco); (OTC)

Products are also available that include calcium, phosphorus, potassium and/or dextrose; refer to the individual product's labeling for specific dosage information. Trade names for these products include: *Norcalciphos®*—Pfizer, and *Cal-Dextro® Special, #2, C, and K*—Fort Dodge; (Rx).

**Oral Products:** No products containing only calcium (as a salt) are available commercially with veterinary labeling. There are several products (*e.g.*, *Pet-Cal®* and *Osteoform® Improved*) that contain calcium with phosphorous and vitamin D (plus other ingredients in some preparations).

### HUMAN-APPROVED PRODUCTS: (not a complete list)

#### Parenteral Products:

Calcium Gluconate Injection 10% 100 mg/mL; equivalent to elemental calcium 0.465 mEq/mL (9.3 mg), preservative-free in 10 & 50 mL single-dose vials & 100 & 200 mL pharmacy bulk vials; generic; (Rx)

Calcium Chloride Injection 10% [100 mg/mL; 27.2 mg (1.36 mEq) calcium per mL] in 10 mL amp vials and syringes; generic; (Rx)

Calcium Injection 10% [100 mg/mL], 27.2 mg (1.56 mEq) calcium per mL] in 10 mL amps, vials, and syringes, generic, (Rx)

## Oral Products:

Calcium Gluconate (9.3% calcium) Tablets: 500 mg (45 mg calcium), approx. 555.6 mg (50 mg calcium), 648 to 650 mg (58.5 to 60 mg calcium), 972 to 975 mg (87.75 to 90 mg calcium); generic; (OTC)

Calcium Gluconate Oral Powder: 1,040 mg/15 mL (346.7 mg/15 mL calcium, gluten free, sugar free) in 448 g; Calcium Gluconate (Freeda) (OTC)

Calcium Gluconate Capsules: 500 mg; Calcium Gluconate (Bio-Tech); 700 mg; *Cal-G*® (Key); (OTC)

Calcium Lactate (13% calcium) Tablets: 648 mg to 650 mg (84.5 mg calcium); 100 mg elemental calcium; generic (OTC); Capsules 500 mg (96 mg calcium), *Cal-Lac*® (Bio Tech); (OTC)

Also available are calcium carbonate tablets, suspension and capsules, calcium acetate tablets, calcium citrate tablets, and tricalcium phosphate tablets.

## Camphorated Tincture of Opium — See [Paregoric](#)

---

## CAPTOPRIL

(*kap-toe-pril*) Capoten®

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR

### Prescriber Highlights

- **First available ACE inhibitor; use largely supplanted by enalapril & other newer ACE inhibitors**
- **Shorter duration of activity & more adverse effects than other newer ACE inhibitors**

---

## Uses/Indications

The principle uses of captopril in veterinary medicine, are as a vasodilator in the treatment of CHF and hypertension. Because of approval status and fewer adverse effects, enalapril and benazepril have largely supplanted the use of this drug in veterinary medicine.

## Pharmacology/Actions

Captopril prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for captopril than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased.

The cardiovascular effects of captopril in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure; no change or decrease in heart rate; and increased cardiac index and output, stroke volume, and exercise tolerance. Renal blood flow can be increased with little change in hepatic blood flow.

## Pharmacokinetics

In dogs, approximately 75% of an oral dose is absorbed but food in the GI tract reduces bioavailability by 30–40%. It is distributed to most tissues (not the CNS) and is 40% bound to plasma proteins in dogs. The half-life of captopril is about 2.8 hours in dogs and less than 2 hours in humans. Its duration of effect in dogs may only persist for 4 hours. The drug is metabolized and renally excreted. More than 95% of a dose is excreted renally, both as unchanged (45–50%) drug and as metabolites. Patients with significant renal dysfunction can have significantly prolonged half-lives.

## Contraindications/Precautions/Warnings

Captopril is contraindicated in patients who have demonstrated hypersensitivity with ACE inhibitors. It should be used with caution and under close supervision in patients with renal insufficiency; doses may need to be reduced.

Captopril should also be used with caution in patients with hyponatremia or sodium depletion, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities or a collagen vascular disease (*e.g.*, SLE).

Patients with severe CHF should be monitored very closely upon initiation of therapy.

## Adverse Effects

There have been some reports of hypotension, renal failure, hyperkalemia, vomiting and diarrhea developing in dogs after captopril administration. Captopril may have a higher incidence of gastrointestinal effects in dogs than other available ACE inhibitors. Although seen in people, skin rashes (4–7% incidence) and neutropenia/agranulocytosis (rare) have not been reported in dogs.

## Reproductive/Nursing Safety

Captopril apparently crosses the placenta. High doses of ACE inhibitors in rodents have caused decreased fetal weights and increases in fetal and maternal death rates; no teratogenic effects have been reported to date, but use during pregnancy should occur only when the potential benefits of therapy outweigh the risks to the

offspring. In humans, the FDA categorizes this drug as category **C** for use during the first trimester of pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) During the second and third trimesters, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Captopril enters milk in concentrations of about 1% of that found in maternal plasma.

### Overdosage/Acute Toxicity

In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Dogs given 1.5 g/kg orally developed emesis and decreased blood pressure. Dogs receiving doses greater than 6.6 mg/kg q8h may develop renal failure.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving captopril and may be of significance in veterinary patients:

- **ANTACIDS:** Reduced oral absorption of captopril may occur if given concomitantly with antacids; it is suggested to separate dosing by at least two hours
- **CIMETIDINE:** Used concomitantly with captopril has caused neurologic dysfunction in two human patients
- **DIGOXIN:** Levels may increase 15–30% when captopril is added, automatic reduction in dosage is not recommended, but monitoring of serum digoxin levels should be performed
- **DIURETICS:** Concomitant diuretics may cause hypotension if used with captopril; titrate dosages carefully
- **NON-STEROIDAL ANTIINFLAMMATORY AGENTS (NSAIDS):** May reduce the clinical efficacy of captopril when it is being used as an antihypertensive agent
- **POTASSIUM or POTASSIUM SPARING DIURETICS (e.g., spironolactone):** Hyperkalemia may develop with captopril
- **PROBENECID:** Can decrease renal excretion of captopril and possibly enhance the clinical and toxic effects of the drug
- **VASODILATORS (e.g., prazosin, hydralazine, nitrates):** Concomitant vasodilators may cause hypotension if used with captopril; titrate dosages carefully

### Laboratory Considerations

- Captopril may cause a false positive **urine acetone test** (sodium nitroprusside reagent).
- When using **iodohippurate sodium I123/I134 or Technetium Tc99 pententate renal imaging** in patients with renal artery stenosis, ACE inhibitors may cause a reversible decrease in localization and excretion of these agents in the affected kidney which may lead confusion in test interpretation.

### Doses

**Note:** Because of fewer adverse effects in dogs, longer duration of activity, and/or veterinary labeling/dosage forms, enalapril and other newer ACE inhibitors have largely supplanted the use of this drug in veterinary medicine.

- **DOGS:**
  - a) 0.5–2 mg/kg PO three times daily (Atkins 2008)
  - b) 0.5–2 mg/kg PO q8–12h (Bonagura & Muir 1986)
- **CATS:**
  - a) ¼ to ½ of a 12.5 mg tablet PO q8–12h (Bonagura 1989)
  - b) For dilative, restrictive or hypertrophic cardiomyopathy: 0.55–1.54 mg/kg PO q8–12h (Kittleson 2000))

### Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential; periodic
- Blood pressure (if treating hypertension or signs associated with hypotension arise).

### Client Information

- Give medication on an empty stomach unless otherwise instructed. Do not abruptly stop or reduce therapy without veterinarian's approval. Contact veterinarian if vomiting or diarrhea persist or are severe, or if animal's condition deteriorates.

### Chemistry/Synonyms

Related to a peptide isolated from the venom of a South American pit viper, captopril occurs as a slightly sulfurous smelling, white to off-white, crystalline powder. It is freely soluble in water or alcohol.

Captopril may also be known as: captoprilum, or SQ-14225; many trade names are available.

### Storage/Stability

Captopril tablets should be stored in tight containers at temperatures not greater than 30°C.

### Compatibility/Compounding Considerations

**Compounded preparation stability:** Captopril oral suspension compounded from commercially available tablets has been published (Allen & Erickson 1996). Triturating one (1) captopril 100 mg tablet with 65 mL of *Ora-Plus*® and *qs ad* to 134 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 0.75 mg/mL oral suspension that retains >90% potency for 14 days stored at 5°C and for 7 days at 25°C. Compounded preparations of captopril should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Captopril Oral Tablets: 12.5 mg, 25 mg, 50 mg, & 100 mg; *Capoten*® (Par); generic; (Rx)

Captopril and Hydrochlorothiazide Oral Tablets: 15 mg hydrochlorothiazide and 25 mg captopril; 15 mg hydrochlorothiazide and 50 mg captopril; 25 mg hydrochlorothiazide and 25 mg captopril; 25 mg hydrochlorothiazide and 50 mg captopril. *Capozide*® (Par); generic; (Rx)

---

## CARBAMAZEPINE

(*Kar-bam-aye-zuh-peen*) Tegretol®

DIBENZAZEPINE ANTICONVULSANT, NEUROPATHIC PAIN & PSYCHOTHERAPEUTIC AGENT

### Prescriber Highlights

- Potentially useful for behavior disorders (aggression), neuropathic pain states, or epilepsy in dogs and cats
- Very little information published on use, adverse effects, etc. for veterinary patients
- Pharmacokinetic profile in dogs a serious roadblock for clinical use
- Reportedly can be used successfully for photic head shaking in horses not responding to cyproheptadine
- Many potential drug interactions

---

## Uses/Indications

Carbamazepine potentially could be useful for treating behavior disorders, neuropathic pain states, or epilepsy in dogs and cats, but its unfavorable pharmacokinetic profile in dogs is problematic, however. Despite this, there are sporadic case reports that it has had efficacy in dogs (aggression, psychomotor seizures) and it has been proposed that there may be an as of yet unidentified active metabolite in dogs that is more slowly eliminated. There is extremely scant information published on the use of this drug in cats, but it has been stated that it has had some efficacy in reducing aggression.

Until more information is available, carbamazepine should be considered as a 3rd-line agent for use in small animals, but if formulations can be developed to increase absorption and methods developed to reduce hepatic metabolism (*e.g.*, ketoconazole, grapefruit juice powder), its potential is intriguing.

In horses, with photic head shaking, cyproheptadine is generally the drug of first choice, but carbamazepine has been used.

## Pharmacology/Actions

Carbamazepine has a variety of pharmacological effects similar to drugs such as phenytoin in the central nervous system, including modulation of ion channels (sodium and calcium) and receptor-mediated neurotransmission (GABA, glutamate, monoamines). Its antiseizure effects are due primarily to limiting seizure propagation by reduction of post-tetanic potentiation (PTP) of synaptic transmission. It also has antiarrhythmic, antidiuretic, anticholinergic, antidepressant, sedative, muscle relaxant, and neuromuscular transmission-inhibitory actions, but only mild analgesic effects.

Carbamazepine has been shown to reduce electrical- and chemical-induced seizures in rats and mice. It appears to act by reducing polysynaptic responses and blocking the post-tetanic potentiation. Carbamazepine has been shown in cats and rats to reduce or block pain induced by stimulation of the infraorbital nerve. Also in cats, it depresses thalamic potential and bulbar and polysynaptic reflexes, including the linguomandibular reflex.

The principal metabolite of carbamazepine, carbamazepine-10,11-epoxide, also has anticonvulsant activity.

## Pharmacokinetics

When compared to humans, carbamazepine is eliminated much more rapidly in dogs. Humans may eliminate carbamazepine and its active metabolite, carbamazepine-10,11-epoxide, up to 25 times more slowly than dogs.

The pharmacokinetics of carbamazepine were reported in the dog in 1980 (Frey & Loscher 1980). Like the above study, the drug was better absorbed when given as liquid preparation than from tablets. Elimination half-life was 1.5 hours for carbamazepine and 2.2 hours for carbamazepine-10,11-epoxide. However after dosing for a week, plasma concentrations showed a pronounced and progressive decline from Day 2 and the authors concluded that carbamazepine was not a suitable drug for treating epilepsy in dogs.

A study evaluating the pharmacokinetics of carbamazepine in the dog using a 2-hydroxypropyl-beta-cyclodextrin-based formulation administered orally and intravenously compared with oral commercially available tablets and suspensions was published (Brewster *et al.* 1997). They found that the oral bioavailability of tablets was low in dogs (around 28%) and that oral suspensions or solutions increased bioavailability. After IV dosing, volume of distribution (steady-state) was 0.58 L/kg, and elimination half-life of carbamazepine was 38 minutes and 110 minutes for the epoxide metabolite. Renal clearance was only 12 mL/min or about 4% of total body clearance. Elimination half-life after tablet administration was 116 minutes. As this was a single-dose study (with a 2-week washout period between doses), no effect of hepatic enzyme induction could be measured.

A study comparing the oral bioavailability of carbamazepine in a beta-cyclodextrin complex with hydroxymethylcellulose matrix tablets (sustained-release; *Tegretol*® CR 200) in 4 Beagles found that the experimentally produced beta-cyclodextrin complexes had higher bioavailability than the commercial product. However, there was significant inter-subject variability. The dose given to these dogs was approximately 20 mg/kg of the commercial sustained release tablets. At this dosage, peak

levels occurred at approximately 1 hour after dosing and averaged 0.5 micrograms/mL. Elimination half-life was 46 minutes. No determination of any metabolites was measured in this study.

### Contraindications/Precautions/Warnings

There is extremely limited information for carbamazepine's safety in animals; the following pertains to humans and may apply to veterinary patients: Carbamazepine is **contraindicated** in patients with a history of bone marrow depression; concomitant use of an MAO-I, or use within 14 days of discontinuing an MAOI or hypersensitivity to carbamazepine or tricyclic compounds. Use with caution in patients with significant hepatic dysfunction.

### Adverse Effects

There is extremely limited information for carbamazepine's adverse effect profile in animals. In humans, adverse effects (dizziness, drowsiness, nausea, and vomiting) are often seen when therapy is begun and the drug is usually started at a low dosage and then increased as the patient tolerates. Serious adverse effects reported in humans are usually associated with the cardiovascular (AV block, CHF) or hemopoietic system (aplastic anemia, agranulocytosis), skin (TEN, Stevens-Johnson Syndrome), and liver.

### Reproductive/Nursing Safety

Carbamazepine can cause teratogenic effects. The drug crosses the placenta readily and has been implicated in increased rates of congenital malformations in humans. The FDA lists carbamazepine as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

While carbamazepine is excreted into maternal milk and has the potential for some risks to nursing offspring, it is generally considered compatible with breast-feeding in humans.

### Overdosage/Acute Toxicity

Reported oral median lethal dose (LD<sub>50</sub>) in animals include: Mice: 1,100 to 3,750 mg/kg; Rats: 3,850 to 4,025 mg/kg; Rabbits: 1,500 to 2,680 mg/kg; and Guinea pigs: 920 mg/kg. Overdose treatment consists of using decontamination protocols when appropriate, and supportive care. In the event of an overdose in a veterinary species, contact a veterinary poison control center for further guidance.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carbamazepine and may be of significance in veterinary patients:

The following drugs may *increase* the plasma levels or effects of carbamazepine:

- **ACETAZOLAMIDE**
- **AZOLE ANTIFUNGALS** (*e.g.*, KETACONAZOLE, ITRACONAZOLE)
- **CALCIUM CHANNEL BLOCKERS**, (*e.g.*, DILTIAZEM, VERAPAMIL)
- **CIMETIDINE**
- **DANAZOL**
- **GRAPEFRUIT JUICE**
- **ISONIAZID**
- **MACROLIDES** (*e.g.*, ERYTHROMYCIN, CLARITHROMYCIN)
- **MAO INHIBITORS** (including SELEGILINE) Contraindicated in humans; discontinue MAOI at least 14 days prior to carbamazepine.
- **NIACIN**
- **SSRI ANTIDEPRESSANTS** (FLUOXETINE, *etc.*)
- **TRICYCLIC ANTIDEPRESSANTS** (CLOMIPRAMINE, AMITRIPTYLINE, *etc.*)

#### ■ **VALPROIC ACID**

The following drugs may *decrease* the plasma levels or effects of carbamazepine:

- **BARBITURATES** (*e.g.*, PHENOBARBITAL)
- **CISPLATIN**
- **DOXORUBICIN**
- **FELBAMATE**
- **PHENYTOIN**
- **PRIMIDONE**
- **RIFAMPIN**
- **THEOPHYLLINE**

Carbamazepine may *increase* the plasma levels or effects of the following drugs:

- **CLOMIPRAMINE**
- **ISONIAZID**

Carbamazepine (particularly after chronic therapy) may *decrease* the effect of the following drugs/drug classes by lowering their serum concentrations or pharmacological effects:

- **ACETAMINOPHEN**
- **BENZODIAZEPINES**
- **BUPROPION**

- BUSPRIONE
- CALCIUM CHANNEL BLOCKERS
- CYCLOSPORINE
- DOXYCYCLINE
- GLUCOCORTICOIDS
- ITRACONAZOLE
- LAMOTRIGINE
- LEVOTHYROXINE
- METHADONE
- MIRTAZAPINE
- NON-DEPOLARIZING MUSCLE BLOCKERS (*e.g.*, ATRACURIUM)
- PRAZIQUANTEL
- TOPIRAMATE
- TRAMADOL
- ZONISAMIDE
- TOPIRAMATE
- TRAZODONE
- TRICYCLIC ANTIDEPRESSANTS
- VALPROIC ACID (may also increase risk for phenobarbital toxicity)
- VERAPAMIL
- WARFARIN

### Laboratory Considerations

- In humans, thyroid function tests have been reported to show decreased values and interference with some pregnancy tests has been reported. Veterinary significance is unclear.

### Doses

#### ■DOGS:

- a) As a psychotherapeutic agent: 4–8 mg/kg PO q12h; not commonly used, but may have some utility in dogs that seem to have amygdalar hyperactivity; sometimes used in conjunction with SSRIs to control explosive aggression. (Haug 2008)

#### ■HORSES:

- a) For photic head shaking: 10 mg/kg PO q6h or 29 mg/kg PO q12h. May be helpful in some horses that do not respond to cyproheptadine. (Brooks 2008)

### Monitoring

- Occasional CBC's and liver function tests are suggested
- Clinical efficacy

### Client Information

- Clients should understand that this drug has been used very infrequently in animals and may not be safe or effective
- This medication may need to be administered frequently if it is to be effective
- Report any adverse effects noted to the veterinarian

### Chemistry/Synonyms

Carbamazepine is a dibenzoazepine iminostilbene derivative and is chemically related to imipramine. It has the chemical name 5H-Dibenz[b,f]azepine-5-carboxamide and a molecular weight of 236.3. Carbamazepine is a white or off-white powder and is practically insoluble in water, but soluble in alcohol and in acetone.

Carbamazepine may also be known as G-32883, carbamazepine, carbamazepine, carbamazepinum, karbamatsepiini, karbamazepin, karbamazepinas, or karbamazepinum. Trade names include: *Tegretol*® and *Carbatrol*®.

### Storage/Stability

Carbamazepine should be stored below 30°C (86°F) in airtight containers as humid conditions can reduce potency by up to one-third. Protect from light.

### Compatibility/Compounding Considerations

**Compounded preparation stability:** Carbamazepine oral suspension compounded from commercially available tablets has been published (Burkart *et al.* 1981). Triturating one (1) carbamazepine 200 mg tablet with 5 mL simple syrup yields a 40 mg/mL oral suspension that retains >90% potency for 90 days stored at both 5°C and 25°C. Suspensions may separate over the 90 day storage period but can be resuspended when shaken vigorously. Compounded preparations of carbamazepine should be protected from light.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Carbamazepine Oral Tablets: 100 mg (regular and chewable), & 200 mg; *Tegretol*®, (Ciba-Geigy); *Epitol*® (Teva); generic; (Rx)

Carbamazepine Oral Tablets or Capsules Extended-Release (12-hour); *Tegretol*® XR (Ciba-Geigy); *Carbatrol*® (Rexar); *Equetro*® (Validus); generic; (Rx)

Carbamazepine Oral Suspension: *Tegretol*® (Ciba-Geigy), generic; (Rx)

## CARBIMAZOLE

(kar-bi-ma-zole) Neo-Carbimazole®, Carbazole®

### ANTI-THYROID

**Note:** This drug is not available in the USA, but is routinely used in Europe and elsewhere in place of methimazole

### Prescriber Highlights

- **Used outside of USA & Canada for medical treatment of feline hyperthyroidism**
- **Contraindications/Cautions: Hypersensitive to carbimazole; not recommended in cats intolerant to methimazole; history of or concurrent hematologic abnormalities, liver disease or autoimmune disease**
- **Adverse Effects: Most occur within first 3 months of treatment; vomiting, anorexia & depression most frequent. Eosinophilia, leukopenia, & lymphocytosis are usually transient. Rare, but serious: self-induced excoriations, bleeding, hepatopathy, thrombocytopenia, agranulocytosis, positive direct antiglobulin test, & acquired myasthenia gravis**
- **Dosing requirements may change with time**
- **Place kittens on milk replacer if mother receiving carbimazole**
- **Unlike methimazole, has no bitter taste**
- **Potentially efficacious when used transdermally in cats**

---

## Uses/Indications

Carbimazole (a pro-drug of methimazole) or methimazole are considered by most clinicians to be the agents of choice when using drugs to treat feline hyperthyroidism. Propylthiouracil has significantly higher incidences of adverse reactions when compared to methimazole.

Methimazole and therefore, carbimazole, may be useful for the prophylactic prevention of cisplatin-induced nephrotoxicity in dogs.

## Pharmacology/Actions

Carbimazole is converted almost entirely to methimazole *in vivo*. Methimazole interferes with iodine incorporation into tyrosyl residues of thyroglobulin thereby inhibiting the synthesis of thyroid hormones. It also inhibits iodinated tyrosyl residues from coupling to form iodothyronine. Methimazole has no effect on the release or activity of thyroid hormones already formed or in the general circulation.

## Pharmacokinetics

Carbimazole is rapidly absorbed from the GI tract and rapidly and nearly totally converted to methimazole. Because of differences in molar weight, to attain an equivalent serum level, carbimazole must be dosed approximately 2 times that of methimazole.

In cats, the volume of distribution of methimazole is variable (0.12-0.84 L/kg). Methimazole apparently concentrates in thyroid tissue and biologic effects persist beyond measurable blood levels. After oral dosing, plasma elimination half-life ranges from 2.3-10.2 hours. There is usually a 1-3 week lag time between starting the drug and significant reductions in serum T<sub>4</sub>. Carbimazole may be amenable for use transdermally in cats to control hyperthyroidism.

In dogs, methimazole has a serum half-life of 8-9 hours.

## Contraindications/Precautions/Warnings

Carbimazole is contraindicated in patients who are hypersensitive to it or methimazole. It should be used very cautiously in patients with a history of or concurrent hematologic abnormalities, liver disease or autoimmune disease.

Because carbimazole is a prodrug and is converted into methimazole, cats who have had prior serious reactions to methimazole should receive carbimazole with great caution.

## Adverse Effects

Adverse effects are reported less often with carbimazole than methimazole. Whether they indeed occur less frequently is debatable. Most adverse effects associated with carbimazole or methimazole use in cats occur within the first three months of therapy with vomiting, anorexia and depression occurring most frequently. The GI effects may be related to the drug's bitter taste and are usually transient. Eosinophilia, leukopenia, and lymphocytosis may be noted in approximately 15% of cats treated within the first 8 weeks of therapy. These hematologic effects usually are also transient and generally do not require drug withdrawal. Other more serious but rare adverse effects include: self-induced excoriations (2.3%), bleeding (2.3%), hepatopathy (1.5%), thrombocytopenia (2.7%), agranulocytosis (1.5%), and positive direct antiglobulin test (1.9%). These effects generally require withdrawal of the drug and adjunctive therapy. Up to 50% of cats receiving methimazole chronically (>6

months), will develop a positive ANA, which requires dosage reduction. Rarely, cats will develop an acquired myasthenia gravis that requires either withdrawal of concomitant glucocorticoid therapy.

High levels of methimazole cross the placenta and may induce hypothyroidism in kittens born of queens receiving the drug. Levels higher than those found in plasma are found in human breast milk. It is suggested that kittens be placed on a milk replacer after receiving colostrum from mothers on methimazole.

### Reproductive/Nursing Safety

Carbimazole, like methimazole (carbimazole is converted to methimazole), has been associated with teratogenic effects in humans (scalp defects). It may also affect offspring thyroid development or function. In humans, the FDA categorizes methimazole as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

As methimazole can enter milk and have deleterious effects on offspring, switch to milk replacer if carbimazole or methimazole are required for nursing dams.

### Overdosage

Acute toxicity that may be seen with overdosage include those that are listed above under Adverse Effects. Agranulocytosis, hepatopathy, and thrombocytopenias are perhaps the most serious effects that may be seen. Treatment consists of following standard protocols in handling an oral ingestion (empty stomach if not contraindicated, administer charcoal, etc.) and to treat symptomatically and supportively.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carbimazole and may be of significance in veterinary patients:

- **BUPROPION:** Potential for increased risk for hepatotoxicity; increased monitoring (LFT's) necessary
- **DIGOXIN:** Carbimazole may decrease digoxin efficacy
- **WARFARIN:** Potential for decreased anticoagulant efficacy if carbimazole added

### Doses

See also Methimazole. Usually, carbimazole dosages are twice that of methimazole.

#### ■ **CATS:**

For hyperthyroidism:

- a) 2.5–5 mg (total dose) per cat PO twice daily (Trepanier 2007)
- b) 10–15 mg total dose daily per cat in divided doses for 1–3 weeks will produce a euthyroid state for most patients. Then adjust dosage for the patient to the lowest effective dose. Most cats will need dosing at least once daily. (Debuf 1991)
- c) Initially, give 5 mg (total dose) q8h for 2–3 weeks. Then adjust. May need to increase dose in approximately 10% of cats (be sure owner was compliant with previous dose). Most cats require 5 mg PO q12h to maintain euthyroidism. (Peterson 2000)
- d) Using the sustained-release tablets (*Vidalta*®): 15 mg PO once daily at the same time each day. Do not break or crush tabs. Adjust dose upwards or downwards within a range of 10 mg–25 mg per day in 5 mg increments depending on clinical signs and TT4 (tablets cannot be split, so combinations of 10 mg and 15 mg tablets must be used). If cat requires doses less than 10 mg per day, use alternative treatment. (Adapted from label information; *Vidalta*®—Intervet UK)

### Monitoring

*During first 3 months of therapy (baseline values and every 2–3 weeks):*

- CBC, platelet counts
- Serum T<sub>4</sub>
- If indicated by clinical signs: liver function tests, ANA
- After stabilized (at least 3 months of therapy):
- T<sub>4</sub> at 3–6 month intervals
- Other diagnostic tests as dictated by adverse effects

### Client Information

- It must be stressed to owners that this drug will decrease excessive thyroid hormones, but does not cure the condition
- Adherence with the treatment regimen is necessary for success

### Chemistry/Synonyms

A thioimidazole-derivative antithyroid drug, carbimazole occurs as a white to creamy white powder having a characteristic odor. It is slightly soluble in water and soluble in alcohol.

Carbimazole may also be known as: carbimazolium, *Basolest*®, *Camazol*®, *Carbimazole*®, *Carbazole*®, *Carbistad*®, *Cazole*®, *Neo Tomizol*®, *Neo-Mercazole*®, *Neo-Thyreostat*®, *Thyreostat*®, *Tyrazol*®, or *Neo-morphazole*®.

### Storage/Stability

Unless otherwise labeled, carbimazole tablets should be stored at room temperature in well-closed containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

There are no FDA-approved products in the USA; elsewhere it may be available as:

Carbimazole Oral Tablets: 5 mg & 20 mg. Trade names include *Neo-Carbimazole*®, *Carbazole*®, *Neo Mercazole*®, etc.

Carbimazole Oral Sustained-Release Tablets: 10 mg & 15 mg; *Vidata*® (Intervet-UK); POM-V

---

## CARBOPLATIN

(kar-boe-pla-tin) Paraplatin®

ANTINEOPLASTIC

### Prescriber Highlights

- **Platinum antineoplastic agent used for a variety of carcinomas & sarcomas**
  - **Unlike cisplatin, may be used in cats**
  - **Contraindications: History of hypersensitivity to it or other platinum agents; severe bone marrow depression**
  - **Caution: Hepatic/renal disease, hearing impairment, active infection**
  - **Primary adverse effects: GI, Bone marrow depression. Nadir (neutrophils/platelets) in dogs about 14 days; in cats (neutrophils) about 17–21 days**
  - **Fetotoxic**
  - **Must be given IV in D5W**
  - **May adversely affect vaccinations (safety/efficacy)**
  - **Treatment may be very expensive**
- 

## Uses/Indications

Like cisplatin, carboplatin may be useful in a variety of veterinary neoplastic diseases including squamous cell carcinomas, ovarian carcinomas, mediastinal carcinomas, pleural adenocarcinomas, nasal carcinomas and thyroid adenocarcinomas. Carboplatin's primary use currently in small animal medicine is in the adjunctive treatment (post amputation) of osteogenic sarcomas. Its effectiveness in treating transitional cell carcinoma of the bladder has been disappointing; however, intra-arterial administration with NSAID (*e.g.*, meloxicam) may prove to enhance efficacy. Intracavitary carboplatin for recurrent idiopathic or malignant pleural effusion after pericardectomy holds promise.

Carboplatin, unlike cisplatin, appears to be relatively safe to use in cats.

Carboplatin may be considered for intralesional use in conditions such as equine sarcoids or in treating adenocarcinoma in birds.

Whether carboplatin is more efficacious than cisplatin for certain cancers does not appear to be decided at this point, but the drug does appear to have fewer adverse effects (less renal toxicity and reduced vomiting) in dogs.

## Pharmacology/Actions

Carboplatin's exact mechanism of action is not fully understood. Both carboplatin's and cisplatin's properties are analogous to those of bifunctional alkylating agents producing inter- and intrastrand crosslinks in DNA, thereby inhibiting DNA replication, RNA transcription, and protein synthesis. Carboplatin is cell-cycle nonspecific.

## Pharmacokinetics

After IV administration, carboplatin is well distributed throughout the body; highest concentrations are found in the liver, kidney, skin and tumor tissue. The metabolic fate and elimination of carboplatin are complex and the discussion of this aspect of the drug's pharmacokinetics is beyond the scope of this reference. Suffice it to say, the parent drug degrades into platinum and platinum-complexed compounds that are primarily eliminated by kidneys. In dogs, almost one half of the dose is excreted in the urine within 24 hours and approximately 70% of the platinum administered is secreted in the urine after 72 hours.

## Contraindications/Precautions/Warnings

Carboplatin is contraindicated in patients hypersensitive to it or other platinum-containing compounds. It is also contraindicated in patients with severe bone marrow suppression. Patients with severe carboplatin-induced myelosuppression should be allowed to recover their counts before additional therapy.

Caution is advised in patients with active infections, hearing impairment or preexisting renal or hepatic disease.

Do not give carboplatin IM or SC.

## Adverse Effects

Established adverse effects in dogs include anorexia and/or vomiting that usually occur 2–4 days after a dose, and dose-related bone marrow suppression that is exhibited primarily as thrombocytopenia and/or neutropenia. The nadir of platelet and neutrophil counts generally occur about 14 days post treatment in dogs. Recovery is generally seen by day 21. In cats, thrombocytopenia occurs infrequently, but the neutrophil nadir occurs about 21 days post treatment. Recovery usually occurs by day 28 in cats.

Hepatotoxicity (increased serum bilirubin and liver enzymes) is seen in about 15% of human patients treated with carboplatin. Other potential adverse effects include: nephrotoxicity, neuropathies and ototoxicity. These effects occur with carboplatin therapy much less frequently than with cisplatin therapy. Anaphylactoid reactions have been reported rarely in humans that have received platinum-containing compounds (*e.g.*, cisplatin). Hyperuricemia may occur after therapy in a small percentage of patients.

## Reproductive/Nursing Safety

Carboplatin is fetotoxic and embryotoxic in rats and the risks of its use during pregnancy should be weighed with its potential benefits. In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown whether carboplatin enters maternal milk. In humans, it is recommended to discontinue nursing if the mother is receiving the drug.

## Overdosage/Acute Toxicity

There is limited information available. An overdose of carboplatin would be expected to cause aggravated effects associated with the drug's bone marrow nephro- and liver toxicity. Monitor for neurotoxicity, ototoxicity, hepatotoxicity and nephrotoxicity.

Treatment is basically supportive; no specific antidote is available. Plasmapheresis or hemodialysis could potentially be of benefit in removing the drug.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carboplatin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Potential for increased risk of nephrotoxicity or ototoxicity
- **CISPLATIN:** Human patients previously treated with cisplatin have an increased risk of developing neurotoxicity or ototoxicity after receiving carboplatin
- **MYELOSUPPRESSIVE DRUGS:** The leukopenic or thrombocytopenic effects secondary to carboplatin may be enhanced by other myelosuppressive medications
- **RADIATION THERAPY:** Potential for increased hematologic toxicity
- **VACCINES:** Live or killed virus vaccines administered after carboplatin therapy may not be as effective as the immune response to these vaccines may be modified by carboplatin therapy; carboplatin may also potentiate live virus vaccines replication and increase the adverse effects associated with these vaccines

## Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

Do not confuse cisplatin and carboplatin dosages; cisplatin dosages are much lower.

The following is a usual dosage (dosage may need adjustment in patients with reduced renal function) or dose range for carboplatin and should be used only as a general guide:

**Dogs:** 300–350 mg/m<sup>2</sup> IV every 3 weeks.

**Cats and Rabbits:** 180–260 mg/m<sup>2</sup> IV every 3 weeks. It has also been administered intratumorally in cats for nasal planum carcinomas.

## Monitoring

- CBC
- Serum electrolytes, uric acid
- Baseline renal and hepatic function tests

## Client Information

- Clients should fully understand the potential toxicity of this agent and, ideally, should give informed consent for its use.
- As carboplatin (and any platinum containing metabolites) is principally excreted in the urine over several days after treatment, clients should be warned to avoid direct contact with patient's urine.

## Chemistry/Synonyms

Carboplatin, like cisplatin, is a platinum-containing antineoplastic agent. It occurs as white to off-white crystalline powder having a solubility of 14 mg/mL in water and is insoluble in alcohol. The commercially available powder for injection contains equal parts of mannitol and carboplatin. After reconstitution with sterile water for injection, a resulting solution of 10 mg/mL of carboplatin has a pH of 5–7 and an osmolality of 94 mOsm/kg.

Carboplatin may also be known as: cis-Diammine-1,1-cyclobutanedicarboxylato-platinum, carboplatinum; CBDCA; JM-8; or NSC-241240; many trade names are available.

## Storage/Stability

The powder for injection should be kept stored at room temperature and protected from light.

After reconstitution, solutions containing 10 mg/mL are stable for at least 8 hours. Some sources say that the solution is stable for up to 24 hours and can be refrigerated, but because there are no preservatives in the solution, the manufacturer recommends discarding unused portions after 8 hours. Previous recommendations to avoid the use of solutions to dilute carboplatin containing sodium chloride are no longer warranted as only a minimal amount of carboplatin is converted to cisplatin in these solutions.

Because aluminum can displace platinum from carboplatin, the solution should not be prepared, stored or administered where aluminum-containing items can come into contact with the solution. Should carboplatin come into contact with aluminum, a black precipitate will form and the product should not be used.

## Compatibility/Compounding Considerations

Directions for reconstitution for the 50 mg vial: Add 5 mL of either sterile water for injection, normal saline injection or D5W that will provide a solution containing 10 mg/mL. May infuse directly (usually over 15 minutes) or further dilute. Visually inspect after reconstitution/dilution for discoloration or particulate matter.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELLED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Carboplatin lyophilized Powder for reconstitution and IV Injection: 50 mg, 150 mg, & 450 mg in single-dose vials (contains mannitol); generic (Baxter); (Rx)

Carboplatin Injection: 10 mg/mL in 5 mL, 15 mL & 45 mL single-use vials; generic; (Rx)

**CARNITINE****LEVOCARNITINE****L-CARNITINE**

(*kar-ni-teen*) Carnitor®

**NUTRIENT****Prescriber Highlights**

- **Nutrient required for normal fat utilization & energy metabolism**
- **May be useful in certain cardiomyopathies (including doxorubicin induced) in dogs**
- **Use only L (levo-) forms**
- **Preferably give with meals**

**Uses/Indications**

Levocarnitine may be useful as adjunctive therapy of dilated cardiomyopathy in dogs. Up to 90% of dogs with dilated cardiomyopathy may have a carnitine deficiency. American Cocker spaniels, Boxers, dogs with cysteine or urate urolithiasis, and dilated cardiomyopathy may all especially benefit. Any breed with dilated cardiomyopathy may receive a trial of the drug as approximately 5% will respond.

Levocarnitine may also protect against doxorubicin-induced cardiomyopathy and reduce risks of myocardial infarction and it may be beneficial in the adjunctive treatment of valproic acid toxicity.

In cats, levocarnitine has been recommended as being useful as an adjunctive therapy in feline hepatic lipidosis by facilitating hepatic lipid metabolism. Its use for this indication is somewhat controversial.

**Pharmacology/Actions**

Levocarnitine is required for normal fat utilization and energy metabolism in mammalian species. It serves to facilitate entry of long-chain fatty acids into cellular mitochondria where they can be used during oxidation and energy production.

Severe chronic deficiency is generally a result of an inborn genetic defect where levocarnitine utilization is impaired and not the result of dietary insufficiency. Effects seen in levocarnitine deficiency may include hypoglycemia, progressive myasthenia, hepatomegaly, CHF, cardiomegaly, hepatic coma, neurologic disturbances, encephalopathy, hypotonia and lethargy.

**Pharmacokinetics**

In humans, levocarnitine is absorbed via the GI with a bioavailability of about 15%, but is absorbed rapidly in the intestine via passive and active mechanisms. Highest levels of levocarnitine are found in skeletal muscle. Levocarnitine is distributed in milk. Exogenously administered levocarnitine is eliminated by both renal and fecal routes. Plasma levocarnitine levels may be increased in patients with renal failure.

**Contraindications/Precautions/Warnings**

Levocarnitine may also be known as Vitamin BT. Products labeled as such may have both D and L racemic forms. Use only Levo- (L-) forms as the D- form may competitively inhibit L- uptake with a resulting deficiency.

**Adverse Effects**

Adverse effect profile is minimal. Gastrointestinal upset is the most likely effect that may be noted and is usually associated with high dosages but is usually mild and limited to loose stools or possibly diarrhea; nausea and vomiting are possible. Human patients have reported increased body odor.

**Reproductive/Nursing Safety**

Studies done in rats and rabbits have demonstrated no teratogenic effects and it is generally believed that levocarnitine is safe to use in pregnancy though documented safety during pregnancy has not been established. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

**Overdosage/Acute Toxicity**

Levocarnitine is a relatively safe drug. Minor overdoses need only to be monitored; with massive overdoses consider gut emptying. Refer to a poison control center for more information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving levocarnitine and may be of significance in veterinary patients:

- **VALPROIC ACID:** Patients receiving valproic acid may require higher dosages of levocarnitine

## Doses

### ■ DOGS:

For myocardial carnitine deficiency associated with dilated cardiomyopathy:

- As a trial for treating canine dilated cardiomyopathy: For a large or giant breed dog: 2 grams (approximately 1 teaspoonful of pure powder) PO q8–12h;  
For adjunctive (with traditional pharmacotherapy) therapy of dilated cardiomyopathy in American Cocker spaniels: 1 gram (approximately 1/2 teaspoonful) PO q8–12h with taurine (Keene 2002)
- For boxers with severe myocardial failure: Give 2–3 grams carnitine PO q12h for 2–4 months to determine if they respond (Kittleson 2006)
- For adjunctive treatment of American cocker spaniels with dilated cardiomyopathy: Carnitine 1 g PO q12h with taurine 500 mg q12h PO (Kittleson 2006)
- For cardiac indications (dilated cardiomyopathy) when carnitine supplementation may benefit:
  - American Cocker spaniels: 1 g PO q8h
  - Boxer dogs with dilated cardiomyopathy: 2 g PO q8h
  - Documented systemic carnitine deficiency: 50–100 mg/kg PO q8h.
  - Myocardial carnitine deficiency only: 200 mg/kg PO q8h (Smith 2009)

### ■ CATS:

- As adjunctive dietary therapy in cats with severe hepatic lipidosis: 250 mg PO once daily (use *Carnitor*®); also supplement with taurine (250 mg once to twice daily), Vitamin E (10 Units/kg/day), water soluble vitamins and determine B12 status (treat while awaiting data at 1 mg/cat SC). See also Acetylcysteine. (Center 2006)
- For supplementation in cats with liver disease: 250–500 mg/day (Zoran 2006)

## Monitoring

- Efficacy
- Periodic blood chemistries have been recommended for human patients, their value in veterinary medicine is undetermined.

## Client Information

- Give with meals when possible to reduce likelihood of GI side effects.
- The majority of dogs responding to carnitine therapy for dilated cardiomyopathy will require other medication to control clinical signs.

## Chemistry/Synonyms

Levocarnitine (the L-isomer of carnitine) is an amino acid derivative, synthesized *in vivo* from methionine and lysine. It is required for energy metabolism and has a molecular weight of 161.

Carnitine may also be known as: vitamin B(T), L-carnitine, or levocarnitinum; many trade names are available.

## Storage/Stability

Levocarnitine capsules, tablets and powder should be stored in well-closed containers at room temperature. The oral solution should be kept in tight containers at room temperature. The injection should be stored at room temperature in the original carton; discard any unused portion after opening, as the injection contains no preservative.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

### **HUMAN-LABELED PRODUCTS:**

Levocarnitine Oral Tablets: 330 mg & 500 mg; *Carnitor*® (Sigma-Tau); L-Carnitine (Freeda Vitamins); Levocarnitine (Rising); (Rx & OTC)

Levocarnitine or L-Carnitine Oral Capsules: 250 mg; generic; (OTC—as a food supplement)

Levocarnitine Oral Solution: 100 mg/mL in 118 mL; *Carnitor*® (Sigma-Tau); Levocarnitine (Rising); (Rx)

Levocarnitine Injection: 200 mg/mL in single-dose vials & preservative-free in single-dose vials and amps; *Carnitor*® (Sigma-Tau); generic; (Rx)

**Note:** L-carnitine may also be available in bulk powder form from local health food stores

## CARPROFEN

(kar-pro-fen) Rimadyl®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

- NSAID used in dogs & other small animals
  - Contraindicated in dogs with bleeding disorders (*e.g.*, Von Willebrand's), history of serious reactions to it or other propionic-class NSAIDs
  - Caution: Geriatric patients or those with preexisting chronic diseases (*e.g.*, inflammatory bowel disease, renal or hepatic insufficiency)
  - GI adverse effects are less likely than with older NSAIDs but can occur
  - Rarely may cause hepatic failure; monitor liver enzymes
- 

## Uses/Indications

Carprofen is labeled (in the USA) for the relief of pain and inflammation in dogs. It may also prove to be of benefit in other species as well, but data is scant to support its safety beyond very short-term use at this time. In Europe, carprofen is reportedly registered for single dose use in cats, but there have been reported problems (*e.g.*, vomiting) with cats receiving more than a single dose.

Carprofen is being investigated for antineoplastic effects in dogs and may be a useful adjunctive treatment for some types of tumors with COX-2 overexpression.

## Pharmacology/Actions

Like other NSAIDs, carprofen exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase, phospholipase A2 and inhibition of prostaglandin synthesis. Carprofen appears to be more sparing of COX-1 *in vitro* and in dogs appears to have fewer COX-1 effects (GI distress/ulceration, platelet inhibition, renal damage) when compared to older non-COX-2 specific agents. COX-2 specificity appears to be species, dose, and tissue dependent. Carprofen in horses or cats does not seem to be as COX-2 specific as it is in dogs.

## Pharmacokinetics

When administered orally to dogs, carprofen is approximately 90% bioavailable. Peak serum levels occur between 1–3 hours post dosing. The drug is highly bound to plasma proteins (99%) and has a low volume of distribution (0.12–0.22 L/kg). Carprofen is extensively metabolized in the liver primarily via glucuronidation and oxidative processes. About 70–80% of a dose is eliminated in the feces; 10–20% eliminated in the urine. Some enterohepatic recycling of the drug occurs.

Elimination half-life of carprofen in the dog is approximately 8 hours with the S form having a longer half-life than the R form. The half-life of carprofen is reportedly 22 hours in horses and averages 20 hours in cats, but interindividual variability is very high in cats (9–49 hours). Half-life is not necessarily a good predictor of duration of effect, as the drug's high affinity for tissue proteins may act as a reservoir for the drug at inflamed tissue.

## Contraindications/Precautions/Warnings

Carprofen is contraindicated in dogs with bleeding disorders (*e.g.*, Von Willebrand's) or those that have had prior serious reactions to it or other propionic-class antiinflammatory agents. It should be used with caution in geriatric patients or those with preexisting chronic diseases (*e.g.*, inflammatory bowel disease, renal or hepatic insufficiency).

## Adverse Effects

Although adverse effects appear to be uncommon with carprofen use in dogs, they can occur. Mild gastrointestinal effects (vomiting, diarrhea, inappetence) or lethargy are the most likely to appear but incidence is low (<2%). Rarely, serious effects including hepatocellular damage and/or renal disease; hematologic and serious gastrointestinal effects (ulceration) have been reported. Increased risks for the development of renal toxicity include preexisting renal insufficiency, dehydration or sodium depletion.

Reported incidence of hepatopathy is approximately 0.05% or less in dogs. It has been postulated that this adverse effect could be caused by formation of reactive acyl glucuronide metabolites that bind to and form haptites on hepatocytes; an immunological reaction then occurs causing hepatotoxicity. Geriatric dogs or dogs with chronic diseases (*e.g.*, inflammatory bowel disease, renal or hepatic insufficiency) may be at greater risk for developing hepatic toxicity while receiving this drug, but the effect may be idiosyncratic and unpredictable. Although not proven statistically significant, Labrador Retrievers have been associated with 1/4 of the initially reported cases associated with the reported hepatic syndrome; but it is not believed that this breed has any greater chance of developing this adverse effect than others. Before initiating therapy, pre-treatment patient evaluation and discussion with the owner regarding the potential risks versus benefits of therapy are advised.

Carprofen has been used in cats, but as cats have limited ability hepatically to glucuronidate there is a greater potential for drug accumulation with resultant adverse effects. In particular, cats appear to be more susceptible to developing renal adverse effects from NSAIDs. Prolonged administration of carprofen in cats has also caused gastrointestinal effects. Hepatotoxicity does not appear to be a significant concern with NSAID use in cats, perhaps since they do not form significant amounts of glucuronidated metabolites.

## Reproductive/Nursing Safety

The manufacturer states that the safe use of carprofen in dogs less than 6 weeks of age, pregnant dogs, dogs used for breeding purposes, or lactating bitches has not been established. Carprofen has been given to pregnant rats at dosages of up to 20 mg/kg during day 7–15 of gestation. While no teratogenic effects were noted in pups, the drug did delay parturition with an increased number of dead pups at birth.

## Overdosage/Acute Toxicity

In dog toxicologic studies, repeated doses of up to 10X resulted in little adversity. Some dogs exhibited hypoalbuminemia, melena or slight increases in ALT. However, post-marketing surveillance suggests that there may be significant interpatient variability in response to acute or chronic overdoses. According to the APCC database, vomiting has been reported at doses as low as 5.3 mg/kg in dogs and 3.9 mg/kg in cats. The APCC level of concern for renal damage is 50 mg/kg in dogs and 8 mg/kg in cats.

There were 2235 exposures to carprofen reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 1952 were dogs with 296 showing clinical signs and the remaining 283 cases were cats with 41 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, anorexia, diarrhea, azotemia, bloody vomitus, elevated BUN, elevated alkaline phosphatase, and elevated creatinine. Common findings in cats recorded in decreasing frequency included vomiting, anorexia, azotemia, hyperphosphatemia, and lethargy.

This medication is a NSAID. As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated

charcoal, in doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis is warranted.

## Drug Interactions

**Note:** Although the manufacturer does not list any specific drug interactions in the package insert, it does caution to avoid or closely monitor carprofen's use with other ulcerogenic drugs (*e.g.*, **corticosteroids** or other **NSAIDs**). While some advocate a multi-day washout period when switching from one NSAID to another (not aspirin—see below), there does not appear to be any credible evidence that this is required. Until so, consider starting the new NSAID when the next dose would be due for the old one.

The following drug interactions have either been reported or are theoretical in humans or animals receiving carprofen and may be of significance in veterinary patients:

- **ACE INHIBITORS** (*e.g.*, **benazepril**, **enalapril**): Because ACE inhibitors potentially can reduce renal blood flow, use with NSAIDs could increase the risk for renal injury. However, one study in dogs receiving tepoxalin did not show any adverse effect. It is unknown what effects, if any, occur if other NSAIDs and ACE inhibitors are used together in dogs.
- **ASPIRIN**: When aspirin is used concurrently with carprofen, plasma levels of carprofen could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with carprofen cannot be recommended. Washout periods of several days is probably warranted when switching from an NSAID to aspirin therapy in dogs.
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **DIGOXIN**: Carprofen may increase serum levels of digoxin; use with caution in patients with severe cardiac failure
- **FUROSEMIDE**: Carprofen may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (*e.g.*, **phenytoin**, **valproic acid**, **oral anticoagulants**, **other antiinflammatory agents**, **salicylates**, **sulfonamides**, **sulfonylurea antidiabetic agents**): Because carprofen is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **PHENOBARBITAL, RIFAMPIN, or OTHER HEPATIC ENZYME INDUCING AGENTS**: As carprofen hepatotoxicity may be mediated by its hepatic metabolites, these drugs should be avoided if carprofen is required. One source states: Patients should not receive phenobarbital or other hepatic drug metabolizing enzyme inducers when receiving this drug (Boothe 2005).
- **PROBENECID**: May cause a significant increase in serum levels and half-life of carprofen

## Laboratory Considerations

- In dogs, carprofen can have no effect or slightly lower **Free T<sub>4</sub>**, **Total T<sub>4</sub>** and **TSH** levels in dogs.

## Doses

### ■ DOGS:

As an antiinflammatory/analgesic:

- a) 4.4 mg/kg PO; may be given once daily or divided and given as 2.2 mg/kg twice daily; round dose to nearest half caplet increment. For postoperative pain, administer approximately 2 hours before the procedure. Injectable is dosed as the oral products, but administered SC. (Package Insert; *Rimadyl*®—Pfizer)
- b) Surgical pain: 4 mg/kg PO, IM, SC once. Pain/inflammation (non-surgical): 2.2 mg/kg PO q12–24h (Boothe 2005)

### ■ CATS:

As an antiinflammatory/analgesic: Extreme caution is advised, particularly with continued dosing.

- a) For surgical pain: 1–4 mg/kg SC pre- or post-operatively. Analgesia may last 12–18 hours. Use of 1–2 mg/kg SC gives similar efficacy as the higher doses, but is safer (Robertson & Lascelles 2003)
- b) 2 mg/kg PO q12h; limit to 2 days of therapy (Hardie 2000)
- c) Less than 1 mg/kg PO once daily (q24h) for 2–3 treatments (Boothe 2005)
- d) For surgical pain: 2 mg/kg or less (lean weight) SC once at induction (Mathews 2005)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

- a) **Rabbits**: For chronic joint pain: 2.2 mg/kg PO q12h (Ivey & Morrissey 2000)
- b) **Rats**: 5 mg/kg SC or 5–10 mg/kg PO. Chinchillas: 4 mg/kg SC once daily (Adamcak & Otten 2000)
- c) 1–4 mg/kg PO, SC q12–24h (Bays 2006)

### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) As an antiinflammatory/analgesic: 0.7 mg/kg IV, one time (Clark & Clark 1999)
- b) 0.7 mg/kg IV, one time; may follow with 0.7 mg/kg PO (granules, mixed with a little feed) for up to 4–9 days according to clinical response (Label information; *Rimadyl*® *Large Animal Solution*, *Rimadyl Granules*®—Pfizer U.K.)

### ■ CATTLE:

- a) In young cattle (<12 months old) for adjunctive therapy of acute inflammation associated with respiratory disease: 1.4 mg/kg IV or SC once. Slaughter withdrawal = 21 days; not to be used in cows producing milk for human consumption. (Label information; *Rimadyl*® *Large Animal Solution*—Pfizer U.K.)

### ■ BIRDS:

As an antiinflammatory/analgesic:

- a) 2 mg/kg PO q8–24 hours (Clyde & Paul-Murphy 2000)
- b) 1 mg/kg SC. Study demonstrated increased walking ability in lame chickens. (Paul Murphy 2003)

b) 1 mg/kg SC. Study demonstrated walking ability in lame chickens. (Paul-Murphy 2003)

c) 1–4 mg/kg IM, IV, PO (Bays 2006)

## ■ REPTILES:

As an antiinflammatory/analgesic:

a) 1–4 mg/kg IV, IM, SC, PO q 24–72h (Bays 2006)

## ■ ZOO, EXOTIC, WILDLIFE SPECIES:

For use of carprofen in zoo, exotic and wildlife medicine refer to specific references, including:

a) *Exotic Animal Formulary, 3rd Ed.* Carpenter J. W. Saunders. 2005

b) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

## Monitoring

■ Baseline (especially in geriatric dogs, dogs with chronic diseases, or when prolonged treatment is likely): physical exam, CBC, Serum chemistry panel (including liver and renal function tests), and UA. It is recommended to reassess the liver enzymes at one, two and 4 weeks of therapy and then at 3–6 month intervals. Should elevation occur, recommend discontinuing the drug.

■ Clinical efficacy

■ Signs of potential adverse reactions: inappetence, diarrhea, vomiting, melena, polyuria/polydipsia, anemia, jaundice, lethargy, behavior changes, ataxia or seizures

■ Chronic therapy: Consider repeating CBC, UA and serum chemistries on an ongoing basis

## Client Information

■ Although rare, serious adverse effects have been reported with the use of this drug. Read and understand the client information sheet provided with this medication; contact the veterinarian with any questions or concerns.

■ Watch for signs of potential adverse effects including: decreased appetite, vomiting, diarrhea, dark or tarry stools, increased water consumption, increased urination, pale gums due to anemia, yellowing of gums, skin or white of the eye due to jaundice, incoordination, seizures, or behavioral changes. Should these signs present, clients should stop the drug immediately and contact their veterinarian.

■ Store the flavored chewable tablets out of reach of dogs to avoid the potential for overdose.

## Chemistry/Synonyms

A propionic acid derivative non-steroidal antiinflammatory agent, carprofen occurs as a white crystalline compound. It is practically insoluble in water and freely soluble in ethanol at room temperature. Carprofen has both an S (+) enantiomer and R (-) enantiomer. The commercial product contains a racemic mixture of both. The S (+) enantiomer has greater antiinflammatory potency than the R (-) form.

Carprofen may also be known as: C-5720; Ro-20-5720/000, *Rimadyl*®, *Zinecarp*®, *Canidryl*®, *Novox*®, *Carprodyl*® or *Norocarp*®.

## Storage/Stability

The commercially available caplets or chewable tablets should be stored at room temperature (15–30°C).

The commercially available (in the USA) injection should be stored in the refrigerator (2–8°C; 36–46°F). Once broached, the injection may be stored at temperatures of up to 25°C for 28 days.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Carprofen oral suspension compounded from commercially available tablets has been published (Hawkins *et al.* 2006). Triturating one (1) carprofen 100 mg tablet with 10 mL of *Ora-Plus*® and *qs ad* to 20 mL with *Ora-Sweet*® yields a 5 mg/mL suspension that retains 90% potency for 21 days stored at both 5°C and 25°C. Compounded preparations of carprofen should be protected from light.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Carprofen Scored Caplets: 25 mg, 75 mg & 100 mg; *Rimadyl*® Caplets (Pfizer), *Novocox*® (Impax), *Vetprofen*® (Belcher), *Norocarp*® (Norbrook); (Rx). FDA-approved for use in dogs.

Carprofen Chewable Tablets: 25 mg, 75 mg & 100 mg; *Rimadyl*® Chewable Tablets (Pfizer); (Rx). FDA-approved for use in dogs.

Carprofen Sterile Injectable Solution: 50 mg/mL in 20 mL vials; *Rimadyl*® (Pfizer); (Rx). FDA-approved for use in dogs.

In the U.K., *Rimadyl*® Injection is labeled for use in dogs, cats, horses, ponies and cattle (less than 12 months old; slaughter withdrawal = 21 days; not to be used in cattle producing milk for human consumption). *Rimadyl*® Granules are labeled for use in horses and ponies. See Doses for more information.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS: None

## CARVEDILOL

(kar-*vah*-da-lol) Coreg®

BETA & ALPHA-1 ADRENERGIC BLOCKER

### Prescriber Highlights

- **Non-selective Beta-adrenergic blocker with selective alpha<sub>1</sub>-adrenergic blocking activity that could be useful for treating heart failure in dogs; use is controversial**
  - **Limited veterinary experience**
  - **Negative inotrope that may prohibit its use in severely symptomatic patients; potentially could decompensate patient**
  - **Additional adverse effects that may demonstrate intolerance include lassitude, inappetence, & hypotension**
- 

### Uses/Indications

Carvedilol may be useful as adjunctive therapy in the treatment of heart failure (dilated cardiomyopathy) in dogs. There is a fair amount of controversy at present among veterinary cardiologists as to whether this drug will find a therapeutic niche. One study (Oyama & Prosek 2006) done in dogs with dilated cardiomyopathy showed that carvedilol dosed at 0.3 mg/kg PO q12h for 3 months did not produce any significant improvements in neurohormonal activation, heart size, or owner-perceived quality of life. The authors state that doses >0.3 mg/kg q12h are likely to be required to effect changes in ventricular remodeling and function.

### Pharmacology/Actions

Carvedilol is a non-selective, beta-adrenergic blocker with selective alpha<sub>1</sub>-adrenergic blocking activity. Despite their negative inotropic effects, chronic dosing of beta blockers in human patients with dilated cardiomyopathy can be useful in reducing both morbidity and mortality. Patients in heart failure, chronically activate their sympathetic nervous system, thereby leading to tachycardia, activation of the renin-angiotensin-aldosterone system, down-regulation of beta-receptors, induction of myocyte necrosis and myocyte energy substrate and calcium ion handling. By giving beta-blockers, these negative effects may be reversed or diminished. As carvedilol also inhibits alpha<sub>1</sub>-adrenergic activity, it can cause vasodilation and reduce afterload. Carvedilol has free-radical scavenging and antidysrhythmic effects that could be beneficial in heart failure patients.

### Pharmacokinetics

In dogs, a pilot study (Arsenault *et al.* 2003) showed carvedilol's bioavailability after oral dosing averaged about 23% in the 4 dogs studied, but in 3 of the 4, bioavailability ranged from 3–10%. Volume of distribution averaged about 1.4 L/kg; elimination half-life was about 100 minutes. At least 15 different metabolites of carvedilol have been identified after dosing in dogs. Hydroxylation of the carbazolyl ring and glucuronidation of the parent compound are the most predominant processes of metabolism in dogs.

In humans, carvedilol is rapidly and extensively absorbed but due to a high first-pass effect, bioavailability is about 30%. The drug is extensively bound to plasma proteins (98%). It is extensively metabolized and the R(+) enantiomer is metabolized 2–3 times greater than the S(-) form during the first pass. Both the R(+) and S(-) enantiomers have equal potency as non-specific beta- or alpha-adrenergic blockers. CYP2D6 and CYP2C9 are the P450 isoenzymes most responsible for hepatic metabolism. Some of these metabolites have pharmacologic activity. Metabolites are primarily excreted via the bile and feces. Elimination half-life of carvedilol in humans is about 8–9 hours.

### Contraindications/Precautions/Warnings

In humans, carvedilol is contraindicated in class IV decompensated heart failure, bronchial asthma, 2nd or 3rd degree AV block, sick sinus syndrome (unless artificially paced), severe bradycardia, cardiogenic shock or hypersensitivity to the drug. Dogs with equivalent conditions should not receive the drug.

### Adverse Effects

Veterinary experience is very limited and an accurate portrayal of adverse effects in dogs has yet to be elucidated. Too rapid beta blockade can cause decompensation in patients with heart failure; cautious dosage titration is mandatory. Dogs that do not tolerate the medication may show signs of inappetence, lassitude, or hypotension. Bronchospasm has been reported in humans.

Because the drug is extensively metabolized in the liver, patients with hepatic insufficiency should receive the drug with caution. In humans, carvedilol has on rare occasions, caused mild hepatocellular injury.

### Reproductive/Nursing Safety

In humans, the FDA categorizes carvedilol as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). In rats and rabbits, carvedilol increased post-implantation loss.

It is unknown if carvedilol enters maternal milk in dogs, but it does enter milk in rats. Use with caution in nursing patients.

### Overdosage/Acute Toxicity

The acute oral LD<sub>50</sub> in healthy rats and mice is greater than 8 grams/kg. Clinical signs associated with large overdoses include: severe hypotension, cardiac insufficiency, bradycardia, cardiogenic shock and death due to cardiac arrest. Gut emptying protocols should be considered if ingestion was recent. In humans, bradycardia is treated with atropine, and cardiovascular function supported with glucagon and sympathomimetics (*e.g.*, dobutamine, epinephrine, etc.). Contact an animal poison control center for specific information in the case of overdose.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving carvedilol and may be of significance in veterinary patients:

■ **BETA-BLOCKERS (other):** Use with carvedilol may cause additive effects

- **CALCIUM CHANNEL BLOCKERS (e.g., diltiazem, verapamil):** Carvedilol may rarely cause hemodynamic compromise in patients taking diltiazem or verapamil
- **CIMETIDINE:** May decrease metabolism and increase AUC of carvedilol
- **CLONIDINE:** Carvedilol may potentiate the cardiovascular effects of clonidine
- **CYCLOSPORINE:** Carvedilol may increase cyclosporine levels
- **DIGOXIN:** Carvedilol can increase (in humans) digoxin plasma concentrations by approximately 15%
- **FLUOXETINE, PAROXETINE, QUINIDINE:** May increase R(+)-carvedilol concentrations and increase alpha-1 blocking effects (vasodilation)
- **INSULIN; ORAL ANTIDIABETIC AGENTS:** Carvedilol may enhance the blood glucose lowering effects of insulin or other antidiabetic agents
- **RIFAMPIN:** Can decrease carvedilol plasma concentrations by as much as 70%
- **RESERPINE:** Drugs such as reserpine can cause increased bradycardia and hypotension in patients taking carvedilol

### Laboratory Considerations

- No specific laboratory interactions or considerations noted

### Doses

#### ■ DOGS:

- a) Start at the low end of the dosing range and gradually titrate upward carefully watching to avoid negative inotropic effects. Usual starting dose: ¼–½ of a 3.125 mg tablet PO twice daily. (Kramer 2008)
- b) Beta blockers are best employed in dogs that are minimally symptomatic with early/mild heart failure, or animals in later stages of CHF. Some cardiologists have used carvedilol at 0.2 mg/kg PO twice daily initially with slow titration upwards towards a dose of 0.8 mg/kg twice daily. Many dogs with CHF will not tolerate this upward titration. (Rush 2008)
- c) A reasonable target plasma carvedilol concentration is 50–100 nanograms/mL. Based upon prior studies and the small series of dogs studied in this study, doses of 0.5 mg/kg PO twice daily should result in beta-blockade, but maximum beta-blockade may require doses of >0.7–0.9 mg/kg. Because of bioavailability variations, plasma monitoring, clinical trials and uptitration protocols may be beneficial. (Gordon *et al.* 2004)

### Monitoring

- Clinical efficacy
- Adverse effects
- Plasma drug levels (see Doses above)

### Client Information

- Give this medication exactly as veterinarian prescribes. Do not stop the medication without the approval and guidance of veterinarian
- Contact veterinarian if animal's condition worsens while receiving this medication, or if it shows signs of reduced appetite, fatigue or listlessness, and dizziness or unsteadiness
- Medication is best given with food

### Chemistry/Synonyms

A non-selective beta-adrenergic blocker with selective alpha<sub>1</sub>-adrenergic blocking activity, carvedilol occurs as a white to off-white crystalline powder that is practically insoluble in water, dilute acids, and gastric or intestinal fluids. It is sparingly soluble in ethanol. The compound exhibits polymorphism and contains both R(+) and S(-) enantiomers. It is a basic, lipophilic compound.

Carvedilol may also be known as: BM-14190, carvedilolum, *Cardilol*®, *Cardiol*®, *Carloc*®, *Carvil*®, *Carvipress*®, *Coreg*®, *Coritensil*®, *Coropres*®, *Dilatrend*®, *Dilbloc*®, *Dimitone*®, *Divelol*®, *Eucardic*®, *Hybridil*®, *Kredex*®, or *Querto*®.

### Storage/Stability

Carvedilol tablets and extended release capsules should be stored below 30°C (86°F) and protected from moisture. They should be dispensed in tight, light-resistant containers.

### Compatibility/Compounding Considerations

**Compounded preparation stability:** Carvedilol oral suspension compounded from commercially available tablets has been published (Yamreudeewong *et al.* 2006); however, HPLC analysis of drug samples in this study gave erratic and variable results indicating a loss of potency at refrigerated temperatures as compared to room temperature. Results of this study do not necessarily confirm that carvedilol is stable when prepared as an oral liquid.

Another published (Gordon *et al.* 2006) compounded oral suspension with documented 90 day stability to accurately dose dogs is to powder 25 mg tablets and add enough de-ionized water to make a paste, allowing the tablet coating to dissolve. Then suspend in a commercially available simple syrup to a concentration of either 2 mg/mL or 10 mg/mL. Store in amber bottles at temperatures not exceeding 25°C and protect from light for up to 90 days. Shake well before administering.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Carvedilol Oral Tablets: 3.125 mg, 6.25 mg, 12.5 mg, & 25 mg; *Coreg*® (GlaxoSmithKline); generic; (Rx)

Carvedilol Extended-Release Oral Capsules: 10 mg, 20 mg, 40 mg & 80 mg (as phosphate); *Coreg CR*® (GlaxoSmithKline); (Rx)

## CASPOFUNGIN ACETATE

(kas-poe-fun-jin) Cancidas®

PARENTERAL ANTIFUNGAL

### Prescriber Highlights

- Parenteral antifungal that has potential for treating invasive aspergillosis or disseminated candidal infections in companion animals
  - Very limited clinical experience in veterinary medicine
  - Very Expensive
- 

## Uses/Indications

Caspofungin has potential for treating invasive aspergillosis or disseminated candidal infections in companion animals although little, if any, information on its use in dogs or cats is available.

## Pharmacology/Actions

Caspofungin represents the echinocandins, a new class of antifungal agent. These drugs inhibit beta-glucan synthase, thereby blocking the synthesis of beta-(1,3)-D-glucan, a component found in cell walls of filamentous fungi. Caspofungin has activity against *Aspergillus* and *Candida* species and is effective in treating pneumonia caused by *Pneumocystis carinii*. Because it contains very little beta-glucan synthase, *Cryptococcus neoformans* infections are not effectively treated with caspofungin.

## Pharmacokinetics

No information was located on the pharmacokinetics of caspofungin in dogs or cats.

In humans, the drug is not appreciably absorbed from the gut and must be administered IV. Protein binding (primarily to albumin) is high (97%) and the drug is distributed to tissues over a 36–48 hour period. Caspofungin is slowly metabolized via hydrolysis and N-acetylation. It also spontaneously degrades chemically. Caspofungin exhibits polyphasic elimination, but little drug is excreted or biotransformed during the first 30 hours post-administration. Elimination half-life for the primary phase is about 10 hours; the secondary phase between 40–50 hours. Excretion, consisting mostly as metabolites, is via the feces and urine. Only small amounts (1–2%) are excreted unchanged into the urine.

## Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. Caspofungin is contraindicated in human patients hypersensitive to it. Dosage adjustment is recommended in humans with moderate hepatic impairment. No information is available for use in patients with significant hepatic impairment; avoid use.

## Reproductive/Nursing Safety

In humans, the FDA categorizes caspofungin as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) Studies with caspofungin performed in pregnant rats and rabbits demonstrated changes in fetal ossification. The drug should be avoided during the first trimester of pregnancy unless the benefits associated with treating outweigh the risks.

Although no data is available, because the drug is not appreciably absorbed from the gut, it would be expected that caspofungin would be safe to administer during lactation.

## Adverse Effects

An adverse effect profile for animals has not been determined. In humans, caspofungin is generally well tolerated. Histamine-mediated signs have occurred (rash, facial swelling, pruritus) and anaphylaxis has been reported. Intravenous site reactions (pain, redness, phlebitis) have occurred. Hepatic dysfunction has been reported but frequency is unknown.

## Overdosage/Acute Toxicity

Limited information is available. Dosages of 210 mg (about 3x) in humans were well tolerated. Some monkeys receiving 5–8 mg/kg (approx. 4–6X) over 5 weeks developed sites of microscopic subcapsular necrosis on their livers.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving caspofungin and may be of significance in veterinary patients:

- **CARBAMAZEPINE:** Reduced caspofungin plasma levels
- **CYCLOSPORINE:** Increased caspofungin plasma levels and increased risk of hepatic enzyme increases
- **DEXAMETHASONE:** Reduced caspofungin plasma levels
- **PHENYTOIN:** Reduced caspofungin plasma levels

■**RIFAMPIN:** Reduced caspofungin plasma levels

### Laboratory Considerations

- No specific concerns noted; see Monitoring

### Doses

#### ■**DOGS/CATS:**

No published doses for dogs or cats were located and the use of this medication in these patients must be considered highly investigational. Although not labeled for use in human pediatric patients, one study performed in immunocompromised human pediatric patients administered doses of 0.8–1.6 mg/kg in patients weighing less than 50 kg and 50–75 mg (total dose) in those weighing more than 50 kg. The drug was well tolerated in both groups.

### Monitoring

- Clinical efficacy
- Periodic liver function tests, CBC, serum electrolytes

### Client Information

- This medication is appropriate for inpatient use only
- Clients should understand the investigational nature and the associated expense of using this drug on veterinary patients

### Chemistry/Synonyms

Caspofungin acetate is a semisynthetic echinocandin compound produced from a fermentation product of *Glarea lozoyensis*. It occurs as a white to off-white powder that is freely soluble in water and slightly soluble in ethanol. The commercially available lyophilized powder for injection also contains acetic acid, sodium hydroxide, mannitol and sucrose.

Caspofungin may also be known as: caspofungina, caspofungine, caspofungini, kaspofungiinia, kaspofungina, L-743873, MK-0991, or *Candidas*®.

### Storage/Stability

The commercially available product should be stored refrigerated (2–8°C). Refer to the package insert for very specific directions on preparing the solution for intravenous use.

Do not use if the solution is cloudy or has precipitated.

### Compatibility/Compounding Considerations

It is recommended not to mix or infuse with any other medications and not to use with intravenous solutions containing dextrose.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Caspofungin Acetate Lyophilized Powder for Injection: 50 & 70 mg in single-use vials; *Candidas*® (Merck); (Rx)

---

## CEFACLOR

(*sef-a-klor*) Ceclor®

ORAL 2ND GENERATION CEPHALOSPORIN

### Prescriber Highlights

- Oral 2nd generation cephalosporin that is more active against some gram-negative bacteria than first generation (*e.g.*, cephalexin) cephalosporins
  - Potentially useful when an oral cephalosporin is desired to treat bacterial infections that are susceptible to cefaclor, but resistant to first generation cephalosporins
  - Limited clinical experience in veterinary medicine
  - Adverse effects most likely seen in small animals would be GI-related
- 

### Uses/Indications

Cefaclor may potentially be useful when an oral cephalosporin is desired to treat infections that are susceptible to it but resistant to first generation cephalosporins such as cephalexin or cefadroxil. Little information is available with regard to its clinical use in small animals, however.

### Pharmacology/Actions

Cefaclor, like other cephalosporins, is bactericidal and acts via inhibiting cell wall synthesis. Its spectrum of activity is similar to that of cephalexin, but it is more active against gram-negative bacteria including strains of *E. coli*, *Klebsiella pneumoniae*, and *Proteus mirabilis*.

### Pharmacokinetics

Limited information is available on the pharmacokinetics of cefaclor in dogs and none was located for cats. In dogs, about 75% of an oral dose is absorbed, but an

apparent first-pass effect reduces bioavailability to about 60%. Cefaclor is distributed to many tissues, but levels are lower in interstitial fluid than those found in serum. Very high levels are excreted into the urine unchanged. Bile levels are higher than those found in serum. Dogs appear to metabolize a greater percentage of cefaclor than do rats, mice, or humans. Approximate elimination half-life is about 2 hours in dogs.

In humans, cefaclor is well absorbed after oral administration; food delays, but does not appreciably alter the amount absorbed. The drug is widely distributed, crosses the placenta and enters breast milk. Up to 85% of a dose is excreted unchanged into the urine; elimination half-life is less than 1 hour in patients with normal renal function.

### Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. Cefaclor is contraindicated in human patients hypersensitive to it and must be cautiously used in patients with penicillin-allergy. Dosage adjustment is recommended in humans with severe renal impairment.

### Reproductive/Nursing Safety

In humans, the FDA categorizes cefaclor as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) Studies performed in pregnant rats (doses up to 12X human dose) and ferrets (doses up to 3X human dose) demonstrated no overt fetal harm.

Cefaclor enters maternal milk in low concentrations. Although probably safe for nursing offspring the potential for adverse effects cannot be ruled out, particularly, alterations to gut flora with resultant diarrhea.

### Adverse Effects

As usage of cefaclor in animals has been very limited, a comprehensive adverse effect profile has not been determined. In humans, cefaclor is generally well tolerated but commonly can cause gastrointestinal effects (nausea, diarrhea). Hypersensitivity reactions including anaphylaxis are possible; cefaclor appears to cause a higher incidence of serum-sickness-like reactions than other cephalosporins, particularly in children who have received multiple courses of treatment. Rare adverse effects reported include erythema multiforme, rash, increases in liver function tests, and transient increases in BUN and serum creatinine.

### Overdosage/Acute Toxicity

Cefaclor appears quite safe in dogs. Dogs given daily PO doses of 200 mg/kg/day for 30 days developed soft stools and occasional emesis. Two dogs in this study group developed transient moderate decreases in hemoglobin. One dog in another study group that was given 400 mg/kg/day for one year developed a reversible thrombocytopenia.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefaclor and may be of significance in veterinary patients:

- **ANTACIDS (magnesium- or aluminum-containing):** Reduces extent of absorption of extended-release cefaclor tablets
- **PROBENECID:** Reduced renal excretion of cefaclor
- **WARFARIN:** Rare reports of increased anticoagulant effect

### Laboratory Considerations

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) given in high dosages may cause falsely elevated values
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine

### Doses

#### ■ DOGS/CATS:

For susceptible infections:

a) For skin or soft tissue infections: 7 mg/kg PO q8h for 21–30 days.

For systemic, lower respiratory tract infections: 10–13 mg/kg PO q8h for 14 days. Maximum daily dose is 1 gram. (Greene *et al.* 2006)

### Monitoring

- Clinical efficacy
- Patients with renal insufficiency should have renal function monitored

### Client Information

- Preferably should be administered to animal without food; however, if patient vomits or develops a lack of appetite while receiving medication it can be administered with food
- Give as directed by the veterinarian; even if animal appears well, continue treating for the full duration prescribed
- Contact veterinarian if animal develops severe vomiting/diarrhea or rash/itching

### Chemistry/Synonyms

Cefaclor occurs as a white to off-white powder that is slightly soluble in water.

Cefaclor may also be known as: cefaclorum, cefaklor, cefkloras, kefakloori or compound 99638. There are many internationally registered trade names.

### Storage/Stability

Capsules, tablets, and powder for suspension should be stored at room temperature (15–30°C). After reconstituting, the oral suspension should be stored in the refrigerator and discarded after 14 days.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cefaclor Oral Capsules: 250 mg & 500 mg; *Ceclor® Pulvules* (Lilly), generic; (Rx)

Cefaclor Chewable Tablets: 125 mg, 187 mg, 250 mg, & 375 mg; *Raniclor®* (Ranbaxy); (Rx)

Cefaclor Extended-Release Oral Tablets: 375 mg & 500 mg; generic (*Zenith Goldline*); (Rx)

Cefaclor Powder for Oral Suspension: 125 mg/5 mL, 187 mg/5 mL, 250 mg/5 mL, & 375 mg/5 mL; *Ceclor®* (Eli Lilly); generic; (Rx)

---

## CEFADROXIL

(sef-a-drox-ill) Cefa-Drops®, Duricef®

1ST GENERATION CEPHALOSPORIN

### Prescriber Highlights

- Oral 1st generation cephalosporin
- May be administered with food (especially if GI upset occurs)
- Most likely adverse effects are GI in nature
- May need to reduce dose in renal failure
- May be expensive when compared to generic cephalixin

---

## Uses/Indications

Cefadroxil is FDA-approved for oral therapy in treating susceptible infections of the skin, soft tissue, and genitourinary tract in dogs and cats. The veterinary oral tablets have been discontinued (in the USA), but human-labeled oral capsules and tablets are still available.

## Pharmacology/Actions

A first generation cephalosporin, cefadroxil exhibits activity against the bacteria usually covered by this class. First generation cephalosporins are usually bactericidal and act via inhibition of cell wall synthesis.

While there may be differences in MIC's for individual first generation cephalosporins, their spectrums of activity are quite similar. They generally possess excellent coverage against most gram-positive pathogens; variable to poor coverage against most gram-negative pathogens. These drugs are very active *in vitro* against groups A beta-hemolytic and B Streptococci, non-enterococcal group D Streptococci (*S. bovis*), *Staphylococcus intermedius* and *aureas*, *Proteus mirabilis* and some strains of *E. coli*, *Klebsiella* spp., *Actinobacillus*, *Pasturella*, *Haemophilus equigenitalis*, *Shigella* and *Salmonella*. With the exception of *Bacteroides fragilis*, most anaerobes are very susceptible to the first generation agents. Most species of *Corynebacteria* are susceptible, but *C. equi* (*Rhodococcus*) is usually resistant. Strains of *Staphylococcus epidermidis* are usually sensitive to the parenterally administered 1st generation drugs, but may have variable susceptibilities to the oral drugs. The following bacteria are regularly resistant to the 1st generation agents: Group D streptococci/enterococci (*S. faecalis*, *S. faecium*), Methicillin-resistant *Staphylococci*, *indole-positive Proteus* spp., *Pseudomonas* spp., *Enterobacter* spp., *Serratia* spp. and *Citrobacter* spp.

## Pharmacokinetics

Cefadroxil is reportedly well absorbed after oral administration to dogs without regard to feeding state. After an oral dose of 22 mg/kg, peak serum levels of approximately 18.6 micrograms/mL occur within 1–2 hours of dosing. Only about 20% of the drug is bound to canine plasma proteins. The drug is excreted into the urine and has a half-life of about 2 hours. Over 50% of a dose can be recovered unchanged in the urine within 24 hours of dosing.

In cats, the serum half-life has been reported as approximately 3 hours.

Oral absorption of cefadroxil in adult horses after oral suspension was administered was characterized as poor and erratic. In a study done in foals (Duffee, Christensen, and Craig 1989), oral bioavailability ranged from 36–99.8% (mean=58.2%); mean elimination half-life was 3.75 hours after oral dosing.

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Oral systemic antibiotics should not be administered in patients with septicemia, shock or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral routes (preferably IV) should be used for these cases.

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin class antibiotics is controversial. In humans, it is estimated that up

15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, cephalosporins may cause GI effects (anorexia, vomiting, diarrhea). Administering the drug with a small meal may help alleviate these effects. Because the cephalosporins may alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity, at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal.

Cefadroxil or cephalexin may rarely cause tachypnea.

High doses or very prolonged use of cephalosporins have been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Comb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

### Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Cephalosporins can be distributed into milk, but are unlikely to pose much risk to nursing offspring; diarrhea is possible.

### Overdosage/Acute Toxicity

Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefadroxil and may be of significance in veterinary patients:

■ **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives

### Laboratory Considerations

■ Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins

■ When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values

■ In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Combs' test**

■ Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine

### Doses

#### ■ DOGS:

For susceptible infections:

a) 22 mg/kg PO twice daily. Treat skin and soft tissue infections for at least 3 days, and GU infections for at least 7 days. Treat for at least 48 hours after animal is afebrile and asymptomatic. Reevaluate therapy if no response after 3 days of treatment. Maximum therapy is 30 days. (Package Insert; *Cefa-Tabs*®—Fort-Dodge).

b) For susceptible Staph infections: 30 mg/kg PO q12h (may not be adequate dose for non-UTI's caused by *E. coli*) (Campbell & Rosin 1998)

c) For UTI: 11–22 mg/kg PO q12h for 7–30 days

For skin, pyoderma: 22–35 mg/kg PO q12h for 3–30 days

For systemic, orthopedic infections: 22 mg/kg PO q8–12h for 30 days (Greene & Watson 1998), (Greene *et al.* 2006)

d) 10 mg/kg q12h for susceptible gram-positive infections; 30 mg/kg q8h for susceptible gram-negative infections (Aucoin 2000)

e) For canine pyoderma/infectious otitis: 22 mg/kg PO q12h (Kwochka 2003); (Kwochka 2002)

f) For UTI: 10–20 mg/kg PO q8h. For acute urethrocystitis, treatment may be 7–10 days; for chronic urethrocystitis, up to 4 weeks of treatment may be necessary; for pyelonephritis, 4–8 weeks may be adequate (Brovida 2003)

g) For UTI: 30 mg/kg PO q8h (Dowling 2009)

h) For superficial and deep bacterial pyoderma: 22–33 mg/kg PO 2–3 times daily (Beale & Murphy 2006)

#### ■ CATS:

For susceptible infections:

a) For UTI: 22 mg/kg PO once daily for 21 days or less

For skin, pyoderma: 22–35 mg/kg PO q12h for 3–30 days

For systemic, orthopedic infections: 22 mg/kg PO q8–12h for 30 days (Greene & Watson 1998)

b) 10 mg/kg q12h for susceptible gram-positive infections; 30 mg/kg q8h for susceptible gram-negative infections (Aucoin 2000)

c) 22 mg/kg PO q12h (Lappin 2002)

#### ■ FERRETS:

For susceptible infections:

a) 15–20 mg/kg PO twice daily (Williams 2000)

### Monitoring

■ Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.

- Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely performed with these agents.

## Chemistry/Synonyms

A semisynthetic cephalosporin antibiotic, cefadroxil occurs as a white to yellowish-white, crystalline powder that is soluble in water and slightly soluble in alcohol. The commercially available product is available as the monohydrate.

Cefadroxil may also be known as: BL-S578; cefadroxilum, cephadroxil, or MJF-11567-3; many trade names are available.

## Storage/Stability

Cefadroxil tablets, capsules and powder for oral suspension should be stored at room temperature (15–30°C) in tight containers. After reconstitution, the oral suspension is stable for 14 days when kept refrigerated (2–8°C).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Cefadroxil Powder for Oral Suspension: 50 mg/mL in 15 mL and 50 mL btl (orange-pineapple flavor); *Cefa-Drops*® (BIVI) (Rx). FDA-approved for use in dogs and cats.

### HUMAN-LABELED PRODUCTS:

Cefadroxil Oral Tablets: 1 gram; generic; (Rx)

Cefadroxil Oral Capsules: 500 mg; generic; (Rx)

Cefadroxil Powder for Oral Suspension: 125 mg/5 mL, 250 mg/5 mL, & 500 mg/5 mL in 50, 75 (500 mg/5 mL only) & 100 mL; generic; (Rx)

## CEFAZOLIN SODIUM

(sef-a-zoe-lin) Ancef®, Kefzol®, Zolicef®

1ST GENERATION CEPHALOSPORIN

### Prescriber Highlights

- 1st generation parenteral cephalosporin
- Potentially could cause hypersensitivity reactions
- Can cause pain on IM injection; Give IV over 3–5 minutes (or more)
- May need to reduce dose in renal failure

---

## Uses/Indications

In the United States, there are no cefazolin products FDA-approved for veterinary species but it has been used clinically in several species when an injectable, first generation cephalosporin is indicated. It is used for surgical prophylaxis, and for a variety of systemic infections (including orthopedic, soft tissue, sepsis) caused by susceptible bacteria. Most commonly given every 6–8 hours via parenteral routes, cefazolin constant rate intravenous infusion protocols are being developed as cefazolin is a time (above MIC)-dependent antibiotic, and serum/tissue concentrations can remain above MIC.

## Pharmacology/Actions

A first generation cephalosporin, cefazolin exhibits activity against the bacteria usually covered by this class. First generation cephalosporins are usually bactericidal and act via inhibition of cell wall synthesis. They are considered time-dependent antibiotics.

While there may be differences in MIC's for individual first generation cephalosporins, their spectrums of activity are quite similar. They possess generally excellent coverage against most gram-positive pathogens; variable to poor coverage against most gram-negative pathogens. These drugs are very active *in vitro* against groups A beta-hemolytic and B Streptococci, non-enterococcal group D Streptococci (*S. bovis*), *Staphylococcus intermedius* and *aureas*, *Proteus mirabilis* and some strains of *E. coli*, *Klebsiella* spp., *Actinobacillus*, *Pasturella*, *Haemophilus equigenitalis*, *Shigella* and *Salmonella*. With the exception of *Bacteroides fragilis*, most anaerobes are very susceptible to the first generation agents. Most species of Corynebacteria are susceptible, but *C. equi* (Rhodococcus) is usually resistant. Strains of *Staphylococcus epidermidis* are usually sensitive to the parenterally administered 1st generation drugs, but may have variable susceptibilities to the oral drugs. The following bacteria are regularly resistant to the 1st generation agents: Group D streptococci/enterococci (*S. faecalis*, *S. faecium*), Methicillin-resistant Staphylococci, *indole-positive* *Proteus* spp., *Pseudomonas* spp., *Enterobacter* spp., *Serratia* spp. and *Citrobacter* spp.

## Pharmacokinetics

Cefazolin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum levels. Absorbed drug is excreted

unchanged by the kidneys into the urine. Elimination half-lives may be significantly prolonged in patients with severely diminished renal function.

In dogs, peak levels occur in about 30 minutes after IM administration. The apparent volume of distribution at steady state is 700 mL/kg, total body clearance of 10.4 mL/min/kg with a serum elimination half-life of 48 minutes. Approximately 64% of the clearance can be attributed to renal tubular secretion. The drug is approximately 16–28% bound to plasma proteins in dogs.

In horses, the apparent volume of distribution at steady state is 190 mL/kg, total body clearance of 5.51 mL/min/kg with a serum elimination half-life of 38 minutes when given IV and 84 minutes after IM injection (gluteal muscles). Cefazolin is about 4–8% bound to equine plasma proteins. Because of the significant tubular secretion of the drug, it would be expected that probenecid administration would alter the kinetics of cefazolin. One study performed in horses (Donecker, Sams, and Ashcroft 1986), did not show any effect, but the authors concluded that the dosage of probenecid may have been sub-therapeutic in this species.

In calves, the volume of distribution is 165 mL/kg, and had a terminal elimination half-life of 49–99 minutes after IM administration.

### Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Patients in renal failure may need dosage adjustments.

### Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered intramuscularly, although this effect occurs less with cefazolin than with other agents. Sterile abscesses or other severe local tissue reactions are possible but are much less common. Thrombophlebitis is also possible after IV administration of these drugs.

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal.

High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Comb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component. Cefazolin may be more likely than other cephalosporins to cause seizures at very high doses.

### Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Cefazolin is distributed into milk and could potentially alter neonatal gut flora. Use with caution in nursing dams.

### Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible (see Adverse Effects section). Very high doses given IV rapidly could potentially cause seizures.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefazolin and may be of significance in veterinary patients:

■ **NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). Nevertheless, use caution.

■ **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives.

### Laboratory Considerations

■ Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.

■ When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.

■ In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.

■ Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

### Doses

**Note:** If injecting IM, must be injected into a large muscle mass. IV injections should not be given faster than over 3–5 minutes.

#### ■ DOGS:

For susceptible infections:

a) For surgical prophylaxis: Orthopedic procedures: 20 mg/kg IV at induction followed by 20 mg/kg IV every 90 minutes until wound closure; Soft tissue surgery: 20 mg/kg IV at time of surgery followed by a second dose of 20 mg/kg SC 6 hours later (Trepanier 2003)

b) Gram-positive infections: 10 mg/kg IV, or IM q8h; 10–30 mg/kg IV q8h

Gram-negative infections: 30 mg/kg IM or SC; 10–30 mg/kg IV q8h (Aucoin 2000)

c) For sepsis: 20–25 mg/kg IV q4–8h (Hardie 2000)

d) For surgical prophylaxis: 8 mg/kg IV just before and during surgery 1 hour apart or 20–22 mg/kg IV just before and during surgery 2 hours apart.

For systemic infections: 5–25 mg/kg IM or IV q6–8h as long as necessary.

For orthopedic infections: 22 mg/kg IV, IM or SC q6–8h for 7 days or less.

For sepsis, bacteremia: 15–25 mg/kg IV, IM or SC q4–8h for 7 days or less (Greene & Watson 1998)

e) For infections in neonates: 10–30 mg/kg IV or IO (intraosseous) q8h (Kampschmidt 2006)

#### ■CATS:

For susceptible infections:

a) Gram-positive infections: 10 mg/kg IV, or IM q8h; 10–30 mg/kg IV q8h

Gram-negative infections: 30 mg/kg IM or SC; 10–30 mg/kg IV q8h (Aucoin 2000)

b) For surgical prophylaxis: Orthopedic procedures: 20 mg/kg IV at induction followed by 20 mg/kg IV every 90 minutes until wound closure; Soft tissue surgery: 20 mg/kg IV at time of surgery followed by a second dose of 20 mg/kg SC 6 hours later (Trepanier 2003)

c) For sepsis: 20–25 mg/kg IV q4–8h (Hardie 2000)

d) For systemic infections: 33 mg/kg IV, or IM q8–12h as long as necessary (Greene & Watson 1998)

e) 20–25 mg/kg q8h IM or IV (Lappin 2002)

f) For infections in neonates: 10–30 mg/kg IV or IO (intraosseous) q8h (Kampschmidt 2006)

#### ■HORSES:

For susceptible infections:

a) 25 mg/kg IV, IM q6h (Bertone 2003)

b) 25 mg/kg IV, IM q6–8h (Papich 2003)

c) **Foals:** 20 mg/kg IV q8–12h (Caprile & Short 1987); (Brumbaugh 1999)

d) **Neonatal foals:** 15–20 mg/kg IV q8h (Magdesian 2003)

#### ■REPTILES:

For susceptible infections:

a) **Chelonians:** 22 mg/kg IM q24h (Johnson 2002)

### Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

### Chemistry/Synonyms

An injectable, semi-synthetic cephalosporin antibiotic, cefazolin sodium occurs as a practically odorless or having a faint odor, white to off-white, crystalline powder or lyophilized solid. It is freely soluble in water and very slightly soluble in alcohol. Each gram of the injection contains 2 mEq of sodium. After reconstitution, the solution for injection has a pH of 4.5–6 and has a light-yellow to yellow color.

Cefazolin sodium may also be known as: 46083, cefazolinum natrium, cephalozin sodium, or SKF-41558; many trade names are available.

### Storage/Stability

Cefazolin sodium powder for injection and solutions for injection should be protected from light. The powder for injection should be stored at room temperature (15–30°C); avoid temperatures above 40°C. The frozen solution for injection should be stored at temperatures no higher than -20°C.

After reconstitution, the solution is stable for 24 hours when kept at room temperature; 96 hours if refrigerated. If after reconstitution, the solution is immediately frozen in the original container, the preparation is stable for at least 12 weeks when stored at -20°C.

### Compatibility/Compounding Considerations

The following solutions are reportedly **compatible** with cefazolin: Amino acids 4.25%/dextrose 25%, D<sub>5</sub>W in Ringer's, D<sub>5</sub>W in Lactated Ringer's, D<sub>5</sub>W in sodium chloride 0.2%–0.9%, D<sub>5</sub>W, D<sub>10</sub>W, Ringer's Injection, Lactated Ringer's Injection, and normal saline The following drugs are reportedly **compatible with cefazolin when given together at a Y-site**: amiodarone, atracurium, calcium gluconate, famotidine, cyclophosphamide, dexmedetomidine, diltiazem, doxorubicin liposome, heparin, hetastarch, insulin, lidocaine, magnesium sulfate, midazolam, metronidazole, morphine, propofol, ranitidine, vancomycin, vecuronium, verapamil HCl, and vitamin B-complex.

The following drugs or solutions are reportedly **incompatible** or only compatible in specific situations with cefazolin: amikacin sulfate, amobarbital sodium, ascorbic acid injection, bleomycin sulfate, calcium chloride/gluconate, cimetidine HCl, erythromycin gluceptate, kanamycin sulfate, lidocaine HCl, oxytetracycline HCl, pentobarbital sodium, polymyxin B sulfate, tetracycline HCl and vitamin B-complex with C injection.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cefazolin Sodium Powder for Injection: 500 mg, 1 g, 5 g, 10 g, & 20 g in vials & piggyback vials; generic (Apothecon); (Rx)

Cefazolin Sodium for Injection (IV infusion): 1 g; in 50 mL plastic containers, or duplex bags; generic; (Rx)

## CEFEPIME HCL

(sef-eh-pim) Maxipime®

4TH GENERATION CEPHALOSPORIN

### Prescriber Highlights

- **Injectable 4th generation cephalosporin that is more active against some gram-negative & gram-positive bacteria than 3rd generation cephalosporins**
  - **Potentially useful for treating neonatal foals & dogs with serious infections**
  - **Limited clinical experience in veterinary medicine**
  - **Adverse effects most likely seen in small animals or foals would be GI-related (diarrhea)**
  - **Treatment may be very expensive**
- 

### Uses/Indications

Cefepime is a semi-synthetic 4th generation cephalosporin with enhanced activity against many gram-negative and gram-positive pathogens. It potentially may be useful in treating serious infections in dogs or foals particularly when aminoglycosides, fluoroquinolones or other more commonly used beta-lactam drugs are ineffective or contraindicated.

### Pharmacology/Actions

Cefepime, like other cephalosporins, is usually bactericidal and acts by inhibiting cell wall synthesis. It is classified as a 4th-generation cephalosporin, implying increased gram-negative activity (particularly against *Pseudomonas*) and better activity against many gram-positive bacteria than would be seen with the 3rd generation agents. It rapidly penetrates into gram-negative bacteria and targets penicillin-binding proteins (PBPs). Cefepime does not readily induce beta-lactamases and is highly resistant to hydrolysis by them.

Cefepime has activity against many gram-positive aerobes including many species and strains of Staphylococci and Streptococci. It is not clinically effective in treating infections caused by enterococci, *L. monocytogenes*, or methicillin-resistant staphylococci.

Cefepime has good activity against many gram-negative bacteria and has better activity than other cephalosporins against many Enterobacteriaceae including *Enterobacter* spp., *E. coli*, *Proteus* spp. and Klebsiella. Its activity against *Pseudomonas* is similar to, or slightly less than, that of ceftazidime.

Cefepime also has activity against certain atypicals like *Mycobacterium avium-intracellulare* complex.

Some anaerobes are sensitive to cefepime, but *Clostridia* and *Bacteroides* are not.

### Pharmacokinetics

Cefepime is not absorbed from the GI tract and must be administered parenterally. In dogs, cefepime's volume of distribution at steady state is approximately 0.14 L/kg, elimination half-life about 1.1 hours and clearance 0.13 L/kg/hr.

In neonatal foals, cefepime's volume of distribution at steady state is approximately 0.18 L/kg, elimination half-life about 1.65 hours and clearance 0.08 L/kg/hr.

In humans, volume of distribution is about 18 L in adults; 20% of the drug is bound to plasma proteins. Elimination half-life is about 2 hours. Approximately 85% of a dose is excreted unchanged into the urine, less than 1% is metabolized.

### Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. Cefepime is contraindicated in human patients hypersensitive to it or other cephalosporins. Dosage adjustment is recommended in humans with severe renal impairment.

### Adverse Effects

As usage of cefepime in animals has been very limited, a comprehensive adverse effect profile has not been determined.

There are some reports of dogs or foals developing loose stools or diarrhea after receiving cefepime. IM injections may be painful (alleviated by using 1% lidocaine as diluent).

Human patients generally tolerate cefepime well. Injection site inflammation and rashes occur in approximately 1% of treated patients. Gastrointestinal effects (dyspepsia, diarrhea) occur in less than 1% treated patients. Hypersensitivity reactions including anaphylaxis are possible. Rarely, patients with renal dysfunction who have received cefepime without any dosage adjustment will develop neurologic effects (see Overdosage).

### Reproductive/Nursing Safety

Studies performed in pregnant mice, rats, and rabbits demonstrated no overt fetal harm. In humans, the FDA categorizes cefepime as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Cefepime enters maternal milk in very low concentrations. Although probably safe for nursing offspring, the potential for adverse effects cannot be ruled out, particularly alterations to gut flora with resultant diarrhea.

## Overdosage/Acute Toxicity

No specific information was located for acute toxicity in veterinary patients.

Humans with impaired renal function receiving inadvertent overdoses have developed encephalopathy, seizures and neuromuscular excitability.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefepime and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Potential for increased risk of nephrotoxicity—monitor renal function

## Laboratory Considerations

- Cefepime may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**

## Doses

### ■ DOGS:

For susceptible infections:

- a) 40 mg/kg IV q6h (Gardner & Papich 2001)

### ■ HORSES:

For susceptible infections in foals:

- a) 11 mg/kg IV q8h; for gram-negative infections (Gardner & Papich 2001)
- b) 11 mg/kg IV q8h; use has been limited primarily to neonates with poor aminoglycoside kinetics or documented multi-resistant infections (McKenzie 2005)

## Monitoring

- Clinical efficacy
- Monitor renal function in patients with renal insufficiency

## Client Information

- Veterinary professionals only should administer this medication
- Because of the dosing intervals required, this drug is best administered to inpatients only

## Chemistry/Synonyms

Cefepime HCl occurs as a white to off-white, non-hygroscopic powder that is freely soluble in water.

Cefepime may also be known as: BMY-28142, cefepimi, or cefepima; internationally registered trade names include: *Axepime*®, *Biopime*®, *Cefepen*®, *Ceficad*®, *Cemax*®, *Cepim*®, *Cepimix*®, *Forpar*®, *Maxcef*®, *Maxipime*® or *Maxil*®.

## Storage/Stability

The powder for injection should be stored between (2–25°C) and protected from light. Cefepime can be reconstituted and administered with a variety of diluents including normal saline and D5W. Generally, the solution is stable for up to 24 hours at room temperature; up to 7 days if kept refrigerated.

## Compatibility/Compounding Considerations

Drugs that may be admixed with cefepime include: amikacin (but not gentamicin or tobramycin), ampicillin, vancomycin, metronidazole and clindamycin. These admixtures have varying times that they remain stable. For more information on dosage preparation, stability and compatibility, refer to the package insert for *Maxipime*® or contact a hospital pharmacist.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

### **HUMAN-LABELED PRODUCTS:**

Cefepime Powder for Injection: 500 mg, 1 gram & 2 gram in vials, 15 mL & 20 mL vials, ADD-Vantage vials, & 100 mL piggyback bottles; *Maxipime*® (Dura); generic (Apotex USA); (Rx)

Cefepime Injection Solution: 1g & 2 g in 50 mL & 100 mL (respectively) single-dose *Galaxy* containers; generic (Baxter); (Rx)

---

## CEFIXIME

(sef-ix-eem) *Suprax*®

3RD GENERATION CEPHALOSPORIN

### Prescriber Highlights

- Oral 3rd generation cephalosporin that may be useful in dogs; only available commercially (in the USA) as a pediatric oral suspension

- **Contraindications: Hypersensitivity to it or other cephalosporins**
  - **May need to adjust dose if patient has renal disease**
  - **Adverse Effects: Primarily GI, but hypersensitivity possible**
- 

## Uses/Indications

Uses for cefixime are limited in veterinary medicine. Its use should be reserved for those times when infections (systemic or urinary tract) are caused by susceptible gram-negative organisms where oral treatment is indicated or when FDA-approved fluoroquinolones or other 3rd generation cephalosporins (*e.g.*, cefpodoxime) are either contraindicated or ineffective.

## Pharmacology/Actions

Like other cephalosporins, cefixime inhibits bacteria cell wall synthesis. It is considered bactericidal and relatively resistant to bacterial beta-lactamases.

Cefixime's main spectrum of activity is against gram-negative bacteria in the family Enterobacteriaceae (excluding *Pseudomonas*) including *Escherichia*, *Proteus*, and *Klebsiella*. It is efficacious against *Streptococcus*, *Rhodococcus*, and apparently, *Borrelia*. Efficacy for *E. coli* is rapidly decreasing as significant resistance has developed in recent years.

Cefixime is not efficacious against *Pseudomonas aeruginosa*, *Enterococcus*, *Staphylococcus*, *Bordetella*, *Listeria*, *Enterobacter*, *Bacteroides*, *Actinomyces* or *Clostridium*. For other than *Streptococcus* spp., it has limited efficacy against many gram-positive organisms or anaerobes.

Because sensitivity of various bacteria to the 3rd generation cephalosporin antibiotics is unique to a given agent, cefixime specific disks or dilutions must be used to determine susceptibility.

## Pharmacokinetics

Cefixime is relatively rapidly absorbed after oral administration. Bioavailability in the dog is about 50%. Food may impede the rate, but not the extent, of absorption. The suspension may have a higher bioavailability than tablets. The drug is fairly highly bound to plasma proteins in the dog (about 90%). It is unknown if the drug penetrates into the CSF.

Elimination of cefixime is by both renal and non-renal means, but serum half-lives are prolonged in patients with decreased renal function. In dogs, elimination half-life is about 7 hours.

## Contraindications/Precautions/Warnings

Cefixime is contraindicated in patients hypersensitive to it or other cephalosporins. Because cefixime is excreted by the kidneys dosages and/or dosage frequency may need to be adjusted in patients with significantly diminished renal function. Use with caution in patients with seizure disorders and patients allergic to penicillins.

## Adverse Effects

Adverse effects in the dog may include GI distress (vomiting, etc.) and hypersensitivity reactions (urticaria and pruritus, possibly fever).

## Reproductive/Nursing Safety

Cefixime has not been shown to be teratogenic, but should only be used during pregnancy when clearly indicated. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

## Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible (see Adverse Effects section).

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefixime and may be of significance in veterinary patients:

- **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives
- **SALICYLATES:** May displace cefixime from plasma protein binding sites; clinical significance is unclear

## Laboratory Considerations

- Cefixime may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- If using the nitroprusside test for determining **urinary ketones**, cefixime may cause false-positive results.

## Doses

### ■ DOGS:

For susceptible infections:

- a) For infectious endocarditis when documented resistance against or other contraindications for fluoroquinolones and aminoglycosides: 10 mg/kg PO q12h (DeFrancesco 2000)
- b) For UTI: 5 mg/kg PO once to twice daily for 7–14 days  
For respiratory, systemic infections: 12.5 mg/kg PO q12h for 7–14 days. Duration of treatment dependent on chronicity of infection. (Greene & Watson 1998), (Greene *et al.* 2006)
- c) 5 mg/kg PO once to twice a day (Boothe 1999)

### ■ CATS:

For susceptible infections:

a) 5–12.5 mg/kg PO q12h (Lappin 2002)

## Monitoring

- Efficacy
- Adverse effects

## Client Information

- Can be given without regard to meals
- Give as directed for as long as veterinarian recommends, even if patient appears well

## Chemistry/Synonyms

An oral 3rd generation semisynthetic cephalosporin antibiotic, cefixime is available commercially as the trihydrate. Cefixime occurs as a white to slightly yellowish white crystalline powder with a characteristic odor and a pKa of 3.73. Solubility in water is pH dependent. At a pH of 3.2, 0.5 mg/mL is soluble and 18 mg/mL at pH 4.2. The oral suspension is strawberry flavored and after reconstitution has pH of 2.5–4.2.

Cefixime may also be known as: cefiximum, CL-284635, FK-027, FR-17027 and *Suprax*®; many internationally registered trade names are available.

## Storage/Stability

Cefixime powder for suspension should be stored at room temperature in tight containers. After reconstitution of the oral suspension, refrigeration is not required, but it should be discarded after 14 days whether refrigerated or not.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cefixime Powder for Oral Suspension: 100 mg/5 mL in 50 mL, 75 mL & 100 mL, 200 mg/5 mL in 25 mL, 37.5 mL, 50 mL, 75 mL & 100 mL; *Suprax*® (Lupin Pharma); (Rx)

## CEFOTAXIME SODIUM

(sef-oh-taks-eem) Claforan®

3RD GENERATION CEPHALOSPORIN

### Prescriber Highlights

- **3rd generation parenteral cephalosporin**
  - **Potentially could cause hypersensitivity reactions, granulocytopenia, or diarrhea**
  - **Causes pain on IM injection; give IV over 3–5 minutes (or more)**
  - **May need to reduce dose in renal failure**
- 

## Uses/Indications

In the United States, there are no cefotaxime products FDA-approved for veterinary species but it has been used clinically in several species when an injectable 3rd generation cephalosporin may be indicated.

## Pharmacology/Actions

Cefotaxime is a third generation injectable cephalosporin agent and, like other cephalosporins, inhibits bacteria cell wall synthesis. It is usually bactericidal and it is a time-dependent antibiotic. Cefotaxime has a relatively wide spectrum of activity against both gram-positive and gram-negative bacteria. While less active against *Staphylococcus* spp. than the first generation agents, it still has significant activity against those and other gram-positive cocci. Cefotaxime, like the other 3rd generation agents, has extended coverage of gram-negative aerobes particularly in the family *Enterobacteriaceae*, including *Klebsiella* spp., *E. coli*, *Salmonella*, *Serratia marcescens*, *Proteus* spp., and *Enterobacter* spp. Cefotaxime's *in vitro* activity against *Pseudomonas aeruginosa* is variable and results are usually disappointing when the drug is used clinically against this organism. Many anaerobes are also susceptible to cefotaxime including strains of *Bacteroides fragilis*, *Clostridium* spp., *Fusobacterium* spp., *Peptococcus* spp., and *Peptostreptococcus* spp.

Because 3rd generation cephalosporins exhibit specific activities against bacteria, a 30 microgram cefotaxime disk should be used when performing Kirby-Bauer disk susceptibility tests for this antibiotic.

## Pharmacokinetics

Cefotaxime is not appreciably absorbed after oral administration and must be given parenterally to attain therapeutic serum levels. After administration, the drug is widely distributed in body tissues including bone, prostatic fluid (human), aqueous humor, bile, ascitic and pleural fluids. Cefotaxime crosses the placenta and activity

is bound to plasma proteins.

Unlike the first generation cephalosporins (and most 2nd generation agents), cefotaxime will enter the CSF in therapeutic levels (at high dosages) when the patient's meninges are inflamed.

Cefotaxime is partially metabolized by the liver to desacetylcefotaxime which exhibits some antibacterial activity. Desacetylcefotaxime is partially degraded to inactive metabolites by the liver. Cefotaxime and its metabolites are primarily excreted in the urine. Because tubular secretion is involved in the renal excretion of the drug, in several species probenecid has been demonstrated to prolong the serum half-life of cefotaxime.

Pharmacokinetic parameters in certain veterinary species follow: In dogs, the apparent volume of distribution at steady state is 480 mL/kg, and a total body clearance of 10.5 mL/min/kg after intravenous injection. Serum elimination half-lives of 45 minutes when given IV, 50 minutes after IM injection, and 103 minutes after SC injection have been noted. Bioavailability is about 87% after IM injection and approximately 100% after SC injection.

In cats, total body clearance is approximately 3 mL/min/kg after intravenous injection and the serum elimination half-life is about 1 hour. Bioavailability is about 93–98% after IM injection.

### Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Patients in renal failure may need dosage adjustments.

### Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered intramuscularly. Sterile abscesses or other severe local tissue reactions are also possible but are much less common. Thrombophlebitis is also possible after IV administration of these drugs.

Because the cephalosporins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal.

High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Comb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

### Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this cefotaxime as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Most of these agents (cephalosporins) are excreted in milk in small quantities. Modification/alteration of bowel flora with resultant diarrhea is theoretically possible.

### Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems, but other effects are possible (see Adverse effects section).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefotaxime and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).
- **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives

### Laboratory Considerations

- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may cause falsely elevated **17-ketosteroid** values in urine.
- Cefotaxime like most other cephalosporins, may cause a **false-positive urine glucose determination** when using the cupric sulfate solution test (*e.g.*, *Clinitest*®), Benedict's solution or Fehling's solution.

### Doses

#### ■ DOGS:

For susceptible infections:

a) For soft tissue infections: 22 mg/kg IV, IM or SC q8h for 7 days or less or 50 mg/kg IV or IM q12h for 7 days or less.

For orthopedic infections: 20–40 mg/kg IV, IM or SC q6–8h for 7 days or less.

For severe bacteremia: 20–80 mg/kg IV q6h or 10–50 mg/kg IV q4–6h for as long as necessary (Greene & Watson 1998)

b) 25–50 mg/kg IV, IM or SC q8h (Riviere 1989); (Vaden & Papich 1995)

c) For sepsis: 20–80 mg/kg IV, IM q8h (Tellez 2002)

c) For sepsis: 20–80 mg/kg IV, IM q8h (Tello 2002)

d) For CNS infections (spinal cord): 25 mg–50 mg/kg IV, IM q8h (Dickinson 2003)

#### ■CATS:

For susceptible infections:

a) For severe bacteremia: 20–80 mg/kg IV or IM q6h as long as necessary (Greene & Watson 1998)

b) 25–50 mg/kg IV, IM or SC q8h (Vaden & Papich 1995), (Lappin 2002)

c) For sepsis: 20–80 mg/kg IV, IM q8h (Tello 2003)

For CNS infections (spinal cord): 25 mg–50 mg/kg IV, IM q8h (Dickinson 2003)

d) To prevent bacterial colonization of pancreas in cats with severe pancreatitis, anorexia for long periods, or with systemic inflammatory response (SIRS): 50 mg/kg IM q8h (Zoran 2008)

#### ■HORSES:

For susceptible infections:

a) **Foals:** 40 mg/kg IV q6h (Giguere 2003)

b) For meningitis in foals: 40 mg/kg IV 3–4 times a day (Furr 1999)

c) Foals for systemic therapy: 20–30 mg/kg IV or IM q6–8h

**Foals:** As regional perfusion for adjunctive treatment of septic arthritis: 1 gram cefotaxime in 20 mL of saline. Tourniquet above and below joint. Inject antibiotic solution and leave tourniquet in place for 20 minutes. (Stewart 2008)

#### ■BIRDS:

For susceptible infections:

a) For most birds: 50–100 mg/kg IM three times a day; may be used with aminoglycosides, but nephrotoxicity may occur. Reconstituted vial good for 13 weeks if frozen. (Clubb 1986)

b) For bacterial infections, bacterial hepatitis: 75–100 mg/kg IM or IV q4–8h (Oglesbee 2009a), (Oglesbee 2009b)

c) Ratites (young birds): 25 mg/kg IM 3 times daily (Jenson 1998)

d) 75–100 mg/kg IM or IV q4–8h (Hess 2002)

e) 75 mg/kg IM q8h (Tully 2002)

#### ■REPTILES:

For susceptible infections:

a) 20–40 mg/kg IM once daily for 7–14 days (Gauvin 1993)

b) **Chelonians:** 20–40 mg/kg IM q24h (Johnson 2002)

c) Nebulized antibiotic therapy: 100 mg twice daily (Raiti 2003)

#### Monitoring

■ Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.

■ Patients with diminished renal function may require intensified renal monitoring.

#### Chemistry/Synonyms

A semisynthetic, 3rd generation, aminothiazolyl cephalosporin, cefotaxime sodium occurs as an odorless, white to off-white crystalline powder with a pKa of 3.4. It is sparingly soluble in water and slightly soluble in alcohol. Potency of cefotaxime sodium is expressed in terms of cefotaxime. One gram of cefotaxime (sodium) contains 2.2 mEq of sodium.

Cefotaxime sodium may also be known as: cefotaximum natriicum, CTX, HR-756, RU-24756 and *Claforan*®; many other trade names are available internationally.

#### Storage/Stability

Cefotaxime sodium sterile powder for injection should be stored at temperatures of less than 30°C; protected from light. The commercially available frozen injection should be stored at temperatures no greater than -20°C. Depending on storage conditions, the powder or solutions may darken which may indicate a loss in potency. Cefotaxime is not stable in solutions with pH >7.5 (sodium bicarbonate).

#### Compatibility/Compounding Considerations

All commonly used IV fluids and the following drugs are reportedly **compatible** with cefotaxime: clindamycin, metronidazole and verapamil. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### HUMAN-LABELED PRODUCTS:

Cefotaxime Sodium Powder for Injection: 500 mg, 1 g, 2 g, & 10 g in vials, bottles, infusion bottles & *ADD-Vantage* system vials; *Claforan*® (Hoechst Marion Roussel); generic; (Rx)

Cefotaxime Sodium for Injection: 1 g & 2 g in infusion bottles, & premixed, frozen 50 mL; *Claforan*® (Hoechst Marion Roussel); generic (Cura); (Rx)

## CEFOTETAN DISODIUM

(*sef-oh-tee-tan*) Cefotan®

2ND GENERATION CEPHALOSPORIN (CEPHAMYCIN)

### Prescriber Highlights

- **2nd to 3rd generation parenteral cephalosporin (cephamycin) similar to cefoxitin**
  - **Pharmacokinetic profile better and may be more effective against *E. coli* in dogs than cefoxitin**
  - **Contraindications: Hypersensitivity to it or cephalosporins**
  - **Adverse Effects: Unlikely; potentially could cause bleeding**
  - **If severe renal dysfunction, may need to increase time between doses**
- 

### Uses/Indications

Cefotetan may be a reasonable choice for treating serious infections caused by susceptible bacteria, including *E. coli* or anaerobes. It appears to be well tolerated in small animals and may be given less frequently than cefoxitin.

### Pharmacology/Actions

Often categorized as a 2nd or 3rd generation cephalosporin, cefotetan is usually bactericidal and acts by inhibiting mucopeptide synthesis in the bacterial cell wall.

Cefotetan's *in vitro* activity against aerobes include *E. coli*, *Proteus*, *Klebsiella*, *Salmonella*, *Staphylococcus* and most *Streptococcus*. It has efficacy against most strains of the following anaerobes: *Actinomyces*, *Clostridium*, *Peptococcus*, *Peptostreptococcus* and *Propionibacterium*. Many strains of *Bacteroides* are still sensitive to cefotetan.

Cefotetan is generally ineffective against *Pseudomonas aeruginosa* and *Enterococci*.

Because 2nd generation cephalosporins exhibit specific activities against bacteria, a 30-microgram cefoxitin disk should be used when performing Kirby-Bauer disk susceptibility tests for this antibiotic.

### Pharmacokinetics

Cefotetan is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum levels. The drug is well distributed into most tissues, but only has limited penetration into the CSF. Cefotetan is primarily excreted unchanged by the kidneys into the urine via both glomerular filtration (primarily) and tubular secretion. Elimination half-lives may be significantly prolonged in patients with severely diminished renal function.

### Contraindications/Precautions/Warnings

Cephams are contraindicated in patients who have a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented to be hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cephalosporins, carbapenems).

### Adverse Effects

There is little information on the adverse effect profile of this medication in veterinary species, but it appears to be well tolerated. In humans, less than 5% of patients report adverse effects. Because cefotetan contains an N-methylthiotetrazole side chain (like cefoperazone), it may have a greater tendency to cause hematologic effects (*e.g.* hypoprothrombinemia) or disulfiram-like reactions (vomiting, etc.) than other parenteral cephalosporins.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered intramuscularly. Sterile abscesses or other severe local tissue reactions are also possible but are less common. Thrombophlebitis is also possible after IV administration of these drugs.

Even when administered parenterally, cephalosporins may alter gut flora and antibiotic-associated diarrhea or the proliferation of resistant bacteria in the colon (superinfections) can occur.

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal. High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Comb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

### Reproductive/Nursing Safety

Safe use during pregnancy has not been established; use only when justified. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters*)

Cefotetan enters maternal milk in small quantities. Alteration of bowel flora with resultant diarrhea is theoretically possible.

## Overdosage/Acute Toxicity

Unlikely to cause adverse effects, unless massive or chronically overdosed; seizures possible. Treat symptomatically.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefotetan and may be of significance in veterinary patients:

- **ALCOHOL:** A disulfiram reaction is possible
- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).

## Laboratory Considerations

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

## Doses

### ■ DOGS:

For susceptible infections:

a) 30 mg/kg SC q12h (Autran de Morais 2009)

b) For soft tissue infections: 30 mg/kg SC q12h for 7 days or less;

For bacteremia, sepsis: 30 mg/kg IV, SC q8h for as long as required. (Greene *et al.* 2006)

### ■ CATS:

For susceptible infections:

a) For sepsis: 30 mg/kg q5-8h IV (Hardie 2000)

## Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

## Chemistry/Synonyms

A semisynthetic cephamycin similar to cefoxitin, cefotetan disodium occurs as a white to pale yellow, lyophilized powder. It is very soluble in water and alcohol. The injection contains approximately 3.5 mEq of sodium per gram of cefotetan and after reconstitution has a pH of 4–6.5.

Cefotetan Disodium may also be known as: ICI-156834, YM-09330, *Apaccef*®, *Apatef*®, *Cefotan*®, *Ceftenon*®, *Cepan*®, *Darvilen*®, or *Yamatetan*®.

## Storage/Stability

The sterile powder for injection should be stored below 22°C and protected from light. A darkening of the powder with time does not indicate lessened potency. After reconstituting with sterile water for injection, the resultant solution is stable for 24 hours if stored at room temperature, 96 hours if refrigerated, and at least one week if frozen at -20C.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cefotetan Disodium Powder for Solution: 1 g, 2 g, & 10 g in 10 mL & 20 mL vials; generic; (Rx)

---

## CEFOVECIN SODIUM

(sef-oh-vee-sin) *Convenia*®

INJECTABLE LONG-ACTING CEPHALOSPORIN

### Prescriber Highlights

- Long-acting injectable cephalosporin labeled for use in dogs and cats

- **Primary benefit is for patients whose owners have difficulty adhering to an oral dosing regimen or when oral antibiotics are not tolerated or absorbed**

## Uses/Indications

In the USA, cefovecin is FDA-approved for dogs to treat skin infections (secondary superficial pyoderma, abscesses, and wounds) caused by susceptible strains of *Staphylococcus intermedius* and *Streptococcus canis* (Group G) and in cats to treat skin infections (wounds and abscesses) caused by susceptible strains of *Pasteurella multocida*.

In the UK, cefovecin is also labeled for dogs for skin and soft tissue infections caused by *E. coli* and/or *Pasteurella multocida*, for the treatment of urinary tract infections associated with *E. coli* and/or *Proteus* spp., and as adjunctive treatment to mechanical or surgical periodontal therapy of severe infections of the gingival and periodontal tissues associated with *Porphyromonas* spp. and *Prevotella* spp. Also in the UK, cefovecin is labeled for use in cats for skin infections caused by *Fusobacterium* spp., *Bacteroides* spp., *Prevotella oralis*, beta-hemolytic *Streptococci* and/or *Staphylococcus pseudintermedius*, and the treatment of urinary tract infections associated with *E. coli*.

Cefovecin's long half-life in dogs and cats allows a single dose or extended dosing intervals (determined by organism susceptibility and MIC) for treating a variety of infections off-label (in USA).

## Pharmacology/Actions

Cefovecin is a cephalosporin antibiotic, one source describes it as a 3<sup>rd</sup>-generation cephalosporin. Its mechanism of action in susceptible bacteria, like other beta-lactams, is to bind to and disrupt the actions of bacterial transpeptidase and carboxypeptidase thereby interfering with bacterial cell wall synthesis.

Cefovecin is not active against *Pseudomonas* spp. or enterococci and its high protein-binding does not allow it (at labeled doses) to achieve effective serum levels to treat systemic (non-UTI) *E. coli* infections.

## Pharmacokinetics

After SC injection in dogs or cats, cefovecin is completely absorbed. In dogs, peak levels occur about 6 hours after a dose, and in cats, about 2 hours. The drug is highly bound to plasma proteins (98.5% dogs; 99.8% cats) that slowly dissociate giving the drug its long elimination half-life. As cefovecin exhibits non-linear kinetics, an increase in dosage does not proportionally increase the plasma concentration. In the product label the following additional pharmacokinetic values are listed: terminal elimination half-life: 133 ± 16 hours (dog), 166 ± 18 hours (cat), maximum plasma concentration: 121 ± 51 micrograms/mL (dog), 141 ± 12 micrograms/mL (cat); volume of distribution (steady-state): 0.122 ± 0.011 L/kg (dog), 0.09 ± 0.01 L/kg (cat); total body clearance: 0.76 ± 0.13 mL/hr/kg (dog), 0.350 ± 0.40 mL/kg/hr (cat).

Elimination of cefovecin is primarily via renal mechanism and the majority of a dose is excreted unchanged in the urine, but a small amount is excreted unchanged in the bile. Cefovecin is a highly protein-bound molecule in dog plasma (98.5%) and cat plasma (99.8%) and may compete with other highly protein-bound drugs for plasma protein binding sites. Cefovecin may persist in the body for up to 65 days.

## Contraindications/Precautions/Warnings

Cefovecin is contraindicated in animals with a known allergy to cefovecin or to other beta-lactam antibiotics. Anaphylaxis has been reported with the use of this product. Because cefovecin is primarily eliminated via renal mechanisms, use with caution in animals with severe renal dysfunction.

The UK labeling warns against using in small herbivores (Guinea pigs, rabbits).

Safe use in dogs or cats less than 4 months of age has not been established. The UK labeling warns against using in dogs or cats less than 8 weeks old.

## Adverse Effects

In dogs and cats, cefovecin appears to be well tolerated. Pre-marketing (USA) studies in dogs and cats found no significant increases in adverse effect types or rates when compared with control. However, treated animals did have some changes in laboratory values. Several dogs had mild to moderate increases in liver enzymes (GGT, ALT). In treated cats, 4/147 cats had increases (mild) in ALT concentrations, 24/147 had increases in BUN, and 6/147 had moderately elevated serum creatinine values.

In the FDA's Cumulative Veterinary Adverse Drug Experience (ADE) Reports (through November 2010), the most common adverse effects listed (in decreasing order of frequency) are: Dogs: depression/lethargy, anorexia, and vomiting; Cats: anorexia, depression/lethargy, and vomiting. As more experience is gained with this agent, a clearer adverse drug reaction profile is expected.

Hypersensitivity reactions, anaphylaxis and death associated with this drug are possible and have been reported. The manufacturer also states: Occasionally, cephalosporins and NSAIDs have been associated with myelotoxicity, thereby creating a toxic neutropenia. Other hematological reactions seen with cephalosporins include neutropenia, anemia, hypoprothrombinemia, thrombocytopenia, prolonged prothrombin time (PT) and partial thromboplastin time (PTT), platelet dysfunction and transient increases in serum aminotransferases.

Because the drug can persist in the body for up to 65 days, adverse reactions may occur that require prolonged treatment.

## Reproductive/Nursing Safety

The manufacturer states that safe use in breeding or lactating animals has not been determined. However, cephalosporins are generally considered safe to use during pregnancy and lactation and veterinarians and owners can weigh any risks of using the drug versus the benefits to the dam and offspring.

## Overdosage/Acute Toxicity

Acute overdoses should be relatively safe. Dogs administered cefovecin SC up to 180 mg/kg (22.5X) showed only site irritation, vocalization, and edema. Edema resolved within 8–24 hours. Cats given the same dose (22.5X) injection showed the same signs but 10 days post had a lower mean white blood cell counts than controls, and one cat had a small amount of bilirubinuria on day 10.

## Drug Interactions

As cefovecin is so highly bound to plasma proteins it potentially could displace (or be displaced) from plasma protein binding sites by other highly bound agents. The manufacturer reports that in an experimental *in vitro* system, cefovecin demonstrated that it could increase the free (active) concentrations of other highly protein-bound drugs such as **carprofen, furosemide, doxycycline, and ketoconazole**. They caution that concurrent use of these or other drugs that have a high degree of protein binding (*e.g.*, **NSAIDs, propofol, cardiac, anticonvulsant, and behavioral medications**) may compete with cefovecin-binding and cause adverse reactions; actual clinical significance has not been established, however.

## Laboratory Considerations

- Cephalosporins may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) given in high dosages may cause falsely elevated values
- Cephalosporins may cause falsely lowered **albumin** levels when certain tests are used to measure albumin
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine

## Doses

### ■ DOGS:

For labeled indications

a) USA: Skin infections due to *S. intermedius* or *S. canis* (Group G): Administer 8 mg/kg SC once. A second injection (same dose/route) may be administered if response to therapy is not complete 7 days later (for *S. intermedius* infections) and 14 days later for *S. canis* (Group G) infections. Maximum treatment should not exceed 2 injections. (Adapted from label information; *Convenia*®—Pfizer)

b) UK (for indicated organisms see Uses above): Skin and soft tissue infections: 8 mg/kg SC once. If required, treatment may be repeated at 14 day intervals up to a further three times. In accordance with good veterinary practice, treatment of pyoderma should be extended beyond complete resolution of clinical signs.

Severe infections of the gingival and periodontal tissues: 8 mg/kg SC once.

UTI: 8 mg/kg SC once. (Adapted from label information; *Convenia*®—Pfizer UK)

### ■ CATS:

For labeled indications:

a) USA: Skin infections (wounds and abscesses) caused by susceptible strains of *Pasteurella multocida*: 8 mg/kg SC as a single, one-time subcutaneous injection. Therapeutic concentrations are maintained for approximately 7 days for *Pasteurella multocida* infections. (Adapted from label information; *Convenia*®—Pfizer USA)

b) UK (for indicated organisms see Uses above): Skin and soft tissue abscesses and wounds: 8 mg/kg SC once. If required, an additional dose may be administered 14 days after the first injection.

UTI: 8 mg/kg SC once. (Adapted from label information; *Convenia*®—Pfizer UK)

## Monitoring

- Efficacy
- Adverse effects

## Client Information

- Clients should understand that this drug may persist in the body of a treated animal for approximately 2 months after injection and if any occur, report them to the veterinarian.

## Chemistry/Synonyms

Cefovecin sodium is a 3rd-generation cephalosporin antibacterial agent with a molecular weight of 475.5. Each mL of reconstituted lyophilized powder contains cefovecin sodium equivalent to 80 mg of cefovecin; methylparaben 1.8 mg and propylparaben 0.2 mg are added as preservatives, and sodium citrate dihydrate 5.8 mg and citric acid monohydrate 0.1 mg, sodium hydroxide or hydrochloric acid are added to adjust pH.

Cefovecin sodium may also be known as UK-287074-02, cefovecina sodica, céfovécine sodique or natrii cefovecinum. A trade name is *Convenia*®.

## Storage/Stability

Store the powder and the reconstituted product in the original carton, refrigerated at 2°–8°C (36°–46°F). Use the entire contents of the vial within 28 days of reconstitution. Cefovecin is light sensitive; protect from light. After each use return the unused portion back to the refrigerator in the original carton. Color of the solution may vary from clear to amber at reconstitution and may darken over time, but if stored as recommended, solution color does not adversely affect potency.

## Compatibility/Compounding Considerations

To deliver the appropriate dose, aseptically reconstitute vial with 10 mL sterile water for injection. Shake and allow vial to sit until all material is visually dissolved. The resulting solution contains cefovecin sodium equivalent to 80 mg/mL of cefovecin.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Cefovecin Sodium (lyophilized) 800 mg (of cefovecin) per 10 mL multidose vial (80 mg/mL when reconstituted); *Convenia*® (Pfizer); (Rx). FDA-approved as labeled for use in dogs and cats.

**HUMAN-LABELED PRODUCTS:** None

## Prescriber Highlights

- **2nd generation parenteral cephalosporin; effective against anaerobes, including Bacteroides**
  - **Potentially could cause hypersensitivity reactions, thrombocytopenia, & diarrhea**
  - **Causes pain on IM injection; Give IV over 3–5 minutes (or more)**
  - **May need to reduce dose in renal failure**
- 

## Uses/Indications

In the United States, there are no cefoxitin products FDA-approved for veterinary species, but it has been used clinically in several species when an injectable second generation cephalosporin may be indicated.

## Pharmacology/Actions

Although not a true cephalosporin, cefoxitin is usually classified as a 2nd generation agent. Cefoxitin has activity against gram-positive cocci, but less so on a per weight basis than the 1st generation agents. Unlike the first generation agents, it has good activity against many strains of *E. coli*, *Klebsiella* and *Proteus* that may be resistant to the first generation agents. In human medicine, cefoxitin's activity against many strains of *Bacteroides fragilis* has placed it in a significant therapeutic role. While *Bacteroides fragilis* has been isolated from anaerobic infections in veterinary patients, it may not be as significant a pathogen in veterinary species as in humans.

Because 2nd generation cephalosporins exhibit specific activities against bacteria, a 30-microgram cefoxitin disk should be used when performing Kirby-Bauer disk susceptibility tests for this antibiotic.

## Pharmacokinetics

Cefoxitin is not appreciably absorbed after oral administration and must be given parenterally to achieve therapeutic serum levels. The absorbed drug is primarily excreted unchanged by the kidneys into the urine via both tubular secretion and glomerular filtration. In humans, approximately 2% of a dose is metabolized to descarbamylcefoxitin, which is inactive. Elimination half-lives may be significantly prolonged in patients with severely diminished renal function.

In horses, the apparent volume of distribution at steady state is 110 mL/kg, total body clearance of 4.32 mL/min/kg with a serum elimination half-life of 49 minutes.

In calves, the volume of distribution is 318 mL/kg, and it has a terminal elimination half-life of 67 minutes after IV dosing, and 81 minutes after IM administration. Cefoxitin is approximately 50% bound to calf plasma proteins. Probenecid (40 mg/kg) has been demonstrated to significantly prolong elimination half-lives.

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Patients in renal failure may need dosage adjustments.

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Cephalosporins can cause pain at the injection site when administered intramuscularly. Sterile abscesses or other severe local tissue reactions are also possible but are less common. Thrombophlebitis is also possible after IV administration of these drugs.

Even when administered parenterally, cephalosporins may alter gut flora and antibiotic-associated diarrhea or the proliferation of resistant bacteria in the colon (superinfections) can occur.

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal. High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Comb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

## Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Cefoxitin can be distributed into milk in low concentrations. It is unlikely to pose significant risk to nursing offspring.

## Overdosage/Acute Toxicity

Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section).

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefoxitin and may be of significance in veterinary patients:

■ **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity

against certain bacteria when used with aminoglycosides, but they cannot be mixed together (administer separately).

■ **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives.

### Laboratory Considerations

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-KETOSTEROID** values in urine.

### Doses

#### ■ DOGS:

For susceptible infections:

- a) For mixed infections (e.g., aspiration pneumonia, bowel perforation): 30 mg/kg SC q8h; 30 mg/kg IV q4–6h (Trepanier 1999)
- b) For sepsis: 30 mg/kg IV q5h (Hardie 2000)
- c) For soft tissue infections: 30 mg/kg SC q8h or 30 mg/kg IV q5h
  - For bacteremia: 15–30 mg/kg IV, IM SC q6–8h
  - For orthopedic infections: 22 mg/kg IV, IM q6–8hUse for all indications above as long as necessary to control initial infection, then switch to oral drugs for longer therapy. (Greene *et al.* 2006)
- d) 30 mg/kg SC q8h (Autran de Morais 2009)

#### ■ CATS:

For susceptible infections:

- a) For systemic infections: 25–30 mg/kg IV or IM q8h; use for as long as necessary to control initial infection, then switch to oral drugs for longer therapy (Greene *et al.* 2006)
- b) For sepsis: 30 mg/kg IV q5h (Hardie 2000)
- c) 30 mg/kg IV q8h (Vaden & Papich 1995)
- d) For second line treatment of non-tuberculosis mycobacteria (NTM): 30–40 mg/kg IV, IM or SC q6–8h (causes pain on injection with IM or SC) (Gunn-Moore 2008)

#### ■ HORSES:

For susceptible infections:

- a) **Foals:** 20 mg/kg IV q4–6h (Caprile and Short 1987); (Brumbaugh 1999)

### Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring.

### Chemistry/Synonyms

Actually a cephamycin, cefoxitin sodium is a semisynthetic antibiotic that is derived from cephamycin C that is produced by *Streptomyces lactamdurans*. It occurs as a white to off-white, somewhat hygroscopic powder or granules with a faint but characteristic odor. It is very soluble in water and only slightly soluble in alcohol. Each gram of cefoxitin sodium contains 2.3 mEq of sodium.

Cefoxitin may also be known as: MK-306, L-620-388, cefoxitinum, cefoxitina, cefoxitine, *Mefoxin*®, *Mefoxitin*®, *Cefociclin*®, or *Cefoxin*®.

### Storage/Stability

Cefoxitin sodium powder for injection should be stored at temperatures less than 30°C and should not be exposed to temperatures greater than 50°C. The frozen solution for injection should be stored at temperatures no higher than -20°C.

After reconstitution, the solution is stable for 24 hours when kept at room temperature and from 48 hours to 1 week if refrigerated. If after reconstitution the solution is immediately frozen in the original container, the preparation is stable up to 30 weeks when stored at -20°C. Stability is dependent on the diluent used and the reader should refer to the package insert or other specialized references for more information. The powder or reconstituted solution may darken but this apparently does not affect the potency of the product.

### Compatibility/Compounding Considerations

All commonly used IV fluids and the following drugs are reportedly **compatible** with cefoxitin: amikacin sulfate, cimetidine HCl, gentamicin sulfate, kanamycin sulfate, mannitol, metronidazole, multivitamin infusion concentrate, sodium bicarbonate, tobramycin sulfate and vitamin B-complex with C. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### **HUMAN-LABELED PRODUCTS:**

Cefoxitin Sodium Powder for Injection: 1 g, 2 g, & 10 g in vials & infusion bottles; generic (American Pharmaceutical Partners); (Rx)

### References

---

## CEFPODOXIME PROXETIL

(sef-poe-docks-see) Simplicef®, Vantin®

3RD GENERATION CEPHALOSPORIN

### Prescriber Highlights

- Oral 3rd generation cephalosporin that may be useful in dogs or cats
  - Contraindications: Hypersensitivity to it or other cephalosporins
  - May need to adjust dose if patient has renal disease
  - Adverse Effects: Primarily GI, but hypersensitivity possible
- 

### Uses/Indications

In dogs, cefpodoxime is indicated for the treatment of skin infections caused by *Staphylococcus intermedius*, *Staphylococcus aureus*, *Streptococcus canis*, *E. coli*, *Proteus mirabilis*, and *Pasteurella multocida*. Although not currently FDA-approved for cats, it may also be useful as well.

### Pharmacology/Actions

Like other cephalosporins, cefpodoxime inhibits bacterial cell wall synthesis. It is considered bactericidal and relatively resistant to bacterial beta-lactamases.

Cefpodoxime's main spectrum of activity is against gram-negative bacteria in the family *Enterobacteriaceae* (excluding *Pseudomonas*) including *Escherichia*, *Proteus*, and *Klebsiella*, and gram-positive streptococci (not enterococcus) and *Staphylococci*.

Cefpodoxime is not efficacious against *Pseudomonas aeruginosa*, *Enterococcus*, anaerobes, and methicillin-resistant *Staphylococcus* strains.

Because sensitivity of various bacteria to the 3rd generation cephalosporin antibiotics is unique to a given agent, cefpodoxime specific disks or dilutions must be used to determine susceptibility.

### Pharmacokinetics

Cefpodoxime proxetil is not active as an antibiotic. Cefpodoxime is active after the proxetil ester is cleaved *in vivo*. After single oral doses (10 mg/kg) to fasted dogs, bioavailability is approximately 63%; volume of distribution 150 mL/kg; peak concentrations about 16 mg/mL; time to peak was 2.2 hours; and terminal elimination half-life of approximately 5–6 hours.

In humans, cefpodoxime proxetil is about 40–50% absorbed from the GI tract. Food can alter the rate, but not the extent, of absorption. Cefpodoxime penetrates most tissues well; it is unknown if it penetrates into the CSF. The drug is eliminated in both the urine and feces. Serum half-life may be prolonged in patients with impaired renal function.

In foals after an oral dose (suspension) of 10 mg/kg, peak levels occur in about 100 minutes and peak at about 0.8 micrograms/mL. Elimination half-life is about 7 hours in foals. Levels in synovial and peritoneal fluids were similar to those found in the serum, but no drug was detected in the CSF.

### Contraindications/Precautions/Warnings

Cefpodoxime is contraindicated in patients hypersensitive to it or other cephalosporins. Because cefpodoxime is excreted by the kidneys, dosages and/or dosage frequency may need to be adjusted in patients with significantly diminished renal function. Use with caution in patients with seizure disorders.

### Adverse Effects

Although usage of this drug in veterinary patients remains limited to date, it appears to be tolerated very well. The most likely adverse effects seen with this medication have been inappetence, diarrhea, and vomiting. Hypersensitivity reactions are a possibility.

Cefpodoxime may occasionally induce a positive direct Coombs' test. Rarely, blood dyscrasias may be seen following high doses of cephalosporins.

### Reproductive/Nursing Safety

Cefpodoxime has not shown to be teratogenic but should only be used during pregnancy when clearly indicated. The veterinary product is labeled: "The safety of cefpodoxime proxetil in dogs used for breeding, pregnant dogs, or lactating bitches has not been demonstrated." In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

The drug enters maternal milk in low concentrations. Modification/alteration of bowel flora with resultant diarrhea is theoretically possible.

### Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems but other effects are possible (see Adverse effects section).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefpodoxime and may be of significance in veterinary patients:

■ **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with

cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephalexin (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).

- **ANTACIDS:** Drugs that can increase stomach pH may decrease the absorption of the drug
- **H-2 ANTAGONISTS (ranitidine, famotidine, etc.):** Drugs that can increase stomach pH may decrease the absorption of the drug
- **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives
- **PROTON PUMP INHIBITORS (e.g., omeprazole):** Drugs that can increase stomach pH may decrease the absorption of the drug

### Laboratory Considerations

- Cefpodoxime may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- If using the nitroprusside test for determining **urinary ketones**, cefpodoxime may cause false-positive results.

### Doses

#### ■ DOGS:

- a) For susceptible skin infections: 5–10 mg/kg PO once daily. Should be administered for 5–7 days or 2–3 days beyond cessation of clinical signs, up to a maximum of 28 days. Treatment of acute infections should not be continued for more than 3–4 days if no response to therapy is seen. May be given with or without food. (Label information; *Simplicef*®—Pfizer)

#### ■ CATS:

- a) For susceptible skin and soft tissue infections: 5 mg/kg PO q12h or 10 mg/kg PO once daily (**Note:** Extrapolated from human dosage) (Greene & Watson 1998)

#### ■ HORSES:

- a) Foals (neonates) with bacterial infections: 10 mg/kg PO q6-12 hours. Additional studies required to confirm clinical efficacy and safety. (Carrillo *et al.* 2005)

### Monitoring

- Clinical efficacy

### Client Information

- Can be given without regard to meals (in humans presence of food enhances absorption).
- Give as directed for as long as veterinarian recommends, even if patient appears well.

### Chemistry/Synonyms

An orally administered semisynthetic 3rd generation cephalosporin, cefpodoxime proxetil is a prodrug that is hydrolyzed *in vivo* to cefpodoxime. The esterified form (proxetil) enhances lipid solubility and oral absorption.

Cefpodoxime proxetil may also be known as: CS-807; R-3763, U-76252, U-76253, *Banan*®, *Biocef*®, *Cefodox*®, *Cepodem*®, *Garia*®, *Instana*®, *Kelbium*®, *Orelox*®, *Otreon*®, *Podomexef*®, *Simplicef*®, or *Vantin*®.

### Storage/Stability

Tablets and unconstituted powder should be stored at 20–25°C in well-closed containers. After reconstitution, the oral suspension should be stored in the refrigerator and discarded after 14 days.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Cefpodoxime Proxetil Tablets: 100 mg & 200 mg; *Simplicef*® (Pfizer); (Rx). FDA-approved for use in dogs.

#### HUMAN-LABELED PRODUCTS:

Cefpodoxime Proxetil Oral Tablets: 100 mg & 200 mg; *Vantin*® (Pharmacia & Upjohn), generic (Aurobindo); (Rx)

Cefpodoxime Proxetil Granules for Suspension, Oral: 50 mg/5 mL & 100 mg/5 mL in 50 mL, 75 mL & 100 mL bottles; *Vantin*® (Pharmacia & Upjohn), generic (Aurobindo); (Rx)

## CEFTAZIDIME

(sef-taz-i-deem) Ceptaz®, Fortaz®, Tazicef®

### 3RD GENERATION CEPHALOSPORIN

#### Prescriber Highlights

- 3rd generation cephalosporin used parenterally for gram-negative infections
- Particularly useful in reptiles

- Could cause hypersensitivity reactions, granulocytopenia, thrombocytopenia, diarrhea, mild azotemia
  - May cause pain on IM injection; SC injection probably less painful
  - May need to reduce dose in renal failure; use with caution
  - Check drug-lab interactions
- 

### Uses/Indications

Ceftazidime is potentially useful in treating serious gram-negative bacterial infections particularly against susceptible Enterobacteriaceae including *Pseudomonas aeruginosa*, that are not susceptible to other, less-expensive agents, or when aminoglycosides are not indicated (due to their potential toxicity). It is of particular interest for treating gram-negative infections in reptiles due to a very long half-life.

### Pharmacology/Actions

Ceftazidime is a third generation injectable cephalosporin agent. It is bactericidal and acts via its inhibition of enzymes responsible for bacterial cell wall synthesis. The third generation cephalosporins retain much of the gram-positive activity of the first and second generation agents, but, have much expanded gram-negative activity. As with the 2nd generation agents, enough variability exists with individual bacterial sensitivities that susceptibility testing is necessary for most bacteria. Ceftazidime is considered an anti-pseudomonal cephalosporin, but resistance development is an issue. A European study (Seol *et al.* 2002) looking at antibiotic susceptibility of *Pseudomonas aeruginosa* isolates obtained from dogs, demonstrated that 77% of strains tested were sensitive to ceftazidime.

### Pharmacokinetics

Ceftazidime is not appreciably absorbed after oral administration. In dogs after SC injection, the terminal half-life of ceftazidime was 0.8 hours; a 30 mg/kg dose was above the MIC for *Pseudomonas aeruginosa* for 4.3 hours. When administered as a 4.1 mg/kg/hr constant rate infusion (after a loading dose of 4.4 mg/kg), mean serum concentration was above 165 micrograms/mL. The authors concluded that either dosage regimen would be appropriate treatment for infections in dogs caused by *Pseudomonas aeruginosa* (Moore *et al.* 2000). Ceftazidime is widely distributed throughout the body, including into bone and CSF and is primarily excreted unchanged by the kidneys via glomerular filtration. As renal tubular excretion does not play a major role in the drug's excretion probenecid does not affect elimination kinetics.

### Contraindications/Precautions/Warnings

Only prior allergic reaction to cephalosporins contraindicates ceftazidime's use. In humans documented hypersensitive to penicillin, up to 16% may also be allergic to cephalosporins; veterinary significance is unclear.

Because the drug is primarily excreted via the kidneys, accumulation may result in patients with significantly impaired renal function; use with caution and adjust dose as required.

### Adverse Effects

Because veterinary usage of ceftazidime has been very limited, a full adverse effect profile has not been determined for veterinary patients. Gastrointestinal effects have been reported in dogs that have received the drug subcutaneously. When given IM, pain may be noted at the injection site; pain on injection could also occur after SC administration in animals.

Hypersensitivity reactions and gastrointestinal signs have been reported in humans and may or may not apply to veterinary patients. Pseudomembranous colitis (*C. difficile*) may occur with this antibiotic. Increased serum concentrations of liver enzymes have been described in 1–8% of human patients given ceftazidime.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) No teratogenic effects were demonstrated in studies in pregnant mice and rats given up to 40X labeled doses of ceftazidime.

Because of the drug's low absorbability, it is unlikely to be harmful to nursing offspring, but alterations to GI flora of nursing animals could occur.

### Overdosage/Acute Toxicity

An acute overdose in patients with normal renal function is unlikely to be of great concern; but in humans with renal failure, overdosage of ceftazidime has caused seizures, encephalopathy, coma, neuromuscular excitability, asterixis, and myoclonia. Treatment of signs associated with overdose is primarily symptomatic and supportive. Hemodialysis could be used to enhance elimination.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftazidime and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).
- **CHLORAMPHENICOL:** May be antagonistic to the ceftazidime's effects on gram-negative bacilli; concurrent use is not recommended

### Laboratory Considerations

- Ceftazidime, like most other cephalosporins, may cause a **false-positive urine glucose** determination when using the cupric sulfate solution test (*e.g.*, Clinitest®).
- In humans, ceftazidime rarely causes positive direct antiglobulin (**Coombs'**) tests and increased **prothrombin times**.
- When using Kirby-Bauer disk diffusion procedures for testing susceptibility, a specific 30 microgram ceftazidime disk should be used. An inhibition zone of 18 mm indicates susceptibility to ceftazidime. MICs of 15, 17, 20, 25, 31, 39, 49, and 62 µg/mL have been reported. When using diffusion methods, ceftazidime should be used with a MIC of 8 µg/mL.

or more indicates susceptibility; 15–17 mm, intermediate; and 14 mm or less, resistant. When using a dilution susceptibility procedure, an organism with a MIC of 8 micrograms/mL or less is considered susceptible; 16 micrograms/mL intermediate; and 32 micrograms/mL or greater is resistant. With either method, infections caused by organisms with intermediate susceptibility may be effectively treated if the infection is limited to tissues where the drug concentrates, or when a higher than normal dose is used.

## Doses

### ■ DOGS:

- For initial antibiotic therapy of gram-negative infections: 25 mg/kg IM or SC q8–12h (Kruth 1998)
- For initial treatment of orthopedic infections: 25 mg/kg IV, IM q8–12h;  
For initial treatment of soft tissue infections: 30–50 mg/kg IV, IM q8–12h;  
For initial treatment of sepsis, bacteremia: 15–30 mg/kg IV, IM q6–8h. (Greene & Watson 1998)

### ■ CATS:

- For initial treatment of systemic infections: 25–30 mg/kg IV, IM or intraosseous q8–12h (Greene & Watson 1998)

### ■ REPTILES:

- For susceptible infections: 20 mg/kg IM or SC q72hours (every 3 days). (Lewbart 2001)
- For bacterial infections in snakes, particularly when Enterobacteriaceae or *Pseudomonas aeruginosa* are confronted: 20 mg/kg IM q72h at 30°C. (Klingenberg 1996), (Johnson, R. 2008)
- For chelonians: 50 mg/kg IM q24h (Johnson, J. 2002)

## Monitoring

- Efficacy
- Baseline renal function

## Client Information

- Clients may be instructed to administer this drug SC for outpatient therapy. Be certain they understand the storage and stability issues before dispensing.

## Chemistry/Synonyms

A semi-synthetic, third-generation cephalosporin antibiotic, ceftazidime occurs as a white to cream-colored crystalline powder that is slightly soluble in water (5 mg/mL) and insoluble in alcohol, chloroform and ether. The pH of a 0.5% solution in water is between 3 and 4.

Ceftazidime may also be known as ceftazidimum, GR-20263, or LY-139381, *Fortaz*®, *Ceptaz*®, *Tazicef*®, and *Tazidime*®; there are many international trade names.

## Storage/Stability

Commercially available powders for injection should be stored at 15–30°C (59–86°F) and protected from light. The commercially available frozen ceftazidime for injection should be stored at temperatures no higher than –20°C (–4°F).

The commercial products containing the sodium carbonate (*Fortaz*®, *Tazicef*®, *Tazidime*®) all release carbon dioxide (effervesce) when reconstituted and are supplied in vials under negative pressure; do not allow pressure to normalize before adding diluent. The product containing arginine (*Ceptaz*®), does not effervesce.

Once reconstituted, the solution retains potency for 24 hours (18 hours for arginine formulation) at room temperature and 7 days when refrigerated. Solutions frozen in the original glass vial after reconstitution with sterile water are stable for 3 months when stored at –20°C (–4°F). While no stability data was located, veterinarians have anecdotally reported efficacy when individual dosages are frozen in plastic syringes. Once thawed, they should not be refrozen. Thawed solutions are stable for 8 hours at room temperature and 4 days when refrigerated.

## Compatibility/Compounding Considerations

Ceftazidime is **compatible** with the following diluents when being prepared for IM (or SC) injection: sterile or bacteriostatic water for injection, 0.5% or 1% lidocaine. Once reconstituted it is **compatible** with the more commonly used IV fluids, including: D5W, normal saline or half-normal saline, Ringer's, or lactated Ringer's.

Do not use sodium bicarbonate solution for a diluent; it is not recommended to mix with aminoglycosides, vancomycin or metronidazole.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Ceftazidime Powder for Injection: 500 mg, 1 g, 2 g, & 6 g in 20 mL & 100 mL vials, infusion packs, *ADD-Vantage* vials & piggyback vials; *Fortaz*® & *Ceptaz*® (GlaxoWellcome); *Tazicef*® (Hospira); *Tazidime*® (Eli Lilly); (Rx)

Ceftazidime Injection: 1 g & 2 g premixed, frozen in 50 mL *Fortaz*® (GlaxoWellcome); 1 & 2 g in *Galaxy* containers; *Tazicef*® (Hospira); (Rx)

## Prescriber Highlights

- **Veterinary-only 3rd generation cephalosporin labeled for use in cattle, horses & swine**
  - **Potentially could cause hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea**
  - **Administered SC at the posterior aspect of ear in cattle; administered IM in swine**
  - **Shake well prior to use**
- 

## Uses/Indications

In beef, lactating and non-lactating cattle, ceftiofur crystalline free acid (CCFA) is labeled for the treatment of bovine respiratory disease (BRD, shipping fever, pneumonia) associated with *Mannheimia haemolytica*, *Pasteurella multocida*, and *Histophilus somni* and for the control of respiratory disease in cattle at high risk of developing BRD associated with *M. haemolytica*, *P. multocida*, and *H. somni*. It is also indicated for the treatment of foot rot (interdigital necrobacillosis) associated with *Fusobacterium necrophorum* and *Porphyromonas levii*.

In swine, ceftiofur CFA is labeled for the treatment of swine respiratory disease (SRD) associated with *Actinobacillus pleuropneumoniae*, *Pasteurella multocida*, *Haemophilus parasuis*, and *Streptococcus suis*.

In horses, ceftiofur CFA is FDA-approved for the treatment of lower respiratory tract infections caused by susceptible strains of *Streptococcus equi* ssp. *zooepidemicus*.

## Pharmacology/Actions

Ceftiofur is a 3rd generation cephalosporin antibiotic active against a variety of gram-positive and gram-negative bacteria and like other cephalosporins, inhibits bacteria cell wall synthesis; it is usually bactericidal and is a time-dependent antibiotic.

After administration, the parent compound (ceftiofur) is rapidly cleaved into furoic acid and desfuroylceftiofur (active). Desfuroylceftiofur inhibits cell wall synthesis (at stage three) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime. Parent ceftiofur and the primary metabolite are equally potent and assays to measure microbial sensitivity (plasma and tissue levels) are based on ceftiofur equivalents referred to as CE. The protein binding activity of ceftiofur creates a “reservoir effect” to maintain active levels at the site of infection.

In cattle, ceftiofur has a broad range of *in vitro* activity against a variety of pathogens including many species of *Pasteurella*, *Streptococcus*, *Staphylococcus*, *Salmonella*, and *E. coli*.

In Swine, ceftiofur CFA at a single IM dosage of 2.27 mg/lb (5 mg/kg) BW provides concentrations of ceftiofur and desfuroylceftiofur-related metabolites in plasma that are multiples above the MIC<sub>90</sub> for an extended period of time for the swine respiratory disease (SRD) label pathogens *Actinobacillus pleuropneumoniae*, *Pasteurella multocida*, *Haemophilus parasuis* and *Streptococcus suis*.

## Pharmacokinetics

In cattle, subcutaneous administration of ceftiofur CFA, in the middle third of the posterior aspect of the ear (middle third of the ear) of beef and non-lactating dairy cattle, or in the posterior aspect of the ear where it attaches to the head (base of the ear) of beef, non-lactating dairy, and lactating dairy cattle, provides therapeutic concentrations of ceftiofur and desfuroylceftiofur-related metabolites in plasma above the MIC<sub>90</sub> for the bovine respiratory disease (BRD) label pathogens, *Pasteurella multocida*, *Mannheimia haemolytica* and *Histophilus somni* for generally not less than 150 hours after single administration.

Pharmacokinetic studies indicate that base of ear administrations (BOE) in dairy cattle are consistent with middle of ear (MOE) administration in beef cattle with blood levels at therapeutic threshold within 2 hours of administration at labeled doses.

The systemic safety of ceftiofur concentrations resulting from product administration at the base of the ear was established via a pharmacokinetic comparison of the two routes of administration (base of the ear versus middle third of the ear). Based upon the results of this relative bioavailability study, the two routes of administration are therapeutically equivalent.

In swine, therapeutic plasma levels for the parent compound and primary metabolite, desfuroylceftiofur, are reached within 1 hour of treatment. Plasma levels remained above the MIC for nearly 100% of target swine respiratory disease (SRD) pathogens for an average of 8 days.

In horses, ceftiofur CFA at 6.6 mg/kg IM is relatively slowly absorbed and eliminated. After the first dose the time to peak serum level is about 22 hours and after a second dose 96 hours apart from the first, time to peak was about 16 hours. When dosed at this regimen the drug and its active metabolites stay above the determined therapeutic concentration (0.2 micrograms/mL) for susceptible strains of *Streptococcus equi* spp. *zooepidemicus* for 10 days.

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., penicillins, cefamycins, carbapenems).

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Avoid direct contact of the product with the skin, eyes, mouth and clothing. Sensitization of the skin may be avoided by wearing latex gloves. Persons with a known hypersensitivity to penicillin or cephalosporins should avoid exposure to this product.

Administration of ceftiofur free acid into the ear arteries is likely to result in sudden death in cattle.

Following label use as a single treatment in cattle, slaughter withdrawal time = 13 days and zero day (no) milk discard time. Extra-label drug use may result in violative residues. A withdrawal period has not been established for this product in pre-ruminating calves; do not use in calves to be processed for veal.

In swine, slaughter withdrawal is 14 days. A maximum of 2 mL of formulation should be injected at each injection site. Injection volumes in excess of 2 mL may result in violative residues.

In horses, the manufacturer warns that if acute diarrhea is observed after dosing, additional doses should not be administered and appropriate therapy should be initiated. Use has not been evaluated in horses less than 4 months of age and inbreeding, pregnant, or lactating horses. The long-term effects on injection sites have not been evaluated. Additionally the manufacturer warns that due to the extended exposure in horses, based on the drug's pharmacokinetic properties, adverse reactions

may require prolonged care. Approximately 17 days are needed to eliminate 97% of the dose from the body. Animals experiencing adverse reactions may need to be monitored for this duration of time.

### Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence, but cephalosporins can cause allergic reactions in sensitized individuals. Topical exposures to such antimicrobials, including ceftiofur, may elicit mild to severe allergic reactions in some individuals. Repeated or prolonged exposure may lead to sensitization.

In cattle, administration of ceftiofur free acid into the ear arteries is likely to result in sudden death. Following SC injection in the middle third of the posterior aspect of the ear, thickening and swelling (characterized by aseptic cellular infiltrate) of the ear may occur. As with other parenteral injections, localized post-injection bacterial infections may result in abscess formation; attention to hygienic procedures can minimize occurrence. Following SC injections at the posterior aspect of the ear where it attaches to the head (base of the ear), areas of discoloration and signs of inflammation may persist at least 13 days post administration resulting in trim loss of edible tissue at slaughter. Injection of volumes greater than 20 mL in the middle third of the ear, may result in open draining lesions in a small percentage of cattle.

In horses, ceftiofur CFA may cause swelling at the injection site and diarrhea, soft or loose stools.

### Reproductive/Nursing Safety

The manufacturer states that the effects of ceftiofur on bovine reproductive performance, pregnancy, and lactation have not been determined and the safety of ceftiofur has not been demonstrated for pregnant swine or swine intended for breeding. However, cephalosporins as a class are relatively safe to use during pregnancy, and teratogenic or embryotoxic effects would not be anticipated.

Target animal safety studies report administration of a single dose of ceftiofur free acid at the base of the ear to high-producing dairy cattle did not adversely affect milk production compared to untreated controls. Ceftiofur in maternal milk would unlikely pose significant risk to offspring.

### Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section). Use of dosages in excess of 6.6 mg ceftiofur equivalents (CE)/kg or administration by unapproved routes in cattle (subcutaneous injection in the neck or intramuscular injection) may cause violative residues. Dosages in excess of 5 mg ceftiofur equivalents (CE)/kg or administration by an unapproved route in swine may result in illegal residues in edible tissues. Contact FARAD (see appendix) for assistance in determining appropriate withdrawal times in circumstances where the drug has been used at higher than labeled dosages.

### Drug Interactions

Although the manufacturer does not list any drug interactions on the label for ceftiofur, the following drug interactions have either been reported or are theoretical in humans or animals receiving injectable 3rd generation cephalosporins and may be of significance in veterinary patients receiving ceftiofur:

- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).
- **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins, thereby increasing serum levels and serum half-lives

### Laboratory Considerations

**Note:** Ceftiofur is structurally similar to cefotaxime and it is not known if these interactions occur with ceftiofur.

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

### Doses

#### ■ CATTLE:

**Beef and lactating cattle treatment dose:** Administer as a single SC injection in the posterior aspect of the ear where it attaches to the head at the *base of the ear* to cattle at 3 mg per lb (6.6 mg ceftiofur equivalents per kg) body weight (1.5 mL sterile suspension per 100 lb body weight). The approved site of injection in lactating dairy cattle is at the base of the ear (BOE). (*Excede*® *Sterile Suspension*; Package Insert—Pfizer)

**Beef and non-lactating dairy cattle treatment dose:** Administer as a single SC injection in the *middle third* of the posterior aspect of the ear at a dosage of 6.6 mg ceftiofur equivalents/kg body weight (1.5 mL sterile suspension per 100 lb body weight).

Most animals will respond to treatment within 3–5 days. If no improvement is observed, the diagnosis should be reevaluated. Administration of ceftiofur free acid into the ear arteries is likely to result in sudden death in cattle.

**Beef and non-lactating dairy cattle control dose:** Administer as a SC injection either in the middle third of the posterior aspect of the ear or in the posterior aspect of the ear where it attaches to the head (base of the ear) to beef and non-lactating dairy cattle at a dosage of 6.6 mg ceftiofur equivalents (CE)/kg body weight (1.5 mL sterile suspension per 100 lb body weight). See package insert for graphics depicting locations of injection and anatomical landmarks to avoid. (*Excede*® *Sterile Suspension*; Package Insert—Pfizer)

#### ■ SWINE:

Administer by IM injection in the post-auricular region of the neck as a single dosage of 2.27 mg ceftiofur equivalents (CE) per lb (5 mg CE/kg) body weight (BW). This is equivalent to 1 mL sterile suspension per 44 lb (20 kg) BW. No more than 2 mL should be injected in a single injection site

Injection volumes in excess of 2 mL may result in violative residues. Pigs heavier than 88 lb (40 kg) will require more than one injection.

Most animals will respond to treatment within 3–5 days. If no improvement is observed, the diagnosis should be reevaluated. (*Excede*® *For Swine*; Package Insert—Pfizer)

**HORSES:**

For lower respiratory tract infections caused by susceptible strains of *Streptococcus equi* ssp. *zooepidemicus*: 6.6 mg/kg IM; repeat in 4 days. A maximum of 20 mL per injection site may be administered. Shake well before using. (*Excede® Sterile Suspension*; Package Insert—Pfizer)

**Monitoring**

Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required. Some clinicians recommend weekly CBC monitoring of small animals receiving ceftiofur. Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

**Chemistry/Synonyms**

Ceftiofur CFA has a molecular weight of 523.58.

Ceftiofur may also be known as CM-31916, ceftiofuri, or *Excede®*.

**Storage/Stability**

Ceftiofur CFA cattle and swine products should be stored at controlled room temperature 20–25 °C (68–77°F). Shake well before using. Contents should be used within 12 weeks after the first dose is removed.

**Dosage Forms/Regulatory Status****VETERINARY-LABELED PRODUCTS:**

Ceftiofur Crystalline Free Acid equivalent to 200 mg/mL ceftiofur (in a *Miglyol®* cottonseed oil based suspension) in 100 mL vials; *Excede®* (Pfizer). FDA-approved for use in beef, lactating and non-lactating cattle. If used in an extra-label manner, contact FARAD (see appendix) for guidance in determining withdrawal times for milk or meat.

Ceftiofur Crystalline Free Acid equivalent to 100 mg/mL ceftiofur (in a *Miglyol®* cottonseed oil based suspension) in 100 mL vials; *Excede® for Swine* (Pfizer);

**HUMAN-LABELED PRODUCTS:** None

**CEFTIOFUR HCL**

(sef-tee-oh-fur) Excenel®, Spectramast®

3RD GENERATION CEPHALOSPORIN

**Prescriber Highlights**

- A veterinary-only 3rd generation cephalosporin
- Potentially could cause hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea
- Causes pain on IM injection to small animals
- May need to reduce dose in renal failure

**Uses/Indications**

In swine, ceftiofur HCl injection is labeled for the treatment and control of swine bacterial respiratory disease (swine bacterial pneumonia) associated with *Actinobacillus (Haemophilus) pleuropneumoniae*, *Pasteurella multocida*, *Salmonella choleraesuis* and *Streptococcus suis*.

In cattle, ceftiofur HCl is labeled for the treatment of the following bacterial diseases: Bovine respiratory disease (BRD, shipping fever, pneumonia) associated with *Mannheimia haemolytica*, *Pasteurella multocida*, and *Histophilus somni*; Acute bovine interdigital necrobacillosis (foot rot, pododermatitis) associated with *Fusobacterium necrophorum* and *Bacteroides melaninogenicus*; and acute metritis (0–14 days post-partum) associated with bacterial organisms susceptible to ceftiofur.

The intramammary syringe for dry dairy cattle (*Spectramast DC®*) is labeled for the treatment of subclinical mastitis in dairy cattle at the time of dry off associated with *Staphylococcus aureus*, *Streptococcus dysgalactiae*, and *Streptococcus uberis*. The intramammary syringe for lactating dairy cattle (*Spectramast LC®*) is labeled for the treatment of clinical mastitis in lactating dairy cattle associated with coagulase-negative staphylococci, *Streptococcus dysgalactiae*, and *Escherichia coli*.

**Pharmacology**

Ceftiofur is a 3rd generation cephalosporin antibiotic active against a variety of gram-positive and gram-negative bacteria and like other cephalosporins inhibits bacteria cell wall synthesis; it is usually bactericidal and is a time-dependent antibiotic.

After administration, the parent compound (ceftiofur) is rapidly cleaved into furoic acid and desfuroylceftiofur (active). Desfuroylceftiofur inhibits cell wall synthesis (at stage three) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime. Parent ceftiofur and the primary metabolite are equally potent and assays to measure microbial sensitivity (plasma and tissue levels) are based on ceftiofur equivalents referred to as CE. The protein binding activity of ceftiofur creates a “reservoir effect” to maintain active levels at the site of infection.

In cattle, ceftiofur has a broad range of *in vitro* activity against a variety of pathogens, including many species of *Pasteurella*, *Streptococcus*, *Staphylococcus*, *Salmonella*, and *E. coli*.

In swine, ceftiofur HCl has activity against the pathogens *Actinobacillus pleuropneumoniae*, *Pasteurella multocida*, *Haemophilus parasuis* and *Streptococcus suis* for an extended period of time.

## Pharmacokinetics

In cattle and swine, ceftiofur is rapidly metabolized to desfuroylceftiofur, the primary metabolite. In cattle, ceftiofur sodium and HCl have practically equivalent pharmacokinetic parameters. The following pharmacokinetic values for cattle are for the active metabolite desfuroylceftiofur. The volume of distribution in cattle is about 0.3 L/kg. Peak levels are about 7 micrograms/mL after IM injection of ceftiofur sodium (*Naxcel*®), but areas under the curve are practically equal as well as elimination half-lives (approx. 8–12 hours).

The elimination kinetics of ceftiofur HCl in milk when used in an extralabel manner to treat coliform mastitis has been studied. Milk samples were tested after two, 300 mg doses (6 mL), administered 12 hours apart into the affected mammary quarters. The samples tested at less than the tolerance level for this drug set by FDA by 7 hours after the last intramammary administration. However, the authors noted considerable variability in the time required for samples from individual cows and mammary gland quarters to consistently have drug residues less than the tolerance level and reported that elimination rates of the drug may be related to milk production. Therefore, cows producing smaller volumes of milk many have prolonged withdrawal times. (Smith *et al.* 2004)

In lactating dairy cattle, active ceftiofur concentrations were measured after the administration of 1 mg/kg SC in healthy dairy cattle within 24 hours of calving. Drug concentrations were found to exceed MIC in uterine tissues and lochial fluid for common pathogens (Okker *et al.* 2002).

In swine, a study measuring tissue distribution following IM injection of varying doses revealed the highest concentration were detected in the kidneys, followed by lungs, liver and muscle tissue (Beconi-Barker *et al.* 1996). In swine, the intramuscular bioavailability of the ceftiofur sodium salt and the hydrochloride salt at doses of 3mg/kg or 5mg/kg were compared. The study reported similar therapeutic efficacy for both salt forms (Brown *et al.* 1999).

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

In swine, areas of discoloration associated with the injection site at time periods of 11 days or less may result in trim-out of edible tissues at slaughter.

In cattle, after intramuscular or subcutaneous administration in the neck, areas of discoloration at the site may persist beyond 11 days resulting in trim loss of edible tissues at slaughter. Following intramuscular administration in the rear leg, areas of discoloration at the injection site may persist beyond 28 days resulting in trim loss of edible tissues at slaughter.

Swine treated with ceftiofur HCl (*Excenel*® RTU) must not be slaughtered for 4 days following the last treatment.

Cattle treated with ceftiofur HCl (*Excenel*® RTU) must not be slaughtered for 3 days following the last treatment. There is no required milk discard time.

Cattle treated with *Spectramast DC*®, must not be slaughtered for 16 days following the last treatment. Milk taken from cows completing a 30 day dry cow period may be used with no milk discard. Following label use, no slaughter withdrawal period is required for neonatal calves born from treated cows regardless of colostrum consumption.

Cattle treated with *Spectramast LC*®, must not be slaughtered for 2 days following the last treatment. Milk taken from cows during treatment and for 72 hours after the last treatment must be discarded.

Patients in renal failure may need dosage adjustments.

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Swine safety data: results from a five-day tolerance study in normal feeder pigs indicated that ceftiofur sodium was well tolerated when administered at 125 mg ceftiofur equivalents/kg BW (more than 25 times the highest recommended daily dosage) for five consecutive days. Ceftiofur administered intramuscularly to pigs produced no overt adverse signs of toxicity.

Cattle safety data: results from a five-day tolerance study in feeder calves indicated that ceftiofur sodium was well tolerated at 55 mg ceftiofur equivalents/kg BW (25 times the highest recommended dose) for five consecutive days. Ceftiofur administered intramuscularly had no adverse systemic effects.

## Reproductive/Nursing Safety

The effects of ceftiofur on cattle and swine reproductive performance, pregnancy, and lactation have not been determined. However, cephalosporins as a class are relatively safe to use during pregnancy, and teratogenic or embryotoxic effects would not be anticipated.

## Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section).

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section). Use of dosages in excess of those labeled or by unapproved routes of administration may cause violative residues. Contact FARAD (see appendix) for assistance in determining appropriate withdrawal times in circumstances where the drug has been used at higher than labeled dosages.

## Drug Interactions

Although the manufacturer does not list any drug interactions on the label for ceftiofur, the following drug interactions have either been reported or are theoretical in humans or animals receiving injectable 3rd generation cephalosporins and may be of significance in veterinary patients receiving injectable ceftiofur:

■ **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).

■ **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives

## Laboratory Considerations

**Note:** Ceftiofur is structurally similar to cefotaxime and it is not known if these interactions occur with ceftiofur.

■ Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.

■ When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.

■ In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.

■ Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

## Doses

### ■SWINE:

a) Administer IM at 3 to 5 mg/kg body weight (1 mL of sterile suspension per 22 to 37 lb body weight). Treatment should be repeated at 24-hour intervals for a total of three consecutive days. (*Excenel® RTU*; Package Insert—Pfizer)

### ■CATTLE:

For bovine respiratory disease and acute bovine interdigital necrobacillosis:

a) Administer IM or SC at 1.1 to 2.2 mg/kg (1 to 2 mL sterile suspension per 100 lb) daily for a total of three consecutive days. Additional treatments may be administered on Days 4 and 5 for animals which do not show a satisfactory response. For or BRD only, administer IM or SC 2.2 mg/kg every other day on Days 1 and 3 (48h interval). Do not inject more than 15 mL per injection site. (*Excenel® RTU*; Package Insert—Pfizer)

For acute post-partum metritis:

a) Administer by IM or SC 2.2 mg/kg (2 mL sterile suspension per 100 lb) daily for five consecutive days. Do not inject more than 15 mL per injection site. (*Excenel® RTU*; Package Insert—Pfizer)

For neonatal salmonellosis:

a) Ceftiofur HCl 5 mg/kg IM once daily for 5 days (Fecteau *et al.* 2002)

For the treatment of subclinical mastitis in dairy cattle at time of dry off associated with *Staphylococcal aureus*, *Streptococcus dysgalactiae* or *Streptococcus uberis*:

a) Infuse one syringe of *Spectramast® DC* into each affected quarter at the time of dry off. (*Spectramast® DC*; Package Insert—Pfizer)

For the treatment of clinical mastitis in lactating dairy cattle associated with coagulase-negative staphylococci *Streptococcus dysgalactiae* or *E. coli*:

a) Infuse one syringe of *Spectromast® LC* into each affected quarter. Repeat this treatment in 24 hours. For extended duration therapy, once daily treatment may be repeated for up to 8 consecutive days. (*Spectramast® LC* Package Insert—Pfizer)

## Monitoring

Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required. Some clinicians recommend weekly CBC monitoring of small animals receiving ceftiofur. Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely performed with these agents.

## Chemistry/Synonyms

Ceftiofur HCl is a semisynthetic 3rd generation cephalosporin. Ceftiofur HCl is a weak acid and is acid stable and water-soluble with a molecular weight of 560. The injectable sterile suspension in a ready to use formulation that contains ceftiofur hydrochloride equivalent to 50 mg ceftiofur, 0.50 mg phospholipon, 1.5 mg sorbitan monooleate, 2.25 mg sterile water for injection, and cottonseed oil. Both *Spectramast®* products are sterile, oil based suspensions of ceftiofur HCl.

Ceftiofur HCl may also be known as U-64279A, ceftiofuri hydrochloridum or *Excenel RTU®*.

## Storage/Stability

The ready-to-use injectable product should be stored at controlled room temperature 20 to 25 °C (68 to 77 °F). Shake well before using; protect from freezing.

The intramammary syringes should be stored at controlled room temperature 20 to 25 °C (68 to 77 °F). Protect from light. Store plastets in carton until used.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Ceftiofur HCL Sterile Suspension for injection, 50 mg/mL in 100 mL vials; *Excenel RTU®* (Pharmacia/Upjohn); (Rx). FDA-approved for use in cattle and swine. Slaughter withdrawal = 3 days in cattle, and 4 days in swine. There is no required milk discard time.

Ceftiofur HCl Sterile Suspension for Intramammary Infusion in Dry Cows 500 mg ceftiofur equivalents (as the HCl) per 10 mL syringe (plastets) in packages of 12 syringes with 70% isopropyl alcohol pads; *Spectramast® DC* (Pfizer); (Rx) Slaughter withdrawal for cattle = 16 days (no slaughter withdrawal required for neonatal calves born from treated cows)

Ceftiofur HCl Sterile Suspension for Intramammary Infusion in Lactating Cows 125 mg ceftiofur equivalents (as the HCl) per 10 mL syringe (plastets) in packages of 12 syringes with 70% isopropyl alcohol pads; *Spectramast® LC* (Pfizer); (Rx) Cattle slaughter withdrawal = 2 days; milk discard = 72 hours

**HUMAN-LABELED PRODUCTS:** None

## CEFTIOFUR SODIUM

(sef-tee-oh-fur) Naxcel®

3RD GENERATION CEPHALOSPORIN

Prescriber Highlights

- A veterinary-only 3rd generation cephalosporin
- Potentially could cause hypersensitivity reactions, granulocytopenia, thrombocytopenia, or diarrhea
- Causes pain on IM injection to small animals
- May need to reduce dose in patients with renal failure

*Monograph by Elaine Lust, PharmD*

---

## Uses/Indications

*Labeled indications for ceftiofur sodium:*

In cattle for treatment of bovine respiratory disease (shipping fever, pneumonia) associated with *Mannheimia haemolytica*, *Pasteurella multocida* and *Histophilus somni*. It is also indicated for treatment of acute bovine interdigital necrobacillosis (foot rot, pododermatitis) associated with *Fusobacterium necrophorum* and *Bacteroides melaninogenicus*.

In swine for treatment/control of swine bacterial respiratory disease (swine bacterial pneumonia) associated with *Actinobacillus (Haemophilus) pleuropneumoniae*, *Pasteurella multocida*, *Salmonella choleraesuis* and *Streptococcus suis*.

In sheep/goats for treatment of sheep/caprine respiratory disease (sheep/goat pneumonia) associated with *Mannheimia haemolytica* and *Pasteurella multocida*.

In horses for treatment of respiratory infections in horses associated with *Streptococcus zooepidemicus*.

In dogs for the treatment of canine urinary tract infections associated with *E. coli* and *Proteus mirabilis*.

In day old chicks/poults for the control of early mortality, associated with *E. coli* organisms susceptible to ceftiofur.

Ceftiofur sodium has also been used in an extra-label manner in a variety of veterinary species (see Doses) to treat infections that likely to be susceptible to a 3rd generation cephalosporin.

## Pharmacology/Actions

Ceftiofur is a 3rd generation cephalosporin antibiotic active against a variety of gram-positive and gram-negative bacteria and like other cephalosporins inhibits bacterial cell wall synthesis, is usually bactericidal and is a time-dependent antibiotic.

Ceftiofur is rapidly cleaved into furoic acid and desfuroylceftiofur, which is active. Desfuroylceftiofur inhibits cell wall synthesis (at stage three) of susceptible multiplying bacteria and exhibits a spectrum of activity similar to that of cefotaxime. It has a broad range of *in vitro* activity against a variety of pathogens, including many species of *Pasteurella*, *Streptococcus*, *Staphylococcus*, *Salmonella*, and *E. coli*.

## Pharmacokinetics

In cattle, ceftiofur sodium and HCl have practically equivalent pharmacokinetic parameters. The following pharmacokinetic values for cattle are for the active metabolite desfuroylceftiofur. The volume of distribution in cattle is about 0.3 L/kg. Peak levels are about 7 micrograms/mL after IM injection of *Naxcel*®, but areas under the curve are practically equal as well as elimination half-lives (approx. 8–12 hours). Peak levels occur 30–45 minutes after IM dosing. Pharmacokinetic parameters of ceftiofur sodium are very similar for either SC or IM injection in cattle.

In dairy goats, dosing at 1.1 mg/kg or 2.2 mg/kg, administered IV or IM, demonstrated 100% bioavailability via the IM route. After 5 daily IM doses of the drug, serum concentrations were found to be dose-proportional (Courtin *et al.* 1997).

In horses, 2 grams of ceftiofur were administered via regional IV perfusion or systemic IV to determine radiocarpal joint synovial fluid and plasma concentrations. Mean synovial fluid concentrations were higher for the regional IV perfusion than systemic IV administration. The study concluded regional IV perfusion induced significantly higher intraarticular antibiotic concentrations in the radiocarpal joint compared to systemic IV administration. Additionally, synovial fluid drug concentrations remained above the MIC for common pathogens for more than 24 hours (Pille *et al.* 2005).

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to the drug. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

Withdrawal times: Cattle: 4-day slaughter withdrawal time is required. No milk discard time is required. Swine: A 4-day slaughter withdrawal time is required. Sheep/Goats: No slaughter withdrawal time or milk discard time is required. Not to be used in horses intended for human consumption.

Patients in renal failure may need dosage adjustments.

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence. The use of ceftiofur may result in some signs of immediate and transient local pain to the animal. Following subcutaneous administration of ceftiofur sodium in the neck, small areas of discoloration at the site may persist beyond five days, potentially resulting in trim loss of edible tissues at slaughter. Localized post-injection bacterial infections may result in abscess formation in cattle. Attention to hygienic procedures can minimize their occurrence.

The administration of antimicrobials to horses under conditions of stress may be associated with acute diarrhea that could be fatal. If acute diarrhea is observed, discontinue use of this antimicrobial and initiate appropriate therapy. One report however, found that ceftiofur administered to horses (4 mg/kg IM) had minimal effects on fecal flora (Clark & Dowling 2005).

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

## Reproductive/Nursing Safety

The effects of ceftiofur on the reproductive performance, pregnancy, and lactation of cattle, dogs, horses, swine, sheep, and goats have not been determined.

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy have not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks.

documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. Most of these agents (cephalosporins) are excreted in milk in small quantities. Modification/alteration of bowel flora with resultant diarrhea is theoretically possible. When dosed as labeled, there are no milk withdrawal times necessary for ceftiofur products in dairy cattle.

### Overdosage/Acute Toxicity

Cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section). However, overdoses in food animals may result in significantly extended withdrawal times, contact FARAD (see appendix) for assistance.

### Drug Interactions

Although the manufacturer does not list any drug interactions on the label for ceftiofur, the following drug interactions have either been reported or are theoretical in humans or animals receiving injectable 3rd generation cephalosporins and may be of significance in veterinary patients receiving ceftiofur:

- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides, but they should not be mixed together (administer separately).
- **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives.

### Laboratory Considerations

**Note:** Ceftiofur is structurally similar to cefotaxime and it is not known if these interactions occur with ceftiofur.

- Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.
- When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**.
- Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

### Doses

#### ■ CATTLE:

a) Administer to cattle by IM or SC injection at 1.1 to 2.2 mg/kg of body weight (1–2 mL reconstituted sterile solution per 100 lbs body weight). Treatment should be repeated at 24-hour intervals for a total of three consecutive days. Additional treatments may be given on days four and five for animals which do not show a satisfactory response (not recovered) after the initial three treatments. (Package Insert; *Naxcel*®—Pfizer)

#### ■ SWINE:

a) Administer to swine by IM injection at 3 to 5 mg/kg of body weight (1 mL of reconstituted sterile solution per 22 to 37 lbs body weight). Treatment should be repeated at 24-hour intervals for a total of three consecutive days. (Package Insert; *Naxcel*®—Pfizer)

#### ■ SHEEP/GOATS:

a) Administer to sheep/goats by IM injection at 1.1 to 2.2 mg/kg of body weight (1–2 mL reconstituted sterile solution per 100 lbs body weight). Treatment should be repeated at 24 hour intervals for a total of three consecutive days. Additional treatments may be given on days four and five for animals which do not show a satisfactory response (not recovered) after the initial three treatments. When used in lactating does, the high end of the dosage is recommended. (Package Insert; *Naxcel*®—Pfizer)

#### ■ HORSES:

a) Administer to horses by IM injection at the dosage of 1 to 2 mg ceftiofur per pound (2.2 to 4.4 mg/kg) of body weight (2–4 mL reconstituted sterile solution per 100 lbs body weight). A maximum of 10 mL may be administered per injection site. Repeat treatment at 24-hour intervals, continued for 48 hours after symptoms have disappeared. Do not exceed 10 days of treatment. (Package Insert; *Naxcel*®—Pfizer)

b) 1–2 mg/kg IV or IM q12–24h (Bertone 2003)

c) For Lyme disease: 2.2–4.4 mg/kg IV q12 hours via a long-term catheter (Divers 1999)

d) Foals: 2.2–4.4 mg/kg IV or IM q12–24h (Brumbaugh 1999)

e) For strangles: Early in infection when only fever and depression are present: ceftiofur sodium 2.2 mg/kg IM q12–24h. If lymphadenopathy noted in otherwise healthy and alert horse do not treat. If lymphadenopathy present and horse is depressed, febrile, anorexic and especially if dyspneic, treat as above. (Foreman 1999)

f) For intrauterine infusion: 1 gram. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

g) Foals: 2.2–5 mg/kg IM q12h (Giguere 2003)

#### ■ DOGS:

a) For susceptible UTI's: 2.2 mg/kg SC once daily for 5–14 days Administer to dogs by subcutaneous injection at the dosage of 1 mg ceftiofur per pound (2.2 mg/kg) of body weight (0.1 mL reconstituted sterile solution per 5 lbs body weight). Treatment should be repeated at 24-hour intervals for 5–14 days. (Package Insert; *Naxcel*®—Pfizer)

b) 10 mg/kg once to twice daily (q12–24h) SC (Aucoin 2000)

c) For UTI: 2.2 mg/kg SC once daily for 5–14 days

For systemic, soft tissue infections: 2.2 mg/kg q12h or 4.4 mg/kg q24h SC for 5–14 days

For sepsis, bacteremia: 4.4 mg/kg q12h SC for 2–5 days (Greene & Watson 1998)

d) For neonatal septicemia: 2.5 mg/kg SC q12h for no longer than 5 days; presumptive therapy with vitamin K1 (0.01–1 mg per neonate SC) may be used in puppies and kittens less than 48 hours old (Davidson 2004) (Davidson 2009)

## ■CATS:

- a) For UTI: 2.2 mg/kg SC once daily for 5–14 days  
For systemic, soft tissue infections: 2.2 mg/kg q12h or 4.4 mg/kg q24h SC for 5–14 days  
For sepsis, bacteremia: 4.4 mg/kg q12h SC for 2–5 days (Greene & Watson 1998)

## ■BIRDS:

- a) Day-Old Turkey Poults: Administer by SC injection in the neck region of day-old turkey poults at the dosage of 0.17 to 0.5 mg ceftiofur/poult. One mL of the 50 mg/mL reconstituted solution will treat approximately 100 to 294 day-old poults.  
Day Old Chicks: Administer by SC injection in the neck region of day-old chicks at the dosage of 0.08 to 0.20 mg ceftiofur per chick. One mL of the 50 mg/mL reconstituted solution will treat approximately 250 to 625 day-old chicks. A sterile 26 gauge needle and syringe or properly cleaned automatic injection machine should be used. (Package Insert; *Naxcel*®—Pfizer)
- b) **Ratites:** 10–20 mg/kg IM twice daily (Jenson 1998)

## ■REPTILES:

- a) **Chelonians:** 4 mg/kg IM once daily for 2 weeks. Commonly used in respiratory infections. (Gauvin 1993)
- b) **Green iguanas:** for microbes susceptible at > 2 µg/mL, 5 mg/kg, IM or SC, every 24 hours (Bensen *et al.* 2003)
- c) For bacterial pneumonia: 2.2 mg/kg IM q24–48h; keep patient at upper end of ideal temperature range (Johnson 2004)

## ■EXOTICS/WILDLIFE:

- a) Captive Female Asian Elephants: 1.1 mg/kg IM given two to three times a day or, alternatively 1.1 mg/kg IV once daily, depending upon the MIC of the pathogen (Dumonceax *et al.* 2005)

## Treatment Monitoring

Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required. Some clinicians recommend weekly CBC monitoring of small animals receiving ceftiofur. Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

## Chemistry/Synonyms

Ceftiofur sodium is a semisynthetic 3rd generation cephalosporin. Ceftiofur sodium is a weak acid and is acid stable and water-soluble.

Ceftiofur sodium may also be known as CM 31-916, U 64279E, ceftiofen sodium, *Excenel*® (not *Excenel*® RTU), *Naxcel*®, or *Accent*®.

## Storage/Stability

Unreconstituted ceftiofur sodium powder for reconstitution should be stored at room temperature. Protect from light. Color of the cake may vary from off-white to tan, but this does not affect potency.

After reconstitution with bacteriostatic water for injection or sterile water for injection, the solution is stable up to 7 days when refrigerated and for 12 hours at room temperature (15–30°C). According to the manufacturer, if a precipitate should form while being stored refrigerated during this time, the product may be used if it goes back into solution after warming. If not, contact the manufacturer. Frozen reconstituted solutions are stable up to 8 weeks. Thawing may be done at room temperature or by swirling the vial under running warm or hot water.

One-time salvage procedure for reconstituted product: At the end of the 7-day refrigeration or 12-hour room temperature storage period following reconstitution, any remaining reconstituted product may be frozen up to 8 weeks without loss in potency or other chemical properties. This is a one-time only salvage procedure for the remaining product. To use this salvaged product at any time during the 8-week storage period, hold the vial under warm running water, gently swirling the container to accelerate thawing, or allow the frozen material to thaw at room temperature. Rapid freezing or thawing may result in vial breakage. Any product not used immediately upon thawing should be discarded.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Ceftiofur Sodium Powder for Injection 50 mg ceftiofur/mL when reconstituted in 1 g & 4 g vials; *Naxcel*® (Pfizer), generic; (Rx). FDA-approved for various indications in cattle, swine, sheep, goats, horses, dogs, and day-old chicks or turkey poults. Withdrawal times: Cattle: 4-day slaughter withdrawal time is required. No milk discard time is required. Swine: A 4-day slaughter withdrawal time is required. Sheep/Goats: No slaughter withdrawal time or milk discard time is required. Not to be used in horses intended for human consumption.

### HUMAN-LABELED PRODUCTS: None

## Prescriber Highlights

- 3rd generation cephalosporin; achieves high levels in CNS; long half life
  - Potentially could cause hypersensitivity reactions, granulocytopenia/thrombocytopenia, diarrhea, mild azotemia, biliary “sludging”
  - Causes pain on IM injection; Give IV over 30 minutes (or more)
  - May need to reduce dose in renal failure; avoid with icterus
- 

## Uses/Indications

Ceftriaxone is used to treat serious infections, particularly against susceptible Enterobacteriaceae that are not susceptible to other less expensive agents or when aminoglycosides are not indicated (due to their potential toxicity). Its long half life, good CNS penetration, and activity against *Borrelia burgdorferi* also has made it a potential choice for treating Lyme’s disease.

## Pharmacology/Actions

Ceftriaxone is a third generation injectable cephalosporin agent. The third generation cephalosporins retain the gram-positive activity of the first and second-generation agents, but, have much expanded gram-negative activity. As with the 2nd generation agents, enough variability exists with individual bacterial sensitivities that susceptibility testing is necessary for most bacteria. Because of the excellent gram-negative coverage of these agents and when compared to the aminoglycosides and their significantly less toxic potential, they have been used on an increasing basis in veterinary medicine.

## Pharmacokinetics

Ceftriaxone is not absorbed after oral administration and must be given parenterally. It is widely distributed throughout the body; CSF levels are higher when meninges are inflamed. Ceftriaxone crosses the placenta and enters maternal milk in low concentrations; no documented adverse effects to offspring have been noted. Ceftriaxone is excreted by both renal and non-renal mechanisms; in humans, elimination half-lives are approximately 6–11 hours.

In dogs, ceftriaxone bioavailability after IM or SC administration equal that of IV, but peak levels occur much faster after IM (approximately 30 minutes) than SC (80 minutes). Peak levels are higher with IM administration than SC, but total area under the curve is similar for both routes. Elimination half-life is longer after SC administration (1.73 hrs) than either IM (1.17 hrs) or IV administration (0.88 hrs). The authors of the study (Rebuelto *et al.* 2002) concluded that once or twice daily IM or SC injections of 50 mg/kg should be adequate to treat most susceptible infections in dogs.

## Contraindications/Precautions/Warnings

Only prior allergic reaction to cephalosporins contraindicates ceftriaxone’s use. In humans documented hypersensitive to penicillin, up to 16% may also be allergic to cephalosporins. The veterinary significance of this is unclear.

Although bleeding times have only been reported rarely in humans, ceftriaxone should be used with caution in patients with vitamin K utilization or synthesis abnormalities (*e.g.*, severe hepatic disease).

Patients in renal failure may need dosage adjustments; but are not generally required unless severely uremic, or with concomitant hepatic impairment.

## Adverse Effects

Because veterinary usage of ceftriaxone is very limited, an accurate adverse effect profile has not been determined. The following adverse effects have been reported in humans and may or may not apply to veterinary patients: hematologic effects, including eosinophilia (6%), thrombocytosis (5%), leukopenia (2%) and, more rarely, anemia, neutropenia, lymphopenia and thrombocytopenia. Approximately 2–4% of humans get diarrhea. Very high dosages (100 mg/kg/day) in dogs have caused a “sludge” in bile. Hypersensitivity reactions (usually a rash) have been noted. Increased serum concentrations of liver enzymes, BUN, creatinine, and urine casts have been described in about 1–3% of patients. When given IM, pain may be noted at the injection site.

## Reproductive/Nursing Safety

No teratogenic effects were demonstrated in studies in pregnant mice and rats given up to 20X labeled doses of ceftriaxone. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Ceftriaxone is distributed into milk in low concentrations and is unlikely to pose much risk to nursing offspring.

## Overdosage/Acute Toxicity

Limited information available; overdoses should be monitored and treated symptomatically and supportively if required.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ceftriaxone and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES/NEPHROTOXIC DRUGS:** The concurrent use of parenteral aminoglycosides or other nephrotoxic drugs (*e.g.*, amphotericin B) with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with these drugs, but this interaction has only been well documented with cephaloridine (no longer marketed). *In vitro* studies have demonstrated that cephalosporins can have synergistic or additive activity against certain bacteria when used with aminoglycosides.
- **CALCIUM:** Concomitant use with calcium containing solutions have caused fatal calcium-ceftriaxone precipitates in lungs and kidneys of neonatal humans. Do not mix with calcium or administer calcium-containing solutions or products within 48 hours of ceftriaxone administration.

## Laboratory Considerations

- When using Kirby-Bauer disk diffusion procedures for testing susceptibility, a specific 30 micrograms ceftriaxone disk should be used. A cephalosporin-class disk containing cephalothin should not be used to test for ceftriaxone susceptibility. An inhibition zone of 18 mm or more indicates susceptibility; 14–17 mm, intermediate; and 13 mm or less, resistant.
- When using a dilution susceptibility procedure, an organism with a MIC of 16 micrograms/mL or less is considered susceptible and 64 micrograms/mL or greater is considered resistant. With either method, infections caused by organisms with intermediate susceptibility may be effectively treated if the infection is limited to tissues where the drug is concentrated or if a higher than normal dose is used.
- Ceftriaxone, like most other cephalosporins, may cause a **false-positive urine glucose** determination when using the cupric sulfate solution test (*e.g.*, *Clinitest*®).
- Ceftriaxone in very high concentrations (50 micrograms/mL or greater) may cause falsely elevated **serum creatinine** levels when manual methods of testing are used. Automated methods do not appear to be affected.

## Doses

### ■DOGS:

- For meningitis/borreliosis: 15–50 mg/kg (maximum single dose in humans is 1 gram) IV or IM q12h for 4–14 days  
For preoperative/intraoperative use: 25 mg/kg (maximum single dose in humans is 1 gram) IM or IV one time  
For skin, genitourinary infections: 25 mg/kg IM once daily (q24h) for 7–14 days (Greene & Watson 1998)
- For infectious endocarditis and documented resistance against or other contraindications for fluoroquinolones and aminoglycosides in dogs: 20 mg/kg IV q12h (DeFrancesco 2000)
- 15–50 mg/kg (route not specified) once daily (Trepanier 1999)

### ■CATS:

- For systemic infections:
- 25–50 mg/kg IV, IM or Intraosseous q12h as long as necessary (Greene & Watson 1998)

### ■HORSES:

- For susceptible infections:
- 25–50 mg/kg q12h IV or IM. Excellent CSF and bone penetration; expensive. (Stewart 2008)
  - 20 mg/kg IV q12h (Brumbaugh 1999)

## Monitoring

- Efficacy
- If long-term therapy, occasional CBC, renal function (BUN, Serum Creatinine, urinalysis) and liver enzymes (AST, ALT) may be considered.

## Chemistry/Synonyms

A third generation cephalosporin, ceftriaxone sodium occurs as a white to yellowish-orange crystalline powder. It is soluble in water (400 mg/mL at 25°C). Potencies of commercial products are expressed in terms of ceftriaxone. One gram of ceftriaxone sodium contains 3.6 mEq of sodium.

Ceftriaxone Sodium may also be known as: ceftriaxonum natrium, Ro-13-9904, or Ro-13-9904/000; many trade names are available.

## Storage/Stability

The sterile powder for reconstitution should be stored at or below 25°C and protected from light.

After reconstituting with either 0.9% sodium chloride or D5W, ceftriaxone solutions (at concentrations of approximately 100 mg/mL) are stable for 3 days at room temperature and for 10 days when refrigerated. Solutions of concentrations of 250 mg/mL are stable for 24 hours at room temperature and 3 days when refrigerated. At concentrations of 10–40 mg/mL solutions frozen at -20°C are stable for 26 weeks.

## Compatibility/Compounding Considerations

The manufacturer does not recommend admixing any other anti-infective drugs with ceftriaxone sodium, but amikacin and metronidazole are reported **compatible**.

*Do not mix* with calcium or calcium-containing solutions, or administer calcium-containing solutions or products within 48 hours of ceftriaxone administration (see Drug Interactions).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Ceftriaxone Injection Powder for Solution: 250 mg & 500 mg, 1 g, 2 g, & 10 g, (as base) in vial/single-use duplex containers and in bulk; *Rocephin*® (Roche); generic; (Rx)

**CEFUROXIME AXETIL**

**CEFUROXIME SODIUM**

(sef-yoor-oks-eem) Cefitin®, Zinacef®

**2ND GENERATION CEPHALOSPORIN**

## Prescriber Highlights

- Oral & parenterally administered 2nd generation cephalosporin that is more active against some gram-negative bacteria than first generation (e.g., cephalexin, cefazolin) cephalosporins
  - Potentially useful in small animals when a cephalosporin is desired to treat bacterial infections susceptible to cefuroxime, but resistant to first generation cephalosporins, when enhanced gram-negative coverage is desired for surgery prophylaxis, or when high CNS levels are necessary
  - Limited clinical experience in veterinary medicine
  - Adverse effects most likely seen in small animals would be GI-related
- 

## Uses/Indications

Cefuroxime is a semi-synthetic 2nd generation cephalosporin with enhanced activity against some gram-negative pathogens when compared to the first generation agents. Cefuroxime is available in both oral and parenteral dosage forms. It potentially may be useful in small animals when a cephalosporin is desired to treat bacterial infections susceptible to cefuroxime, but resistant to first generation cephalosporins, when enhanced gram-negative coverage is desired for surgery prophylaxis, or when high CNS levels are necessary. Little information is available with regard to its clinical use in small animals, however.

## Pharmacology/Actions

Cefuroxime, like other cephalosporins, is bactericidal and acts by inhibiting cell wall synthesis. Its spectrum of activity is similar to that of cephalexin, but it is more active against gram-negative bacteria including strains of *E. coli*, *Klebsiella pneumoniae*, *Salmonella* and *Enterobacter*. It is not effective against methicillin-resistant *Staphylococcus*, *Pseudomonas*, *Serratia* or *Enterococcus*.

## Pharmacokinetics

No information was located for the pharmacokinetics of cefuroxime in dogs, cats or horses.

In humans, cefuroxime axetil is well absorbed after oral administration and is rapidly hydrolyzed in the intestinal mucosa and circulation to the parent compound. Bioavailability ranges on average from 37% (fasted) to 52% (with food). Peak serum levels occur in about 2–3 hours after oral dosing. When the sodium salt is administered IM, peak levels occur within 15 minutes to 1 hour. Cefuroxime is widely distributed after absorption, including to bone, aqueous humor and joint fluid. Therapeutic levels can be attained in the CSF if meninges are inflamed. Binding to human plasma proteins ranges from 35–50%. Cefuroxime is primarily excreted unchanged in the urine; elimination half-life in patients with normal renal function is between 1–2 hours.

## Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. In humans, cefuroxime is contraindicated in patients hypersensitive to it or other cephalosporins. Dosage adjustment is recommended in humans with severe renal impairment.

## Adverse Effects

As usage of cefuroxime in animals has been limited, a comprehensive adverse effect profile has not been determined. A six-month toxicity study of oral cefuroxime axetil given at dosages ranging from 100 mg/kg/day to 1600 mg/kg/day in Beagles demonstrated little adversity associated with cefuroxime. At the highest dosing levels (approximately 80X), some vomiting and slight suppression of body weight gain were noted. Minor reductions in neutrophils and red cells, with increases in prothrombin times were also seen.

When used clinically in dogs, gastrointestinal effects (inappetence, vomiting, diarrhea) would be the most likely expected adverse effects, but incidence rates are not known.

Cefuroxime is generally well tolerated in human patients. Injection site inflammation can occur when cefuroxime is used intravenously. Gastrointestinal effects (nausea, diarrhea) may occur, but are not frequently reported. Eosinophilia and hypersensitivity reactions (including anaphylaxis) are possible. Neurologic effects (hearing loss, seizures), pseudomembranous colitis, serious dermatologic reactions (TEN, Stevens-Johnson syndrome, etc.), hematologic effects (pancytopenia, thrombocytopenia), and interstitial nephritis have all been reported rarely in humans.

## Reproductive/Nursing Safety

Studies performed in pregnant mice at dosages of up to 6400 mg/kg and rabbits at 400 mg/kg demonstrated no adverse fetal effects. In humans, the FDA categorizes cefuroxime as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Cefuroxime enters maternal milk in low concentrations. Although probably safe for nursing offspring the potential for adverse effects cannot be ruled out, particularly alterations to gut flora with resultant diarrhea.

## Overdosage/Acute Toxicity

Beagles receiving daily dosages of up to 1600 mg/kg/day orally tolerated cefuroxime well (see Adverse Effects).

Cerebral irritation with seizures has been reported with large overdoses in humans. Plasma levels of cefuroxime can be reduced with hemodialysis or peritoneal dialysis.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cefuroxime and may be of significance in veterinary patients:

■ **AMINOGLYCOSIDES:** Potential for increased risk of nephrotoxicity—monitor renal function; however, aminoglycosides and cephalosporins may have synergistic or additive actions against some gram-negative bacteria (*Enterobacteriaceae*)

■ **FUROSEMIDE, TORSEMIDE:** Possible increased risk of nephrotoxicity

■**PROBENECID:** Reduced renal excretion of cefaclor

## Laboratory Considerations

- Cefuroxime may cause false-positive **urine glucose determinations** when using the copper reduction method (Benedict's solution, Fehling's solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins
- In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**

## Doses

### ■**DOGS:**

For susceptible infections:

a) For soft tissue infections: 10 mg/kg PO q12h for 10 days. For systemic infections: 15 mg/kg IV q8h. For meningitis: 30 mg/kg IV q8h. **Note:** All dosages extrapolated from human dosages. (Greene *et al.* 2006)

For surgery prophylaxis:

a) 20 mg/kg IV 30 minutes prior to surgery and every 2 hours during surgery. (Greene *et al.* 2006)

## Monitoring

- Clinical efficacy
- Monitor renal function in patients with renal insufficiency

## Client Information

- Give the oral tablets with food as it may enhance the absorption of the drug
- Avoid crushing tablets; a strong, bitter taste results even if mixed into food; if tablets must be crushed, give with dairy products such as milk or chocolate milk to improve absorption and palatability
- Give as directed by the veterinarian; even if animal appears well, continue treating for the full duration prescribed
- Contact veterinarian if animal develops severe vomiting/diarrhea or rash/itching

## Chemistry/Synonyms

Cefuroxime axetil occurs as a white or almost white, powder that is insoluble in water and slightly soluble in dehydrated alcohol.

Cefuroxime sodium occurs as a white or almost white, hygroscopic powder that is freely soluble in water.

Cefuroxime may also be known as: CCI-15641, cefuroxim, cefuroxima, cefuroximum, cefuroksiimi, or cefuroksimas; many internationally registered trade names are available.

## Storage/Stability

Cefuroxime axetil tablets should be stored in tight containers at room temperature (15–30°C); protect from excessive moisture.

The powder for suspension should be stored at 2–30°C. Once reconstituted, it should be kept refrigerated (2–8°C) and any unused suspension discarded after 10 days.

The powder for injection of infusion should be stored at room temperature (15–30°C). The powder may darken, but this does not indicate any loss of potency. When reconstituted with sterile water to a concentration of 90 mg/mL, the resulting solution is stable for 24 hours at room temperature; 48 hours if refrigerated. If further diluted into a **compatible** IV solution such as D5W, normal saline or Ringer's, the resulting solution is stable for 24 hours at room temperature; up to 7 days if refrigerated.

## Compatibility/Compounding Considerations

Drugs that are reportedly **compatible** when mixed with cefuroxime for IV use include, clindamycin, furosemide and metronidazole. Drugs that may be given at a Y-site with a cefuroxime infusion running include, morphine, hydromorphone, and propofol. Aminoglycosides, ciprofloxacin, or ranitidine should not be admixed with cefuroxime.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cefuroxime Axetil Oral Tablets (film coated): 125 mg, 250 mg, & 500 mg; *Ceftin*® (GlaxoWellcome), generic (Ranbaxy); (Rx)

Cefuroxime Axetil Oral Suspension: 25 mg/mL & 50 mg/mL (125 mg/5 mL & 250 mg/5 mL; as base) when reconstituted in 50 & 100 mL; generic, (Ranbaxy); (Rx)

Cefuroxime Sodium Powder for Injection: 750 mg, 1.5 g & 7.5 g (as sodium) in 10 mL & 20 mL vials, 100 mL piggyback vials, infusion packs, ADD-Vantage vials & bulk package; *Zinacef*® (GlaxoWellcome); generic; (Rx)

Cefuroxime Sodium Injection: 750 mg & 1.5 g (as sodium), premixed, frozen in 50 mL; *Zinacef*® (GlaxoWellcome); (Rx)

---

## CEPHALEXIN

(sef-a-lex-in) **Keflex**®

1ST GENERATION CEPHALOSPORIN

- **1st generation oral cephalosporin (available for injection in other countries)**
  - **May be administered with food (especially if GI upset occurs)**
  - **Most likely adverse effects are GI in nature; hypersensitivity reactions possible**
  - **May need to reduce dose in patients with renal failure**
- 

## Uses/Indications

There are no FDA-approved cephalexin products for veterinary use in the USA. However, it has been used clinically in dogs, cats, horses, rabbits, ferrets, and birds, particularly for susceptible Staphylococcal infections.

## Pharmacology/Actions

A first generation cephalosporin, cephalexin exhibits activity against the bacteria usually covered by this class. Cephalosporins are bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in spectrums of activity of these drugs that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered to be more effective against actively growing bacteria.

While there may be differences in MIC's for individual first generation cephalosporins, their spectrums of activity are quite similar. They possess generally excellent coverage against most gram-positive pathogens and variable to poor coverage against most gram-negative pathogens. These drugs are very active *in vitro* against groups A beta-hemolytic and B Streptococci, non-enterococcal group D Streptococci (*S. bovis*), *Staphylococcus intermedius* and *aureus*, *Proteus mirabilis* and some strains of *E. coli*, *Klebsiella* spp., *Actinobacillus*, *Pasturella*, *Haemophilus equigenitalis*, *Shigella* and *Salmonella*. With the exception of *Bacteroides fragilis*, most anaerobes are very susceptible to the first generation agents. Most species of Corynebacteria are susceptible, but *C. equi* (Rhodococcus) is usually resistant. Strains of *Staphylococcus epidermidis* are usually sensitive to the parenterally administered 1st generation drugs, but may have variable susceptibilities to the oral drugs. The following bacteria are regularly resistant to the 1st generation agents: Group D streptococci/enterococci (*S. faecalis*, *S. faecium*), Methicillin-resistant Staphylococci, *indole-positive Proteus* spp., *Pseudomonas* spp., *Enterobacter* spp., *Serratia* spp. and *Citrobacter* spp.

## Pharmacokinetics

After oral administration, cephalexin is rapidly and completely absorbed in humans. Cephalexin (base) must be converted to the HCl before absorption can occur and, therefore, absorption can be delayed. There is a form of cephalexin HCl commercially available for oral use that apparently is absorbed more rapidly, but the clinical significance of this is in question. Food apparently has little impact on absorption.

In a study done in dogs and cats (Silley et al. 1988), peak serum levels reached 18.6 micrograms/mL about 1.8 hours after a mean oral dose of 12.7 mg/kg in dogs, and 18.7 micrograms/mL, 2.6 hours after an oral dose of 22.9 mg/kg in cats. Elimination half-lives ranged from 1–2 hours in both species. Bioavailability was about 75% in both species after oral administration.

There may be temporal differences in pharmacokinetics depending on the time of day the drug is administered. Six beagles given cephalexin orally at 10:00 and 22:00 had significantly lower peak levels (77%) after the 22:00 dose versus the 10:00 dose. Additionally, the elimination half-life was approximately 50% longer with the evening dose versus the morning dose. Clinical significance is not clear as times above an MIC of 0.5 micrograms/mL were not different (Prados *et al.* 2007).

In horses, oral cephalexin has low bioavailability (approx. 5%) and a short plasma half-life (about 2 hours), but at doses of 30 mg/kg PO q8h sufficient plasma and interstitial levels were achieved to treat gram-positive bacteria (MIC ≤5 micrograms/mL) (Davis *et al.* 2005).

Outside the USA, an oily suspension of the sodium salt (*Ceporex® Injection*—Glaxovet; Cefalexina Injection 20%—Laborino Burnet) is available in several countries for IM or SC injection in animals. In calves, the sodium salt had a 74% bioavailability after IM injection and a serum half-life of about 90 minutes. When 7.5 mg/kg was injected either SC or IM in adult cattle, the 20% suspension had longer durations of time above MIC<sub>90</sub> for common gram positive pathogens when injected SC versus IM (11–14 hours vs. 8–9 hours) (Dova *et al.* 2008).

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

Oral systemic antibiotics should not be administered in patients with septicemia, shock or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral routes (preferably IV) should be used for these cases.

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

In addition to the adverse effects listed below, cephalexin has reportedly caused salivation, tachypnea and excitability in dogs, and emesis and fever in cats. Nephrotoxicity occurs rarely during therapy with cephalexin, but patients with renal dysfunction, receiving other nephrotoxic drugs or that are geriatric may be more susceptible. Interstitial nephritis, a hypersensitivity reaction, has been reported with many of the cephalosporins including cephalexin. The incidence of these effects is not known.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, cephalosporins may cause GI effects (anorexia, vomiting, diarrhea). Administering the drug with a small meal may help alleviate these effects. Because the cephalosporins may also alter gut flora, antibiotic-associated diarrhea or proliferation of resistant bacteria in the colon can occur.

Rarely, cephalexin has been implicated in causing toxic epidermal necrolysis in cats.

While cephalosporins (particularly cephalothin) have the potential for causing nephrotoxicity at clinically used doses in patients with normal renal function, risks for the occurrence of this adverse effect appear minimal.

High doses or very prolonged use has been associated with neurotoxicity, neutropenia, agranulocytosis, thrombocytopenia, hepatitis, positive Coomb's test, interstitial nephritis, and tubular necrosis. Except for tubular necrosis and neurotoxicity, these effects have an immunologic component.

### Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes cephalexin as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Small amounts of cephalexin may be distributed into maternal milk; it could potentially affect gut flora in neonates.

### Overdosage/Acute Toxicity

Acute oral cephalosporin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse Effects section).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cephalexin and may be of significance in veterinary patients:

■ **PROBENECID:** Competitively blocks the tubular secretion of most cephalosporins thereby increasing serum levels and serum half-lives

### Laboratory Considerations

■ Except for cefotaxime, cephalosporins may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®). Tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected by cephalosporins.

■ When using the Jaffe reaction to measure **serum or urine creatinine**, cephalosporins (not ceftazidime or cefotaxime) in high dosages may falsely cause elevated values.

■ In humans, particularly with azotemia, cephalosporins have caused a false-positive direct **Coombs' test**. Cephalosporins may also cause falsely elevated **17-ketosteroid** values in urine.

### Doses

#### ■ DOGS:

For susceptible infections:

a) For superficial and deep pyoderma: 22–33 mg/kg PO two to three times daily (Beale & Murphy 2006)

b) For recurrent pyoderma: 22 mg/kg PO q12h (use at q8h for deep pyoderma) (Hillier 2006)

c) For superficial canine pyoderma: 30–40 mg/kg PO once daily (q24h) for 4 weeks. (Toma *et al.* 2008)

d) For pyoderma: 22–35 mg/kg PO q12h or 22 mg/kg PO q8h

For respiratory infections: 20–40 mg/kg PO q8h; For soft tissue infections: 30–50 mg/kg PO q12h

For systemic infections: 25–60 mg/kg PO q8h

For orthopedic infections: 22–30 mg/kg PO q6–8h for 28 days

For above doses, guideline for duration of therapy is treat for 5–7 days beyond resolution of clinical disease or preferably negative culture (Greene & Watson 1998)

e) For pyometra/metritis: 10–30 mg/kg PO q8–12h (Freshman 2002a)

f) For UTI: 30–40 mg/kg PO q8h. For acute urethrocystitis, treatment may be 7–10 days for chronic urethrocystitis, up to 4 weeks of treatment may be necessary; for pyelonephritis, 4–8 weeks may be adequate (Brovida 2003)

g) For neonates: 10–30 mg/kg PO (weak neonates should be given via stomach tube) twice daily–three times daily (Freshman 2002b)

h) For juvenile cellulitis in 3–16 week old puppies: 20 mg/kg PO three times daily (Macintire 2004)

i) For treating infectious otitis: 22 mg/kg PO q12h (Kwochka 2002)

#### ■ CATS:

For susceptible infections:

a) For soft tissue infections: 30–50 mg/kg PO q12h

For systemic infections: 35 mg/kg PO q6–8h.

For above doses, guideline for duration of therapy is treat for 5–7 days beyond resolution of clinical disease or preferably negative culture (Greene & Watson 1998)

b) 22 mg/kg PO q8h; administer with food if GI upset occurs (Vaden & Papich 1995)

c) For Gram-positive infections: 22 mg/kg PO twice daily

d) For Gram-negative infections: 30 mg/kg PO three times daily (Aucoin 2000)

e) 20–40 mg/kg PO q8h (Lappin 2002)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** 11–22 mg/kg PO q8h (Ivey & Morrisey 2000)

b) **Guinea pigs:** 50 mg/kg IM q24h (Adamcak & Otten 2000))

#### ■ FERRETS:

For susceptible infections:

a) 15–25 mg/kg PO 2–3 times daily (Williams 2000)

## ■HORSES:

For susceptible infections:

a) 30 mg/kg PO q8h (Davis *et al.* 2005)

b) 22–33 mg/kg PO q6h (Brumbaugh 1999)

## ■BIRDS:

For susceptible infections:

a) 35–50 mg/kg PO four times daily (using suspension); most preps are well accepted (Clubb 1986)

b) 40–100 mg/kg q6h PO (Hoeffler 1995)

c) **Ratites:** 15–22 mg/kg PO three times daily; For megabacteriosis: 50 mg/kg PO 4 times daily for 5 days (Jenson 1998)

## Monitoring

■ Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required

■ Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents

## Chemistry/Synonyms

A semi-synthetic oral cephalosporin, cephalexin (as the monohydrate) occurs as a white to off-white crystalline powder. It is slightly soluble in water and practically insoluble in alcohol.

Cephalexin may also be known as: cefalexin, 66873, or cefalexinum; many trade names are available.

## Storage/Stability

Cephalexin tablets, capsules, and powder for oral suspension should be stored at room temperature (15–30°C) in tight containers. After reconstitution, the oral suspension is stable for 2 weeks.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cephalexin Oral Capsules: 250 mg, 333 mg, 500 mg & 750 mg; Oral Tablets: 250 mg & 500 mg; *Keflex*® (Advancis); generic; (Rx)

Cephalexin Powder for Oral Suspension: 125 mg/5mL & 250 mg/5 mL (after reconstitution) in 100 mL & 200 mL; *Keflex*® (Advancis); generic; (Rx)

## CEPHAPIRIN SODIUM

## CEPHAPIRIN BENZATHINE

(sef-a-pye-rin) Cefa-Lak®, Cefa-Dri®

1ST GENERATION CEPHALOSPORIN

## Prescriber Highlights

- **1st generation intramammary cephalosporin; also used via intrauterine infusions for endometritis**
  - **Potentially could cause hypersensitivity reactions**
  - **Watch withdrawal times**
- 

## Uses/Indications

In the USA, there are no longer parenterally administered cephalirin products available. A 500 mg intrauterine suspension (*Metricure*®) is available in many countries worldwide.

An intramammary cephalirin sodium product is FDA-approved in the USA for use in the treatment of mastitis in lactating dairy cows and cephalirin benzathine is

## Pharmacology/Actions

A first generation cephalosporin, cephapirin exhibits activity against the bacteria usually covered by this class. A cephalothin disk is usually used to determine bacterial susceptibility to this antibiotic when using the Kirby-Bauer method. Cephalosporins are usually bactericidal against susceptible bacteria and act by inhibiting mucopeptide synthesis in the cell wall resulting in a defective barrier and an osmotically unstable spheroplast. The exact mechanism for this effect has not been definitively determined, but beta-lactam antibiotics have been shown to bind to several enzymes (carboxypeptidases, transpeptidases, endopeptidases) within the bacterial cytoplasmic membrane that are involved with cell wall synthesis. The different affinities that various beta-lactam antibiotics have for these enzymes (also known as penicillin-binding proteins; PBPs) help explain the differences in these drugs' spectrums of activity that are not explained by the influence of beta-lactamases. Like other beta-lactam antibiotics, cephalosporins are generally considered more effective against actively growing bacteria.

## Pharmacokinetics

In cattle when used systemically, the apparent volume of distribution has been reported as 0.335–0.399 L/kg; total body clearance is 12.66 mL/min/kg and serum elimination half-life is about 64–70 minutes in cattle.

When cephapirin sodium (*Cefa-Lak*®) was administered to healthy (no mastitis) dairy cattle via intramammary infusion it was rapidly metabolized to the active metabolite desacetylcephapirin in milk. Times above MIC<sub>90</sub> for common mastitis pathogens and time to reach FDA tolerance concentrations is similar whether the cow was milked two or three times daily. Additionally, giving the second dose 16 hours later (rather than 12 hours as labeled) to cows that are milked three times daily caused no significant effect on withdrawal times or times above MIC. Cows with low daily milk production (<25kg) appear to absorb more cephalothin systemically and had longer mean residence times than those with high milk production. The authors caution that extended withdrawal times would be prudent in cows with very low milk production and that more studies are required to determine the pharmacokinetics in animals with mastitis. (Stockler *et al.* 2009).

## Contraindications/Precautions/Warnings

Cephalosporins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use cephalosporins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, penicillins, cefamycins, carbapenems).

## Adverse Effects

Adverse effects with the cephalosporins are usually not serious and have a relatively low frequency of occurrence.

Potentially, hypersensitivity reactions could occur with intramammary infusion. Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, lymphadenopathy, or full-blown anaphylaxis. The use of cephalosporins in patients documented to be hypersensitive to penicillin-class antibiotics is controversial. In humans, it is estimated 1–15% of patients hypersensitive to penicillins will also be hypersensitive to cephalosporins. The incidence of cross-reactivity in veterinary patients is unknown.

## Reproductive/Nursing Safety

Cephalosporins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. See label information for more information.

## Overdosage/Acute Toxicity

No clinical effects would be expected but if used at doses or rates higher than labeled, withdrawal times may be prolonged.

## Drug Interactions

No significant concerns when used via the intramammary or intrauterine routes.

## Laboratory Considerations

- No significant concerns when used via the intramammary route or intrauterine routes.

## Doses

### ■ CATTLE:

For mastitis:

- a) Lactating cow (*Cefa-Lak*®): After milking out udder, clean and dry teat area. Swab teat tip with alcohol wipe and allow to dry. Insert tip of syringe into teat canal; push plunger to instill entire contents. Massage quarter and do not milk out for 12 hours. May repeat dose q12h. (Label directions; *Cefa-Lak*®—BIVI)
- b) Dry Cow (*Cefa-Dri*®): Same basic directions as above, but should be done at the time of drying off and not later than 30 days prior to calving. (Label directions; *Cefa-Dri*®—BIVI)

For subacute and chronic endometritis (at least 14 days after parturition) caused by cephapirin sensitive bacteria:

- a) Using the Intrauterine suspension: Contents of syringe (500 mg) instilled through the cervix into the lumen of the uterus; depending on response may re-treat in 7-14 days if signs persist. May be used one day after insemination. If pyometra, pretreatment with a prostaglandin recommended. (From label information; *Metricure*®—Intervet U.K.)

## Monitoring

- Because cephalosporins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required.
- Patients with diminished renal function may require intensified renal monitoring. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

## Chemistry/Synonyms

A semi-synthetic cephalosporin antibiotic, cephapirin sodium occurs as a white to off-white, crystalline powder having a faint odor. It is very soluble in water and slightly soluble in alcohol. Each gram of the injection contains 2.36 mEq of sodium. After reconstitution, the solution for injection has a pH of 6.5–8.5.

Cephapirin sodium may also be known as: BL-P-1322, cefapirin, cefapirinum natriicum, *Brisfirina*®, *Cefa-Dri*®, *Cefa-Lak*®, *Cefaloject*®, *Cefatrex*®, *Lopitrex*®, *Metricure*®, *Piricef*®, *ToDAY*® or *ToMORROW*®.

## Storage/Stability

Cephapirin intramammary syringes should be stored at controlled room temperature (15–30°C); avoid excessive heat.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Cephapirin Sodium Mastitis Tube; 200 mg cephapirin per 10 mL tube; *ToDAY*® (BIVI), *Cefa-Lak*® (BIVI); (OTC). FDA-approved for use in lactating dairy cattle. Milk withdrawal = 96 hours; Slaughter withdrawal = 4 days.

Cephapirin Benzathine Mastitis Tube; 300 mg cephapirin per 10 mL tube; *ToMORROW*® (BIVI), *Cefa-Dri*® (BIVI); (OTC). FDA-approved for use in dry dairy cattle. Milk withdrawal = 72 hours after calving and must not be administered within 30 days of calving; Slaughter withdrawal = 42 days.

In many countries, including Canada, Australia and the UK, 500 mg cephapirin benzathine intrauterine infusion syringes are available for treating endometritis in dairy or beef cattle. *Metricure*® (Intervet); (Rx). Milk and meat withdrawal times may vary with each country; refer to the label, but usually: milk withdrawal = 0 hours and meat withdrawal = 48 hours.

**HUMAN-LABELED PRODUCTS:** None

## References

Stockler, RM, DE Morin, et al. (2009). Effect of milking frequency and dosing interval on the pharmacokinetics of cephapirin after intramammary infusion in lactating dairy cows. *Journal of Dairy Science* 92(9): 4262–4275.

---

## CETIRIZINE HCL

(she-tih-ra-zeen) Zyrtec®

2ND GENERATION ANTIHISTAMINE

### Prescriber Highlights

- **Oral, relatively non-sedating antihistamine**
  - **Limited clinical experience in veterinary medicine; recommended dosages for dogs & cats vary widely but the drug appears well tolerated**
  - **Potentially may cause vomiting, hypersalivation, or somnolence in small animals**
  - **Expensive when compared to 1st generation antihistamines; generic products becoming available**
- 

## Uses/Indications

Cetirizine is a H1 receptor blocking antihistamine agent that may be useful for the adjunctive treatment of histamine-mediated pruritic conditions in dogs or cats. It may also find a role in treating horses.

## Pharmacology/Actions

Cetirizine, a human metabolite of hydroxyzine, is a piperazine-class non-sedating (when compared to first generation drugs) antihistamine. It selectively inhibits peripheral H1 receptors. Also, cetirizine appears to decrease histamine release from basophils in some species, but in cats, cetirizine or cyproheptadine do not reduce eosinophilic airway inflammation (experimentally produced) (Schooley *et al.* 2007). Cetirizine does not possess significant anticholinergic or anti-serotonergic effects. Tolerance to its antihistaminic effects is thought not to occur.

## Pharmacokinetics

No specific information was located for the pharmacokinetics of cetirizine in dogs. In a study performed in cats (Papich *et al.* 2006) after an oral dose of 5 mg, volume of distribution was 0.26 L/kg and clearance about 0.3 mL/L/minute. Terminal elimination half-life was approximately 11 hours. The mean plasma concentrations remained above 0.85 micrograms/mL (a concentration reported to be effective for humans) for 24 hours after dosing. In horses, the terminal elimination half-life is reported to be around 6 hours (Olsen *et al.* 2008). After oral administration to humans, cetirizine peak concentrations occur in about one hour. Food can delay, but not affect the extent of, absorption. It is 93% bound to human plasma proteins and brain levels are approximately 10% of those found in plasma. Approximately 80% is excreted in the urine, primarily as unchanged drug. Terminal elimination half-life is around 8 hours; antihistaminic effect generally persists for 24 hours after a dose.

## Contraindications/Precautions/Warnings

No specific information is available for veterinary patients. In humans, cetirizine is contraindicated in patients hypersensitive to it or hydroxyzine. Dosage adjustment is recommended in humans with severe renal or hepatic impairment, or older than 76 years of age.

The combination product containing pseudoephedrine is not appropriate for use in dogs or cats.

## Adverse Effects

Cetirizine appears well tolerated in dogs and cats. Vomiting or hypersalivation after dosing have been reported in some dogs. Drowsiness has been reported in small dogs at higher dosages.

A pharmacokinetic/pharmacodynamic study performed in a small number of horses yielded no visible adverse effects.

In humans, the primary adverse effects reported have been drowsiness (13%) and dry mouth (5%). Rarely, hypersensitivity reactions or hepatitis have been reported.

## Reproductive/Nursing Safety

In pregnant mice, rats, and rabbits, dosages of approximately 40X, 180X, and 220X respectively, of the human dose when compared on mg/m<sup>2</sup> basis, caused no teratogenic effects. In humans, the FDA categorizes cetirizine as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but*

there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

In Beagles, approximately 3% of a dose was excreted into milk. Although probably safe for use in nursing veterinary patients, the manufacturer does not recommend using cetirizine in nursing women.

### Overdosage/Acute Toxicity

Limited information is available. Reported minimum lethal oral doses for mice and rats are 237 mg/kg (95X human adult dose on a mg/m<sup>2</sup> basis) and 562 mg/kg (460X human adult dose on a mg/m<sup>2</sup> basis), respectively. Cetirizine may cross into the CNS in overdose situations and cause neurologic signs. Unlike the earlier non-sedating antihistamines, terfenadine and astemizole (both no longer available in the USA), cetirizine does not appreciably prolong the QT interval on ECG at high serum levels.

Overdoses of cetirizine products that also contain pseudoephedrine (*Zyrtec-D 12 Hour*®) may be serious. It is advised to contact an animal poison control center in this event.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cetirizine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS:** Additive CNS depression if used with cetirizine

### Laboratory Considerations

- None noted, however discontinue medication well in advance of any **hypersensitivity skin testing**

### Doses

#### ■ DOGS:

- For atopic dermatitis: 1 mg/kg PO once daily with or without food. Satisfactory control of pruritus in 18% of dogs evaluated in the study. (Cook *et al.* 2004)
- For atopic dermatitis: 5–10 mg (total dose) PO once daily (Thomas 2005)
- For allergic dermatitis: 1 mg/kg PO q12h (Hillier 2004)
- For adjunctive treatment of pruritus: 0.5–1 mg/kg or 5–10 mg total dose once to twice daily. (MacDonald 2007)

#### ■ CATS:

- For adjunctive treatment of non-responsive chronic rhinosinusitis: 5 mg (total dose) PO q12h (Hawkins & Cohn 2006)
- 5 mg (total dose) per cat PO once daily, no controlled studies evaluating effectiveness against other antihistamines. (Ashley 2009)
- For adjunctive treatment of pruritus: 2.5–5 mg (total dose) per cat once daily. (MacDonald 2002), (MacDonald 2007)

#### ■ HORSES:

- Based on pharmacokinetic and pharmacodynamic data, cetirizine at 0.2–0.4 mg/kg PO q12h may be a useful antihistamine in horses. (Olsen *et al.* 2008)

### Monitoring

- Clinical efficacy
- Adverse effects (vomiting, somnolence)

### Client Information

- Warn clients of the potential costs
- Potential adverse effects include GI effects (vomiting, hypersalivation) and somnolence
- May be given without regard to feeding status

### Chemistry/Synonyms

Cetirizine HCl occurs as a white to almost white, crystalline powder that is freely soluble in water. A 5% solution has a pH of 1.2–1.8.

Cetirizine may also be known as: UCB-P071, P-071, cetirizina, cetirizini, cetirizin, ceterizino, or *Zyrtec*®; many internationally registered trade names are available.

### Storage/Stability

Tablets should be stored at 20–25°C; excursions are permitted to 15–30°C. The oral syrup may be stored at room temperature or in the refrigerator.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

#### **HUMAN-LABELED PRODUCTS:**

Cetirizine HCl Oral Tablets (film-coated): 5 mg & 10 mg; *Zyrtec*® (McNeil Consumer), generic; (Rx)

Cetirizine HCl Chewable Tablets (grape flavor): 5 mg & 10 mg; *Zyrtec*® (McNeil Consumer); (Rx)

Cetirizine HCl Oral Syrup: 1 mg/mL (grape flavor) in 118 & 473 mL; *Zyrtec*® (McNeil Consumer); generic; (Rx)

Cetirizine HCl 5 mg with Pseudoephedrine HCl 120 mg Extended-Release Tablets; *Zyrtec-D 12 Hour*® (Pfizer); (Rx)

---

## CHARCOAL, ACTIVATED

(*char-kole*) Toxiban®

ORAL ADSORBENT

### Prescriber Highlights

- Orally administered adsorbent for GI tract toxins/drug overdoses; recommend consulting with an animal poison control center before use
  - Not effective for mineral acids/alkalis
  - Too rapid administration may induce emesis/aspiration
  - In small dogs & cats, monitor for hypernatremia
  - Handle with care as charcoal stains clothing very easily; dry powder “floats”
- 

### Uses/Indications

Activated charcoal is administered orally to adsorb certain drugs or toxins to prevent or reduce their systemic absorption.

### Pharmacology/Actions

Activated charcoal has a large surface area and adsorbs many chemicals and drugs via ion-ion, hydrogen bonding, dipole and Van der Waals forces in the upper GI tract thereby preventing or reducing their absorption. Efficiency of adsorption increases with the molecular size of the toxin and poorly water soluble organic substances are better adsorbed than small, polar, water-soluble organic compounds.

While activated charcoal also adsorbs various nutrients and enzymes from the gut, when used for acute poisonings, no clinical significance usually results. Activated charcoal reportedly is not effective in adsorbing cyanide, but this has been disputed in a recent study. It is not very effective in adsorbing alcohols, ferrous sulfate, lithium, caustic alkalies, nitrates, sodium chloride/chlorate, petroleum distillates or mineral acids. Activated charcoal slurries are more effective in adsorbing most toxins than are tablets.

### Pharmacokinetics

Activated charcoal is not absorbed nor metabolized in the gut. As activated charcoal slurries can slow GI transit times, an osmotic cathartic is often given concurrently which can enhance expulsion of the toxin-charcoal moiety.

### Contraindications/Precautions/Warnings

Charcoal should not be used for mineral acids or caustic alkalies as it is ineffective. Although not contraindicated for ethanol, methanol, or iron salts, activated charcoal is ineffective in adsorbing these products and may obscure GI lesions during endoscopy.

To enhance elimination of the charcoal-toxin moiety, an osmotic cathartic (*e.g.*, sorbitol) is often given with activated charcoal. If multiple doses of activated charcoal are administered, it has been recommended that only the first dose contain the cathartic to prevent diarrhea and dehydration (Jutkowitz & Schildt 2009).

### Adverse Effects

Very rapid GI administration of charcoal can induce emesis. If aspiration occurs after activated charcoal is administered, pneumonitis/aspiration pneumonia may result. Charcoal can cause either constipation or diarrhea and feces will be black. Products containing sorbitol may cause loose stools and vomiting.

There have been reports of hypernatremia occurring in small dogs and cats after charcoal (with or without sorbitol) administration, presumably due an osmotic effect pulling water into the GI tract. Reduced sodium fluids (*e.g.*, D5W, 1/2 normal saline/D2.5W) with warm water enemas can be administered to alleviate the condition.

Charcoal powder is very staining and the dry powder tends to “float” covering wide areas.

### Overdosage/Acute Toxicity

Potentially could cause electrolyte abnormalities; see Adverse Effects for more information.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving charcoal and may be of significance in veterinary patients:

- **OTHER ORALLY ADMINISTERED THERAPEUTIC AGENTS:** Separate by at least 3 hours the administration of any other orally administered therapeutic agents from the charcoal dose
- **DAIRY PRODUCTS:** May reduce the adsorptive capacity of activated charcoal
- **MINERAL OIL:** May reduce the adsorptive capacity of activated charcoal
- **POLYETHYLENE GLYCOL; ELECTROLYTE SOLUTIONS (*e.g.*, *Go-Lytely*®):** May reduce the adsorptive capacity of activated charcoal

### Doses

#### ■ DOGS & CATS:

**Note:** Depending on the toxin exposure, recommendations for using activated charcoal can vary. It is highly recommended to contact an animal poison control center for specific guidance on using activated charcoal in veterinary patients.

Dogs and cats with no clinical signs may freely drink the charcoal suspension if administered via syringe. A small amount of food may be added to the solution to

enhance palatability. In animals exhibiting clinical signs, administration of activated charcoal slurries/suspensions may be administered via an orogastric tube with a cuffed endotracheal tube in place to help prevent aspiration. Administration via a nasogastric tube may be useful, particularly in cats. (Jutkowitz & Schildt 2009)

As a gastrointestinal absorbent:

a) 10 mL of a 20% slurry (1 g of charcoal in 5 mL of water) per kg of body weight by stomach tube (Carson & Osweiler 2003)

For acute poisoning:

a) After decontamination of the GI tract give activated charcoal at 1–4 g/kg PO. Placement of a nasogastric tube can facilitate administration and reduce the incidence of aspiration in the sedated/fractious animal particularly when repeated administration is desired; repeat every 4–6 hours for toxins that are recirculated through the intestinal capillary network. (Rudloff 2006)

b) 1–4 g/kg in 50–200 mL of water. Concurrent with or within 30 minutes of giving charcoal, give an osmotic cathartic. Repeated doses of activated charcoal may also bind drugs that are enterohepatically recycled. (Beasley & Dorman 1990)

c) Administer in a bathtub or other easily cleanable area. Give activated charcoal at 1–5 g/kg PO (via stomach tube using either a funnel or large syringe) diluted in water at a concentration of 1 g charcoal/5–10 mL of water. Follow in 30 minutes with sodium sulfate oral cathartic. (Bailey 1989)

#### ■ RUMINANTS:

a) As a cathartic for plant intoxications: Activated charcoal (AC) slurry dosage range of 1–5 g/kg (~1 g of activated charcoal per 5 ml of water). Multi-dose activated charcoal is beneficial for a number of plant intoxications, including oleander. Administration of a cathartic mixed in the AC slurry helps to hasten elimination of contents from the gastrointestinal tract. Commonly used cathartics include sodium sulfate (Glauber's salts), magnesium sulfate (Epsom salts), and sorbitol. Sodium or magnesium sulfate can be administered at 250–500 mg/kg mixed in the AC slurry. Sorbitol (70%), also mixed in the AC slurry, can be administered at 3 ml/kg. There is little need to administer a cathartic if significant diarrhea is already present. (Puschner 2010)

#### ■ HORSES:

a) **Foals:** 250 grams (minimum). Adult horses: up to 750 grams. Make a slurry by mixing with up to 4 L (depending on animal's size) of warm water and administer via stomach tube. Leave in stomach for 20–30 minutes and then give a laxative to hasten removal of toxicants. (Oehme 1987)

b) See the reference by Puschner in the Ruminants section above

#### Monitoring

■ Monitoring for efficacy of charcoal is usually dependent upon the toxin/drug that it is being used for and could include the drug/toxin's serum level, clinical signs, etc.

■ Serum sodium, particularly if patient develops neurologic signs associated with hypernatremia (tremors, ataxia, seizures)

#### Client Information

■ This agent should generally be used with professional supervision; if used on an outpatient basis patients must be observed for at least 4 hours after administration for signs associated with too much sodium in the blood (weakness, unsteadiness, tremors, convulsions). Should these occur, patients must immediately be seen by a veterinarian.

■ Charcoal can easily stain fabrics

#### Chemistry/Synonyms

Activated charcoal occurs as a fine, black, odorless, tasteless powder that is insoluble in water or alcohol. Commercially available activated charcoal products may differ in their adsorptive properties, but one gram must adsorb 100 mg of strychnine sulfate in 50 mL of water to meet USP standards.

Activated charcoal may also be known as: active carbon, activated carbon, carbo activatus, adsorbent charcoal, decolorizing carbon, or medicinal charcoal. There are many trade names available.

#### Storage/Stability

Store activated charcoal in well-closed glass or metal containers or in the manufacturer's supplied container.

#### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

In the USA, the following products are labeled for veterinary use, but there are no oral activated charcoal products listed as FDA-approved on the FDA's "Green Book" website.

Activated charcoal 47.5%, Kaolin 10% granules (free flowing and wettable) in 1 lb bottles, and 5 kg pails: *Toxiban® Granules* (Vet-A-Mix); (OTC). Labeled for use in both large and small animals.

Activated charcoal 10.4%, Kaolin 6.25% suspension in 240 mL bottles: *Toxiban® Suspension* (Vet-A-Mix); (OTC). Labeled for use in both large and small animals.

Activated charcoal 10%, Kaolin 6.25%, sorbitol 10% suspension in 240 mL bottles: *Toxiban® Suspension with Sorbitol* Vet-A-Mix); (OTC). Labeled for use in small animals.

Activated Charcoal 10%, Attapulgit 20%, sodium chloride 35 mg/mL, potassium chloride 35 mg/mL Gel/Paste in 80 mL & 300 mL: *D-Tox-Besc®* (AgriPharm); *Activated Charcoal Gel with Electrolytes®* & *DVM Formula®* (Bomac Plus Vet), *Activated Charcoal Paste®* (First Priority); (OTC). Labeled for use in small and large animals.

Activated Hardwood Charcoal and thermally activated attapulgit clay (concentrations not labeled) in an aqueous gel suspension in 8 fl oz bottle, 60 mL tube and 300 mL tube with easy dose syringe. *UAA® (Universal Animal Antidote) Gel* (Vedco); (OTC). Labeled for use in dogs, cats and grain overload in ruminants.

#### HUMAN-LABELED PRODUCTS:

Activated Charcoal Oral Powder: 15 g, 30 g, 40 g, 120 g, 240 g and UD 30 g; generic; (OTC)

Activated Charcoal Oral Liquid/Suspension with sorbitol: 15 g & 30 g in 150 mL & 50 g in 240 mL; *CharcoAid®* (Requa); 25 g in 120 mL & 50 g in 240 mL; *Actidose® with Sorbitol* (Paddock); (OTC)

Activated Charcoal Liquid/Suspension without sorbitol: 15 g & 50 g in 120 mL & 240 mL; *CharcoAid® 2000* (Requa); (OTC); 208 mg/mL — 12.5 g in 60 mL & 25 g in 120 mL; 12.5 g in 60 mL, 15 g in 75 mL, 25 g in 120 mL, 30 g in 120 mL, 50 g in 240 mL; *Actidose-Aqua®* (Paddock); generic; (OTC)

Activated Charcoal Oral Granules: 15 g in 120 mL; *CharcoAid® 2000* (Requa); (OTC)

## CHLORAMBUCIL

(*klor-am-byoo-sil*) Leukeran®

IMMUNOSUPPRESSANT/ANTINEOPLASTIC

### Prescriber Highlights

- **Nitrogen mustard derivative immunosuppressant & antineoplastic**
- **Used for severe autoimmune diseases in cats (e.g., IBD, pemphigus, etc.) as it is less toxic than cyclophosphamide or azathioprine in cats**
- **Caution: Preexisting bone marrow depression, infection**
- **Potential teratogen**
- **Adverse Effects primarily myelosuppression & GI toxicity**

---

## Uses/Indications

Chlorambucil may be useful in a variety of neoplastic diseases, including lymphocytic leukemia, multiple myeloma, polycythemia vera, macroglobulinemia, and ovarian adenocarcinoma. It may also be useful as adjunctive therapy for some immune-mediated conditions (e.g., glomerulonephritis, inflammatory bowel disease, non-erosive arthritis, or immune-mediated skin disease). It has found favor as a routine treatment for feline pemphigus foliaceus and severe feline eosinophilic granuloma complex due to the drug's relative lack of toxicity in cats and efficacy.

## Pharmacology/Actions

Chlorambucil is a cell-cycle nonspecific alkylating antineoplastic/immunosuppressive agent. Its cytotoxic activity stems from cross-linking with cellular DNA.

## Pharmacokinetics

Chlorambucil is rapidly and nearly completely absorbed after oral administration; peak levels occur in about one hour. It is highly bound to plasma proteins. While it is not known whether it crosses the blood-brain barrier, neurological side effects have been reported. Chlorambucil crosses the placenta, but it is not known whether it enters maternal milk. Chlorambucil is extensively metabolized in the liver, primarily to phenylacetic acid mustard, which is active. Phenylacetic acid mustard is further metabolized to other metabolites that are excreted in the urine.

## Contraindications/Precautions/Warnings

Chlorambucil is contraindicated in patients who are hypersensitive to it or have demonstrated resistance to its effects. It should be used with caution in patients with preexisting bone marrow depression or infection, or are susceptible to bone marrow depression or infection.

## Adverse Effects

The most commonly associated major adverse effects seen with chlorambucil therapy is myelosuppression manifested by anemia, leukopenia, and thrombocytopenia and gastrointestinal toxicity (vomiting, diarrhea). A greater likelihood of toxicity occurs with higher dosages. This may occur gradually with nadirs occurring usually within 7–14 days of the start of therapy. Recovery generally takes from 7–14 days. Severe bone marrow depression can result in pancytopenia that may take months to years for recovery. Alopecia and delayed regrowth of shaven fur have been reported in dogs; Poodles or Kerry blues are reportedly more likely to be affected than other breeds. One case report of neurotoxicity (facial twitching, myoclonus, agitation, seizures) after chlorambucil therapy in a cat has been reported (Benitah *et al.* 2003).

In humans, bronchopulmonary dysplasia with pulmonary fibrosis, neurotoxicity, and uric acid nephropathy have been reported. These effects are uncommon and generally associated with chronic, higher dose therapy. Hepatotoxicity has been reported rarely in humans.

## Reproductive/Nursing Safety

Chlorambucil's teratogenic potential remains poorly documented, but it may potentially cause a variety of fetal abnormalities. It is generally recommended to avoid the drug during pregnancy, but because of the seriousness of the diseases treated with chlorambucil, the potential benefits to the mother must be considered. Chlorambucil has been documented to cause irreversible infertility in male humans, particularly when given during pre-puberty and puberty. In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

## Overdosage/Acute Toxicity

The oral LD<sub>50</sub> in mice is 123 mg/kg. There have been limited experiences with acute overdoses in humans. Doses of up to 5 mg/kg resulted in neurologic (seizures)

The oral LD<sub>50</sub> in mice is 123 mg/kg. There have been limited experiences with acute overdoses in humans. Doses of up to 5 mg/kg resulted in neurologic (seizures) toxicity and pancytopenia (nadir at 1–6 weeks post ingestion). All patients recovered without long-term sequelae. Treatment should consist of gut emptying when appropriate (beware of rapidly changing neurologic status if inducing vomiting). Monitoring of CBC's several times a week for several weeks should be performed after overdoses and blood component therapy may be necessary.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorambucil and may be of significance in veterinary patients:

- **MYELOSUPPRESSIVE DRUGS** (e.g., other antineoplastics, chloramphenicol, flucytosine, amphotericin B, or colchicine): Bone marrow depression may be additive
- **IMMUNOSUPPRESSIVE DRUGS** (e.g., azathioprine, cyclophosphamide, cyclosporine, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection

### Laboratory Considerations

- Chlorambucil may raise serum **uric acid** levels. Drugs such as **allopurinol** may be required to control hyperuricemia in some patients.

### Doses

For current specific dosing recommendations, indications, treatment protocols, monitoring and safety guidelines when chlorambucil is used as an antineoplastic agent, it is strongly recommended to work in collaboration with a veterinary oncologist and to refer to veterinary oncology references (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001).

#### ■ DOGS:

For adjunctive therapy (as an immunosuppressant) in the treatment of glomerulonephritis:

- a) 0.1–0.2 mg/kg PO once daily or every other day (Vaden & Grauer 1992)

For adjunctive therapy of lymphoreticular neoplasms, macroglobulinemia, and polycythemia vera:

- a) For first level treatment of dogs of canine lymphoma where clients cannot afford, or will not accept combination chemotherapy due to risks of toxicity:

Prednisone alone 40 mg/m<sup>2</sup> (NOT mg/kg) PO daily for 7 days then every other day) or in combination with chlorambucil at 6–8 mg/m<sup>2</sup> (NOT mg/kg) PO every other day. Perform a CBC every 2–3 weeks. (Ogilvie 2006)

- b) For lymphoproliferative disease; macroglobulinemia: 2–4 mg/m<sup>2</sup> (NOT mg/kg) PO q24–48h (Gilson & Page 1994)

For treatment of pemphigus complex:

- a) Prednisone 2–4 mg/kg PO divided q12h with chlorambucil 0.2 mg/kg q24–48h (Helton-Rhodes 1994)

- b) Used in combination with corticosteroids. Chlorambucil 0.1–0.2 mg/kg once daily initially until marked improvement (or 75% improvement) of clinical signs (may require 4–8 weeks). Then alternate day dosing is begun and maintained for several weeks. If no exacerbation, alternately decrease chlorambucil and corticosteroids until lowest possible dose is attained. (White 2000)

For adjunctive treatment of inflammatory bowel disease:

- a) 1.5 mg/m<sup>2</sup> (NOT mg/kg) PO every other day (Marks 2007)

#### ■ CATS:

For adjunctive treatment of inflammatory bowel disease:

- a) As a second choice (corticosteroids first choice) or refractory or severe IBD: Cats greater than 4 kg: 2 mg (total dose) PO q48 hours (every other day) for 2–4 weeks then tapered to the lowest effective dose (2 mg per cat q72–96 hours; every 3rd to 4th day). Cats less than 4 kg are started at 2 mg (total dose) q72 hours (every 3rd day). (Moore 2004)

- b) 15 mg/m<sup>2</sup> (NOT mg/kg) PO once per day for 4 consecutive days, repeated every 3 weeks (in combination with prednisolone) appears highly effective in managing cats with severe IBD or intestinal lymphoma. Alternatively, may dose at 2 mg (total dose) per cat every 4 days indefinitely. (Marks 2007)

- c) For lymphocytic-plasmacytic enteritis (LPE): Chlorambucil is sometimes useful for cats that do not respond to diet, prednisolone and metronidazole; limited experience, but seems it should be administered with prednisolone. Two methods for dosing: **1**) Initial dose is 2 mg/m<sup>2</sup> (NOT mg/kg) PO for 4–7 days, then decreased to 1 mg/m<sup>2</sup> (NOT mg/kg) for 7 days. If clinical signs are lessening, continue daily dosing but only every other week; it is common for patients to develop anemia. **2**) Large cats (>7 lb.) 2 mg PO twice weekly; smaller cats (<7 lb) 1 mg PO twice weekly. If a clinical response will occur, it should be seen in 4–6 weeks, after which the drug is slowly tapered to the lowest effective dose. Monitor CBC's anytime the cat seems to feel bad. (Willard 2006)

- d) As an alternative (chlorambucil usually reserved for refractory cases) to prednisolone therapy: For cats < 2 kg: 2 mg (total dose) PO once weekly. For cats > 2 kg: 2 mg (total dose) PO once every 4 days. A good choice if no clear differentiation can be made between severe IBD and lymphoma. (Gruffyd-Jones 2009)

For adjunctive treatment of pemphigus complex or other immune-mediated dermatoses:

- a) 2 mg (total dose per cat) every 48 hours. May be used in combination with or as an alternative to steroids. (Ashley 2009)

- b) For generalized pemphigus foliaceus: If cats have a poor response to prednisolone alone, may add chlorambucil at 0.1–0.2 mg/kg PO q24–48h; has slow onset of action and can cause bone marrow depression. (Hillier 2006)

- c) For idiopathic dermatitis when nothing else works: 0.2 mg/kg PO q24–48h. Closely monitor during treatment. (Hnilica 2003)

For adjunctive treatment of FIP:

- a) Prednisolone 4 mg/kg PO once daily with chlorambucil 20 mg/m<sup>2</sup> (NOT mg/kg) every 2–3 weeks (Weiss 1994)

For lymphocytic leukemia:

- a) Chlorambucil 6 mg/m<sup>2</sup> (2 mg/5.3 kg cat) PO every other day and prednisolone 5 mg/cat/day. Supplemental cobalamin (1 mL SC q2–3 weeks) and folate/B-complex vitamins should also be given. (Simpson 2003)

#### ■ HORSES:

For adjunctive therapy in treating lymphoma using the LAP protocol:

a) Cytosine arabinoside 200–300 mg/m<sup>2</sup> (NOT mg/kg) SC or IM once every 1–2 weeks; Chlorambucil 20 mg/m<sup>2</sup> (NOT mg/kg) PO every 2 weeks (alternating with cytosine arabinoside) and Prednisone 1.1–2.2 mg/kg PO every other day. If this protocol is not effective (no response seen in 2–4 weeks) add vincristine at 0.5 mg/m<sup>2</sup> (NOT mg/kg) IV once a week. Side effects are rare. (Couto 1994)

## Monitoring

- Efficacy
- CBC, Platelets once weekly (or once stable every other week) during therapy; once stable, dogs may require only monthly monitoring. If neutrophils are <3,000/microL hold drug until recovered and reduce dose by 25% or increase dosing interval. Other references recommend CBCs at 0, 1, 2, 4, 8, & 12 weeks and then every 3-6 months (Mueller 2000) or in cats, CBCs at 2 to 3 weeks after starting therapy and every 3-6 months thereafter (Ashley 2009).
- Uric acid, liver enzymes; if warranted

## Client Information

- Clients must understand the importance of both administering chlorambucil as directed and immediately reporting any signs associated with toxicity (*e.g.*, abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.)

## Chemistry/Synonyms

A nitrogen mustard derivative antineoplastic agent, chlorambucil occurs as an off-white, slightly granular powder. It is very slightly soluble in water.

Chlorambucil may also be known as: CB-1348, NSC-3088, WR-139013, chlorambucilum, chloraminophene, chlorbutinum, *Chloraminophene*®, *Leukeran*®, or *Linfolysin*®.

## Storage/Stability

Chlorambucil tablets should be stored in light-resistant, well-closed containers under refrigeration (2–8°C; 36–46°F). Tablets can be stored at a maximum of 30°C (86°F) up to one week. An expiration date of one year after manufacture is assigned to the commercially available tablets.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Chlorambucil oral suspension compounded from commercially available tablets has been published (Dressman & Poust 1983). Triturating six (6) chlorambucil 2 mg tablets with 2 mL *Cologel*® and *qs ad* to 6 mL with simple syrup yields a 2 mg/mL oral suspension that retains 90% potency for 7 days at 5°C. Suspensions of chlorambucil stored at room temperature rapidly decompose with losses >15% in one day. Chlorambucil is rapidly hydrolyzed independently of pH, but minimal hydrolysis occurs at pH 2. Refrigeration also slows hydrolysis.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Chlorambucil Oral Tablets (film-coated): 2 mg; *Leukeran*® (GlaxoSmithKline); (Rx)

## CHLORAMPHENICOL

### CHLORAMPHENICOL SODIUM SUCCINATE

(klor-am-fen-i-kole) Chloromycetin®, Duricol®, Viceton®

BROAD-SPECTRUM ANTIBACTERIAL

## Prescriber Highlights

- **Broad spectrum antibiotic**
- **Contraindications: Food animals (banned)**
- **Extreme caution/avoid use: Preexisting hematologic disorders, pregnancy, neonates, hepatic failure, renal failure (cats); IV use in patients with cardiac failure; use long-term (>14 days) in cats with caution**
- **May need to reduce dose in patients with hepatic or renal insufficiency**

- **Adverse Effects: GI; potentially myelosuppressive, especially with high dose, long-term treatment**
  - **Potentially toxic to humans; have dosage-giver avoid direct contact with medication**
- 

### Uses/Indications

Chloramphenicol is used for a variety of infections in small animals and horses, particularly those caused by anaerobic bacteria. The FDA has prohibited the use of chloramphenicol in animals used for food production because of the human public health implications.

### Pharmacology/Actions

Chloramphenicol usually acts as a bacteriostatic antibiotic, but at higher concentrations or against some very susceptible organisms it can be bactericidal. Chloramphenicol acts by binding to the 50S ribosomal subunit of susceptible bacteria, thereby preventing bacterial protein synthesis. Erythromycin, clindamycin, lincomycin, tylosin, etc., also bind to the same site, but unlike these drugs, chloramphenicol appears to also have an affinity for mitochondrial ribosomes of rapidly proliferating mammalian cells (*e.g.*, bone marrow) that may result in reversible bone marrow suppression.

Chloramphenicol has a wide spectrum of activity against many gram-positive and gram-negative organisms. Gram-positive aerobic organisms that are generally susceptible to chloramphenicol include many streptococci and staphylococci. It is also effective against some gram-negative aerobes including *Neisseria*, *Brucella*, *Salmonella*, *Shigella*, and *Haemophilus*. Many anaerobic bacteria are sensitive to chloramphenicol including *Clostridium*, *Bacteroides* (including *B. fragilis*), *Fusobacterium*, and *Veillonella*. Chloramphenicol also has activity against *Nocardia*, *Chlamydia*, *Mycoplasma*, and *Rickettsia*.

### Pharmacokinetics

Chloramphenicol is rapidly absorbed after oral administration with peak serum levels occurring approximately 30 minutes after dosing. The palmitate oral suspension produces significantly lower peak serum levels when administered to fasted cats. The sodium succinate salt is rapidly and well absorbed after IM or SC administration in animals and, contrary to some recommendations, need not be administered only intravenously. The palmitate and sodium succinate is hydrolyzed in the GI tract and liver to the base.

Chloramphenicol is widely distributed throughout the body. Highest levels are found in the liver and kidney, but the drug attains therapeutic levels in most tissues and fluids, including the aqueous and vitreous humor, and synovial fluid. CSF concentrations may be up to 50% of those in the serum when meninges are uninfamed and higher when meninges are inflamed. A 4–6 hour lag time before CSF peak levels occur may be seen. Chloramphenicol concentrations in the prostate are approximately 50% of those in the serum. Because only a small amount of the drug is excreted unchanged into the urine in dogs, chloramphenicol may not be the best choice for lower urinary tract infections in that species. The volume of distribution of chloramphenicol has been reported as 1.8 L/kg in the dog, 2.4 L/kg in the cat, and 1.41 L/kg in horses. Chloramphenicol is about 30–60% bound to plasma proteins, enters milk and crosses the placenta.

In most species, chloramphenicol is eliminated primarily by hepatic metabolism via glucuronidative mechanisms. Only about 5–15% of the drug is excreted unchanged in the urine. The cat, having little ability to glucuronidate drugs, excretes 25% or more of a dose as unchanged drug in the urine.

The elimination half-life has been reported as 1.1–5 hours in dogs, <1 hour in foals and ponies, and 4–8 hours in cats. The elimination half-life of chloramphenicol in birds is highly species variable, ranging from 26 minutes in pigeons to nearly 5 hours in bald eagles and peafowl.

The usual serum therapeutic range for chloramphenicol is 5–15 micrograms/mL.

### Contraindications/Precautions/Warnings

Chloramphenicol is prohibited by the FDA for use in food animals.

Chloramphenicol is contraindicated in patients hypersensitive to it. Because of the potential for hematopoietic toxicity, the drug should be used with extreme caution, if at all, in patients with preexisting hematologic abnormalities, especially a preexisting non-regenerative anemia. The drug should only be used in patients in hepatic failure when no other effective antibiotics are available. Chloramphenicol should be used with caution in patients with impaired hepatic or renal function as drug accumulation may occur. Those patients may need dosing adjustment, and monitoring of blood levels should be considered.

Chloramphenicol should be used with caution in neonatal animals, particularly in young kittens. In neonates (humans), circulatory collapse (so-called “Gray-baby syndrome”) has occurred with chloramphenicol, probably due to toxic levels accumulating secondary to an inability to conjugate the drug or excrete the conjugate effectively.

### Adverse Effects

While the toxicity of chloramphenicol in humans has been much discussed, the drug is considered by most to have a low order of toxicity in adult companion animals when appropriately dosed.

The development of aplastic anemia reported in humans, does not appear to be a significant problem for veterinary patients; however, a dose-related bone marrow suppression (reversible) is seen in all species, primarily with long-term therapy. Early signs of bone marrow toxicity can include vacuolation of many of the early cells of the myeloid and erythroid series, lymphocytopenia, and neutropenia. Thrombocytopenia associated with chloramphenicol use in cats has been reported.

Other effects that may be noted include anorexia, vomiting, diarrhea, and depression.

It has been said that cats tend to be more sensitive to developing adverse reactions to chloramphenicol than dogs, but this is probably more as a result of the drug’s longer half-life in the cat. Cats dosed at 50 mg/kg q12h for 2–3 weeks do develop a high incidence of adverse effects and should be closely monitored when prolonged high-dose therapy is necessary.

### Reproductive/Nursing Safety

Chloramphenicol has not been determined to be safe for use during pregnancy. The drug may decrease protein synthesis in the fetus, particularly in the bone marrow. It should only be used when the benefits of therapy clearly outweigh the risks. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Because chloramphenicol is found in milk in humans at 50% of serum levels, the drug should be given with caution to nursing bitches or queens, particularly within the first week after giving birth.

### Overdosage/Acute Toxicity

Because of the potential for serious bone marrow toxicity, large overdoses of chloramphenicol should be handled by emptying the gut using standard protocols. For more information on the toxicity of chloramphenicol, refer to the Adverse Effects section above.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chloramphenicol and may be of significance in veterinary patients (**Note:** cats may be particularly susceptible to chloramphenicol's effects on the hepatic metabolism of other drugs):

- **ANTI-ANEMIA DRUGS (Iron, Vitamin B12, folic acid):** Chloramphenicol may delay hematopoietic response
- **BETA-LACTAM ANTIBIOTICS (penicillins, cephalosporins, aminoglycosides):** Potential for antagonism
- **CIMETIDINE:** May reduce the metabolism of chloramphenicol increasing the risks for toxicity
- **LIDOCAINE:** Chloramphenicol may delay hepatic metabolism
- **MYELOSUPPRESSIVE DRUGS (e.g., cyclophosphamide):** Potential for additive bone marrow depression
- **PENTOBARBITAL:** Chloramphenicol has been demonstrated to prolong the duration of pentobarbital anesthesia by 120% in dogs, and 260% in cats
- **PHENOBARBITAL:** Chloramphenicol may inhibit hepatic metabolism and phenobarbital may decrease chloramphenicol concentrations
- **PRIMIDONE:** Anorexia and CNS effects may occur in dogs
- **PROPOFOL:** Chloramphenicol may prolong anesthesia
- **RIFAMPIN:** May decrease serum chloramphenicol levels

## Laboratory Considerations

- False-positive **glucosuria** has been reported, but the incidence is unknown.

## Doses

### ■ DOGS:

For susceptible infections:

- a) 45–60 mg/kg PO q8h; 45–60 mg/kg IM, SC or IV q6–8h (USPC 1990)
- b) 40–50 mg/kg IV, IM, SC or PO q8h; avoid in young animals or in breeding or pregnant animals; avoid or reduce dosage in animals with severe liver failure. (Vaden & Papich 1995)
- c) For urinary, rickettsial, localized soft tissue infections: 25–50 mg/kg PO q8h for 7 days.  
For systemic infections: 50 mg/kg PO, IV, IM, SC q6–8h for 3–5 days  
For severe bacteremia, sepsis: 50 mg/kg IV, IM or SC q4–6h for 3 days (Greene & Watson 1998)
- d) For Rocky Mountain Spotted Fever: 15–20 mg/kg q8h PO, IM or IV for 14–21 days (Sellon & Breitschwerdt 1995)
- e) For susceptible infectious otitis: 50 mg/kg PO q8h (Rosenkrantz 2006)

### ■ CATS:

For susceptible infections:

- a) 25–50 mg/kg PO q12h; 12–30 mg/kg IM, SC or IV q12h (USPC 1990)
- b) 50 mg (total dose) IV, IM, SC or PO q8h; avoid in young animals or in breeding or pregnant animals; avoid or reduce dosage in animals with severe liver failure (Vaden & Papich 1995)
- c) For urinary, localized soft tissue infections: 50 mg per cat (total dose) PO q12h for 14 days.  
For systemic infections: 25–50 mg/kg PO, IV, IM, SC q12h for 14 days or less  
For severe bacteremia, sepsis: 50 mg per cat (total dose) PO, IV, IM or SC q6–8h for 5 days or less. (Greene & Watson 1998)

### ■ RABBITS/RODENTS/SMALL MAMMALS:

- a) **Rabbits:** 30–50 mg/kg PO, SC, IM, IV q8–24h (Ivey & Morrisey 2000)
- b) **Hedgehogs:** 50 mg/kg PO q12h; 30–50 mg/kg SC, IM, IV or IO q12h (Smith 2000)
- c) **Chinchillas:** 30–50 mg/kg PO, SC, IM q12h (Hayes 2000)
- d) **Gerbils, Guinea Pigs, Hamsters, Mice, Rats:** 20–50 mg/kg (succinate salt) SC q6–12h (Adamcak & Otten 2000)
- e) **Guinea pigs for pneumonia:** 30–50 mg/kg PO q12h (Johnson 2006b)

### ■ FERRETS:

For proliferative colitis:

- a) 50 mg/kg q12h PO for 14–21 days (Johnson 2006a)

For susceptible infections:

- a) 50 mg/kg PO twice daily (using palmitate salt—may be unavailable) or 50 mg/kg SC or IM twice daily (succinate salt) (Williams 2000)

### ■ HORSES:

For susceptible infections:

- a) 45–60 mg/kg PO q8h; 45–60 mg/kg IM, SC or IV q6–8h (USPC 1990)
- b) **Foals:** 20 mg/kg PO or IV q4h (Furr 1999)
- c) **Foals:** Chloramphenicol sodium succinate: 25–50 mg/kg IV q4–8h; chloramphenicol base or palmitate: 40–50 mg/kg PO q6–8h (Brumbaugh 1999)

### ■ BIRDS:

For susceptible infections:

a) Chloramphenicol sodium succinate: 80 mg/kg IM two to three times daily, 50 mg/kg IV three to four times daily

Chloramphenicol palmitate suspension (30 mg/mL): 0.1 mL/30 grams of body weight three to four times daily. Do not use for initial therapy in life-threatening infections. Must use parenteral form if crop stasis occurs. (Clubb 1986)

b) Chloramphenicol palmitate suspension (30 mg/mL): 75 mg/kg three times a day; absorption is erratic, but well-tolerated and efficacious in baby birds with enteric infections being hand fed. Will settle out if added to drinking water. (McDonald 1989)

c) Succinate: 50 mg/kg IM or IV q8h; Palmitate: 75 mg/kg PO q8h (Hoeffler 1995)

d) Ratites (not to be used for food): 35–50 mg/kg PO, IM, IV or SC 3 times daily for 3 days (Jenson 1998)

## ■ REPTILES:

For susceptible infections:

a) For most species using the sodium succinate salt: 20–50 mg/kg IM or SC for up to 3 weeks. Chloramphenicol is often a good initial choice until sensitivity results are available. (Gauvin 1993)

b) 30–50 mg/kg/day IV, or IM for 7–14 days (Lewbart 2001)

## Monitoring

■ Clinical efficacy

■ Adverse effects; chronic therapy should be associated with routine CBC monitoring

## Client Information

■ **MUST NOT** be used in any animal to be used for food production

■ There is evidence that humans exposed to chloramphenicol have an increased risk of developing fatal aplastic anemia. Products should be handled with care. Do not inhale powder and wash hands after handling tablets.

■ Crushed tablets or capsule contents are very bitter tasting and animals may not accept the drug if presented in this manner

## Chemistry/Synonyms

Originally isolated from *Streptomyces venezuelae*, chloramphenicol is now produced synthetically. It occurs as fine, white to grayish, yellow white, elongated plates or needle-like crystals with a pKa of 5.5. It is freely soluble in alcohol and about 2.5 mg are soluble in 1 mL of water at 25°C.

Chloramphenicol sodium succinate occurs as a white to light yellow powder. It is freely soluble in both water and alcohol. Commercially available chloramphenicol sodium succinate for injection contains 2.3 mEq of sodium per gram of chloramphenicol.

Chloramphenicol may also be known as: chloramphenicolium, chloranfenicol, cloranfenicol, kloramfenikol, or laevomycetinum; many trade names are available.

## Storage/Stability

Chloramphenicol capsules and tablets should be stored in tight containers at room temperature (15–30°C). The palmitate oral suspension should be stored in tight containers at room temperature and protected from light or freezing.

The sodium succinate powder for injection should be stored at temperatures less than 40°, preferably between 15–30°C. After reconstituting the sodium succinate injection with sterile water, the solution is stable for 30 days at room temperature and 6 months if frozen. The solution should be discarded if it becomes cloudy.

## Compatibility/Compounding Considerations

The following drugs and solutions are reportedly **compatible** with chloramphenicol sodium succinate injection: all commonly used intravenous fluids, amikacin sulfate, aminophylline, ampicillin sodium (in syringe for 1 hr.) ascorbic acid, calcium chloride/gluconate, cephalothin sodium, cephapirin sodium, colistimethate sodium, corticotropin, cyanocobalamin, dimenhydrinate, dopamine HCl, ephedrine sulfate, heparin sodium, hydrocortisone sodium succinate, hydroxyzine HCl, kanamycin sulfate, lidocaine HCl, magnesium sulfate, metaraminol bitartrate, methicillin sodium, methylodopate HCl, methylprednisolone sodium succinate, metronidazole with or without sodium bicarbonate, nafcillin sodium, oxacillin sodium, oxytocin, penicillin G potassium/sodium, pentobarbital sodium, phenylephrine HCl with or without sodium bicarbonate, phytonadione, plasma protein fraction, potassium chloride, promazine HCl, ranitidine HCl, sodium bicarbonate, thiopental sodium, verapamil HCl, and vitamin B-complex with C.

The following drugs and solutions are reportedly **incompatible** (or compatibility data conflicts) with chloramphenicol sodium succinate injection: chlorpromazine HCl, glycopyrrolate, metoclopramide HCl, oxytetracycline HCl, polymyxin B sulfate, prochlorperazine edisylate/mesylate, promethazine HCl, tetracycline HCl, and vancomycin HCl.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Chloramphenicol Oral Tablets and Capsules: 50 mg, 100 mg, 250 mg, 500 mg, & 1 g; FDA-approved for use in dogs only. *Trade names and manufacturers/sponsors vary (Rx)*

Chloramphenicol Injection: 100 mg/mL; (Rx). FDA-approved for use in dogs, but availability and marketing status unknown.

Chloramphenicol (as palmitate) Oral Suspension: 30 mg/mL, *Chloromycetin*® (BIVI); (Rx). FDA-approved for use in dogs, but availability and marketing status unknown.

Veterinary-labeled ophthalmic 1% ointments are also available.

### HUMAN-LABELED PRODUCTS:

Chloramphenicol Powder for Injection: 1 gram (100 mg/mL (as sodium succinate when reconstituted); *Chloromycetin*® *Sodium Succinate* (Parke-Davis); generic; (Rx)

Ophthalmic preparations are also available.

## CHLORDIAZEPOXIDE ± CLIDINIUM BR

(klor-dye-az-e-pox-ide) ± (kli-din-ee-um) Librium®, Librax®

BENZODIAZEPINE ± ANTIMUSCARINIC

### Prescriber Highlights

- **Benzodiazepine for behavior problems (phobias, etc.) & with an antimuscarinic (clidinium) for irritable bowel syndrome in dogs**
- **Not commonly used, so little has been published on adverse effects (similar to diazepam +/- atropine)**
- **Potentially teratogenic**

## Uses/Indications

Chlordiazepoxide alone may be a useful adjunct to treating certain behaviors where benzodiazepines may be useful including noise phobias in dogs; inter-cat aggression and urine spraying in cats. When combined with clidinium, it may be useful symptomatic therapy for dogs with irritable bowel syndrome.

## Pharmacology/Actions

The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by chlordiazepoxide and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant and anticonvulsant effects seen. The exact mechanism of action is unknown but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

Clidinium bromide is an antimuscarinic with its main action to reduce GI motility and secretion similarly to atropine. Clidinium is a quaternary ammonium compound and, unlike atropine, does not cross appreciably into the CNS or the eye and should not exhibit the same extent of CNS or ocular adverse effects that atropine possesses. For further information, refer to the atropine monograph.

## Pharmacokinetics

Chlordiazepoxide is rapidly absorbed following oral administration. It is highly lipid soluble and is widely distributed throughout the body. It readily crosses the blood-brain barrier and is fairly highly bound to plasma proteins. Chlordiazepoxide is metabolized in the liver to several metabolites, including: desmethyldiazepam (nordiazepam), desmethylchlordiazepoxide and oxazepam, all of which are pharmacologically active and can have considerable half lives. These are eventually conjugated with glucuronide and eliminated primarily in the urine. Because of the active metabolites, serum values of chlordiazepoxide are not useful in predicting efficacy.

Little pharmacokinetic data for clidinium is available. The drug is incompletely absorbed from the gut (small intestine). Effects in humans are seen in about an hour; duration of effect is about 3 hours. As the compound is completely ionized *in vivo*, it does not enter the CNS or the eye and therefore unlike atropine does not have effects on those systems. The drug is metabolized principally in the liver, but is also excreted unchanged in the urine.

## Contraindications/Precautions/Warnings

Use benzodiazepines cautiously in patients with hepatic or renal disease and in debilitated or geriatric patients. Chlordiazepoxide should only be administered very cautiously to patients in coma, shock or with significant respiratory depression. It is contraindicated in patients with known hypersensitivity to the drug. Chlordiazepoxide should be used very cautiously, if at all, in aggressive patients as it may disinhibit the anxiety that may help prevent these animals from aggressive behavior. Benzodiazepines may impair the abilities of working animals. If administering the drug IV (rarely warranted), be prepared to administer cardiovascular or respiratory support. Give IV slowly.

Clidinium, like other antimuscarinic agents should not be used in patients with tachycardias secondary to thyrotoxicosis or cardiac insufficiency, myocardial ischemia, unstable cardiac status during acute hemorrhage, GI obstructive disease, paralytic ileus, severe ulcerative colitis, obstructive uropathy, or myasthenia gravis.

Antimuscarinic agents should be used with extreme caution in patients with known or suspected GI infections. Antimuscarinic agents can decrease GI motility and prolong retention of the causative agent(s) or toxin(s) resulting in prolonged effects of the toxin. Antimuscarinic agents must also be used with extreme caution in patients with autonomic neuropathy.

Antimuscarinic agents should be used with caution in patients with hepatic or renal disease, geriatric or pediatric patients, hyperthyroidism, hypertension, CHF, tachyarrhythmias, prostatic hypertrophy, or esophageal reflux. Systemic atropine should be used cautiously in horses as it can decrease gut motility and induce colic in susceptible animals. It may also reduce the arrhythmogenic doses of epinephrine. Use of atropine in cattle may result in inappetence and rumen stasis that may persist for several days

for several days.

## Adverse Effects

Chlordiazepoxide's adverse effects are similar to other benzodiazepines, especially diazepam (they share several active metabolites). As there is much more information with respect to diazepam in dogs or cats than chlordiazepoxide, the following is extrapolated from diazepam information: Dogs could exhibit a contradictory response (CNS excitement) following administration of chlordiazepoxide. The effects with regard to sedation and tranquilization are extremely variable with each dog. Cats could exhibit changes in behavior (irritability, depression, aberrant demeanor) after receiving chlordiazepoxide. There have been reports of cats developing hepatic failure after receiving oral diazepam for several days. It is unknown if chlordiazepoxide also shares this effect. Clinical signs have been reported to occur 5–11 days after beginning oral therapy. Cats that receive diazepam should have baseline liver function tests. These should be repeated and the drug discontinued if emesis, lethargy, inappetence, or ataxia develops.

Clidinium's adverse effects are basically extensions of the drug's pharmacologic effects and are generally dose related. At usual doses effects tend to be mild in relatively healthy patients. More severe effects tend to occur with high or toxic doses. GI effects can include dry mouth (xerostomia), dysphagia, constipation, vomiting, and thirst. GU effects may include urinary retention or hesitancy. Cardiovascular effects include sinus tachycardia (at higher doses), bradycardia (initially or at very low doses), hypertension, hypotension, arrhythmias (ectopic complexes), and circulatory failure.

## Reproductive/Nursing Safety

Benzodiazepines have been implicated in causing congenital abnormalities in humans if administered during the first trimester of pregnancy. Infants born of mothers receiving large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, hypotonia, etc. Withdrawal symptoms have occurred in infants whose mothers chronically took benzodiazepines during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use. In humans, the FDA categorizes chlordiazepoxide as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Benzodiazepines and their metabolites are distributed into milk and may cause CNS effects in nursing neonates.

## Overdosage/Acute Toxicity

When administered alone, chlordiazepoxide overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Hypotension, respiratory depression, and cardiac arrest have been reported in human patients but apparently are quite rare.

Treatment of acute toxicity consists of standard protocols for removing and/or binding the drug in the gut if taken orally, and supportive systemic measures. The use of analeptic agents (CNS stimulants such as caffeine) is generally not recommended. Flumazenil may be considered for adjunctive treatment of overdoses of benzodiazepines.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlordiazepoxide or other benzodiazepines and may be of significance in veterinary patients:

- **DIGOXIN:** The pharmacologic effects of digoxin may be increased; monitor serum digoxin levels or signs of toxicity
- **OTHER CNS DEPRESSANT DRUGS (e.g., barbiturates, opiates, anesthetics):** Additive effects may occur
- **PROBENECID:** May interfere with benzodiazepine metabolism in the liver, causing increased or prolonged effects
- **RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines

The following drugs may decrease the metabolism of chlordiazepoxide and excessive sedation may occur:

- **CIMETIDINE**
- **ERYTHROMYCIN**
- **FLUOXETINE**
- **ISONIAZID**
- **KETOCONAZOLE**
- **METOPROLOL**
- **PROPRANOLOL**

**When using the product containing clidinium** the following potential interactions noted with atropine may apply and the following drugs may enhance the activity or toxicity of clidinium:

- **AMANTADINE**
- **ANTICHOLINERGIC AGENTS (OTHER)**
- **ANTICHOLINERGIC MUSCLE RELAXANTS**
- **ANTIHISTAMINES (e.g., diphenhydramine)**
- **DISOPYRAMIDE**
- **MEPERIDINE**
- **PHENOTHIAZINES**
- **PROCAINAMIDE**
- **PRIMIDONE**
- **TRICYCLIC ANTIDEPRESSANTS (e.g., amitriptyline, clomipramine)**
- **AMITRAZ:** Atropine may aggravate some signs seen with amitraz toxicity; leading to hypertension and further inhibition of peristalsis
- **ANTACIDS:** May decrease PO atropine absorption; give oral atropine at least 1 hour prior to oral antacids
- **CORTICOSTEROIDS (long-term use):** may increase intraocular pressure

- **DIGOXIN (slow-dissolving):** Atropine may increase serum digoxin levels; use regular digoxin tablets or oral liquid
- **KETOCONAZOLE:** Increased gastric pH may decrease GI absorption; administer atropine 2 hours after ketoconazole
- **METOCLOPRAMIDE:** Atropine and its derivatives may antagonize the actions of metoclopramide

### Laboratory Considerations

- Chlordiazepoxide can cause interference with the Zimmerman reaction for **17-ketosteroids**, resulting in false results.
- It can also cause a false-positive result in the *Gravindex*® pregnancy test.

### Doses

#### ■ DOGS:

Chlordiazepoxide alone:

For behavior indications (thunderstorm/noise phobias):

- a) 2.2–6.6 mg/kg PO as needed (start low) (Overall 2000)

Chlordiazepoxide with clidinium:

For symptomatic treatment of irritable bowel syndrome:

- a) Using the combination product (*e.g.*, *Librax*®), give 0.1–0.25 mg/kg of clidinium or 1–2 capsules PO two times to three times a day. Owner may give when abdominal pain or diarrhea first noticed or if stressful conditions are encountered. Drug can usually be discontinued in a few days. (Leib 2004)
- b) Using the combination product (*e.g.*, *Librax*®), give 0.44–1.1 mg/kg of clidinium PO two to three times a day. Use at first signs of cramping or abdominal pain. Most dogs only require for a day to 2 weeks. Some require long-term treatment at 1–2 doses per day. (Tams 2000)

#### ■ CATS:

As an anxiolytic:

- a) Chlordiazepoxide: 0.5–1 mg/kg PO q12–24h (Virga 2002)

### Monitoring

- Clinical efficacy
- Adverse effects

### Client Information

- Keep out of reach of children and in tightly closed containers
- Notify veterinarian if animal's behavior worsens

### Chemistry/Synonyms

A benzodiazepine, chlordiazepoxide HCl occurs as an odorless, white crystalline powder. It is soluble in water and alcohol, but is unstable in aqueous solutions.

A synthetic quaternary antimuscarinic agent similar to glycopyrrolate, clidinium bromide occurs as a white to nearly white, crystalline powder. It is soluble in alcohol and water.

Chlordiazepoxide HCl may also be known as: chlordiazepoxidi hydrochloridum, methamino-diazepoxide hydrochloride, NSC-115748, or Ro-5-0690; many trade names are available.

### Storage/Stability

Chlordiazepoxide HCl capsules or tablets should be stored protected from light. The chlordiazepoxide HCl injection should be prepared immediately prior to use and any unused portions discarded. The diluent should be stored in the refrigerator before use.

Clidinium bromide and chlordiazepoxide capsules should be stored at room temperature in tight, light-resistant containers.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

#### **HUMAN-LABELED PRODUCTS:**

Chlordiazepoxide HCl Oral Capsules: 5 mg, 10 mg & 25 mg; generic; (Rx, C-IV)

Chlordiazepoxide HCl 5 mg and Clidinium Br 2.5 mg Capsules; *Librax*® *Capsules* (Valeant); generic; (Rx, C-IV)

## CHLOROTHIAZIDE

## CHLOROTHIAZIDE SODIUM

(klor-oh-thye-a-zide) Diuril®

THIAZIDE DIURETIC

### Prescriber Highlights

- **Thiazide diuretic used for nephrogenic diabetes insipidus & hypertension in dogs; udder edema in dairy cattle (cattle product now discontinued in USA)**
  - **Contraindications: Hypersensitivity; pregnancy (relative contraindication)**
  - **Extreme caution/avoid: Severe renal disease, preexisting electrolyte/water balance abnormalities, impaired hepatic function, hyperuricemia, SLE, diabetes mellitus**
  - **Adverse Effects: Hypokalemia, hypochloremic alkalosis, other electrolyte imbalances, hyperuricemia, GI effects**
  - **Many drug-drug & laboratory test interactions**
- 

### Uses/Indications

In veterinary medicine, furosemide has largely supplanted the use of thiazides as a general diuretic (edema treatment). Thiazides are still used for the treatment of systemic hypertension, nephrogenic diabetes insipidus, and to help prevent the recurrence of calcium oxalate uroliths in dogs.

Chlorothiazide is FDA-approved for use in dairy cattle for the treatment of post parturient udder edema, but the veterinary labeled product has been discontinued in the USA.

### Pharmacology/Actions

Thiazide diuretics act by interfering with the transport of sodium ions across renal tubular epithelium possibly by altering the metabolism of tubular cells. The principle site of action is at the cortical diluting segment of the nephron; enhanced excretion of sodium, chloride, and water results. Thiazides also increase the excretion of potassium, magnesium, phosphate, iodide, and bromide and decrease the glomerular filtration rate (GFR). Plasma renin and resulting aldosterone levels are increased which contributes to the hypokalemic effects of the thiazides. Bicarbonate excretion is increased, but effects on urine pH are usually minimal. Thiazides usually initially have a hypercalciuric effect but with continued therapy, calcium excretion is significantly decreased. But in dogs, hydrochlorothiazide, but not chlorothiazide, has been shown to decrease urinary calcium excretion. Uric acid excretion is also decreased by the thiazides. Thiazides can cause, or exacerbate, hyperglycemia in diabetic patients, or induce diabetes mellitus in prediabetic patients.

The antihypertensive effects of thiazides are well known, and these agents are used extensively in human medicine for treating essential hypertension. The exact mechanism of this effect has not been established.

Thiazides paradoxically reduce urine output in patients with diabetes insipidus (DI). They have been used as adjunctive therapy in patients with neurogenic DI and are the only drug therapy for nephrogenic DI.

### Pharmacokinetics

The pharmacokinetics of the thiazides have apparently not been studied in domestic animals. In humans, chlorothiazide is only 10–21% absorbed after oral administration. The onset of diuretic activity occurs in 1–2 hours and peaks at about 4 hours. The serum half-life is approximately 1–2 hours and the duration of activity is from 6–12 hours. Like all thiazides, the antihypertensive effects of chlorothiazide can take several days to transpire.

Thiazides are found in the milk of lactating humans. Because of the chance of idiosyncratic or hypersensitive reactions, it is recommended that these drugs not be used in lactating females or nursing mothers.

### Contraindications/Precautions/Warnings

Thiazides are contraindicated in patients hypersensitive to any one of these agents or to sulfonamides, and those with anuria. They are also contraindicated in pregnant females who are otherwise healthy and have only mild edema; newborn human infants have developed thrombocytopenia when their mothers received thiazides.

Thiazides should be used with extreme caution, if at all, in patients with severe renal disease or with preexisting electrolyte or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), hyperuricemia, lupus (SLE); or diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (*e.g.*, vomiting, diarrhea, etc.) should be monitored carefully.

### Adverse Effects

Hypokalemia is one of the most common adverse effects associated with the thiazides but rarely causes clinical signs or progresses further; however, monitoring of potassium is recommended with chronic therapy.

Hypochloremic alkalosis (with hypokalemia) may develop, especially if there are other causes of potassium and chloride loss (*e.g.*, vomiting, diarrhea, potassium-losing nephropathies, etc.) or if the patient has cirrhotic liver disease. Dilutional hyponatremia and hypomagnesemia may also occur. Hyperparathyroid-like effects of hypercalcemia and hypophosphatemia have been reported in humans, but have not led to effects such as nephrolithiasis, bone resorption, or peptic ulceration.

Hyperuricemia can occur but is usually asymptomatic.

Other possible adverse effects include GI reactions (vomiting, diarrhea, etc.), pancreatitis, hypersensitivity/dermatologic reactions, GU reactions (polyuria), hematologic toxicity, hyperglycemia, hyperlipidemias, and orthostatic hypotension.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Chlorothiazide enters maternal milk and can reduce milk volume and suppress lactation. Generally, discontinuation of the drug or nursing is recommended in humans.

### Overdosage

Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures), and GI effects (hypermotility, GI distress). Transient increases in BUN have also been reported.

Treatment consists of emptying the gut after recent oral ingestion using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that may ensue. Monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and

cardiovascular status; treat supportively and symptomatically, if required.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorothiazide and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Use with thiazides can lead to an increased risk for severe hypokalemia
- **CORTICOSTEROIDS, CORTICOTROPIN:** Use with thiazides can lead to an increased risk for severe hypokalemia
- **DIAZOXIDE:** Increased risk for hyperglycemia, hyperuricemia, and hypotension may occur
- **DIGITALIS, DIGOXIN:** Thiazide-induced hypokalemia, hypo-magnesemia, and/or hypercalcemia may increase the likelihood of digitalis toxicity
- **INSULIN:** Thiazides may increase insulin requirements
- **LITHIUM:** Thiazides can increase serum lithium concentrations
- **METHENAMINE:** Thiazides can alkalinize urine and reduce methenamine effectiveness
- **NSAIDS:** Thiazides may increase risk for renal toxicity and NSAIDs may reduce diuretic actions of thiazides
- **NEUROMUSCULAR BLOCKING AGENTS:** Tubocurarine or other nondepolarizing neuromuscular blocking agents response or duration may be increased in patients taking thiazide diuretics
- **PROBENECID:** Blocks thiazide-induced uric acid retention (used to therapeutic advantage)
- **QUINIDINE:** Half-life may be prolonged by thiazides (thiazides can alkalinize the urine)
- **VITAMIN D OR CALCIUM SALTS:** Hypercalcemia may be exacerbated if thiazides are concurrently administered with Vitamin D or calcium salts

## Laboratory Considerations

- **AMYLASE:** Thiazides can increase serum amylase values in asymptomatic patients and those in the developmental stages of acute pancreatitis (humans)
- **CORTISOL:** Thiazides can decrease the renal excretion of cortisol
- **ESTROGEN, URINARY:** Hydrochlorothiazide may falsely decrease total urinary estrogen when using a spectrophotometric assay
- **HISTAMINE:** Thiazides may cause false-negative results when testing for pheochromocytoma
- **PARATHYROID-FUNCTION TESTS:** Thiazides may elevate serum calcium; recommend discontinuing thiazides prior to testing
- **PHENOLSULFONPHTHALEIN (PSP):** Thiazides can compete for secretion at proximal renal tubules
- **PHEHTOLAMINE TEST:** Thiazides may give false-negative results
- **PROTEIN-BOUND IODINE:** Thiazides may decrease values
- **TRIIODOTHYRONINE RESIN UPTAKE TEST:** Thiazides may slightly reduce uptake
- **TYRAMINE:** Thiazides can cause false-negative results.

## Doses

### ■ DOGS:

For treatment of nephrogenic diabetes insipidus:

- a) 20–40 mg/kg PO q12h (Polzin & Osborne 1985), (Nichols 1989), (Behrend 2003)

For treatment of systemic hypertension:

- a) 20–40 mg/kg PO q12–24h with dietary salt restriction (Cowgill & Kallet 1986)

As a diuretic:

- a) 20–40 mg/kg PO q12h (twice daily) (Mucha 2009)

### ■ CATS:

For treatment of diabetes insipidus:

- a) 20–40 mg/kg PO q12h may be tried (Behrend 2003)

As a diuretic:

- a) 20–40 mg/kg PO q12h (twice daily) (Mucha 2009)

### ■ CATTLE:

- a) 4–8 mg/kg once or twice daily PO for adult cattle (Howard 1986)
- b) 2 g PO once to twice daily (Swinyard 1975)

## Monitoring

- Serum electrolytes, BUN, creatinine, glucose
- Hydration status
- Blood pressure, if indicated
- Hemograms, if indicated

## Client Information

- Clients should contact veterinarian if signs of water or electrolyte imbalance occur (*e.g.*, excessive thirst, lethargy, lassitude, restlessness, reduced urination, GI

distress, or rapid heart rate)

## Chemistry/Synonyms

Chlorothiazide is a thiazide diuretic and occurs as a white to practically white, odorless, crystalline powder having a slightly bitter taste. It is very slightly soluble in water and slightly soluble in alcohol.

Chlorothiazide may also be known as: chlorothiazidum, clorotiazida, *Azide*®, *Chlorzide*®, *Chlotride*®, *Diachlor*®, *Diuril*®, *Diurigen*®, *Pahtlisan*®, or *Saluric*®.

## Storage/Stability

Tablets should be stored at room temperature. The oral suspension should be protected from freezing. The injectable preparation is stable for 24 hours after reconstitution. If the pH of the reconstituted solution is less than 7.4, precipitation will occur in less than 24 hours.

## Compatibility/Compounding Considerations

Chlorothiazide sodium for injection is reportedly **compatible** with the following IV solutions: dextrose and/or saline products for IV infusion (with the exception of many Ionosol and Normosol products), Ringer's injection and Lactated Ringer's, 1/6 M sodium lactate, Dextran 6% with dextrose or sodium chloride, and fructose 10%. It is also reportedly **compatible** with the following drugs: cimetidine HCl, lidocaine HCl, nafcillin sodium, and sodium bicarbonate.

Chlorothiazide sodium is reportedly **incompatible** with the following drugs: amikacin sulfate, chlorpromazine HCl, codeine phosphate, hydralazine HCl, insulin (regular), morphine sulfate, norepinephrine bitartrate, polymyxin B sulfate, procaine HCl, prochlorperazine edisylate and mesylate, promazine HCl, promethazine HCl, streptomycin sulfate, tetracycline HCl, trifluopromazine HCl, and vancomycin HCl.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Chlorothiazide Tablets: 250 mg & 500 mg; *Diuril*® (Merck); *Diurigen*® (Goldline); generic; (Rx)

Chlorothiazide Oral Suspension: 50 mg/mL in 237 mL; *Diuril*® (Merck); (Rx)

Chlorothiazide Sodium Powder for Injection (lyophilized): 500 mg (0.25 g mannitol) in 20 mL vials; *Diuril*® (Merck); (Rx)

## CHLORPHENIRAMINE MALEATE

(*klor-fen-ir-a-meen*) Chlor-Trimetron®

ANTIHISTAMINE

### Prescriber Highlights

- An alkylamine antihistamine used primarily for its antihistamine/antipruritic effects; occasionally used for CNS depressant (sedative) effects
- **Contraindications:** Hypersensitivity. **Caution:** narrow angle glaucoma, hypertension, GI or urinary obstruction, hypertension, hyperthyroidism, cardiovascular disease
- **Adverse Effects:** Sedation, anticholinergic effects, GI effects

---

## Uses/Indications

Antihistamines are used in veterinary medicine to reduce or help prevent histamine mediated adverse effects. Chlorpheniramine is one the more commonly used antihistamines in the cat for the treatment of pruritus. It may also be of benefit as a mild sedative in small animals due to its CNS depressant effects.

## Pharmacology/Actions

Antihistamines (H1-receptor antagonists) competitively inhibit histamine at H1 receptor sites. They do not inactivate or prevent the release of histamine, but can prevent histamine's action on the cell. Besides their antihistaminic activity, these agents all have varying degrees of anticholinergic and CNS activity (sedation). Some antihistamines have antiemetic activity (*e.g.*, diphenhydramine) or antiserotonin activity (*e.g.*, cyproheptadine, azatadine).

## Pharmacokinetics

Chlorpheniramine pharmacokinetics have not been described in domestic species. In humans, the drug is well absorbed after oral administration, but because of a relatively high degree of metabolism in the GI mucosa and the liver, only about 25-60% of the drug is available to the systemic circulation.

Chlorpheniramine is well distributed after IV injection; the highest distribution of the drug (in rabbits) occurs in the lungs, heart, kidneys, brain, small intestine, and spleen. In humans, the apparent steady-state volume of distribution is 2.5-3.2 L/kg and about 70% is bound to plasma proteins. It is unknown if chlorpheniramine is excreted into the milk.

Chlorpheniramine is metabolized in the liver and practically all the drug (as metabolites and unchanged drug) is excreted in the urine. In human patients with normal renal and hepatic function, the terminal serum half-life the drug ranges from 13.2-43 hours.

## Contraindications/Precautions/Warnings

Chlorpheniramine is contraindicated in patients who are hypersensitive to it or other antihistamines in its class. Because of their anticholinergic activity, antihistamines should be used with caution in patients with angle closure glaucoma, prostatic hypertrophy, pyloroduodenal or bladder neck obstruction, and COPD if mucosal secretions are a problem. Additionally, they should be cautiously used in patients with hyperthyroidism, cardiovascular disease or hypertension.

## Adverse Effects

Most commonly seen adverse effects are CNS depression (lethargy, somnolence) and GI effects (diarrhea, vomiting, anorexia). The sedative effects of antihistamines may diminish with time. Anticholinergic effects (dry mouth, urinary retention) are a possibility.

The sedative effects of antihistamines may adversely affect the performance of working dogs.

Chlorpheniramine may cause paradoxical excitement in cats. Palatability is also an issue with this drug and felines.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if chlorpheniramine is excreted into milk; use with caution in dams nursing neonates.

## Overdosage/Acute Toxicity

Overdosage may cause CNS stimulation (excitement to seizures) or depression (lethargy to coma), anticholinergic effects, respiratory depression, and death. A 9-month-old dachshund ingesting 25 mg/kg showed signs of ataxia, tremors, bradycardia, coma, & cardiac arrest and died within 11 hours of ingestion (Murphy 2001).

Treatment consists of emptying the gut (if the ingestion was oral) using standard protocols. Induce emesis if the patient is alert and CNS status is stable. Administration of a saline cathartic and/or activated charcoal may be given after emesis or gastric lavage. Treatment of other clinical signs should be performed using symptomatic and supportive therapies. Phenytoin (IV) is recommended in the treatment of seizures caused by antihistamine overdoses in humans; barbiturates and diazepam should be avoided.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorpheniramine and may be of significance in veterinary patients:

- **ANTICOAGULANTS (heparin, warfarin):** Antihistamines may partially counteract the anticoagulation effects of heparin or warfarin
- **MAO INHIBITORS** (including amitraz, and possibly selegiline): May prolong and exacerbate anticholinergic effects
- **OTHER CNS DEPRESSANT DRUGS:** Increased sedation can occur

## Laboratory Considerations

- Antihistamines can decrease the wheal and flare response to **antigen skin testing**. In humans, it is suggested that antihistamines be discontinued at least 4 days before testing.

## Doses

**Note:** Contents of sustained-release capsules may be placed on food, but should not be allowed to dissolve before ingestion.

### ■ DOGS:

- a) 4–8 mg (maximum of 0.5 mg/kg) PO q8–12h PO; many clinicians use as adjunctive treatment of chemotherapy of mast cell tumors (Papich 2000)
- b) 4–12 mg (total dose) two to three times daily (MacDonald 2002)
- c) 2–8 mg (total dose) per dog PO every 12 hours, not to exceed 0.5 mg/kg every 12 hours (Cote 2005)

For pruritus:

- a) As a trial for pruritus in atopic dogs: 0.4–0.8 mg/kg two to three times daily (Rosychuk 2002)
- b) 0.2–0.8 mg/kg PO 2–3 times a day (Marsella 2008)

As a mild sedative:

- a) 0.22 mg/kg PO q8h; 4–20 mg (total dose per day) divided q8–12h (Overall 2000)

### ■ CATS:

- a) 2 mg (total dose) per cat PO every 12 hours (Cote 2005)
- b) 2–4 mg per cat q12–24h PO (Hnilica 2003), (Rosychuk 2002)
- c) Most common dosage in cats is: 2 mg per cat two to three times daily (MacDonald 2002)

For pruritus:

- a) 2–4 mg/cat twice daily; rarely may be maintained on once daily dosing. Palatability may be enhanced by dipping the split tablet into tuna fish “juice”, butter or petrolatum; placing split tablets into empty gelatin capsules or sprinkling or mixing timed release beads (partial contents of an 8 mg capsule) with food. (Messinger 2000)
- b) 0.5–2 mg (total dose; ¼ - ½ of a 4 mg tablet) PO 2–3 times per day (Marsella 2008)

As a mild sedative:

- a) 1–2 mg per cat q12–24h (low dose), 2–4 mg per cat PO q12–24h (high dose) (Overall 2000)

### ■ FERRETS:

- a) 1–2 mg/kg PO 2–3 times a day (Williams 2000)

### ■ BIRDS:

a) One 4 mg tablet in one cup (240 mL; 8 oz.) of bottled water to be used as drinking water; changed daily. (Clubb 2009)

## Monitoring

- Clinical efficacy
- Adverse effects

## Client Information

- Chlorpheniramine is FDA-approved for use in humans; the oral dosage forms are either prescription or non-prescription agents, depending on the product's labeling
- Most common adverse effects are drowsiness/sleepiness; cats may become excited
- Do not crush or allow animal to chew sustained-release products

## Chemistry/Synonyms

A propylamine (alkylamine) antihistaminic agent, chlorpheniramine maleate occurs as an odorless, white, crystalline powder with a melting point between 130–135°C and a pKa of 9.2. One gram is soluble in about 4 mL of water or 10 mL of alcohol.

Chlorpheniramine maleate may also be known as chlorphenamini maleas; many trade names are available.

## Storage/Stability

Chlorpheniramine tablets and sustained-release tablets should be stored in tight containers. The sustained-release capsules should be stored in well-closed containers. The oral solution should be stored in light-resistant containers; avoid freezing. All chlorpheniramine products should be stored at room temperature (15–30°C).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Chlorpheniramine Maleate Oral Tablets: 2 mg (chewable), *Chlo-Amine*® (Hollister-Stier); (OTC); 4 mg tablets, *Aller-Chlor*® (Rugby); *Allergy*® (Major); *Allergy Relief*® (Zee Medical); generic; (OTC); Chlorpheniramine Maleate Extended-release Tablets & Capsules: 8 mg, 12 mg & 16 mg; *Chlor-Trimeton*® *Allergy 8 or 12 Hour* (Schering-Plough Healthcare); *Efidac*® 24 (Hogil); *QDALL AR*® (Atley); generic; (Rx & OTC)

Chlorpheniramine Caplets: 8 mg (as tannate); *ED-CHLOR-TAN*® (Edwards Pharmaceuticals); (Rx)

Chlorpheniramine Maleate Oral Syrup: 2 mg/5 mL in 118 mL; *Aller-Chlor*® (Rugby); (OTC); Oral Suspension: 4 mg/5 mL in 118 mL; *Pediox-S*® (Atley); (Rx)

Many combination products are available that combine chlorpheniramine with decongestants, analgesics, and/or antitussives.

## CHLORPROMAZINE HCL

(klor-proe-ma-zeen) Thorazine®

PHENOTHIAZINE SEDATIVE/ANTIEMETIC

### Prescriber Highlights

- **Prototype phenothiazine used primarily as an antiemetic, may be particularly useful to treat motion sickness in cats**
- **Generally contraindicated in horses**
- **Negligible analgesic effects**
- **Dosage may need to be reduced in debilitated/geriatric animals, those with hepatic or cardiac disease or when combined with other agents**
- **Use with caution in dehydrated patients because phenothiazines can cause vasodilation & reduce perfusion; rehydrate before use**
- **Inject diluted solution IV slowly; do not inject into arteries; do not inject IM in rabbits**
- **May cause significant hypotension, cardiac rate abnormalities, hypo- or hyperthermia; may cause extrapyramidal effects at high doses in cats**

---

## Uses/Indications

The clinical use of chlorpromazine as a neuroleptic agent has diminished, but the drug is still used for its antiemetic effects in small animals and occasionally as a preoperative medication and tranquilizer. As an antiemetic, chlorpromazine will inhibit apomorphine-induced emesis in the dog but not the cat. It will also inhibit the emetic effects of morphine in the dog. It does not inhibit emesis caused by copper sulfate, or digitalis glycosides.

Once the principle phenothiazine used in veterinary medicine, chlorpromazine was largely supplanted by acepromazine. It has similar pharmacologic activities as acepromazine, but is less potent and has a longer duration of action. For further information, refer to the acepromazine monograph.

### Pharmacokinetics

Chlorpromazine is absorbed rapidly after oral administration, but undergoes extensive first pass metabolism in the liver. The drug is also well absorbed after IM injection, but onsets of action are slower than after IV administration.

Chlorpromazine is distributed throughout the body and brain concentrations are higher than those in plasma. Approximately 95% of chlorpromazine in plasma is bound to plasma proteins (primarily albumin).

The drug is extensively metabolized principally in the liver and kidneys, but little specific information is available regarding its excretion in dogs and cats.

### Contraindications/Precautions/Warnings

Chlorpromazine causes severe muscle discomfort and swelling when injected IM into rabbits; use IV only in this species.

Animals may require lower dosages of general anesthetics following phenothiazines. Use cautiously and in smaller doses in animals with hepatic dysfunction, cardiac disease, or general debilitation. Because of its hypotensive effects, phenothiazines are relatively contraindicated in patients with hypovolemia or shock, and in patients with tetanus or strychnine intoxication due to effects on the extrapyramidal system.

Intravenous injections must be diluted with saline to concentrations of no more than 1 mg/mL and administered slowly. Chlorpromazine has no analgesic effects; treat animals with appropriate analgesics to control pain.

Dogs with MDR1 mutations (many Collies, Australian shepherds, etc.) may develop a more pronounced sedation that persists longer than normal with this agent. It may be prudent to reduce initial doses by 25% to determine the reaction of a patient identified or suspect of having this mutation.

Phenothiazines should be used very cautiously as restraining agents in aggressive dogs: it may make the animal more prone to startle and react to noises or other sensory inputs.

### Adverse Effects

In addition to the possible effects listed in the acepromazine monograph (*e.g.*, hypotension, contradictory effects such as CNS stimulation, bradycardia), chlorpromazine may cause extrapyramidal signs in the cat when used at high dosages. These can include tremors, shivering, rigidity and loss of the righting reflexes. Lethargy, diarrhea, and loss of anal sphincter tone may also be seen.

Horses may develop an ataxic reaction with resultant excitation and violent consequences. These ataxic periods may cycle with periods of sedation. Because of this effect, chlorpromazine is rarely used in equine medicine today.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Chlorpromazine is thought to be excreted into maternal milk and safety to nursing offspring cannot be assured.

### Overdosage/Acute Toxicity

Most small overdoses cause only somnolence; larger overdoses can cause serious effects including coma, agitation/seizures, ECG changes/arrhythmias, hypotension and extrapyramidal effects. Contact an animal poison control center in the event of a suspected large overdose or if multiple drugs are involved.

Most overdoses can be handled by monitoring the patient and treating signs as they occur; massive oral overdoses should definitely be treated by emptying the gut if possible. Hypotension should not be treated with epinephrine; use either phenylephrine or norepinephrine (levarterenol). Seizures may be controlled with barbiturates or diazepam.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorpromazine or other phenothiazines and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Possible increased risk for hypothermia
- **ANTACIDS:** May cause reduced GI absorption of oral phenothiazines
- **ANTIDIARRHEAL MIXTURES (*e.g.*, kaolin/pectin, bismuth subsalicylate mixtures):** May cause reduced GI absorption of oral phenothiazines
- **CNS DEPRESSANT AGENTS (barbiturates, narcotics, anesthetics, etc.):** May cause additive CNS depression if used with phenothiazines
- **DIPYRONE:** May cause serious hypothermia
- **EPINEPHRINE:** Phenothiazines block alpha-adrenergic receptors and concomitant epinephrine can lead to unopposed beta-activity causing vasodilation and increased cardiac rate
- **OPIATES:** May enhance the hypotensive effects of the phenothiazines; dosages of chlorpromazine may need to be reduced when used with an opiate
- **ORGANOPHOSPHATE AGENTS:** Phenothiazines should not be given within one month of worming with these agents as their effects may be potentiated
- **PARAQUAT:** Toxicity may be increased by chlorpromazine
- **PHENYTOIN:** Metabolism may be decreased if given concurrently with phenothiazines
- **PHYSOSTIGMINE:** Toxicity may be enhanced by chlorpromazine
- **PROCAINE:** Activity may be enhanced by phenothiazines
- **PROPRANOLOL:** Increased blood levels of both drugs may result if administered with phenothiazines
- **QUINIDINE:** With phenothiazines may cause additive cardiac depression

### Doses

#### ■ DOGS:

As an antiemetic:

- a) 0.5 mg/kg IV, IM or SC three to four times daily (Dowling 2003)

- b) 0.2–0.4 mg/kg SC, IM q8h (Washabau 2006)
- c) 4–8 mg (total dose; do not exceed 0.5 mg/kg) per dog PO q12h (Marks 2008)

As a muscle relaxant during tetanus:

- a) 2 mg/kg IM twice daily (Morgan 1988)

#### ■CATS:

As an antiemetic:

- a) 0.5 mg/kg IV, IM or SC three to four times daily (Dowling 2003)
- b) 2 mg (total dose) per cat PO q12h (Marks 2008)

As a preanesthetic:

- a) up to 1.1 mg/kg IM 1–1.5 hours prior to surgery (Booth 1988)

#### ■CATTLE:

- a) Premedication for cattle undergoing standing procedures: Up to 1 mg/kg IM (may cause regurgitation if animal undergoes general anesthesia) (Hall & Clarke 1983)

#### ■HORSES: (Note: ARCI UCGFS Class 2 Drug)

**Note:** Because of side effects (ataxia, panic reaction) this drug is not recommended for use in horses; use acepromazine or promazine if phenothiazine therapy is desired.

#### ■SWINE:

- a) Premedication: 1 mg/kg IM (Hall & Clarke 1983)
- b) 0.55–3.3 mg/kg IV; 2–4 mg/kg IM
- c) Restraint: 1.1 mg/kg IM (effects are at peak in 45–60 minutes); Prior to barbiturate anesthesia: 2–4 mg/kg IM (Booth 1988)

#### ■SHEEP & GOATS:

- a) 0.55–4.4 mg/kg IV, 2.2–6.6 mg/kg IM (Lumb & Jones 1984)
- b) Goats: 2–3.5 mg/kg IV q5–6h (Booth 1988)

### Monitoring

- Cardiac rate/rhythm/blood pressure if indicated and possible to measure
- Degree of tranquilization/anti-emetic activity if indicated
- Body temperature (especially if ambient temperature is very hot or cold)

### Client Information

- Avoid getting solutions on hands or clothing; contact dermatitis may develop.
- May discolor the urine to a pink or red-brown color; this is not abnormal.

### Chemistry/Synonyms

A propylamino-phenothiazine derivative, chlorpromazine is the prototypic phenothiazine agent. It occurs as a white to slightly creamy white, odorless, bitter tasting, crystalline powder. One g is soluble in 1 mL of water and 1.5 mL of alcohol. The commercially available injection is a solution of chlorpromazine HCl in sterile water at a pH of 3–5.

Chlorpromazine HCl may also be known as aminazine, or chlorpromazini hydrochloridum; many trade names are available.

### Storage/Stability

Protect from light and store at room temperature; avoid freezing the oral solution and injection. Dispense oral solution in amber bottles. Store oral tablets in tight containers. Do not store in plastic syringes or IV bags for prolonged periods as the drug may adsorb to plastic.

Chlorpromazine will darken upon prolonged exposure to light; do not use solutions that are darkly colored or if precipitates have formed. A slight yellowish color will not affect potency or efficacy.

### Compatibility/Compounding Considerations

Alkaline solutions will cause the drug to oxidize.

The following products have been reported to be **compatible** when mixed with chlorpromazine HCl injection: all usual intravenous fluids, ascorbic acid, atropine sulfate, butorphanol tartrate, diphenhydramine, droperidol, fentanyl citrate, glycopyrrolate, heparin sodium, hydromorphone HCl, hydroxyzine HCl, lidocaine HCl, meperidine, metoclopramide, metaraminol bitartrate, morphine sulfate, pentazocine lactate, promazine HCl, promethazine, scopolamine HBr, and tetracycline HCl.

The following products have been reported as being **incompatible** when mixed with chlorpromazine: aminophylline, amphotericin B, chloramphenicol sodium succinate, chlorothiazide sodium, dimenhydrinate, methicillin sodium, methohexital sodium, nafcillin sodium, penicillin g potassium, pentobarbital sodium, phenobarbital sodium, and thiopental sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Chlorpromazine Oral Tablets: 10 mg, 25 mg, 50 mg, 100 mg & 200 mg; generic; (Rx)

Chlorpromazine Injection: 25 mg/mL in 1 & 2 mL ampoules; generic; (Rx)

## CHLORPROPAMIDE

(klor-proe-pa-mide) Diabinese®

SULFONYLUREA ANTIDIABETIC

### Prescriber Highlights

- **Oral sulfonylurea antidiabetic agent sometimes used in dogs or cats for diabetes insipidus; potentially for diabetes mellitus**
  - **Many contraindications/cautions**
  - **Most likely adverse effects are hypoglycemia or GI distress**
- 

## Uses/Indications

While chlorpropamide could potentially be of benefit in the adjunctive treatment of diabetes mellitus in small animals, its use has been primarily for adjunctive therapy in diabetes insipidus in dogs and cats.

## Pharmacology/Actions

Sulfonylureas lower blood glucose concentrations in both diabetic and non-diabetic patients. The exact mechanism of action is not known, but these agents are thought to exert the effect primarily by stimulating the beta cells in the pancreas to secrete additional endogenous insulin. Ongoing use of the sulfonylureas appears to enhance peripheral sensitivity to insulin and reduce the production of hepatic basal glucose. The mechanisms causing these effects are yet to be fully explained. Chlorpropamide has antidiuretic activity, presumably by potentiating vasopressin's effects on the renal tubules. It may also stimulate secretion of vasopressin.

## Pharmacokinetics

Chlorpropamide is absorbed well from the GI tract. Its distribution characteristics have not been well described, but it is highly bound to plasma proteins and is excreted into milk. Elimination half-lives have not been described in domestic animals, but in humans the elimination half-life is about 36 hours. The drug is both metabolized in the liver and excreted unchanged. Elimination of chlorpropamide is enhanced in alkaline urine; decreased in acidic urine.

## Contraindications/Precautions/Warnings

Oral antidiabetic agents are considered contraindicated with the following conditions: severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis, or other significant acidotic conditions. Chlorpropamide should only be used when its potential benefits outweigh its risks during untreated adrenal or pituitary insufficiency, thyroid, cardiac, renal or hepatic function impairment, prolonged vomiting, high fever, malnourishment or debilitated condition, or when fluid retention is present.

## Adverse Effects

Hypoglycemia and GI disturbances are the most common adverse effects noted with this agent. Syndrome of inappropriate antidiuretic hormone (SIADH), anorexia, diarrhea, hepatotoxicity, skin eruptions, lassitude or other CNS effects, and hematologic toxicity are all potentially possible.

## Reproductive/Nursing Safety

Safe use during pregnancy has not been established. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Chlorpropamide enters maternal milk; in humans it is not recommended for use during nursing.

## Overdosage/Acute Toxicity

Profound hypoglycemia is the greatest concern after an overdose. Gut emptying protocols should be employed when warranted. Because of its long half-life, blood glucose monitoring and treatment with parenteral glucose may be required for several days. Overdoses may require additional monitoring (blood gases, serum electrolytes) and supportive therapy.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlorpropamide and may be of significance in veterinary patients:

- **ALCOHOL:** A disulfiram-like reaction (anorexia, nausea, vomiting) has been reported in humans who have ingested alcohol within 48–72 hours of receiving chlorpropamide
- **BARBITURATES:** Barbiturate duration of action may be prolonged

The following drugs may potentiate *hypoglycemia* if administered with chlorpropamide, or be displaced by chlorpropamide from plasma proteins thereby causing enhanced pharmacologic effects of the two drugs involved:

■ **CHLORAMPHENICOL**

■ **BETA-BLOCKERS.**

■MAOIS (including **amitraz** and possibly, **selegiline**)

■NSAIDS

■PROBENECID

■SALICYLATES

■SULFONAMIDES

■WARFARIN

The following drugs may potentiate *hyperglycemia* if administered with chlorpropamide:

■CALCIUM CHANNEL BLOCKERS (*e.g.*, **diltiazem**, **amlodipine**)

■CORTICOSTEROIDS

■ESTROGENS

■ISONIAZID

■PHENOTHIAZINES

■PHENYTOIN

■THIAZIDES

■THYROID MEDICATIONS

### Laboratory Considerations

■ Chlorpropamide may mildly increase values of **liver enzymes**, **BUN**, or **serum creatinine**.

### Doses

For adjunctive therapy in diabetes insipidus in dogs and cats. Beneficial effects may be seen in less than 50% of animals treated. A trial period of at least one week of therapy should be given before assessing effect.

#### ■DOGS & CATS:

For adjunctive treatment of diabetes insipidus in animals with partial ADH deficiency:

a) 10–40 mg/kg PO daily (Randolph and Peterson 1994), (Behrend 2003)

b) Dogs: 50–250 mg (total dose) PO daily; Cats: 50 mg (total dose) PO daily (Hoskins 2005)

### Monitoring

■ Serum electrolytes, plasma and urine osmolarity, urine output; if used for DI

■ Blood Glucose

### Chemistry/Synonyms

An oral sulfonyleurea antidiabetic agent, chlorpropamide occurs as a white, crystalline powder having a slight odor. It is practically insoluble in water.

Chlorpropamide may also be known as: chlorpropamidum, *Anti-D*®, *Chlomid*®, *Clordiabet*®, *Copamide*®, *Deavynfar*®, *Diabecontrol*®, *Diabeedol*®, *Diabemide*®, *Diabenese*®, *Diabet*®, *Diabexan*®, *Diabiclor*®, *Diabines*®, *Diabitek*®, *Dibecon*®, *Glicoben*®, *Gliconorm*®, *Glicorp*®, *Glycemin*®, *Glymese*®, *Hypomide*®, *Idle*®, *Insogen*®, *Normoglic*®, *Novo-Propamide*®, *Propamide*®, or *Trane*®.

### Storage/Stability

Chlorpropamide tablets should be stored in well-closed containers at room temperature.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Chlorpropamide Oral Tablets: 100 mg & 250 mg; generic; (Rx)

## CHLORTETRACYCLINE

(klor-te-tra-sye-kleen) Aureomycin®, Pennchlor®

TETRACYCLINE ANTIBIOTIC

### Prescriber Highlights

- Tetracycline antibiotic used primarily in water or feed treatments or topically for ophthalmic use
- Many bacteria are now resistant; may still be very useful to treat mycoplasma, rickettsia, spirochetes, & Chlamydia
- **Contraindications:** Hypersensitivity. **Extreme caution:** Pregnancy. **Caution:** liver, renal insufficiency

- **Adverse Effects: GI distress, staining of developing teeth & bones, superinfections, photosensitivity**
  - **Drug-drug; drug-lab interactions**
- 

## Uses/Indications

There are a variety of FDA-approved chlortetracycline products for use in food animals. It may also be useful in treating susceptible infections in dogs, cats, birds and small mammals (not Guinea pigs). For more information, refer to the Doses section below.

## Pharmacology/Actions

Tetracyclines generally act as bacteriostatic antibiotics inhibiting protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms thereby preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococcus and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines include: *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and *tetani*, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasturella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, *Enterobacter*, *Proteus* and *Pseudomonas aeruginosa* are resistant to the tetracyclines. While most strains of *Pseudomonas aeruginosa* show *in vitro* resistance to tetracyclines, those compounds attaining high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism.

Oxytetracycline, chlortetracycline, and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance and a tetracycline susceptibility disk is usually used for *in vitro* testing for chlortetracycline susceptibility.

## Pharmacokinetics

Refer to the oxytetracycline monograph for general information on the pharmacokinetics of tetracyclines.

## Contraindications/Precautions/Warnings

Chlortetracycline is contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline, chlortetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, chlortetracycline must be used cautiously. Lower than normal dosages are recommended with enhanced monitoring of renal and hepatic function. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs.

Because it may cause clostridial enterotoxemia in guinea pigs, chlortetracycline should not be used this species.

## Adverse Effects

Chlortetracycline given to young animals can cause discoloration of bones and teeth to a yellow, brown, or gray color. High dosages or chronic administration may delay bone growth and healing.

Tetracyclines in high levels can exert an antianabolic effect that can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiodepressant effects when administered to calves.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well; signs of colic, fever, hair loss, and depression may be seen. There are reports that long-term tetracycline use may cause urolith formation in dogs.

Horses that are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrheas after receiving tetracyclines (especially with oral administration).

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

Tetracyclines have been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** (tetracyclines-general) for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Tetracyclines are excreted in milk, but because much of the drug will be bound to calcium in milk, it is unlikely to be of significant risk to nursing animals.

## Overdosage/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chlortetracycline and may be of significance in veterinary patients:

■ **BETA-LACTAM OR AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides; there is some controversy regarding the actual clinical significance of this interaction, however

- **DIGOXIN:** Tetracyclines may increase the bioavailability of digoxin in a small percentage of patients (human) and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products
- **WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant (*e.g.*, warfarin) therapy may need dosage adjustment.

### Laboratory Considerations

- Tetracyclines (not minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.
- Tetracyclines reportedly can cause false-positive **urine glucose** results if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest*®), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (*Clinistix*®, *Tes-Tape*®).

### Doses

#### ■ DOGS/CATS:

For susceptible infections:

- 25 mg/kg PO q6–8h (Papich 1992)
- To prevent recurrence of mycoplasma or chlamydial conjunctivitis in large catteries where topical therapy is impractical: soluble chlortetracycline powder in food at a dose of 50 mg per day per cat for 1 month (Carro 1994)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

**Note:** Not recommended for use in guinea pigs

- Rabbits:** 50 mg/kg PO q12–24h (Ivey & Morrisey 2000)
- Chinchillas:** 50 mg/kg PO q12h (Hayes 2000)
- Hamsters:** 20 mg/kg IM or SC q12h; Mice: 25 mg/kg SC or IM q12h; Rats: 6–10 mg/kg SC or IM q12h (Adamcak & Otten 2000)

#### ■ BIRDS:

- For the treatment of chlamydiosis: In small birds add chlortetracycline to food in a concentration of 0.05%; larger psittacines require 1% CTC. (Flammer 1992)
- Ratites:** 15–20 mg/kg PO three times daily (Jenson 1998)
- Pigeons:** 50 mg/kg PO q6–8h; or 1000–1500 mg/gallon drinking water; in warm weather mix fresh every 12 hours. Best used in combination with tylosin for ornithosis complex; calcium inhibits absorption therefore grit and layer pellets should be withheld during treatment. (Harlin 2006)

#### ■ CATTLE AND SWINE:

For susceptible infections:

- 6–10 mg/kg IV or IM; 10–20 mg/kg PO (**Note:** Although not specified in this reference, chlortetracycline is generally administered once daily.) (Howard 1993)

### Chemistry/Synonyms

A tetracycline antibiotic, chlortetracycline occurs as yellow, odorless crystals. It is slightly soluble in water.

Chlortetracycline may also be known as clortetraciclina, A-377, NRRL-2209, SF-66, *Aureomycin*® or *CLTC*® 100 MR.

### Storage/Stability

Chlortetracycline should be stored in tight containers and protected from light.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

There are several feed additive/water mix preparations available containing chlortetracycline. Trade names include *Aureomycin*®; (BIVI), *CTC*® (AgriLabs) *CLTC*® 100 MR (Philbro); (AL Labs); *CLTC*® 100 MR (Pennfield/Durvet). There are also combination products containing chlortetracycline and sulfamethazine (*Aureomycin Sulmet*®, *Aureo S 700*®), chlortetracycline, sulfamethazine and penicillin (*Aureomix 500*®, *Pennclor SP 250 & 500*®), chlortetracycline, sulfathiazole, and penicillin (*Aureozol 500*®)

See individual labels for more information.

**HUMAN-LABELED PRODUCTS:** None

### Chondroitin Sulfate–See [Glucosamine/Chondroitin](#)

# CHORIONIC GONADOTROPIN (HCG)

(kor-ee-on-ic goe-nad-oh-troe-pin) Chorulon®

REPRODUCTIVE HORMONE

## Prescriber Highlights

- **Human hormone that mimics luteinizing hormone & some FSH activity; used for a variety of theriogenology conditions in many species**
  - **Only administered parenterally**
  - **Contraindications: Androgen responsive neoplasias, hypersensitivity**
  - **Adverse Effects: Antibodies/hypersensitivity, pain on injection**
- 

## Uses/Indications

The veterinary product's labeled indication is for "parenteral use in cows for the treatment of nymphomania (frequent or constant heat) due to cystic ovaries." It has been used for other purposes in several species; refer to the Dosage section for more information.

## Pharmacology/Actions

HCG mimics quite closely the effects of luteinizing hormone (LH) but also has some FSH-like activity. In males, HCG can stimulate the differentiation of, and androgen production by, testicular interstitial (Leydig) cells. It may also stimulate testicular descent when no anatomical abnormality is present.

In females, HCG will stimulate the corpus luteum to produce progesterone and can induce ovulation (possibly also in patients with cystic ovaries). In the bitch HCG will induce estrogen secretion.

## Pharmacokinetics

HCG is destroyed in the GI tract after oral administration, so it must be given parenterally. After IM injection, peak plasma levels occur in about 6 hours.

HCG is distributed primarily to the ovaries in females and to the testes in males, but some may also be distributed to the proximal tubules in the renal cortex.

HCG is eliminated from the blood in biphasic manner. The initial elimination half-life is about 11 hours and the terminal half-life is approximately 23 hours.

## Contraindications/Precautions/Warnings

In humans, HCG is contraindicated in patients with prostatic carcinoma or other androgen-dependent neoplasias, precocious puberty or having a previous hypersensitivity reaction to HCG. No labeled contraindications for veterinary patients were noted, but the above human contraindications should be used as guidelines.

Antibody production to this hormone has been reported after repetitive use, resulting in diminished effect.

## Adverse Effects

Potentially, hypersensitivity reactions are possible with this agent. HCG may cause abortion in mares prior to the 35th day of pregnancy, perhaps due to increased estrogen levels. No other reported adverse reactions were noted for veterinary patients.

In humans, HCG has caused pain at the injection site, gynecomastia, headache, depression, irritability, and edema.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

It is unknown if HCG enters maternal milk.

## Overdosage/Acute Toxicity

No overdosage cases have been reported with HCG.

## Drug/Lab Interactions

No interactions have apparently been reported with HCG.

## Doses

### ■ DOGS:

For cryptorchidism:

a) 500 Units injected twice weekly for 4–6 weeks (McDonald 1988)

For HCG Challenge test (to determine if testicular tissue remains in castrated male dogs; in females to diagnose sexual differentiation disorders or if functional ovarian tissue remains after ovariectomy):

a) Male dogs or females with suspected sexual differentiation disorder: Take sample for resting testosterone level. Administer 44 micrograms/kg HCG IM and take a 4 hour post sample.

Female dogs: 100–1000 Units IM during apparent estrous episode. Measure progesterone level in 5–7 days. If above 1 ng/mL, this indicates functional ovarian tissue. (Shille & Olson 1989)

To produce luteinization of a persistent follicular cyst:

a) 500 Units IM; repeat in 48 hours. If effective, will convert from proestrus to estrus in 1–2 days and sexual behavior should stop within 2 weeks. (Barton & Wolf 1988)

For infertile bitches cycling normally with low progesterone due to lack of corpus luteum formation:

a) Next cycle, give 500 Units HCG SC on days 10–11 of heat cycle or when vaginal smear indicates breeding readiness. Breed 2 days after HCG administration. (Barton & Wolf 1988)

For male infertility secondary to low testosterone, LH and FSH:

a) HCG 500 Units SC twice weekly for 4 weeks. Add PMSG (Pregnant Mare Serum Gonadotropin) 20 Units/kg SC 3 times weekly. If PMSG is unavailable, use FSH-P at same dose (1 mg FSH = 10–14 IU). Continue for 3 months. Once spermatogenesis ensues, may continue with HCG only. (Barton & Wolf 1988)

#### ■CATS:

For HCG Challenge test (to determine if testicular tissue remains in castrated male cats; in females to diagnose sexual differentiation disorders or if functional ovarian tissue remains after ovariectomy):

a) Male cats or females with suspected sexual differentiation disorder: Take sample for resting testosterone level. Administer 250 micrograms HCG IM and take a 4 hour post sample.

Queens: 50–100 Units IM during apparent estrous episode. Measure progesterone level in 5–7 days. If above 1 ng/mL, this indicates functional ovarian tissue. (Shille & Olson 1989)

For infertility, reduced libido, testis descent in male cats:

a) 50–100 Units repeated if necessary (Verstegen 2000)

For infertility in queens due to confirmed ovulation failure:

a) 100–500 Units IM (Barton & Wolf 1988)

To induce ovulation in anestrus queens:

a) Give FSH-P 2 mg IM daily (for up to 5 days) until estrus is observed. Give 250 micrograms HCG on first and second day of estrus (Kraemer & Bowen 1986)

After artificial insemination:

a) 50–75 Units IM immediately after insemination; repeat insemination and injection in 24 hours (Sojka 1986)

#### ■FERRETS:

a) 100 Units IM; repeat in 1 week as necessary. Most effective 14 days after onset of estrus. (Williams 2000)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

a) **Guinea pigs:** For cystic ovaries: 1000 Units/animal IM, repeat in 7–10 days (Adamcak & Otten 2000)

#### ■BIRDS:

To reduce feather plucking (especially in female birds):

a) Dosage is empirical; 500–1,000 Units/kg IM. If no response in 3 days, repeat. If no response after second injection, unlikely to be of benefit at any dose. If reduces feather plucking, will need to repeat after 4–6 weeks. Major drawback is that with repeated usage, time between treatments is reduced. (Lightfoot 2001)

#### ■CATTLE:

For treatment of ovarian cysts:

a) 10,000 Units deep IM or 2500–5000 Units IV, may repeat in 14 days if animal's behavior or physical exam indicates a need for retreatment. Alternatively, 500–2500 Units injected directly into the follicle. (Package Insert; *Follutein*®—Solvay)

#### ■HORSES:

For cryptorchidism:

a) **Foals:** 1000 Units injected twice weekly for 4–6 weeks (McDonald 1988) (**Note:** Many clinicians believe that medical treatment is unwarranted and that surgery should be performed.)

To induce ovulation in early estrus when one, large, dominant follicle that is palpable with a diameter >35 mm is present:

a) HCG: 2000–3000 Units IV (preferable to treat mare 6 hours before mating) (Hopkins 1987)

For treatment of persistent follicles during the early transition period:

a) 1000–5000 Units (results are variable) (Van Camp 1986)

To hasten ovulation and reduce variability of estrus after prostaglandin synchronization:

a) HCG: 1500–3300 Units 5–6 days after the second prostaglandin treatment or on the first or second day of estrus (Bristol 1986)

#### Chemistry/Synonyms

A gonad-stimulating polypeptide secreted by the placenta, chorionic gonadotropin is obtained from the urine of pregnant women. It occurs as a white or practically white, amorphous, lyophilized powder. It is soluble in water and practically insoluble in alcohol. One International Unit (called Units in this reference) of HCG is equal to one USP unit. There are at least 1500 USP Units per mg.

Chorionic gonadotropin may also be known as: human chorionic gonadotropin, HCG, hCG, LH 500, CG, chorionic gonadotrophin, dynatropin, gonadotropine chorionique, gonadotrophinum chorionicum, choriogonadotrophin, chorionogonadotropin, pregnancy-urine hormone, or PU; there are many trade names internationally.

#### Storage/Stability

Chorionic gonadotropin powder for injection should be stored at room temperature (15–30°C) and protected from light. After reconstitution, the resultant solution is stable for 30–90 days (depending on the product) when stored at 2–15°C. The labels for the veterinary products, *Chorulon*® and *P.G. 600*® state to use the vial immediately after reconstituting with the supplied diluent.

#### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Chorionic Gonadotropin (HCG) Injection: 10,000 Units per 10 mL double vial packs containing 10,000 USP Units per vial with bacteriostatic water for injection; single dose 10 mL vials of freeze-dried powder and five 10 mL vials of sterile diluent; *Chorulon*® (Intervet), *Chorionad*® (Vetcom); (Rx). FDA-approved for use in cows and finfish. No withdrawal time is required when used as labeled.

Chorionic gonadotropin freeze-dried powder: Single dose 5 mL when reconstituted contains pregnant mare serum gonadotropin (PMSG) 400 Units and human chorionic gonadotropin (hCG) 200 Units; five dose 25 mL vials that when reconstituted contains pregnant mare serum gonadotropin (PMSG) 2,000 Units and human chorionic gonadotropin (hCG) 1,000 Units; *P.G. 600®* (Intervet); (OTC). FDA-approved for use in swine (prepuberal gilts and sows at weaning); no meat withdrawal time is required when used as labeled.

## HUMAN-LABELED PRODUCTS:

Chorionic Gonadotropin Powder for Injection: 5,000 Units/vial with 10 mL diluent (to make 500 Units/mL); 10,000 Units/vial with 10 mL diluent (to make 1,000 Units/mL); 20,000 Units/vial with 10 mL diluent (to make 2,000 Units/mL) in 10 mL vials; *Profasi®* (Serono); *Choron 10®* (Forest); *Gonic®* (Hauck); *Novarel®* (Ferring); *Pregnyl®* (Organon); generic; (Rx)

---

## CHROMIUM

### CHROMIUM PICOLINATE

(*kroe-mee-um pik-oh-lin-ate*)

TRANSITION TRACE METAL

### Prescriber Highlights

- Trace metal “nutraceutical” that may be useful as an adjunctive treatment for diabetes mellitus & obesity in cats
- Efficacy in question, but probably safe

---

## Uses/Indications

Chromium supplementation may be useful in the adjunctive treatment of diabetes mellitus or obesity, particularly in cats; there is controversy whether this treatment is beneficial. It does not appear to be useful in dogs with diabetes mellitus.

## Pharmacology/Actions

Metallic chromium has no pharmacologic activity, but other valence states have activity. Chromium VI (hexavalent form) is used in the welding and chemical industries and is considered a carcinogen. Chromium III (trivalent) is the form used in supplements and found naturally in foods. Chromium is thought to play a role in insulin function. It is an active component of so-called glucose tolerance factor (GTF). GTF is a complex of molecules that includes glycine, glutamic acid, cysteine and nicotinic acid. Chromium’s exact role in carbohydrate and nitrogen metabolism is not clear. It does not lower blood glucose levels in normal patients. In humans, chromium deficiency can cause impaired tolerance to glucose and insulin function, increased serum cholesterol and triglyceride levels, neuropathy, weight loss, impaired nitrogen metabolism, and decreased respiratory function.

## Pharmacokinetics

Chromium is not absorbed very well from the GI tract and most of a dose is excreted in the feces. When given as a salt (picolinate, chloride, nicotinate), lipophilicity and solubility are increased and absorption is enhanced. Absorbed chromium is eliminated via the kidneys.

## Contraindications/Precautions/Warnings

Chromium supplements could, potentially, exacerbate renal insufficiency; use with caution in these patients. Because the picolinate salt can potentially alter behavior, consider using chromium chloride, or chromium nicotinate in patients receiving SSRI’s or other behavioral therapies.

## Adverse Effects

Chromium supplements (Cr III) at usual dosages appear to be well tolerated. Some human patients have complained of cognitive, perceptual, and motor dysfunction after receiving the picolinate salt.

## Reproductive/Nursing Safety

In humans, chromium (up to 8 micrograms/kg) is probably safe to use in pregnancy but information remains sketchy. Because cats may receive much higher dosages than the human dosages for treating diabetes, use cautiously in pregnant animals.

Chromium supplements are likely to be safe to use in lactating animals.

## Overdosage/Acute Toxicity

Little information on acute overdoses was located. There are at least two case reports of women developing renal failure after taking excessive doses of chromium picolinate.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving chromium and may be of significance in veterinary patients:

■ **CORTICOSTEROIDS:** May increase the urinary excretion of chromium

■ **H<sub>2</sub> BLOCKERS (cimetidine, ranitidine, famotidine, etc.) or PROTON PUMP INHIBITORS (PPI's, omeprazole, etc.):** May decrease chromium levels by inhibiting their absorption; clinical significance is unclear

■ **NSAIDS:** May increase the absorption and retention of chromium; clinical significance is unlikely

■ **ZINC:** Theoretically, co-administration of zinc with chromium could decrease the oral absorption of both

### Laboratory Considerations

■ No specific laboratory interactions or considerations noted

### Doses

#### ■ CATS:

For use as an oral hypoglycemic agent:

a) Chromium picolinate 200 micrograms (per cat) PO once a day. (Dowling 2000); (Greco 2002)

For adjunctive treatment of feline obesity:

a) Chromium picolinate 20 micrograms/kg PO every other a day (Flores 2004)

### Monitoring

■ As there is no reliable way to measure chromium in the body, a clinical trial is the only way to determine whether chromium is effective in helping to control blood glucose. Standard methods of monitoring diabetes treatment efficacy should be followed (*e.g.*, fasting blood glucose, appetite, attitude, body condition/weight, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels).

### Client Information

■ Clients should give the medication only as prescribed and not change brands without their veterinarian's approval.

### Chemistry/Synonyms

A trace element (Cr; atomic number 24), oral chromium supplements are usually given as the picolinate salt (also known as chromium tripicolinate).

### Storage/Stability

Chromium picolinate should be stored in tight containers. For storage recommendations, refer to the label for each product used.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

No oral products FDA-approved as pharmaceuticals.

Injectable chromium: (as chromic chloride hexahydrate): 4 micrograms/mL (as 20.5 micrograms chromic chloride hexahydrate) and 20 micrograms/mL (as 102.5 micrograms chromic chloride hexahydrate) in 5 mL (20 micrograms/mL only), 10 mL & 30 mL; Chromic Chloride (various); *Chroma-Pak*® (Smith & Nephew SoloPak); generic; (Rx) Oral chromium products are considered to be nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by regulatory bodies.

Supplements are available from a wide variety of sources. Most veterinary use in small animals is with chromium picolinate dosage forms. Common tablet sizes include 200 micrograms, 400 micrograms, 500 micrograms and 800 micrograms. Bioequivalence between products cannot be assumed.

## CIMETIDINE

### CIMETIDINE HCL

(*syē-mēt-i-deen*) Tagamet®

HISTAMINE2 BLOCKER

### Prescriber Highlights

- **Prototype histamine-2 (H<sub>2</sub>) blocker used to reduce GI acid production**
  - **Newer H<sub>2</sub> blockers (*e.g.*, ranitidine, famotidine) & other agents (*e.g.*, omeprazole) may be more effective, have longer duration of activity, & fewer drug interactions**
  - **Caution: Geriatric patients, hepatic or renal insufficiency**
  - **Compared with newer H<sub>2</sub> blockers, there are many drug interactions**
-

## Uses/Indications

In veterinary medicine, cimetidine has been used for the treatment and/or prophylaxis of gastric, abomasal and duodenal ulcers, uremic gastritis, stress-related or drug-induced erosive gastritis, esophagitis, duodenal gastric reflux, and esophageal reflux. It has also been employed to treat hypersecretory conditions associated with gastrinomas and systemic mastocytosis. Cimetidine has also been used investigationally as an immunomodulating agent (see doses) in dogs. Cimetidine has been used for the treatment of melanomas in horses, but the drug's poor bioavailability and subsequent high doses (48 mg/kg/day) in adult horses makes it a very expensive, unproven treatment. Its use in veterinary and human medicine has been largely supplanted by newer agents that compared to cimetidine are more effective, need less frequent dosing, and do not have as many drug interaction issues.

## Pharmacology/Actions

At the H<sub>2</sub> receptors of the parietal cells, cimetidine competitively inhibits histamine thereby reducing gastric acid output both during basal conditions and when stimulated by food, pentagastrin, histamine, or insulin. Gastric emptying time, pancreatic or biliary secretion, and lower esophageal pressures are not altered by cimetidine. By decreasing the amount of gastric juice produced, cimetidine also decreases the amount of pepsin secreted.

Cimetidine has an apparent immunomodulating effect as it has been demonstrated to reverse suppressor T-cell-mediated immune suppression. It also possesses weak anti-androgenic activity.

## Pharmacokinetics

In dogs, the oral bioavailability is reported to be approximately 95%, serum half-life is 1.3 hours and volume of distribution is 1.2 L/kg.

In horses, after intragastric administration oral bioavailability is only about 14%, steady-state volume of distribution 0.77 L/kg, median plasma clearance 8.2 mL/min/kg, and terminal elimination half-life is approximately 90 minutes.

In humans, cimetidine is rapidly and well absorbed after oral administration, but a small amount is metabolized in the liver before entering the systemic circulation (first-pass effect). The oral bioavailability is 70–80%. Food may delay absorption and slightly decrease the amount absorbed, but when given with food, peak levels occur when the stomach is not protected by the buffering capabilities of the ingesta.

Cimetidine is well distributed in body tissues and only 15–20% is bound to plasma proteins. The drug enters milk and crosses the placenta.

Cimetidine is both metabolized in the liver and excreted unchanged by the kidneys. More of the drug is excreted by the kidneys when administered parenterally (75%) than when given orally (48%). The average serum half-life is 2 hours in humans, but can be prolonged in elderly patients and those with renal or hepatic disease. Peritoneal dialysis does not appreciably enhance the removal of cimetidine from the body.

## Contraindications/Precautions/Warnings

Cimetidine is contraindicated in patients with known hypersensitivity to the drug.

Cimetidine should be used cautiously in geriatric patients and in patients with significantly impaired hepatic or renal function. In humans meeting these criteria, increased risk of CNS effects (confusion) may occur; dosage reductions may be necessary.

## Adverse Effects

Adverse effects appear to be very rare in animals at the dosages generally used. Potential adverse effects (documented in humans) that could be seen include mental confusion, headache (upon discontinuation of the drug), gynecomastia, and decreased libido. Rarely, agranulocytosis may develop and, if given rapidly IV, transient cardiac arrhythmias may be seen. Pain at the injection site may occur after IM administration.

Cimetidine does inhibit microsomal enzymes in the liver and may alter the metabolic rates of other drugs (see Drug Interactions below).

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Cimetidine is distributed into milk; while safety during nursing is not assured, it is usually considered compatible with nursing in humans.

## Overdosage/Acute Toxicity

Clinical experience with cimetidine overdosage is limited. In laboratory animals, very high dosages have been associated with tachycardia and respiratory failure; respiratory support and beta-adrenergic blockers have been suggested for use should these signs occur.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cimetidine and may be of significance in veterinary patients:

Cimetidine may inhibit the hepatic microsomal enzyme system and thereby reduce the metabolism, prolong serum half-lives, and increase the serum levels of several drugs and/or reduce the hepatic blood flow and reduce the amount of hepatic extraction of drugs that have a high first-pass effect, including:

■ **BENZODIAZEPINES** (e.g., diazepam)

■ **BETA-BLOCKERS** (e.g., propranolol)

■ **CALCIUM CHANNEL BLOCKERS** (e.g., verapamil)

■ **CHLORAMPHENICOL**

■ **LIDOCAINE**

■ **METRONIDAZOLE**

■ **PHENYTOIN**

■ **PROCAINAMIDE**

■ **THEOPHYLLINE**

■ **TRIAMTERENE**

## ■TRICYCLIC ANTIDEPRESSANTS

## ■WARFARIN

■**ANTACIDS:** May decrease the absorption of cimetidine; stagger doses (separate by 2 hours if possible)

■**KETOCONAZOLE, ITRACONAZOLE, etc:** Cimetidine may decrease the absorption of these drugs; give these medications at least two hours before cimetidine

■**MYELOSUPPRESSIVE DRUGS:** Cimetidine may exacerbate leukopenias when used with myelosuppressive agents

## Laboratory Considerations

■**Creatinine:** Cimetidine may cause small increases in plasma creatinine concentrations early in therapy; these increases are generally mild, non-progressive, and have disappeared when therapy is discontinued

■**Gastric Acid Secretion Tests:** Histamine<sub>2</sub> blockers may antagonize the effects of histamine and pentagastrin in the evaluation of gastric acid secretion; it is recommended that histamine<sub>2</sub> blockers be discontinued at least 24 hours before performing this test

■**Allergen Extract Skin Tests:** Histamine<sub>2</sub> antagonists may inhibit histamine responses; it is recommended that histamine<sub>2</sub> blockers be discontinued at least 24 hours before performing this test

## Doses

### ■DOGS:

For GI indications:

a) 5–10 mg/kg PO four times daily may be given PO or via parenteral routes. (Leib 2008)

As an immunomodulating agent (reverses suppressor T-cell-mediated immune suppression):

a) 10–25 mg/kg PO twice daily (Desiderio & Rankin 1986)

### ■CATS:

a) 5–10 mg/kg PO q6–8h or 10 mg/kg q6h as a slow (over 30 minutes) IV infusion (DeNovo 1986)

### ■FERRETS:

For stress induced ulcers:

a) 5–10 mg/kg PO, SC, IM or IV 3 times daily (Williams 2000)

### ■RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** For GI ulcers: 5–10 mg/kg PO, SC, IM or IV q8–12h (Ivey & Morrissey 2000)

b) **Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:** 5–10 mg/kg PO, IM or SC q6–12h (Adamcak & Otten 2000)

### ■HORSES: (Note: ARCI UCGFS Class 5 Drug)

For foals:

a) 1000 mg divided twice daily or three times daily PO, IV or IM (Robinson 1987)(

b) 300–600 mg PO or IV 4 times a day (Clark & Becht 1987)

For adjunctive treatment of melanomas:

a) 48 mg/kg/day (*dosing interval not specified*) PO for 2–3 weeks following resolution of tumor growth; regression should be seen evident within 3 months of initiating treatment; if no improvement seen it will probably not be effective and should be discontinued. Some horses may require treatment their entire life. (Rashmir-Raven *et al.* 2006)

### ■SWINE:

To treat gastric ulcers:

a) 300 mg per animal twice daily (Wass *et al.* 1986)

### ■REPTILES:

In most species:

a) 4 mg/kg PO q8–12h (Gauvin 1993)

## Monitoring

■ Clinical efficacy (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.

■ Adverse effects if noted

## Client Information

■ To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; signs may reoccur if dosages are missed.

## Chemistry/Synonyms

An H<sub>2</sub>- receptor antagonist, cimetidine occurs as a white to off-white, crystalline powder. It has what is described as an “unpleasant” odor and a pKa of 6.8. Cimetidine is sparingly soluble in water and soluble in alcohol. Cimetidine HCl occurs as white, crystalline powder and is very soluble in water and soluble in alcohol. It has a pKa of 7.11 and the commercial injection has a pH of 3.8–6.

Cimetidine may also be known as: cimetidinum, or SKF-92334; many trade names are available.

## Storage/Stability

Cimetidine products should be stored protected from light and kept at room temperature. Do not refrigerate the injectable product as precipitation may occur. Oral dosage forms should be stored in tight containers.

## Compatibility/Compounding Considerations

The cimetidine injectable product is **compatible** with the commonly used IV infusions solutions, including amino acid (TPN) solutions, but should be used within 48 hours of dilution. Cimetidine is also reported to be **compatible** with the following drugs: acetazolamide sodium, amikacin sulfate, atropine sulfate, carbenicillin disodium, cefoxitin sodium, chlorothiazide sodium, clindamycin phosphate, colistimethate sodium, dexamethasone sodium phosphate, digoxin, epinephrine, erythromycin lactobionate, furosemide, gentamicin sulfate, heparin sodium, insulin (regular), isoproterenol HCl, lidocaine HCl, lincomycin HCl, methylprednisolone sodium succinate, nafcillin sodium, norepinephrine bitartrate, penicillin G potassium/sodium, phytonadione, polymyxin B sulfate, potassium chloride, protamine sulfate, quinidine gluconate, sodium nitroprusside, tetracycline HCl, vancomycin HCl, verapamil HCl, and vitamin B complex (with or without C).

The following drugs are reported to be either **incompatible** with cimetidine or data conflicts: amphotericin B, ampicillin sodium, cefamandole naftate, cefazolin sodium, cephalothin sodium, and pentobarbital sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

**Compounded preparation stability:** Cimetidine oral suspension compounded from commercially available tablets has been published (Tortorici 1979). Triturating twenty-four (24) cimetidine 300 mg tablets with 10 mL of glycerin and *qs ad* to 120 mL with simple syrup yields a 60 mg/mL oral suspension that retains >90% potency for 17 days stored at 4°C.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Cimetidine Oral Tablets: 200 mg, 300 mg, 400 mg, & 800 mg; *Tagamet®* & *Tagamet® HB 200* (GlaxoSmithKline & GSK Consumer); *Acid Reducer 200®* (Major); generic; (Rx, OTC)

Cimetidine HCl Oral Solution: 300 mg (as HCl)/5 mL in 240 mL, 480 mL & UD 5 mL; generic; (Rx)

Cimetidine HCl Injection: 150 mg/mL (as hydrochloride) in 2 mL vials single-dose & 8 mL multiple-dose vials; generic (Rx); Cimetidine in 0.9% Sodium Chloride Injection: 6 mg (as hydrochloride)/mL in premixed 50 mL single-dose container; generic (Hospira); (Rx)

## CIPROFLOXACIN

(*sip-roe-flox-a-sin*) Cipro®

FLUOROQUINOLONE ANTIBIOTIC

### Prescriber Highlights

- **Human-label fluoroquinolone antibiotic**
- **In dogs, oral bioavailability lower than enrofloxacin**
- **Available as a true IV product**
- **Contraindications: Hypersensitivity. Relatively contraindicated for young, growing animals due to cartilage abnormalities**
- **Caution: Hepatic or renal insufficiency, dehydration**
- **Adverse Effects: GI distress, CNS stimulation, crystalluria, & hypersensitivity**
- **Administer PO preferably on an empty stomach**
- **Drug interactions**

---

## Uses/Indications

Because of its similar spectrum of activity, ciprofloxacin could be used as an alternative to enrofloxacin when a larger oral dosage form or intravenous product is desired. But the two compounds cannot be considered equivalent because of pharmacokinetic differences (see below).

## Pharmacology/Actions

Ciprofloxacin is a bactericidal and a concentration dependent agent, with susceptible bacteria cell death occurring within 20–30 minutes of exposure. Ciprofloxacin has demonstrated a significant post-antibiotic effect for both gram-negative and gram-positive bacteria and is active in both stationary and growth phases of bacterial replication. Its mechanism of action is not thoroughly understood, but it is believed to act by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis.

Both enrofloxacin and ciprofloxacin have similar spectra of activity. These agents have good activity against many gram-negative bacilli and cocci, including

Both enrofloxacin and ciprofloxacin have similar spectrums of activity. These agents have good activity against many gram-negative bacilli and cocci, including most species and strains of *Pseudomonas aeruginosa*, *Klebsiella* spp., *E. coli*, Enterobacter, Campylobacter, Shigella, Salmonella, Aeromonas, Haemophilus, Proteus, Yersinia, Serratia, and Vibrio species. Of the currently commercially available quinolones, ciprofloxacin and enrofloxacin have the lowest MIC values for the majority of these pathogens treated. Other organisms that are generally susceptible include *Brucella* spp., *Chlamydia trachomatis*, Staphylococci (including penicillinase-producing and methicillin-resistant strains), Mycoplasma, and *Mycobacterium* spp. (not the etiologic agent for Johne's disease). When combined with either ceftazidime or cefepime, fluorquinolones may have an additive or synergistic effect against certain bacteria.

The fluorquinolones have variable activity against most Streptococci and are not usually recommended for use in treating these infections. These drugs have weak activity against most anaerobes and are ineffective in treating anaerobic infections.

Resistance does occur by mutation, particularly with *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, Acinetobacter, and enterococci, but plasmid-mediated resistance does not seem to occur.

### Pharmacokinetics

Both enrofloxacin and ciprofloxacin are well absorbed after oral administration in most species; in dogs however, enrofloxacin's bioavailability is at least twice that of ciprofloxacin after oral dosing. In humans, the oral bioavailability of ciprofloxacin has been reported to be between 50–85%. Studies of the oral bioavailability in ponies have shown that ciprofloxacin is poorly absorbed (2–12%) while enrofloxacin in foals apparently is well absorbed.

In humans, the volume of distribution in adults for ciprofloxacin is about 2–3.5 L/kg and it is approximately 20–40% bound to serum proteins.

Ciprofloxacin is one of the metabolites of enrofloxacin. Approximately 15–50% of the drugs are eliminated unchanged into the urine by both tubular secretion and glomerular filtration. Enrofloxacin/ciprofloxacin are metabolized to various metabolites that are less active than the parent compounds. Approximately 10–40% of circulating enrofloxacin is metabolized to ciprofloxacin in most species. These metabolites are eliminated in both the urine and feces. Because of the dual (renal and hepatic) means of elimination, patients with severely impaired renal function may have slightly prolonged half-lives and higher serum levels but may not require dosage adjustment.

The pharmacokinetics of ciprofloxacin has been studied in dogs, calves, horses, and pigs. Oral bioavailability is approximately 50% in calves and 40% (only one pig studied) in pigs and it has an elimination half-life of about 2.5 hours in both species. Protein binding was significantly different for each species, with calves having about 70% of the drug bound and pigs only about 23% bound to plasma proteins. Elimination half-life is reported to be about 2.5 hours in dogs.

### Contraindications/Precautions/Warnings

Ciprofloxacin, as is enrofloxacin, should be considered contraindicated in small and medium breed dogs from 2–8 months of age. Bubble-like changes in articular cartilage have been noted when the drug was given at 2–5 times recommended doses for 30 days, although clinical signs have only been seen at the 5X dose. To avoid cartilage damage, large and giant breed dogs may need to wait longer than the recommended 8 months since they may be in the rapid-growth phase past 8 months of age. Quinolones are also contraindicated in patients hypersensitive to them.

Because ciprofloxacin has occasionally been reported to cause crystalluria, animals should not be allowed to become dehydrated during therapy with either ciprofloxacin or enrofloxacin. In humans, ciprofloxacin has been associated with CNS stimulation and should be used with caution in patients with seizure disorders. Patients with severe renal or hepatic impairment may require dosage adjustments to prevent drug accumulation.

Use high dose ciprofloxacin in cats with caution. No reports of retinal toxicity (as can be seen with high dose enrofloxacin) secondary to ciprofloxacin in cats were located and retinal toxicity appears to be less likely since it is less lipophilic than enrofloxacin; however caution is advised.

### Adverse Effects

With the exception of potential cartilage abnormalities in young animals (see Contraindications above), the adverse effect profile of fluoroquinolones appears to be minimal. GI distress (vomiting, anorexia) is the most frequently, yet uncommon, reported adverse effect. Although not reported thus far in animals, hypersensitivity reactions, crystalluria, and CNS effects (dizziness, stimulation) could potentially occur.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Ciprofloxacin is distributed into milk, but oral absorption should be negligible. No adverse effects have been reported in nursing human infants of mothers receiving ciprofloxacin.

### Overdosage

Little specific information is available. See the enrofloxacin monograph for more information.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ciprofloxacin and may be of significance in veterinary patients:

- **ANTACIDS/DAIRY PRODUCTS** containing cations ( $Mg^{++}$ ,  $Al^{+++}$ ,  $Ca^{++}$ ) may bind to ciprofloxacin and prevent its absorption; separate doses of these products by at least 2 hours from ciprofloxacin
- **ANTIBIOTICS, OTHER (aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum):** Synergism may occur, but is not predictable, against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although enrofloxacin/ciprofloxacin has minimal activity against anaerobes, *in vitro* synergy has been reported when used with **clindamycin** against strains of Peptostreptococcus, Lactobacillus and *Bacteroides fragilis*.
- **CYCLOSPORINE:** Fluoroquinolones may exacerbate the nephrotoxicity, and reduce the metabolism of, cyclosporine (used systemically)
- **GLYBURIDE:** Severe hypoglycemia possible
- **IRON, ZINC (oral):** Decreased ciprofloxacin absorption; separate doses by at least two hours
- **METHOTREXATE:** Increased MTX levels possible with resultant toxicity
- **NITROFURANTOIN:** May antagonize the antimicrobial activity of the fluoroquinolones; concomitant use is not recommended
- **PHENYTOIN:** Ciprofloxacin may alter phenytoin levels
- **PROBENECID:** Blocks tubular secretion of ciprofloxacin and may increase its blood level and half-life
- **QUINIDINE:** Increased risk for cardiotoxicity

■ **SUCRALFATE:** May inhibit absorption of ciprofloxacin; separate doses of these drugs by at least 2 hours

■ **THEOPHYLLINE:** Ciprofloxacin may increase theophylline blood levels

■ **WARFARIN:** Potential for increased warfarin effects

### Laboratory Considerations

■ In some human patients, the fluoroquinolones have caused increases in **liver enzymes, BUN, and creatinine** and decreases in **hematocrit**. The clinical relevance of these mild changes is not known at this time.

### Doses

#### ■ DOGS:

For susceptible infections:

a) 5–15 mg/kg PO q12h; Avoid or reduce dosage of these drugs in animals with severe renal failure; avoid in young animals or in pregnant or breeding animals. (Vaden & Papich 1995)

b) For UTI: 10 mg/kg PO once daily (q24h) for 7–14 days

For skin, soft tissue infections: 10–15 mg/kg PO once daily (q24h) for 7–14 days

For bone systemic infections, bacteremia and more resistant pathogens (*e.g.*, Enterobacter): 20 mg/kg PO once daily (q24h) for 7–14 days (Greene *et al.* 2006)

c) For pyoderma: 11 mg/kg PO q12h (Miller 2005)

#### ■ CATS:

For susceptible infections:

a) Ciprofloxacin: 5–15 mg/kg PO q12h

Avoid or reduce dosage of these drugs in animals with severe renal failure; avoid in young animals or in pregnant or breeding animals. (Vaden & Papich 1995)

#### ■ FERRETS:

For susceptible infections:

a) 5–15 mg/kg PO twice daily (Williams 2000)

#### ■ RABBITS/RODENTS/SMALL MAMMALS:

a) **Rabbits:** 5–20 mg/kg PO q12h (Ivey & Morrisey 2000)

b) **Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats:** 7–20 mg/kg PO q12h (Adamcak & Otten 2000)

c) For treating pasteurellosis in rabbits: ciprofloxacin or enrofloxacin 15–20 mg/kg PO twice daily for a minimum of 14 days in mild cases and up to several months in chronic infections. (Antinoff 2008)

#### ■ BIRDS:

For susceptible gram-negative infections:

a) Using ciprofloxacin 500 mg tablets: 20–40 mg/kg PO twice daily. Crushed tablet goes into suspension well, but must be shaken well before administering. (McDonald 1989)

b) Ciprofloxacin (using crushed tablets): 20 mg/kg PO q12h (Bauck & Hoefer 1993)

c) Ciprofloxacin (using crushed tablets or suspend) 10–15 mg/kg PO q12h (Hoeffler 1995)

d) **Ratites:** 3–6 mg/kg PO twice daily (Jenson 1998)

### Monitoring

■ Clinical efficacy

■ Adverse effects

### Chemistry/Synonyms

A fluoroquinolone antibiotic, ciprofloxacin HCl occurs as a faintly yellowish to yellow, crystalline powder. It is slightly soluble in water. Ciprofloxacin is related structurally to the veterinary-FDA-approved drug enrofloxacin (enrofloxacin has an additional ethyl group on the piperazinyl ring).

Ciprofloxacin may also be known as ciprofloxacin, ciprofloxacinum, ciprofloxacin, Bay-q-3939, or *Cipro*®.

### Storage/Stability

Unless otherwise directed by the manufacturer, ciprofloxacin tablets should be stored in tight containers at temperatures less than 30°C. Protect from strong UV light. The injection should be stored at 5°–25°C and protected from light and freezing.

### Compatibility/Compounding Considerations

The manufacturer recommends administering IV ciprofloxacin alone (temporarily discontinuing other solutions or drugs while ciprofloxacin running). However, other sources state that ciprofloxacin injection is reportedly **compatible** with the following IV solutions and drugs: Dextrose 5%, D5 and 1/4 or 1/2 NaCl, Ringer's, LRS, normal saline; **Y-site compatible with** amikacin sulfate, aztreonam, ceftazidime, cimetidine, cyclosporine, dexmedetomidine, dobutamine, dopamine, fluconazole, gentamicin, lidocaine, midazolam, KCl, ranitidine, tobramycin, and vitamin B complex.

Ciprofloxacin injection is reportedly **incompatible** with aminophylline, amphotericin B, azithromycin, cefuroxime, clindamycin, heparin sodium, sodium bicarbonate, and ticarcillin.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more information.

pecific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Ciprofloxacin Oral Tablets: 100 mg, 250 mg, 500 mg & 750 mg; *Cipro*® (Shering-Plough); generic; (Rx)

Ciprofloxacin Extended-Release Oral Tablets: 500 mg & 1000 mg; *Cipro XR*® (Shering-Plough); generic; (Rx)

Ciprofloxacin Microcapsules for Oral Suspension: 250 mg/5 mL (5%) & 500 mg/5 mL (10%) when reconstituted in 100 mL with diluent; *Cipro*® (Schering-Plough); (Rx)

Ciprofloxacin Solution for Injection: 200 mg & 400 mg in 100 mL & 200 mL (respectively) in 5% dextrose flexible containers (0.2%); *Cipro*® I.V. (Schering-Plough); generic (Sandoz); (Rx)

## CISAPRIDE

(*sis-a-pride*)

PROMOTILITY AGENT

### Prescriber Highlights

- **Oral GI prokinetic agent, used in several species for GI stasis, reflux esophagitis, & constipation/megacolon (cats)**
- **No longer commercially available, must be obtained from a compounding pharmacy**
- **Contraindications: Hypersensitivity, GI perforation or obstruction, hemorrhage**
- **Caution: Pregnancy**
- **Adverse effects appear to be minimal in veterinary patients; vomiting, diarrhea, and abdominal discomfort can occur**
- **Drug interactions**

---

## Uses/Indications

Proposed uses for cisapride in small animals include esophageal reflux, esophagitis and treatment of primary gastric stasis disorders. Cisapride has been found to be useful in the treatment of constipation and megacolon in cats.

## Pharmacology/Actions

Cisapride increases lower esophageal peristalsis and sphincter pressure and accelerates gastric emptying. The drug's proposed mechanism of action enhances the release of acetylcholine at the myenteric plexus, but does not induce nicotinic or muscarinic receptor stimulation. Acetylcholinesterase activity is not inhibited. Cisapride blocks dopaminergic receptors to a lesser extent than does metoclopramide and does not increase gastric acid secretion.

## Pharmacokinetics

Human data: After oral administration, cisapride is rapidly absorbed with an absolute bioavailability of 35–40%. The drug is highly bound to plasma proteins and apparently extensively distributed throughout the body. Cisapride is extensively metabolized and its elimination half-life is about 8–10 hours.

## Contraindications/Precautions/Warnings

Cisapride is contraindicated in patients in whom increased gastrointestinal motility could be harmful (*e.g.*, perforation, obstruction, GI hemorrhage) or those who are hypersensitive to the drug.

## Adverse Effects

Cisapride appears to be safe in small animals at the dosages recommended. Occasionally vomiting, diarrhea, and abdominal discomfort may be noted. Although considered very rare in veterinary patients, prolonged QT intervals or other cardiac arrhythmias are possibilities.

In humans, the primary adverse effects are gastrointestinal related with diarrhea and abdominal pain most commonly reported, but the drug was removed from the market due to concerns with QT-interval prolongation.

Dosage may need to be decreased in patients with severe hepatic impairment.

## Reproductive/Nursing Safety

Cisapride at high dosages (>40 mg/kg/day) caused fertility impairment in female rats. At doses 12 to 100 times the maximum recommended, cisapride caused embryotoxicity and fetotoxicity in rabbits and rats. Its use during pregnancy should occur only when the benefits outweigh the risks. Cisapride is excreted in maternal

milk in low levels; use with caution in nursing mothers.

### Overdosage/Acute Toxicity

LD<sub>50</sub> doses in various lab animals range from 160 - 4000 mg/kg. The reported oral lethal dose in dogs is 640 mg/kg. In one reported human overdose of 540 mg, the patient developed GI distress and urinary frequency. There were 29 exposures to cisapride reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 21 were cats with 6 showing clinical signs, and 8 were dogs with 5 showing clinical signs. Most common adverse effects seen in dogs and cats are diarrhea, lethargy, ataxia, hypersalivation, muscle fasciculations, agitation, abnormal behavior, hyperthermia, and possibly seizures (dogs) (APCC unpublished data).

Significant overdoses should be handled using standard gut emptying protocols when appropriate; supportive therapy should be initiated when required. Activated charcoal is effective in binding unabsorbed cisapride (Volmer 1996).

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cisapride and may be of significance in veterinary patients:

■ **ANTICHOLINERGIC AGENTS:** Use of anticholinergic agents may diminish the effects of cisapride

■ **BENZODIAZEPINES:** Cisapride may enhance the sedative effects of alcohol or benzodiazepines

■ **WARFARIN:** Cisapride may enhance anticoagulant effects; additional monitoring and anticoagulant dosage adjustments may be required

■ **ORAL DRUGS WITH A NARROW THERAPEUTIC INDEX:** May need serum levels monitored more closely when adding or discontinuing cisapride as cisapride can decrease GI transit times and potentially affect the absorption of other oral drugs

As cisapride is metabolized via cytochrome P450 (3A4 in humans), the following medications/foods that can inhibit this enzyme may lead to increased cisapride levels with an increased risk for cisapride cardiotoxicity:

■ **AMIODARONE**

■ **ANTIFUNGALS (ketoconazole, itraconazole, fluconazole)**

■ **CHLORAMPHENICOL**

■ **CIMETIDINE**

■ **FLUVOXAMINE**

■ **GRAPEFRUIT JUICE/POWDER**

■ **MACROLIDE ANTIBIOTICS (except azithromycin) Note:** Erythromycin did not alter cisapride pharmacodynamics in one study in dogs

The following drugs may increase QT interval and use with cisapride may increase this risk:

■ **AMIODARONE**

■ **CLARITHROMYCIN**

■ **MOXIFLOXACIN**

■ **PROCAINAMIDE**

■ **QUINIDINE**

■ **SOTALOL**

■ **TRICYCLIC ANTIDEPRESSANTS (amitriptyline, imipramine)**

### Doses

#### ■ DOGS:

As a promotility agent

a) 0.1–0.5 mg/kg PO 2–3 times per day given 30 minutes before meals. Higher doses of 1 mg/kg may be required in some cases. (Twedt 2008)

b) To reduce regurgitation associated with megaesophagus: 0.55 mg/kg PO once to three times daily. Practically: 2.5 mg per dose for dogs weighing between 5–10 lbs.; 5 mg per dose for dogs weighing between 11–40 lbs; and 10 mg per dose for dogs greater than 40 lbs. Administer no closer than 30 minutes before feeding. (Tams 1994)

c) For adjunctive treatment (with H-2 blockers or proton pump inhibitors such as omeprazole—preferred) for esophageal reflux: 0.1–0.5 mg/kg PO q8–24h (Willard 2006)

d) To reduce the risk for esophageal stricture formation in cases of esophagitis: 0.5–0.75 mg/kg PO three times daily. (Richter 2009)

To stimulate detrusor contraction for micturition disorders:

a) 0.5 mg/kg PO q8h (Coates 2004)

#### ■ CATS:

As a promotility agent:

a) For chronic constipation (*e.g.*, megacolon): In combination with a stool softener (author recommends lactulose at a starting dose of 2–3 mL PO three times a day; then adjust as needed) and a bulk agent (*e.g.*, psyllium or pumpkin pie filling) cisapride is given initially at 2.5 mg (for cats up to 10 pounds) or 5 mg (for cats 11 pounds or heavier) three times daily, 30 minutes before food. Cats weighing greater than 16 pounds may require 7.5 mg. (Tams 1994)

b) For chronic constipation (*e.g.*, megacolon): Used adjunctively with conventional dietary therapeutics: 1.25–2.5 mg per cat two to three times a day; cats with hepatic insufficiency should be treated with half the usual dose; probably most effective when given 15 minutes before a meal. (Nixon 1994)

c) For chronic constipation (*e.g.*, megacolon): 2.5–5 mg per cat PO q8–12h (Carr 2009)

d) For chronic constipation (*e.g.*, megacolon): 5 mg per cat (total dose) PO q8–12h (Scherk 2003)

e) For gastric stasis: 0.1 mg/kg PO two to three times daily; cats tolerate 2.5 mg doses without problems (Twedt 2005)

f) To reduce the risk for esophageal stricture formation in cases of esophagitis: 0.5–0.75 mg/kg PO three times daily. (Richter 2009)

1) To reduce the risk for esophageal stricture formation in cases of esophagitis: 0.5–0.75 mg/kg PO three times daily. (Richter 2009)

## ■ RABBITS/RODENTS/SMALL MAMMALS:

- Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:** 0.1–0.5 mg/kg PO q12h (Adamcak & Otten 2000)
- Rabbits for GI stasis: 0.5 mg/kg PO q6–12h. With IV or SC fluids depending on amount of dehydration, feeding a high fiber slurry and with or without metoclopramide (0.2–1 mg/kg PO, SC q6–8h). (Hess 2002)
- For ileus if GI tract not obstructed in Guinea pigs, chinchillas: 0.5 mg/kg q8–12h (*Route not specified; assume PO*) (Orcutt 2005)
- For gastric stasis in rabbits: Usually started at 0.5 mg/kg PO (via NG tube) q8h after first stools were produced or no intestinal obstruction appreciated. May be synergistic if used with ranitidine (0.5 mg/kg IV q24h). (Lichtenberger 2008)

## ■ HORSES:

As a promotility agent:

- Foals with periparturient asphyxia: 10 mg (total dose) PO q6–8h. Adequate time for healing of damaged bowel before using prokinetic agents is essential. (Vaala 2003)

## Monitoring

- Efficacy
- Adverse effects profile

## Client Information

- Inform client to watch carefully and report any adverse effects noted.

## Chemistry/Synonyms

An oral GI prokinetic agent, cisapride is a substituted piperidinyl benzamide and is structurally, but not pharmacologically, related to procainamide. It is available commercially as a monohydrate, but potency is expressed in terms of the anhydrate.

Cisapride may also be known as: cisapridum, or R-51619; many trade names are registered.

## Storage/Stability

Unless otherwise instructed by the manufacturer, store cisapride tablets in tight, light-resistant containers at room temperature.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Cisapride oral suspension compounded from commercially available tablets has been published (Allen & Erickson 1998). Triturating twelve (12) cisapride 10 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® with pH finally adjusted to 7 with sodium bicarbonate yields a 1 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Although cisapride tablets are no longer commercially available, the active pharmaceutical ingredient powder may be used to compound suitable oral suspensions of cisapride. Compounded preparations of cisapride should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

Because of adverse effects in humans, cisapride has been removed from the US market. It may be available from compounding pharmacies.

## CISPLATIN

(*sis-pla-tin*) **Platinol-AQ**®

ANTINEOPLASTIC

### Prescriber Highlights

- **Platinum antineoplastic agent used for a variety of carcinomas & sarcomas; palliative control of neoplastic pulmonary effusions with intracavitary administration; intralesional injection for skin tumors in horses**
- **Contraindications: Cats; preexisting significant renal impairment or myelosuppression**
- **Primary adverse effects: Vomiting (pretreat with antiemetic); nephrotoxicity (use forced saline diuresis); myelosuppression; many other adverse effects possible**
- **Drug related deaths possible**

- **Teratogenic, fetotoxic; may cause azoospermia**
  - **Must be handled with care by dosage preparer/administerer**
  - **Must be given as slow IV infusion; fast administration (<5 minutes) may increase toxicity**
- 

### Uses/Indications

In veterinary medicine, the systemic use of cisplatin is presently limited to use in dogs. The drug has been, or may be, useful in a variety of neoplastic diseases including squamous cell carcinomas, transitional cell carcinomas, ovarian carcinomas, mediastinal carcinomas, osteosarcomas, pleural adenocarcinomas, nasal carcinomas, and thyroid adenocarcinomas.

Cisplatin may be useful for the palliative control of neoplastic pulmonary effusions after intracavitary administration.

In horses, cisplatin has been used for intralesional injection for skin tumors.

### Pharmacology/Actions

While the exact mechanism of action of cisplatin has not been determined, its properties are analogous to those of bifunctional alkylating agents producing inter- and intrastrand crosslinks in DNA. Cisplatin is cell cycle nonspecific.

### Pharmacokinetics

After administration, the drug concentrates in the liver, intestines and kidneys. Platinum will accumulate in the body and may be detected 6 months after a course of therapy has been completed. Cisplatin is highly bound (90%) to serum proteins.

In dogs, cisplatin exhibits a biphasic elimination profile. The initial plasma half-life is short (approximately 20–50 minutes), but the terminal phase is very long (about 60–80 hours). Approximately 80% of a dose can be recovered as free platinum in the urine within 48 hours of dosing in dogs.

### Contraindications/Precautions/Warnings

The drug is contraindicated in cats because of severe dose-related primary pulmonary toxicoses (dyspnea, hydrothorax, pulmonary edema, mediastinal edema, and death). Cisplatin is also contraindicated in patients with preexisting significant renal impairment, myelosuppression, or a history of hypersensitivity to platinum-containing compounds. Because of the fluid loading required prior to dosing, it should be used with caution in patients with congestive heart failure.

When preparing the product for injection, wear gloves and protective clothing as local reactions may occur with skin or mucous membrane contact. Should accidental exposure occur, wash the area thoroughly with soap and water.

### Adverse Effects

In dogs, the most frequent adverse effect seen after cisplatin treatment is vomiting, which usually occurs within 6 hours after dosing and persists for 1–6 hours. This is because of direct effects on the chemoreceptor trigger zone (CTZ). Maropitant, butorphanol, dexamethasone and metoclopramide have all been used successfully as antiemetics when given before cisplatin administration.

Nephrotoxicity may occur unless the animal is adequately diuresed with sodium chloride prior to, and after therapy; diuresis will generally significantly reduce the incidence and severity of nephrotoxicity in the majority of dogs. Intravenous methimazole (40 mg/kg) has been demonstrated to protect cisplatin-induced nephrotoxicity in dogs in experimental models.

Other adverse effects that have been reported include hematologic abnormalities (thrombocytopenia and/or granulocytopenia), ototoxicity (high-frequency hearing loss and tinnitus), anorexia, diarrhea (including hemorrhagic diarrhea), seizures, peripheral neuropathies, electrolyte abnormalities, hyperuricemia, increased hepatic enzymes, anaphylactoid reactions, and death.

Direct IV infusion over 1–5 minutes should be avoided as it may cause increased nephrotoxicity or ototoxicity.

### Reproductive/Nursing Safety

Cisplatin's safe use in pregnancy has not been established. It is teratogenic and embryotoxic in mice. In human males, the drug may cause azoospermia and impaired spermatogenesis. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

### Overdosage/Acute Toxicity

The minimum lethal dose of cisplatin in dogs is reportedly 2.5 mg/kg ( $\approx 80 \text{ mg/m}^2$ ). Because of the potential for serious toxicity associated with this agent, dosage calculations should be checked thoroughly to avoid overdosing. See Adverse Effects above for more information.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cisplatin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Potential for increased risk for nephrotoxicity and/or nephrotoxicity; if possible, delay aminoglycoside administration by at least two weeks after cisplatin
- **AMPHOTERICIN B:** Potential for increased risk for nephrotoxicity; if possible, delay amphotericin B administration by at least two weeks after cisplatin
- **FUROSEMIDE** (and other **loop diuretics**): Potential for increased ototoxicity
- **PHENYTOIN:** Cisplatin may reduce serum levels of phenytoin

### Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie

## ■ DOGS:

For potentially susceptible carcinomas and sarcomas:

a) The following is a usual dosage or dose range for cisplatin and should be used only as a general guide: Dogs: 30–70 mg/m<sup>2</sup> (NOT mg/kg) IV over 20 minutes to several hours every 3–5 weeks.

**Warning:** Do not confuse cisplatin and carboplatin dosages; cisplatin dosages are much lower. Dogs must undergo saline diuresis before and after cisplatin therapy to reduce the potential for nephrotoxicity development. Some clinicians also recommend using either mannitol or furosemide with saline, but this is somewhat controversial.

Intracavitary administration for palliative control of neoplastic pulmonary effusions:

a) Give dog IV normal saline at 10 mL/kg/hr for 4 hours prior to treating. Dose cisplatin at 50 mg/m<sup>2</sup> (NOT mg/kg) (diluted in normal saline to a total volume of 250 mL/m<sup>2</sup>). Warm solution to body temperature; place a 16-gauge over-the-needle catheter into the pleural space using sterile technique. Remove as much pleural fluid as possible and then slowly infuse cisplatin solution through same catheter. Once completed, remove catheter. May repeat every 3–4 weeks as needed to control effusion. If resolves completely, discontinue therapy after the 4th treatment. Reinstigate if effusion recurs. (Hawkins & Fossum 2000)

## ■ HORSES:

For intralesional injection of skin tumors:

a) Add 10 mg of cisplatin powder (if available) to 1 mL of water and 2 mL of medical-grade sesame oil. Resultant solution contains 3.3 mg of cisplatin per mL. Inject 1 mg per cm<sup>3</sup> of tumor/tumor bed intralesionally with a small gauge needle (22–25 gauge) attached to an extension set with Luer-lock connections. Inject in multiple planes no further than 0.6 to 1 cm apart. Because the volume of tumor is difficult to measure, the rule of thumb is to discontinue injection when fluid is extruded from the skin surface. Because recurrence at the periphery of the treated area is the primary cause of treatment failure, injection into 1–2 cm of normal tissue surrounding the tumor has been recommended. Intralesional injection is generally repeated at 2-week intervals for 4 total treatments. (Moll 2002)

## Monitoring

Adapted primarily from the reference by Shapiro (Shapiro 1989).

■ Toxicity. Baseline laboratory data: urinalysis, hemogram, platelet count, serum biochemical and electrolyte determination. Repeat tests before each dose if animal is receiving high-dose therapy (≈monthly) or as needed if signs/symptoms of toxicity develop. Animals receiving frequent small doses should be monitored at least weekly. Not recommended to use cisplatin if WBC is <3200/mcl, platelets <100,000, creatinine clearance is <1.4 mL/min/kg, or uremia, electrolyte or acid-base imbalance is present. Reduce dose if rapid decreases occur with either WBC or platelets, changes in urine specific gravity or serum electrolytes, elevated serum creatinine or BUN, or if creatinine clearance is >1.4 but <2.9 mL/min/kg.

■ Efficacy. Tumor measurement and radiography at least monthly. In one study (Knapp et al. 1988), the authors state that dogs should be evaluated at 42 days into therapy. Dogs demonstrating complete or partial remission or stable disease should receive additional therapy. Dogs whose disease has progressed should have cisplatin therapy stopped and receive alternate therapies if warranted.

## Client Information

■ Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality.

## Chemistry/Synonyms

An inorganic platinum-containing antineoplastic, cisplatin occurs as white powder. One mg is soluble in 1 mL of water or normal saline. The drug is available commercially as a solution for injection. Cisplatin injection (premixed solution) has a pH of 3.7–6.

Cisplatin may also be known as: cis-Platinum II, cis-DDP, CDDP, cis-diamminedichloroplatinum, cisplatina, cisplatinum, cis-platinum, DDP, NSC-119875, Peyrone's salt, or platinum diamminodichloride; many trade names are available.

## Storage/Stability

The injection should be stored at room temperature and away from light; do not refrigerate as a precipitate may form. During use, the injection should be protected from direct bright sunlight, but does not need to be protected from normal room incandescent or fluorescent lights.

Do not use aluminum hub needles or aluminum containing IV sets as aluminum may displace platinum from the cisplatin molecule with the resulting formation of a black precipitate. Should a precipitate form from either cold temperatures or aluminum contact, discard the solution.

## Compatibility/Compounding Considerations

Cisplatin is reportedly **compatible** with the following intravenous solutions and drugs: dextrose/saline combinations, sodium chloride 0.225%–0.9%, magnesium sulfate, and mannitol. It is also **compatible** in syringes or at Y-sites with: bleomycin sulfate, cyclophosphamide, doxorubicin HCl, droperidol, fluorouracil, furosemide, heparin sodium, leucovorin calcium, methotrexate, mitomycin, vinblastine sulfate, and vincristine sulfate.

Cisplatin **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: dextrose/saline combinations, dextrose 5% in water, and metoclopramide. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Cisplatin is reportedly **incompatible** with the following solutions or drugs: sodium chloride 0.1% and sodium bicarbonate 5%.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Cisplatin Injection: 1 mg/mL in 50 mL, 100 mL & 200 mL multi-dose vials; generic; (Rx)

Cisplatin powder or compounded formulations appropriate for intralesional injection may be available from compounding pharmacies.

## CITRATE SALTS

### POTASSIUM CITRATE

### SODIUM CITRATE AND CITRIC ACID

(*si-trate*) Nutrivet®, Urocit-K®

#### URINARY ALKALINIZER

#### Prescriber Highlights

- Oral administered precursor to bicarbonate; used for urinary alkalization & treatment of chronic metabolic acidosis; may be useful to prevent calcium oxalate urolith formation
  - Many contraindications to therapy, including heart failure, severe renal impairment, UTI with calcium or struvite stones
  - Contraindications for potassium citrate alone include hyperkalemia, ulcer disease; tablets in patients with delayed gastric emptying conditions, esophageal compression, or intestinal obstruction
  - Most prevalent adverse effect is GI distress but, potentially, hyperkalemia, fluid retention & metabolic alkalosis possible
  - Adequate lab monitoring mandatory
- 

#### Uses/Indications

Citrate salts serve as source of bicarbonate; they are more pleasant tasting than bicarbonate preparations making them more palatable. They are used as urinary alkalizers when an alkaline urine is desirable and in the management of chronic metabolic acidosis accompanied with conditions such as renal tubular acidosis or chronic renal insufficiency. Potassium citrate alone (*Uracit-K®*) has been used for the prevention of calcium oxalate uroliths. The citrate can complex with calcium thereby decreasing urinary concentrations of calcium oxalate. The urinary alkalizing effects of the citrate also increase the solubility of calcium oxalate.

#### Pharmacology/Actions

Citrate salts are oxidized in the body to bicarbonate thereby acting as alkalizing agents. The citric acid component of multi-component products is converted only to carbon dioxide and water and has only a temporary effect on systemic acid-base status.

#### Pharmacokinetics

Absorption and oxidation are nearly complete after oral administration; less than 5% of a dose is excreted unchanged.

#### Contraindications/Precautions/Warnings

Contraindications for products containing sodium citrate and/or potassium citrate: aluminum toxicity, heart failure, severe renal impairment (with azotemia or oliguria), UTI associated with calcium, or struvite stones. Additional contraindications for potassium citrate alone include hyperkalemia (or conditions that predispose to hyperkalemia such as adrenal insufficiency, acute dehydration, renal failure, uncontrolled diabetes mellitus), or peptic ulcer (particularly with the tablets). The potassium citrate tablets are contraindicated in patients with delayed gastric emptying conditions, esophageal compression, or intestinal obstruction or stricture. These products should be used with caution (weigh risks vs. benefit) in severe renal tubular acidosis or chronic diarrheal syndromes as they may be ineffective. Sodium citrate products should be used with caution in patients with congestive heart disease.

In dosages not resulting in hypernatremia, hyperkalemia or metabolic alkalosis, these products should not cause fetal harm.

#### Adverse Effects

The primary adverse effects noted with these agents are gastrointestinal in nature, however, most dogs receiving these products tolerate them well. Potassium citrate products have the potential of causing hyperkalemia, especially in susceptible patients. Sodium citrate products may lead to increased fluid retention in patients with cardiac disease. Rarely, metabolic alkalosis could occur.

#### Reproductive/Nursing Safety

In humans, the FDA categorizes potassium citrate as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

No specific data is available on the safety of citrates during nursing, but no documented adverse effects have been reported.

#### Overdosage/Acute Toxicity

Overdosage and acute toxicity would generally fall into 4 categories: gastrointestinal distress and ulceration, metabolic alkalosis, hypernatremia (sodium citrate), or hyperkalemia (potassium citrate). Should an overdose occur and there are reasonable expectations of preventing absorption (especially with the tablets), gut-emptying protocols should be employed if not contraindicated. Otherwise, treat GI effects, if necessary, with intravenous fluids or other supportive care. Hyperkalemia, hypernatremia, and metabolic alkalosis should be treated if warranted. It is suggested to refer to an animal poison control center, an internal medicine text or other references for additional information for specific treatment modalities for these conditions.

#### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving citrates and may be of significance in veterinary patients:

■**MPHETAMINES; PSEUDOEPHEDRINE; EPHEDRINE:** Alkalinized urine can decrease excretion

■**ANTACIDS:** Citrate alkalinizers used with antacids (particularly those containing bicarbonate or aluminum salts) may cause systemic alkalosis, and aluminum toxicity (aluminum antacids only) particularly in patients with renal insufficiency. Sodium citrate combined with sodium bicarbonate may cause hypernatremia, and may cause the development of calcium stones in patients with preexisting uric acid stones.

■**ASPIRIN:** Alkalinized urine can increase the excretion of salicylates

■**FLUOROQUINOLONES:** The solubility of ciprofloxacin & enrofloxacin is decreased in an alkaline environment. Patients with alkaline urine should be monitored for signs of crystalluria.

■**LITHIUM:** Alkalinized urine can decrease excretion

■**METHENAMINE:** Concurrent use with methenamine is not recommended as it requires an acidic urine for efficacy.

■**QUINIDINE:** Alkalinized urine can decrease excretion

■**TETRACYCLINES:** Alkalinized urine can decrease excretion

With potassium citrate products, the following agents may lead to increases in serum potassium levels (including severe hyperkalemia), particularly in patients with renal insufficiency:

■**ACE INHIBITORS** (e.g., enalapril, lisinopril)

■**CYCLOSPORINE**

■**DIGOXIN**

■**HEPARIN**

■**NONSTEROIDAL ANTIINFLAMMATORY DRUGS (NSAIDS)**

■**POTASSIUM-CONTAINING DRUGS/FOODS**

■**SPIRONOLACTONE; TRIAMTERENE**

## Doses

### ■**DOGS:**

For adjunctive therapy to inhibit calcium oxalate crystal formation in dogs with hypocitraturia:

a) Potassium citrate: 40–75 mg/kg PO q12h; avoid overzealous urinary alkalinization as calcium phosphate uroliths may form (Grauer 2003)

b) Potassium citrate: Initially 50 mg/kg PO q12h. Monitor urine pH; goal is to obtain values of 7–7.5 (Bartges, JW 2000)

c) To help decrease the possibility of calcium oxalate stone formation using *Nutrived® Potassium Citrate Granules*: 1 scoop mixed or sprinkled on food per 10 lb. body weight per day. (Label information; *Nutrived® Potassium Citrate Granules for Dogs & Cats*—Vedco)

d) If calcium oxalate crystalluria is persistent or calcium oxalate uroliths occur and dietary and hydrochlorothiazide (2 mg/kg PO q12h) therapy have been implemented, give potassium citrate to effect to achieve a urine pH of 6.5–7 using a starting dose of 50–75 mg/kg PO q12h. If urine pH already above 7–7.5, do not use potassium citrate. Monitor serum potassium levels monthly and reduce dose if hyperkalemia occurs. (Adams & Syme 2005)

For adjunctive therapy of chronic renal failure as a potassium supplement and alkalinizing agent:

a) Potassium citrate: Initially, 75 mg/kg PO q12h (Bartges, J 2002)

### ■**CATS:**

For adjunctive therapy to inhibit calcium oxalate formation:

a) Potassium citrate: initially 50–100 mg kg PO q12h. Goal is to achieve a urine pH of approximately 7.5 (Bartges, J 2002)

b) To help decrease the possibility of calcium oxalate stone formation using *Nutrived® Potassium Citrate Granules*: 1 scoop mixed or sprinkled on food per day. (Label information; *Nutrived® Potassium Citrate Granules for Dogs & Cats*—Vedco)

c) Recommended dose is 100–150 mg/kg/day PO, but it is unclear whether this dose will actually increase urinary citrate in cats. (Westropp *et al.* 2005)

For adjunctive therapy of chronic renal failure as a potassium supplement and alkalinizing agent:

a) Potassium citrate: Initially, 75 mg/kg PO q12h (Bartges, J 2002)

b) If cat is significantly acidemic: 2.5 mEq (total dose) potassium or 15–30 mg/kg as potassium citrate PO q12h (Wolf 2006)

c) When cats with CRF are hypokalemic: 2–4 mEq (total dose) of potassium per day as potassium citrate or potassium gluconate. (DiBartola & Chew 2006)

## Monitoring

Depending on patient's condition, product chosen and reason for use:

■ Serum potassium, sodium, bicarbonate, chloride

■ Acid/base status

■ Urine pH, Urinalysis

■ Serum creatinine, CBC, particularly in chronic renal failure

## Chemistry/Synonyms

Generally used as alkalinizing agents, citric acid and citrate salts are available in several commercially available dosage forms. Citric acid occurs as an odorless or practically odorless, colorless, translucent crystal with a strong acidic taste. It is very soluble in water. Potassium citrate occurs as odorless, transparent crystals or a white, granular powder having a cooling, saline taste. It is freely soluble in water. 108 mg of potassium citrate contains approximately 1 mEq of potassium. Sodium citrate occurs as colorless crystals or a white, granular powder. The hydrous form is freely soluble in water.

Potassium citrate may also be known as citrate of potash, or citric acid tripotassium salt monohydrate. Sodium citrate and citric acid solutions may also be known as Shohl's solution.

## Storage/Stability

Store solutions and potassium citrate tablets in tight containers at room temperature unless otherwise recommended by manufacturer.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Potassium Citrate and Fatty Acids Granules: each 5 g (one scoop) contains 300 mg potassium citrate (approximately 2.8 mEq of potassium) and 423 mg total fatty acids; also contains several amino acids—quantities not labeled; *Nutrived® Potassium Citrate Granules for Cats and Dogs* (Vedco); (OTC)

### HUMAN-LABELED PRODUCTS:

Potassium Citrate Extended-Release Oral Tablets: 5 mEq (540 mg), 10 mEq (1080 mg) & 15 mEq; *Urocit-K®*; (Mission); generic (Rising) (Rx)

#### *Potassium Citrate/Sodium Citrate Combinations:*

Tablets: 50 mg potassium citrate and 950 mg sodium citrate. *Citrolith®* (Beach Pharm); (Rx)

Syrup: 550 mg potassium citrate, 500 mg sodium citrate, 334 mg citric acid/5 mL (1 mEq K, 1 mEq Na per mL equivalent to 2 mEq bicarbonate); in 120 and 480 mL, *Polycitra®* (Willen); (Rx)

Solution: 550 mg K citrate, 500 mg sodium citrate, 334 mg citric acid/5 mL (1 mEq K, 1 mEq Na per mL; equiv to 2 mEq bicarbonate) in 120 and 480 mL. *Polycitra-LC®* (Willen); (Rx).

1100 mg potassium citrate, 334 mg citric acid/5 mL, (2 mEq K/mL; equiv. to 2 mEq bicarbonate) in 120 and 480. *Polycitra-K®* (Willen); (Rx)

Crystals for Reconstitution: 3300 mg K citrate, 1002 mg citric acid per UD packet (equiv. To 30 mEq bicarbonate) in single dose packets. *Polycitra-K®* (Willen); (Rx)

#### *Citric Acid/Sodium Citrate Combinations:*

Solutions: Sodium Citrate Dihydrate 490 mg sodium citrate and Citric Acid 640 mg per 5 mL (1 mEq sodium equiv to 1 mEq bicarbonate/mL) in 500 mL and UD 15 and 30 mL, *Oracit®*; (Carolina Medical); (Rx)

Sodium Citrate Dihydrate 500 mg sodium citrate and Citric 334 mg per 5 mL (1 mEq sodium equiv to 1 mEq bicarbonate/mL) in 120 and 473 mL and UD 15 and 30 mL; *Bicitra®*; (Alza Corp); (Rx)

#### *Potassium Citrate, Sodium Citrate/Citric Acid Solutions:*

550 mg potassium citrate monohydrate, 500 mg sodium citrate dihydrate, 334 mg citric acid monohydrate per 5 mL (1 mEq potassium and 1 mEq sodium per mL and is equivalent to 2 mEq bicarbonate in 60 oz bottles; *Cytra-LC®* (Cypress); (Rx)

1100 mg potassium citrate monohydrate and 334 mg citric acid monohydrate per 5 mL (2 mEq potassium per mL and is equivalent to 2 mEq bicarbonate) in 473 mL; *Cytra-K®* (Cypress); (Rx)

20 mEq potassium, 30 mEq citrate (20 g dextrose, 5 g fructose, 35 mEq chloride, 45 mEq sodium)/L in 1 liter; *Naturalyte® Oral Electrolyte Solution* (Unico); (OTC)

## CLARITHROMYCIN

(klar-ith-ro-my-sin) Biaxin®

MACROLIDE ANTIBIOTIC

### Prescriber Highlights

- **Macrolide antibiotic that may be useful for treating atypical mycobacterial infections or treatment of *Helicobacter* spp. infections in dogs, cats, & ferrets; *Rhodococcus equi* infections in foals**
  - **Appears to be well tolerated by domestic animals, but clinical experience is limited**
  - **Many potential drug interactions**
  - **Expense may be an issue, but generics now available**
- 

## Uses/Indications

In small animal medicine, clarithromycin is primarily of interest in treating atypical mycobacterial infections or treatment of *Helicobacter* spp. infections in cats and ferrets. In equine medicine, clarithromycin may be useful in treating *Rhodococcus equi* infections in foals.

## Pharmacology/Actions

Clarithromycin, like other macrolide antibiotics, penetrate susceptible bacterial cell walls and bind to the 50S ribosomal subunit inhibiting protein synthesis. The drug is usually bacteriostatic, but may be bactericidal at high concentrations in very susceptible organisms.

Clarithromycin's spectrum of activity is similar to that of erythromycin, but it also has activity against a variety of bacteria that are not easily treated with other antibiotics (e.g., atypical mycobacteria). Activity against gram-positive aerobic cocci is similar to that of erythromycin, but lower concentrations are required to be effective against susceptible organisms. The drug is typically not effective against oxacillin-resistant Staph or coagulase-negative Staph. Clarithromycin also has

activity against *Rhodococcus equi*. Activity against gram-negative aerobic bacteria includes *Haemophilus influenzae*, *Pasturella multocida*, *Legionella pneumophila*, *Bordetella pertussis* and *Campylobacter* spp. Clarithromycin has inhibitory activity against a variety of atypical mycobacteria, including *M. avium complex* and *M. leprae*. Clarithromycin has good activity against *Mycoplasma pneumoniae* and *Ureaplasma urealyticum*. Other organisms where clarithromycin may have therapeutic usefulness include: *Nocardia* spp. *Toxoplasma gondii*, *Helicobacter pylori*, *Borrelia burgdorferi*, and *Cryptosporidium parvum*.

### Pharmacokinetics

In horses (foals), the drug is apparently well absorbed after intragastric administration with peak serum concentrations occurring about 1.5 hours after dosing. Elimination half-life is about 4.8 hours.

In dogs, clarithromycin bioavailability ranges from 60–83% with the higher values obtained when given to fasted animals.

### Contraindications/Precautions/Warnings

In humans, clarithromycin is contraindicated in patients hypersensitive to it or other macrolide antibiotics (e.g., erythromycin, azithromycin).

### Adverse Effects

The adverse effect profile for clarithromycin in domestic animals is not well described. With limited clinical experience, it appears to be well tolerated in dogs, cats, ferrets, and foals. Like all orally administered antibiotics, GI disturbances are possible. Pinnal or generalized erythema may be associated with this drug when used in cats.

Adverse effects in humans include gastrointestinal adverse effects (primarily nausea, vomiting, abdominal pain, abnormal taste, diarrhea) that, when compared with erythromycin, are milder and occur less frequently. Approximately 4% of treated humans develop transient, mildly elevated BUN levels. Rarely, prolonged QT interval (torsades de pointes), hepatotoxicity, thrombocytopenia, or hypersensitivity reactions have been reported. Pseudomembranous colitis secondary to *Clostridium difficile* has been reported after clarithromycin use.

### Reproductive/Nursing Safety

In humans, the FDA categorizes clarithromycin as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). Teratogenic studies in rats and rabbits failed to document any teratogenic effects in some studies, but, at high dosages (yielding plasma levels 2–17 times achieved in humans with maximum recommended dosages) in pregnant rats, rabbits and monkeys, some effects (cleft palate, cardiovascular abnormalities, fetal growth retardation) were noted.

Clarithromycin is excreted into milk of lactating animals and levels may be higher in milk than in the dam's plasma, but this is unlikely to be of clinical significance.

### Overdosage/Acute Toxicity

Generally, overdoses of clarithromycin are usually not serious with only gastrointestinal effects seen. Patients ingesting large overdoses may be given activated charcoal/cathartic to remove any unabsorbed drug. Forced diuresis, peritoneal dialysis, or hemodialysis do not appear to be effective in removing the drug from the body.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clarithromycin and may be of significance in veterinary patients:

■ **CISAPRIDE:** Clarithromycin can inhibit the metabolism of cisapride and the manufacturer states that use of these drugs together (in humans) is contraindicated

■ **FLUCONAZOLE:** Possible increased clarithromycin levels

■ **DIGOXIN:** Clarithromycin may increase the serum levels of digoxin

■ **OMEPRAZOLE:** Clarithromycin and omeprazole can increase the plasma levels of one another

■ **WARFARIN:** Clarithromycin may potentiate the effects of oral anticoagulant drugs

■ **ZIDOVUDINE:** Clarithromycin may decrease serum concentrations of zidovudine

Clarithromycin, like erythromycin, can inhibit the metabolism of other drugs that use the CYP3A subfamily of the cytochrome P450 enzyme system. Depending on the therapeutic index of the drug(s) involved, therapeutic drug monitoring and/or dosage reduction may be required if the drugs must be used together. These drugs include:

■ **ALFENTANIL**

■ **BROMOCRIPTINE**

■ **BUSPIRONE**

■ **CARBAMAZEPINE**

■ **DISOPYRAMIDE (also risk of increased QT interval)**

■ **METHYLPREDNISOLONE**

■ **MIDAZOLAM, ALPRAZOLAM, TRIAZOLAM**

■ **QUINIDINE (also risk of increased QT interval)**

■ **RIFABUTIN**

■ **TACROLIMUS (systemic)**

■ **THEOPHYLLINE**

### Laboratory Considerations

■ No clarithromycin-related laboratory interactions noted.

### Doses

■ **DOGS:**

For treatment of severe or refractory cases of canine leproid granuloma syndrome:

a) Using a combination of clarithromycin 15–25 mg/kg total daily dose PO given divided q8–12h; and rifampin 10–15 mg/kg PO once daily. Usually treatment should be continued for 4–8 weeks until lesions are at least substantially reduced in size and ideally have resolved completely. (Malik *et al.* 2001)

For susceptible infections:

a) 2.5–10 mg/kg PO twice daily (Boothe 1999)

b) 5–10 mg/kg PO q12h (Greene & Watson 1998)

#### ■CATS:

For treatment of feline leprosy:

a) Using a regimen of either two or three of the following drugs: clarithromycin: 62.5 mg per cat q12h; clofazimine: 25–50 mg once per day or 50 mg every other day; rifampin: 10–15 mg/kg once a day. (Malik *et al.* 2002)

For treatment of *Nocardia (N. nova)* infections:

a) Combination therapy with: amoxicillin 20 mg/kg PO twice daily with clarithromycin 62.5–125 mg (total dose per cat) PO twice daily and/or doxycycline 5 mg/kg or higher PO twice daily. (Malik 2006)

For treatment of *H. pylori* infections:

a) Combination therapy with: clarithromycin 7.5 mg/kg PO twice daily; metronidazole 10–15 mg/kg PO twice daily; amoxicillin 20 mg/kg PO twice daily for 14 days. (Simpson 2003)

For treatment of *M. tuberculosis-bovis* variant infections:

a) Using all three drugs: Clarithromycin 5–10 mg/kg PO q12h; rifampin 10–20 mg/kg PO once daily, enrofloxacin 5–10 mg/kg PO q12–24h. Treatment must continue for at least 2 months. Maintenance for additional 4 months using (at same dosages enrofloxacin and clarithromycin or rifampin and enrofloxacin). (Greene & Gunn-Moore 1998)

For susceptible infections:

a) 7.5 mg/kg PO q12h (Greene & Watson 1998)

#### ■FERRETS:

For treatment of *Helicobacter mustelae* infections:

a) Clarithromycin 12.5 mg/kg PO q12h with ranitidine bismuth citrate (**Note:** not currently available in the USA, but may be available from compounding pharmacies) 24 mg/kg PO q12h. Treat for 14 days. Same regimen, but given q8h is also published. (Johnson-Delaney 2009)

b) 12.5–50 mg/kg q8–24h with omeprazole at 0.7 mg/kg PO once daily (q24h) (Fisher 2005)

#### ■HORSES:

For treatment of *Rhodococcus equi* infection in foals:

a) 7.5 mg/kg PO q12h (Jacks *et al.* 2002), (Chaffin 2006)

b) 7.5 mg/kg PO q12h in combination with rifampin at 5 mg/kg PO q12h or 10 mg/kg PO q24h. (Giguere 2003)

### Monitoring

- Antibacterial efficacy
- Adverse effects

### Client Information

- If using the oral suspension, do *not* refrigerate; keep at room temperature and discard 14 days after reconstituting
- This drug may be given without regard to meals
- Clarithromycin can interact with many other drugs; do not give any drugs to the animal without the veterinarian's knowledge

### Chemistry/Synonyms

Clarithromycin is a semi-synthetic macrolide antibiotic related to erythromycin. It differs from erythromycin by the methylation of position 6 in the lactone ring. Clarithromycin occurs as a white to off-white crystalline powder. It is practically insoluble in water, slightly soluble in ethanol, and soluble in acetone. It is slightly soluble in a phosphate buffer at pH's of 2–5.

Clarithromycin may also be known as: 6-*O*-Methylerythromycin, TE-031, A-56268, *Adel*®, *Biaxin*®, *Biclar*®, *Bremon*®, *Clamicin*®, *Clamycin*®, *Claribid*®, *Clarimac*®, *Clarimax*®, *Claritab*®, *Cyllind*®, *Gervaken*®, *Heliclar*®, *Helicodid*®, *Karin*®, *Klacid*®, *Klacidped*®, *Klaricid*®, *Klaridex*®, *Kofron*®, *Lagur*®, *Mabicrol*®, *Macladin*®, *Maclar*®, *Mavid*®, *Monaxin*®, *Monocid*®, *Naxy*®, *Veclam*®, and *Zeclar*®.

### Storage/Stability

The conventional 250 mg tablets should be protected from light and stored in well-closed containers at 15–30°C (59–86°F). The conventional or extended-release 500 mg tablets should be stored in well-closed containers at controlled room temperature (20–25°C; 68–77°F). The granules for reconstitution into an oral suspension should be stored in well-closed containers at 15–30°C. After reconstitution, it should be stored at room temperature (do not refrigerate) and any unused drug discarded after 14 days.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Clarithromycin Regular & Film-coated Oral Tablets: 250 mg & 500 mg; Extended-release Tablets: 500 mg; *Biaxin*® & *Biaxin*® XL (Abbott), generic; (Rx)

Clarithromycin Granules for Oral Suspension: 125 mg/5 mL & 250 mg/5 mL (after reconstitution) in 50 mL & 100 mL; *Biaxin*® (Abbott), generic; (Rx)

## CLEMASTINE FUMARATE

(*klem-as-teen*) **Tavist®**

ANTIHISTAMINE

### Prescriber Highlights

- **Oral antihistamine with greater anticholinergic, but less sedative activity**
  - **Poor pharmacokinetic profile for oral administration in dogs or horses**
  - **Caution: Prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyeloduodenal obstruction**
  - **Most likely adverse effects: Dogs: Sedation, paradoxical hyperactivity & anticholinergic effects (dryness of mucous membranes, etc.); Cats: Diarrhea**
- 

## Uses/Indications

Clemastine may be used for symptomatic relief of histamine 1-related allergic conditions.

## Pharmacology/Actions

Like other H1-receptor antihistamines, clemastine acts by competing with histamine for sites on H1-receptor sites on effector cells. They do not block histamine release, but can antagonize its effects. Clemastine has greater anticholinergic activity, but less sedation than average.

## Pharmacokinetics

In dogs, oral bioavailability is very low (3%). Clemastine has a high volume of distribution (13.4 L/kg; 98% protein bound) and clearance (2.1 L/hr/kg). After IV administration, elimination half-life is about 4 hours and completely inhibited wheal formation for 7 hours. Oral administration at 0.5 mg/kg only yielded minor inhibition of wheal formation. The authors of the study (Hansson *et al.* 2004) concluded that most oral dosage regimens in the literature are likely to give too low a systemic exposure of the drug to allow effective therapy.

In horses, clemastine has poor oral bioavailability (3–4%), a volume of distribution at steady-state of 3.8 L/kg, a clearance (TBC) of 0.79 L/hr/Kg and a terminal half-life of about 5.4 hours. The authors concluded that the drug is not appropriate for oral administration in the horse and must be dosed at least 3–4 times a day intravenously to maintain therapeutic plasma concentrations. (Torneke *et al.* 2003)

In humans, clemastine has a variable bioavailability (20–70%); its distribution is not well characterized, but does distribute into milk. Metabolic fate has not been clearly determined, but it appears to be extensively metabolized and those metabolites are eliminated in the urine. In humans, its duration of action is about 12 hours.

## Contraindications/Precautions/Warnings

Clemastine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyeloduodenal obstruction.

## Adverse Effects

The most likely adverse effects seen in dogs receiving clemastine are sedation, paradoxical hyperactivity, and anticholinergic effects (dryness of mucous membranes, etc.). In cats, diarrhea has been noted most commonly; one cat reportedly developed a fixed drug reaction while on this medication.

## Reproductive/Nursing Safety

Clemastine has been tested in pregnant lab animals in doses up to 312 times labeled without evidence of harm to fetuses. However, because safety has not been established in other species, its use during pregnancy should be weighed carefully. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Clemastine enters maternal milk and may potentially cause adverse effects in offspring. Use with caution, especially with newborns.

## Overdosage/Acute Toxicity

There are no specific antidotes available. Significant overdoses should be handled using standard gut emptying protocols, when appropriate, and supportive therapy initiated when required. The adverse effects seen with overdoses are an extension of the drug's side effects; principally CNS depression (although CNS stimulation may be seen), anticholinergic effects (severe drying of mucous membranes, tachycardia, urinary retention, hyperthermia, etc.), and possibly hypotension. Physostigmine may be considered to treat serious CNS anticholinergic effects and diazepam employed to treat seizures, if necessary.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clemastine and may be of significance in veterinary patients:

- **CNS DEPRESSANT MEDICATIONS:** Additive CNS depression may be seen if combining clemastine with other CNS depressant medications such as barbiturates, tranquilizers, etc.
- **MONOAMINE OXIDASE INHIBITORS** (including **furazolidone**, **amitraz**, and possibly **selegiline**) may intensify the anticholinergic effects of clemastine

## Laboratory Considerations

Because antihistamines can decrease the wheal and flair response to **skin allergen testing**, antihistamines should be discontinued 3–7 days (depending on the antihistamine used and the reference) before intradermal skin tests.

## Doses

### ■ DOGS:

**Note:** Relatively recent published information (Hansson *et al.* 2004) on the pharmacokinetics of clemastine in dogs puts the efficacy of previously published doses for this drug in doubt, but some veterinary dermatologists still recommend its use. Usual doses published are approximately 0.05–0.1 mg/kg PO q12h; however oral bioavailability (see Pharmacokinetics above) in dogs is less than 5% versus approximately 20–70% in humans, and an oral dose of 0.5 mg/kg (10X most published doses) in dogs only inhibited histamine-induced wheal formation to a slight degree, while IV administration inhibited it for 7 hours. Further dosing studies must be performed before this drug can be recommended for therapeutic use in the dog.

### ■ CATS:

As an antihistamine:

- 0.68 mg per cat PO twice daily (Miller 2005)
- 0.34–0.68 mg per cat PO q12h (Messinger 2000)
- For atopy: 0.15 mg/kg PO q 12 hrs. Efficacy may be increased by combining with omega 3 fatty acids. (Campbell 1999)

## Monitoring

- Efficacy
- Adverse Effects, if any

## Client Information

- Clients should understand that antihistamines may be useful for symptomatic relief of allergic signs, but are not a cure for the underlying disease.

## Chemistry/Synonyms

Also known as meclastine fumarate or mecloprodin fumarate, clemastine fumarate is an ethanolamine antihistamine. It occurs as an odorless, faintly yellow, crystalline powder. It is very slightly soluble in water and sparingly soluble in alcohol.

*Tavist-D*® contains clemastine fumarate in an immediate release outer shell and phenylpropanolamine HCl in a sustained release inner matrix.

Clemastine fumarate may also be known by the following synonyms and internationally registered trade names: clemastini fumaras, HS-592, meclastine fumarate, mecloprodin fumarate, *Agasten*®, *Aller-Eze*®, *Antihist-1*®, *Clamist*®, *Contac 12 Hour Allergy*®, *Dayhist-1*®, *Tavegil*®, *Tavegyl*® or *Tavist*®.

## Storage/Stability

Oral tablets and solution should be stored in tight, light resistant containers at room temperature.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### **HUMAN-LABELED PRODUCTS:**

Clemastine Fumarate Oral Tablets: 1.34 mg as fumarate (equivalent to 1 mg clemastine), 2.68 mg (equivalent to 2 mg clemastine); *Dayhist-1*® (Major); *Tavist*® *Allergy* (Novartis Consumer Health); generic; (Rx & OTC)

Clemastine Oral Syrup: 0.67 mg/5 mL (equivalent to 0.5 mg clemastine) in 118 & 120 mL; generic; (Rx)

## CLENBUTEROL HCL

(klen-byoo-ter-ol) Ventipulmin®

### Prescriber Highlights

- **Beta-2-adrenergic agonist used in horses as a bronchodilator in the management of airway obstruction and for dystocia as a uterine relaxant**
- **Banned in food animals in USA and several other countries**

- **In pregnancy, antagonizes the effects of dinoprost (prostaglandin F2alpha) & oxytocin & can diminish normal uterine contractility**
  - **Acute adverse effects include tachycardia, muscle tremors, sweating, restlessness, & urticaria**
  - **Chronic administration can potentially cause deleterious effects on endocrine, immune and reproductive functions**
- 

### Uses/Indications

Clenbuterol is FDA-approved for use in horses as a bronchodilator in the management of airway obstruction, such as recurrent airway obstruction (RAO; formerly COPD). It has been used both parenterally and orally as a uterine relaxant for the adjunctive treatment of dystocia.

It has been used as a partitioning agent in food producing animals, but its use for this purpose is banned in the USA as relay toxicity in humans has been documented.

### Pharmacology/Actions

Like other beta-2 agonists, clenbuterol is believed to act by stimulating production of cyclic AMP through the activation of adenylyl cyclase. By definition, beta-2 agonists have more smooth muscle relaxation activity (bronchial, vascular, and uterine smooth muscle) versus its cardiac effects (beta-1). Clenbuterol appears to have secondary modes of action in horses as it can inhibit the release from macrophages of pro-inflammatory cytokines such as interleukin-1(beta) and tumor necrosis factor (alpha), and increase ciliary beat frequency to enhance mucous clearance.

Compared to control, when clenbuterol was administered IV to healthy horses, aerobic capacity was not improved, insulin levels were increased, and treadmill velocities for defined heart rates were reduced (Ferraz *et al.* 2007).

Chronic administration of clenbuterol to horses can cause decreased aerobic performance, induce cardiac hypertrophy and infiltration of collagen in cardiac muscle, and suppress cortisol response to exercise. Chronic clenbuterol administration in combination with exercise training can alter immune function (reduced killer and CD8+ cells). In pregnant mares, clenbuterol can inhibit uterine tone and contractility, but these effects are not considered detrimental. In non-pregnant mares, clenbuterol's effects on uterine contractility may potentially increase risks for mating-induced endometritis. Some studies have shown that clenbuterol can impair reproductive function in males. (Kearns & McKeever 2009)

### Pharmacokinetics

After oral administration to horses, peak plasma levels of clenbuterol occur 2 hours after administration and the average half-life is about 10–13 hours. The manufacturer states that the duration of effect varies from 6–8 hours. After multiple oral doses, the drug's volume of distribution is approximately 1.6 L/kg and clearance was 94 mL/kg/hr. Urinary concentrations of clenbuterol are approximately 100X those found in plasma and can persist at quantifiable levels for 288 hours (12 days) in urine after the last oral dose (Soma *et al.* 2004).

### Contraindications/Precautions/Warnings

The drug is contraindicated in food producing animals (legal ramifications). The label states that the drug should not be used in horses suspected of having cardiovascular impairment as tachycardia may occur.

### Adverse Effects

Muscle tremors, sweating, restlessness, urticaria, and tachycardia may be noted, particularly early in the course of therapy. Creatine kinase elevations have been noted in some horses and, rarely, ataxia can occur. Clenbuterol is reported to induce abortion in pregnant animals.

Clenbuterol has been touted in some body building circles as an alternative to anabolic steroids for muscle development and body fat reduction; however, its safe use for this purpose is in serious question. Be alert for scams to divert legitimately obtained clenbuterol for this purpose.

### Reproductive/Nursing Safety

Clenbuterol's safety in breeding stallions and brood mares has not been established. Clenbuterol should not be used in pregnant mares near full-term as it antagonizes the effects of dinoprost (prostaglandin F2alpha) and oxytocin and can diminish normal uterine contractility.

### Overdosage/Acute Toxicity

Some case reports of clenbuterol overdoses have been reported in various species. In recent years, clenbuterol has been used as an adulterant in illicit heroin. Depending on dosage and species, emptying gut may be appropriate, otherwise supportive therapy and administration of parenteral beta-blockers to control heart rate and rhythm and elevated blood pressure may be considered.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clenbuterol and may be of significance in veterinary patients:

- **ANESTHETICS, INHALANT:** Use with inhalation anesthetics (*e.g.*, **halothane, isoflurane, methoxyflurane**), may predispose the patient to ventricular arrhythmias, particularly in patients with preexisting cardiac disease—use cautiously
- **BETA-BLOCKERS** (*e.g.*, **propranolol**): May antagonize clenbuterol's effects
- **DIGOXIN:** Use with digitalis glycosides may increase the risk of cardiac arrhythmias
- **DINOPROST:** Clenbuterol may antagonize the effects of dinoprost (prostaglandin F2alpha)
- **OXYTOCIN:** Clenbuterol may antagonize the effects of oxytocin
- **SYMPATHOMIMETIC AMINES, OTHER** (*e.g.*, **terbutaline, albuterol**): Concomitant administration with other sympathomimetic amines may enhance the adverse effects of clenbuterol
- **TRICYCLIC ANTIDEPRESSANTS or MONOAMINE OXIDASE INHIBITORS:** May potentiate the vascular effects of clenbuterol

### Doses

- **HORSES:** (Note: ARCI UCGFS Class 3 Drug)

As a bronchodilator:

a) Initially, 0.8 micrograms/kg (practically: 0.5 mL of the commercially available syrup/100 lb. BW) twice daily for 3 days; if no improvement increase to 1.6 micrograms/kg (practically: 1 mL of the commercially available syrup/100 lb. BW) twice daily for 3 days; if no improvement increase to 2.4 micrograms/kg (practically: 1.5 mL of the commercially available syrup/100 lb. BW) twice daily for 3 days; if no improvement increase to 3.2 micrograms/kg (practically: 2 mL of the commercially available syrup/100 lb. BW) twice daily for 3 days; if no improvement discontinue therapy. Recommended duration of therapy is 30 days; then withdraw therapy and reevaluate. If signs return, reinitiate therapy as above. (Package Insert; *Ventipulmin*®)

As adjunctive treatment for dystocia emergencies:

a) 300 micrograms per 500 kg mare IV slowly (Note: parenteral formulation not available commercially in the USA). The drug's fast onset of action when given IV allows veterinarian to decide quickly if uterine relaxation will correct the problem. Clenbuterol is particularly useful when repelling the equine fetus to allow manipulation of the head and limbs. May be used in combination with sedatives, analgesics and tranquilizers. Xylazine or detomidine may potentiate uterine relaxant effects of clenbuterol. (Card 2002)

b) At the author's hospital: Upon arrival of a dystocia, on the clinician's orders the nurse administers 10 mls of clenbuterol syrup orally as the mare walks in the door. (McCafferty 2007)

## Monitoring

- Clinical efficacy
- Adverse effects

## Client Information

- Clients should be instructed on the restricted use requirements of this medication and to keep it secure from children or those who may "abuse" it.
- The drug may be prohibited from use by various equine associations (e.g., racing or show).

## Chemistry/Synonyms

A beta-2-adrenergic agonist, clenbuterol HCl's chemical name is 1-(4-Amino-3,5-dichlorophenyl)-2-tert-butyl aminoethanol HCl.

Clenbuterol HCl may also be known as: NAB-365, *Aeropulmin*®, *Broncodil*®, *Broncoterol*®, *Bronq-C*®, *Cesbron*®, *Clebumar*®, *Clenasma*®, *Clenbutol*®, *Contrasmina*®, *Contraspamin*®, *Monores*®, *Novegam*®, *Oxibron*®, *Oxyflux*®, *Prontovent*®, *Spiropent*®, *Ventilan*®, *Ventipulmin*® or *Ventolase*®.

## Storage/Stability

The commercially available syrup is colorless and should be stored at room temperature (avoid freezing). The manufacturer warns to replace the safety cap on the bottle when not in use.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Clenbuterol HCl Oral Syrup: 72.5 micrograms/mL in 100 mL, 330 mL, 460 mL bottles; *Ventipulmin*® Syrup (Boehringer Ingelheim); *Aeropulmin*® Syrup (Butler, Phoenix); (Rx). FDA-approved for use in horses not intended for use as food.

Extra-label clenbuterol use in food animals is prohibited by federal (USA) law.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

## CLINDAMYCIN HCL

## CLINDAMYCIN PALMITATE HCL

## CLINDAMYCIN PHOSPHATE

(klin-da-mye-sin) Antirobe®, Cleocin®

LINCOSAMIDE ANTIBIOTIC

## Prescriber Highlights

- **Lincosamide antibiotic, broad spectrum against many anaerobes, gram-positive aerobic cocci, Toxoplasma, etc.**
  - **Contraindications: Horses, rodents, ruminants, lagomorphs; patients hypersensitive to lincosamides**
  - **Caution: Liver or renal dysfunction; consider reducing dosage if severe**
  - **Adverse Effects: gastroenteritis, esophageal injuries possible if "dry pilld," pain at injection site if given IM**
- 

## Uses/Indications

Clindamycin products are FDA-approved for use in dogs and cats. The labeled indications for dogs include wounds, abscesses and osteomyelitis caused by

Clindamycin products are FDA approved for use in dogs and cats. The labeled indications for dogs include wounds, abscesses and osteomyelitis caused by *Staphylococcus aureus*. Because clindamycin has excellent activity against most pathogenic anaerobic organisms, it is also used extensively for those infections. Clindamycin is used for a variety of protozoal infections, including toxoplasmosis. For further information, refer to the Dosage or Pharmacology sections.

### Pharmacology/Actions

The lincosamide antibiotics, lincomycin and clindamycin, share mechanisms of action and have similar spectrums of activity, although lincomycin is usually less active against susceptible organisms. Complete cross-resistance occurs between the two drugs; at least partial cross-resistance occurs between the lincosamides and erythromycin. They may act as bacteriostatic or bactericidal agents, depending on the concentration of the drug at the infection site and the susceptibility of the organism. The lincosamides are believed to act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation.

Most aerobic gram-positive cocci are susceptible to the lincosamides (*Strep. faecalis* is not) including *Staphylococcus* and *Streptococci*. Other organisms that are generally susceptible include: *Corynebacterium diphtheriae*, *Nocardia asteroides*, Eryseplothrix, Toxoplasma, and *Mycoplasma* spp. Anaerobic bacteria that are generally susceptible to the lincosamides include: *Clostridium perfringens*, *C. tetani* (not *C. difficile*), Bacteroides (including many strains of *B. fragilis*), Fusobacterium, Peptostreptococcus, Actinomyces, and Peptococcus.

### Pharmacokinetics

In dogs, oral bioavailability is about 73%, elimination half-life is reportedly 2–5 hours after oral administration and 10–13 hours after subcutaneous administration. Volume of distribution is about 0.9 L/kg.

In humans, the drug is rapidly absorbed from the gut and about 90% of the total dose is absorbed. Food decreases the rate of absorption, but not the extent. Peak serum levels are attained about 45–60 minutes after oral dosing. IM administration gives peak levels about 1–3 hours post injection.

Clindamycin is distributed into most tissues. Therapeutic levels are achieved in bone, synovial fluid, bile, pleural fluid, peritoneal fluid, skin, and heart muscle. Clindamycin also penetrates well into abscesses, scar tissue, and white blood cells. CNS levels may reach 40% of those in the serum if meninges are inflamed. Clindamycin is about 93% bound to plasma proteins. The drug crosses the placenta and can be distributed into milk at concentrations equal to those in plasma.

Clindamycin is partially metabolized in the liver to both active and inactive metabolites. Unchanged drug and metabolites are excreted in the urine, feces, and bile. Half-lives can be prolonged in patients with severe renal or hepatic dysfunction.

### Contraindications/Precautions/Warnings

Although there have been case reports of parenteral administration of lincosamides to horses, cattle, and sheep, the lincosamides are considered to be contraindicated for use in rabbits, hamsters, chinchillas, guinea pigs, horses, and ruminants because of serious gastrointestinal effects that may occur, including death. Clindamycin is contraindicated in patients with known hypersensitivity to it or lincomycin.

Clindamycin has been implicated in causing esophagitis and potentially, esophageal strictures in small animals. Avoid dry “pilling” when administering this drug.

Patients with very severe renal and/or hepatic disease should receive the drug with caution and the manufacturer suggests monitoring serum clindamycin levels during high-dose therapy; consider dosage reduction.

Clindamycin use is generally avoided in neonatal small animals.

### Adverse Effects

Adverse effects after oral administration reported in dogs and cats include gastroenteritis (emesis, loose stools, and infrequently bloody diarrhea in dogs). There have been case reports of esophageal injuries (esophagitis, strictures) occurring in cats when solid dosage forms were given without food or a water bolus. Cats may occasionally show hypersalivation or lip smacking after oral administration. IM injections reportedly cause pain at the injection site.

*C. difficile*-associated pseudomembranous colitis has been reported in some species, but does not appear to be a significant risk when clindamycin is used in dogs or cats.

### Reproductive/Nursing Safety

Clindamycin crosses the placenta, and cord blood concentrations are approximately 46% of those found in maternal serum. Safe use during pregnancy has not been established, but neither has the drug been implicated in causing teratogenic effects. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Because clindamycin is distributed into milk, nursing puppies or kittens of mothers receiving clindamycin may develop diarrhea. However, in humans, the American Academy of Pediatrics considers clindamycin compatible with breastfeeding.

### Overdosage/Acute Toxicity

There is little information available regarding overdoses of this drug. In dogs, oral doses of up to 300 mg/kg/day for up to one year did not result in toxicity. Dogs receiving 600 mg/kg/day, developed anorexia, vomiting, and weight loss.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clindamycin and may be of significance in veterinary patients:

- **CYCLOSPORINE:** Clindamycin may reduce levels
- **ERYTHROMYCIN:** *in vitro* antagonism when used with clindamycin; concomitant use should probably be avoided
- **NEUROMUSCULAR BLOCKING AGENTS** (e.g., **pancuronium**): Clindamycin possesses intrinsic neuromuscular blocking activity and should be used cautiously with other neuromuscular blocking agents

### Laboratory Considerations

- Slight increases in **liver function tests** (AST, ALT, Alk. Phosph.) may occur. There is apparently not any clinical significance associated with these increases.

### Doses

#### ■ DOGS:

For susceptible bacterial infections:

a) For infected wounds, abscesses and dental infections: 5.5–33 mg/kg PO q12h; for osteomyelitis: 11–33 mg/kg PO q12h. Treatment may continue for up to 28 days. If no response after 3–4 days, discontinue. (Package insert; *Antirobe*®—Pfizer)

b) For staphylococcal pyoderma: 11 mg/kg PO once daily for 7–28 days

For wounds, abscesses, dental infections, stomatitis: 5–11 mg/kg PO q12h for 7–28 days.

For osteomyelitis: 11 mg/kg PO q12h for 28 days

For systemic, bacteremia: 3–10 mg/kg IV, IM SC, PO q8h as long as needed (Greene & Watson 1998)

c) 5–11 mg/kg IM, SC or PO q12h avoid or reduce dose in patients with severe liver failure (Vaden & Papich 1995)

d) For sepsis: 11 mg/kg IV q12h (Hardie 2000)

e) For recurrent superficial pyodermas: 11 mg/kg PO once daily to twice a day; resistance can develop quickly (Logas 2005)

f) For actinomycosis: 5 mg/kg SC q12h (Edwards 2006)

g) For susceptible hepatobiliary infections: 10–16 mg/kg SC once daily or 5–10 mg/kg PO q12h. In patients with liver function impairment: 5 mg/kg PO q12h or SC q24h (Center 2006)

h) For anaerobic infections: 5–10 mg/kg PO, IV q12h (Greene & Jang 2006a)

i) For intra-abdominal sepsis 5–11 mg/kg IV, SC, PO q8–12h for 5–7 days combined with gentamicin or a parenteral 3rd generation cephalosporin (such as cefotaxime) or enrofloxacin.

For pancreatitis: 5–11 mg/kg IV, SC, PO q8–12h for 3–5 days. (Greene 2006)

j) For susceptible respiratory infections: 10 mg/kg PO, SC q12h (Greene & Reinero 2006)

k) For surgical prophylaxis for gram-positive aerobes and anaerobic coverage: 5–11 mg/kg PO 16–60 minutes preoperatively (Greene & Jang 2006b)

For susceptible protozoal infections:

a) For Toxoplasmosis: 12.5 mg/kg PO or IM q12h for 28 days

For Neospora: 10 mg/kg q12h for 4 weeks. Used concurrently with trimethoprim/sulfa (15 mg/kg PO q12h for 4 weeks)

For *Hepatozoon canis*: 10 mg/kg PO q8h for 2–4 weeks. Use concurrently with pyrimethamine (0.25 mg/kg PO once daily for 2–4 weeks) and trimethoprim/sulfa (15 mg/kg PO q12h for 2–4 weeks)

For *Babesia* spp.: 12.5 mg/kg q12h PO for 2 weeks (Lappin 2000)

b) For *Babesia* infections if specific antibabesial drugs (*e.g.*, diminazene, imidocarb, pentamidine) are not available: 25 mg/kg PO q12h for 7–21 days (Taboada & Lobetti 2006)

c) For *Hepatozoon americanum* infections: 10 mg/kg PO q8h for 14 days. Use concurrently with trimethoprim/sulfa (15 mg/kg PO q12h 14 days) and pyrimethamine (0.25 mg/kg PO once daily for 14 days) and then follow with decoquinatate (for 2 years) once clinical signs have resolved. (Macintire *et al.* 2006)

## ■CATS:

For susceptible bacterial infections:

a) 5–10 mg/kg PO q12h (Jenkins 1987b); (Trepanier 1999)

b) For infected wounds, abscesses and dental infections: 11–33 mg/kg PO once a day (q24h). Do not treat acute infections for more than 3–4 days if no clinical response is seen. Maximum labeled treatment period = 14 days (Package insert; *Antirobe*®—Pfizer)

c) For sepsis: 11 mg/kg IV q12h (Hardie 2000)

d) For anaerobic infections: 5–10 mg/kg PO, IV q12h (Greene & Jang 2006a)

e) For intra-abdominal sepsis 5–11 mg/kg IV, SC, PO q8–12h for 5–7 days combined with gentamicin or a parenteral 3rd generation cephalosporin (such as cefotaxime) or enrofloxacin.

For pancreatitis: 5–11 mg/kg IV, SC, PO q8–12h for 3–5 days. (Greene 2006)

f) For susceptible respiratory infections: 10–15 mg/kg PO, SC q12h (Greene & Reinero 2006)

g) For surgical prophylaxis for gram-positive aerobes and anaerobic coverage: 5–11 mg/kg PO 16–60 minutes preoperatively (Greene & Jang 2006b)

For susceptible protozoal infections:

a) Toxoplasmosis:

To decrease zoonotic risk to susceptible humans by reducing shedding period in cats suspected of toxoplasmosis after fecal exam: 25–50 mg/kg PO daily; alternative medications include sulfonamides at 100 mg/kg PO daily, or pyrimethamine at 2 mg/kg daily PO.

For treatment of clinical toxoplasmosis: Clindamycin at 10 mg/kg PO q12h, trimethoprim-sulfonamide combination at 15 mg/kg PO q12h, and azithromycin at 10 mg/kg once daily for at least 28 days. Institute supportive care as needed. Patients with uveitis should receive topical, oral or parenteral glucocorticoids to reduce risk for secondary glaucoma and lens luxations. (Lappin 2004)

b) For enteroepithelial toxoplasmosis: 8–16 mg/kg PO or SC q8h for 14–28 days.

For systemic toxoplasmosis: 12.5–25 mg/kg PO or SC q12h for 14–28 days (Greene & Watson 1998)

## ■FERRETS:

For susceptible infections:

a) 5–10 mg/kg PO twice daily (Williams 2000)

## ■BIRDS:

For susceptible infections:

a) 25 mg/kg PO q8h (Tully 2002)

b) For mild spore-forming enteric bacterial infections: 50 mg/kg PO q12h for 5–10 days (Flammer 2006)

## REPTILES:

For susceptible infections (anaerobes):

a) 5 mg/kg PO once daily (Lewbart 2001)

b) For respiratory infections (anaerobes, mycoplasma): 5 mg/kg PO once daily for 14 days (Klaphake 2005)

## Monitoring

- Clinical efficacy
- Adverse effects; particularly severe diarrhea
- Manufacturer recommends doing periodic liver and kidney function tests and blood counts if therapy persists for more than 30 days

## Client Information

- Clients should be instructed to report the incidence of severe, protracted, or bloody diarrhea to the veterinarian
- If using oral tablets or capsules, especially in cats, give medication followed by at least 6 mL (a little more than a teaspoonful) of liquid

## Chemistry/Synonyms

A semisynthetic derivative of lincomycin, clindamycin is available as the hydrochloride hydrate, phosphate ester, and palmitate hydrochloride. Potency of all three salts is expressed as milligrams of clindamycin. The hydrochloride occurs as a white to practically white, crystalline powder. The phosphate occurs as a white to off-white, hygroscopic crystalline powder. The palmitate HCl occurs as a white to off-white amorphous powder. All may have a faint characteristic odor and are freely soluble in water. With the phosphate, about 400 mg are soluble in one mL of water. Clindamycin has a pKa of 7.45. The commercially available injection has a pH of 5.5–7.

Clindamycin HCl may also be known as: chlorodeoxylincomycin hydrochloride, (7S)-chloro-7-deoxy-lincomycin hydrochloride, clindamycini hydrochloridum, U-28508, or U-25179E; many trade names are available.

## Storage/Stability

Clindamycin capsules and the palmitate powder for oral solution should be stored at room temperature (15–30°C). After reconstitution, the palmitate oral solution (human-product) should not be refrigerated or thickening may occur. It is stable for 2 weeks at room temperature. The veterinary oral solution should be stored at room temperature and has an extended shelf life.

Clindamycin phosphate injection should be stored at room temperature. If refrigerated or frozen, crystals may form which resolubilize upon warming.

## Compatibility/Compounding Considerations

Clindamycin for injection is reportedly **compatible** for at least 24 hours in the following IV infusion solutions: D5W, Dextrose combinations with Ringer's, lactated Ringer's, sodium chloride, D10W, sodium chloride 0.9%, Ringer's injection, and lactated Ringer's injection. Clindamycin for injection is reportedly **compatible** with the following drugs: amikacin sulfate, ampicillin sodium, aztreonam, carbenicillin disodium, cefazolin sodium, cefonicid sodium, cefoperazone sodium, cefotaxime sodium, ceftazidime sodium, ceftizoxime sodium, cefuroxime sodium, cimetidine HCl, gentamicin sulfate, heparin sodium, hydrocortisone sodium succinate, kanamycin sulfate, methylprednisolone sodium succinate, magnesium sulfate, meperidine HCl, metoclopramide HCl, metronidazole, morphine sulfate, penicillin G potassium/sodium, piperacillin sodium, potassium chloride, sodium bicarbonate, tobramycin HCl (not in syringes), verapamil HCl, and vitamin B-complex with C.

Drugs that are reportedly **incompatible** with clindamycin include: aminophylline, ciprofloxacin, ranitidine HCl, and ceftriaxone sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Clindamycin (as the HCl) Oral Capsules: 25 mg, 75 mg, 150 mg, 300 mg; *Antirobe® Capsules* (Pfizer) FDA-approved for use in dogs and cats. Generics also available in 25 mg, 75 mg, 150 mg, and 300 mg capsules; (Rx). FDA-approved for use in dogs.

Clindamycin (as the HCl) Oral Tablets: 25 mg, 75 mg, 150 mg; *Clintabs®* (Virbac); (Rx). FDA-approved for use in dogs.

Clindamycin (as the HCl) Oral Solution 25 mg/mL in 30 mL bottles. *Antirobe® Aquadrops* (Pfizer), *Clinsol®* (Virbac); generic; (Rx). FDA-approved for use in dogs and cats.

### HUMAN-LABELED PRODUCTS:

Clindamycin (as the HCl) Oral Capsules: 75 mg, 150 mg, & 300 mg; *Cleocin®* (Pfizer); generic; (Rx)

Clindamycin (as the palmitate HCl) Granules for Oral Solution: 75 mg/5 mL in 100 mL; *Cleocin® Pediatric* (Pfizer); (Rx)

Clindamycin (as the Phosphate) Solution Concentrate for Injection: 150 mg/mL in 2 mL, 4 mL, 6 mL & 2 mL, 4 mL and 6 mL *ADD-Vantage* vials; *Cleocin® Phosphate* (Pharmacia & Upjohn); generic; (Rx)

Clindamycin (as the Phosphate) Injection: 300 mg, 600 mg & 900 mg in 50 mL *Galaxy* containers with dextrose 5%; *Cleocin Phosphate IV®* (Pharmacia & Upjohn) (Rx)

Clindamycin Phosphate Suppositories: 100 mg (as base) *Cleocin®* (Pfizer); (Rx)

Also available in topical and vaginal preparations.

## CLOFAZIMINE

(kloe-fa-zi-meen) Lamprene®

ANTIMYCOBACTERIAL ANTIBIOTIC

### Prescriber Highlights

- May be difficult for veterinarians to obtain & accurately dose
  - Antimycobacterial antibiotic that may be used as part of multi-drug therapy for leprosy-like or *M. avium*-related diseases in small animals
  - Very limited clinical experience & documentation supporting its use in veterinary patients
  - Skin, eye, excretion staining noted & dose limiting gastrointestinal adverse effects
  - Treatment usually must continue for weeks to months
- 

### Uses/Indications

In small animals, clofazimine is sometimes used as part of multi-drug therapy against mycobacterial diseases, primarily leprosy-like or *M. avium*-related disease states.

In humans, clofazimine is used primarily as part of a multi-drug regimen in the treatment of all forms of leprosy (with rifampin and dapson), or the treatment of Mycobacterium avium complex (MAC) (with at least two of the following agents: clarithromycin or azithromycin, rifampin or rifabutin, and ethambutol). It has also been used in some treatment regimens for Crohn's disease, pyoderma gangrenosum, etc.

### Pharmacology/Actions

Clofazimine binds to mycobacterial DNA and inhibits growth. It is considered to be slowly bactericidal against susceptible organisms. Clofazimine has activity against a variety of mycobacteria including: *M. leprae*, *M. tuberculosis*, *M. avium* complex (MAC), *M. bovis*, and *M. chelonae*. Resistance is thought to occur only rarely; cross-resistance with dapson or rifampin apparently does not occur. Clofazimine may have some antileishmanial activity. Clofazimine has antiinflammatory and immunosuppressive effects, but the mechanisms of action for these effects are not understood.

### Pharmacokinetics

Clofazimine's pharmacokinetics have apparently not been determined in domestic animals. In humans, the microcrystalline form of the drug is variably absorbed after oral administration; bioavailability ranges from 45–70%. Food enhances absorption but increasing the dosage decreases the percentage absorbed. Clofazimine is highly lipid soluble and is distributed primarily to lipid tissue and the reticuloendothelial system. Throughout the body macrophages take up clofazimine. The drug crosses the placenta and is distributed into milk, but does not apparently cross into the CNS or CSF. Clofazimine is retained in the body for a long period; its elimination half-life is at least 70 days long. Bile excretion may be responsible for the majority of the drug's excretion, but excretion in sputum, sebum, and sweat may also contribute.

### Contraindications/Precautions/Warnings

It is suggested that clofazimine be used with caution in patients with pre-existing gastrointestinal conditions such as diarrhea or abdominal pain.

### Adverse Effects

There is very limited clinical experience with this medication in domestic animals and its adverse effect profile is not well documented. Apparently, the skin, eye, and excretion discoloration (described below) also occurs in animals. Gastrointestinal effects have been reported. One case of a dog receiving clofazimine and rifampin to treat canine leproid granuloma resulted in hepatotoxicity. There is a report of one cat treated with clofazimine developing a photosensitization reaction (Bennett 2007).

In humans, clofazimine is usually well tolerated, particularly at dosages of 100 mg/day or less. The most troubling adverse effect in many patients is the dose-related skin, eye, and body fluid discoloration (pink to brownish-black) that occurs in most patients, as it may cause severe psychosocial effects; other drug regimens, not including clofazimine, are often chosen in patients with light skin color. This discoloration can persist for months to years after clofazimine has been discontinued. In dosages greater than 100 mg/day, gastrointestinal effects (pain, nausea, vomiting, diarrhea) become more likely and often limit the dosage that can be administered. Other adverse effects (CNS, increased liver enzymes, etc.) are reported in less than 1% of patients receiving the drug.

### Reproductive/Nursing Safety

In humans, the FDA categorizes clofazimine as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). Very large doses (12–25X) demonstrated no teratogenic effects in rats or rabbits, but some effects were noted in mice. The World Health Organization (WHO) states that the drug is safe to use during pregnancy when used as part of one of their treatment protocols for leprosy.

Clofazimine does enter maternal milk and skin discoloration of nursing offspring can occur.

### Overdosage/Acute Toxicity

Very limited data is available; the LD<sub>50</sub> for rabbits is 3.3 g/kg and is greater than 5 g/kg in mice, rats, and guinea pigs. Treatment, if required, would include gut emptying and supportive care. Contact an animal poison control center for additional guidance.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clofazimine and may be of significance in veterinary patients:

■ **ISONIAZID:** May reduce the clofazimine levels in the skin and increase the amounts in plasma and urine; clinical significance unclear

■ **DAPSONE:** There is sketchy evidence that suggests dapsone may reduce the antiinflammatory effects of clofazimine; clinical significance unclear

## Laboratory Considerations

■ No clofazimine-related laboratory interactions noted

## Doses

### ■ DOGS:

For *Mycobacterium avium* complex (MAC) as part of a multi-drug regimen:

a) 4 mg/kg PO once daily. Other drugs that may be used in combination include doxycycline, clarithromycin, and/or enrofloxacin. (Greene & Gunn-Moore 1998)

For *M. avium intracellulare* complex infections, leprosy, or opportunistic mycobacteriosis:

a) 4–8 mg/kg PO once a day for 4 weeks usually as part of a multi-drug protocol. (Greene & Watson 1998)

### ■ CATS:

For treatment of feline leprosy:

a) Using a regimen of either two or three of the following drugs: clarithromycin: 62.5 mg per cat q12h, clofazimine: 25–50 mg once per day or 50 mg every other day, Rifampin: 10–15 mg/kg once a day. (Malik *et al.* 2002)

For treatment of localized atypical mycobacterial infections:

a) Perform wide surgical excision of lesion if possible. Give long-term systemic antibacterial therapy, continued at least 4 weeks beyond complete clinical resolution. Base antibiotic selection on culture and susceptibility results, if available: Clofazimine 8 mg/kg PO once daily. Other doses listed in reference for marbofloxacin, doxycycline, minocycline, or clarithromycin. (Hnilica 2003)

For *M. avium intracellulare* complex infections, leprosy or opportunistic mycobacteriosis:

a) 4–8 mg/kg PO once a day for 4 weeks usually as part of a multi-drug protocol. (Greene & Watson 1998)

### ■ BIRDS:

For avian mycobacteriosis:

a) Treatment protocols include: **1)** rifampin 45 mg/kg, ethambutol 30 mg/kg and clofazimine 6 mg/kg PO once daily; or **2)** ethambutol 20 mg/kg, cycloserine 5 mg/kg, enrofloxacin 15 mg/kg q12h plus clofazimine 1.5 mg/kg PO q24h (recommended regime for raptors). Regular monitoring of fecal samples is needed; antifungal medication may be required. Surgery for discrete nodules may be curative. (Turner 2008)

## Monitoring

■ Efficacy against mycobacterial disease

■ Adverse effects (primarily GI, but consider monitoring hepatic function in dogs)

## Client Information

■ Unless otherwise instructed give this medication with food

■ This medication may cause your animal's skin to turn color (usually pink, but from red to orange to brown). It may also cause discoloring of tears, urine, feces, and other body fluids to a brownish-black color. This discoloration may persist for many months after therapy is concluded.

## Chemistry/Synonyms

Clofazimine, a phenazine dye antimycobacterial agent, occurs as an odorless or nearly odorless, reddish-brown powder that is highly insoluble in water. In room temperature alcohol, clofazimine's solubility is 1 mg/mL.

Clofazimine may also be known as: B-663, G-30320, NSC-141046, Chlofazimine, *Clofozine*®, *Hansepran*®, *Lamcoin*®, *Lamprene*®, or *Lampren*®.

## Storage/Stability

Clofazimine oral capsules should be stored in tight containers, protected from moisture at temperatures less than 30°C.

## Compatibility/Compounding Considerations

The commercially available capsules are a micronized form of the drug in a wax matrix base; it may be difficult to obtain an accurate dosage for small animals. It is suggested to contact a compounding pharmacist for advice.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:** None

In November 2004, clofazimine (*Lamprene*®) became available in the USA only on a limited basis. The FDA now restricts its use to physicians enrolled as investigators under an Investigational New Drug (IND) for treating Hansen's Disease (Leprosy) or multi-drug resistant tuberculosis. Its status for use in veterinary patients is uncertain at the time of writing; contact the FDA Center for Veterinary Medicine (see appendix) for more information.

## CLOMIPRAMINE HCL

(kloe-mi-pra-meen) Clomicalm®, Anafranil®

TRICYCLIC ANTIDEPRESSANT

### Prescriber Highlights

- Tricyclic antidepressant used in dogs & cats for obsessive compulsive disorders, but may be useful for other behavior disorders
  - Used in birds to treat feather picking
  - **Caution: Seizure disorders, liver disease, cardiac rate/rhythm disorders, urinary retention or reduced GI motility**
  - **Not a teratogen, but may affect testicular size/function**
  - **Adverse Effects: Emesis, diarrhea, sedation, anticholinergic effects (dry mouth, tachycardia, etc.); cats may be more sensitive than dogs**
- 

### Uses/Indications

In veterinary medicine, clomipramine is used primarily in dogs as a treatment for obsessive-compulsive disorders (ritualistic stereotypical behaviors) and may be useful for dominance aggression and anxiety (separation).

Clomipramine may also be useful in cats, particularly for behaviors such as urine spraying. One prospective, double-blinded controlled study in cats with psychogenic alopecia comparing clomipramine (0.5 mg/kg PO daily) versus placebo showed no statistical differences in study parameters (Mertens *et al.* 2006).

Clomipramine has been used to treat feather picking in birds.

### Pharmacology/Actions

While the exact mechanism of action of tricyclic antidepressants is not completely understood, it is believed that their most significant effects result from their action in preventing the reuptake of norepinephrine and serotonin at the neuronal membrane. Clomipramine is predominantly an inhibitor of serotonin (5-HT) reuptake, but it also has effects on other neurotransmitters. Clomipramine's active metabolite, desmethylclomipramine has primarily noradrenergic activity and, at least in humans, may be responsible for the majority of the drug's adverse effects.

### Pharmacokinetics

In dogs, after absorption, clomipramine is rapidly converted in the liver to its active metabolite desmethylclomipramine. Both the parent drug and the active metabolite are highly bound to plasma proteins (96%). Repeated oral dosing increases clomipramine concentrations but not desmethylclomipramine. The presence of food decreases the area under the curve for the parent compound by about 25% but not the metabolite. Giving without food probably is not necessary for efficacy. After a single dose in dogs, the elimination half-life of clomipramine averages 5 hours.

Cats appear to metabolize clomipramine more slowly than dogs and wide interpatient variability in pharmacokinetic parameters have been shown after single oral doses. Male cats may metabolize clomipramine more slowly than female cats. In a limited (6 subject) pharmacokinetic study, oral bioavailability averaged 90%.

In humans, the drug is well absorbed from the GI tract but a substantial first pass effect reduces its systemic bioavailability to approximately 50%. The presence of food in the gut apparently does not significantly alter its absorption.

Clomipramine is highly lipophilic and widely distributed throughout the body with an apparent volume of distribution of 17 L/kg. The drug crosses the placenta and into maternal milk. Plasma levels have been detected in nursing babies of mothers taking the drug. Both clomipramine and its active metabolite (desmethylclomipramine) cross the blood-brain barrier and significant levels are found in the brain. It should be noted that although therapeutic effects may take several weeks to be seen, adverse effects can occur early on in treatment.

Clomipramine is metabolized principally in the liver to several metabolites including desmethylclomipramine, which is active. About two-thirds of these metabolites are eliminated in the urine and the rest in the feces. After a single dose, the elimination half-life of clomipramine averages 32 hours and desmethylclomipramine averages 69 hours, but there remains wide interpatient variation.

### Contraindications/Precautions/Warnings

These agents are contraindicated if prior sensitivity has been noted with any other tricyclic. Concomitant use with monoamine oxidase inhibitors is generally contraindicated. As aged cheeses can contain high levels of tyramine, avoid giving to animals receiving clomipramine.

In humans, these drugs (tricyclic antidepressants) may lower seizure threshold. Use with caution in animals with preexisting seizure disorders. Because of their anticholinergic effects, use with caution in patients with decreased GI motility, urinary retention, cardiac rhythm disturbances, or increased intraocular pressure. One study in dogs however, showed little effect on intra-ocular pressure or cardiac rhythm. In humans, tricyclic antidepressants have caused hepatic abnormalities. Baseline and annual monitoring of liver enzymes is suggested for animals receiving clomipramine long-term. Tricyclics should be used cautiously in patients with hyperthyroidism or those that are receiving thyroid supplementation as there may be an increased risk of cardiac rhythm abnormalities developing.

### Adverse Effects

The primary adverse effects reported thus far with the use of clomipramine in dogs are anorexia, emesis, diarrhea, elevation of liver enzymes, and sedation/lethargy/depression. At therapeutic dosages dogs rarely develop anticholinergic (dry mouth, etc.) effects. Cardiac effects such as tachycardia secondary to the drug's anticholinergic activity may also result. One case of a dog developing pancreatitis after receiving clomipramine has been published (Kook *et al.* 2009).

Cats have been reported to be more susceptible to the adverse effects (anticholinergic effects, sedation) of clomipramine than dogs. This may be the result of slower elimination of the desmethyl metabolite in cats.

Adverse effects reported in birds include ataxia, drowsiness and regurgitation.

### Reproductive/Nursing Safety

No teratogenic effects were noted in mice and rats given clomipramine at dosages of up to 20X usual maximum human dosage. Data in other domestic species appear to be lacking. The manufacturer warns not to use in breeding male dogs as high dose (12.5X) toxicity studies demonstrated testicular atrophy.

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Clomipramine has a narrow margin of safety; significant clinical signs can be seen at or slightly above therapeutic range (at 2–3 mg/kg, APCC database). Overdosage with tricyclics can be life-threatening (arrhythmias, seizures, cardiorespiratory collapse). In dogs, lethal doses are approximately between 50 and 100 mg/kg/day PO (12.5–25X recommended dose).

There were 158 exposures to clomipramine reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases, 112 were dogs with 40 showing clinical signs and the remaining 46 cases were cats with 22 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, tachycardia, ataxia, depression, vocalization, and vomiting. Common findings in cats recorded in decreasing frequency included lethargy, mydriasis, tachypnea, ataxia, depression, and tachycardia. Because the toxicities and therapies for treatment are complicated and controversial, contact an animal poison control center for further information in any potential overdose situation.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clomipramine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Because of additive effects, use with clomipramine cautiously
- **BUTYREPHENONE ANTIPSYCHOTIC AGENTS (e.g., haloperidol):** There is a case report (Starkey *et al.* 2008) of a macaw developing extrapyramidal side effects after it had received a long acting haloperidol injection and then subsequently received clomipramine.
- **CIMETIDINE:** May inhibit tricyclic antidepressant metabolism and increase the risk of toxicity
- **CISAPRIDE:** Increased risk for prolonged QT interval
- **CLONIDINE:** May cause increased blood pressure
- **CNS DEPRESSANTS:** Because of additive effects, use with clomipramine cautiously
- **MEPERIDINE, PENTAZOCINE, DEXTROMETHORPHAN:** Increased risk for serotonin syndrome
- **QUINIDINE:** Increased risk for QTc interval prolongation and tricyclic adverse effects
- **RIFAMPIN:** May decrease tricyclic blood levels
- **SSRIs (e.g., fluoxetine, paroxetine, sertraline, etc.):** Increased risk for serotonin syndrome
- **SYMPATHOMIMETIC AGENTS:** Use in combination with sympathomimetic agents may increase the risk of cardiac effects (arrhythmias, hypertension, hyperpyrexia)
- **MONOAMINE OXIDASE INHIBITORS (including amitraz and possibly, selegiline):** Concomitant use (within 14 days) with monoamine oxidase inhibitors is generally contraindicated (serotonin syndrome)

## Laboratory Considerations

- **ECG:** Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG
- **METAPYRONE TEST:** The response to metapyrone may be decreased by clomipramine
- **GLUCOSE, BLOOD:** Tricyclics may alter (increase or decrease) blood glucose levels
- **THYROID TESTS:** Clomipramine may decrease T<sub>3</sub>, T<sub>4</sub> and free T<sub>4</sub> levels in dogs and cats

## Doses

### ■ DOGS:

- a) 2–4 mg/kg once daily or divided twice daily PO. (Label directions; *Clomicalm*®)
- b) 3 mg/kg q12h; start at a low dose (e.g., 1 mg/kg for 2 weeks, then 2 mg/kg for 2 weeks, then 3 mg/kg) (Reisner & Houpt 2000)
- c) For treatment of male dimorphic behaviors (urine marking, mounting, roaming, inter-male aggression); fearful/fear aggression behaviors; noise phobias; obsessive/compulsive behaviors (self-mutilation, excessive grooming, stereotypies): 1 mg/kg PO every 12 hours for 2 weeks; then 2 mg/kg PO q12h for 2 weeks, then 3 mg/kg PO q12h for 4 weeks and maintain. May take 4–6 weeks to see apparent improvement. (Overall 1997)
- d) For adjunctive treatment (with alprazolam and behavior modification) of storm phobia: Clomipramine 2 mg/kg PO q12h for 3 months, then 1 mg/kg PO q12h, then 0.5 mg/kg PO q12h for 2 weeks. Alprazolam 0.02 mg/kg PO as needed 1 hour before anticipated storms and q4h as needed (Crowell-Davis 2003)

### ■ CATS:

- a) For urine marking/spraying; inter-cat aggression related to social hierarchy; redirected aggression; compulsive grooming/wool sucking: 0.5 mg/kg once daily PO (Overall 1997)
- b) 0.3–0.5 mg/kg PO q24h (Landsberg 2008)
- c) 0.5–1 mg/kg once daily (Reisner & Houpt 2000)
- d) For urine marking: 0.3–0.5 mg/kg PO q24h (2.5–5 mg per cat q24h) (Levine 2008)

### ■ BIRDS:

- a) For adjunctive treatment of feather picking: Reported dosages range from 0.5–9 mg/kg PO q12–24h (Siebert 2007)

## Monitoring

- Clinical efficacy
- Adverse Effects: Baseline liver function tests; EKG

## Client Information

Generally used in combination with behavior modification treatments

- May take several weeks before beneficial effects are seen
- May be given with or without food; if patient vomits from the medication, give with food
- Do not stop therapy without veterinarian's guidance
- Keep well out of reach of pets and children; overdoses can be very toxic

## Chemistry/Synonyms

A dibenzazepine-derivative tricyclic antidepressant, clomipramine HCl occurs as a white to off-white crystalline powder and is freely soluble in water.

Clomipramine HCl may also be known as: chlorimipramine hydrochloride, clomipramini hydrochloridum, G-34586, monochlorimipramine hydrochloride, *Clomfranil*®, *Clomicalm*®, *Clopram*®, *Clopress*®, *Equinorm*®, *Hydiphen*®, *Maronil*®, *Novo-Clopramine*®, *Placil*®, *Tranquax*®, or *Zoiral*®.

## Storage/Stability

The commercially available veterinary tablets should be stored in a dry place at controlled room temperature (15–30°C) in the original closed container. The (human label) capsules should be stored at temperatures less than 30°C in tight containers and protected from moisture. An expiration date of 3 years from the date of manufacture is assigned to the commercially available capsules.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Clomipramine HCl Oral Tablets: 5 mg, 20 mg, 40 mg, & 80 mg; FDA-approved for dogs. *Clomicalm*® (Novartis); (Rx)

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

### HUMAN-LABELED PRODUCTS:

Clomipramine Oral Capsules: 25 mg, 50 mg, & 75 mg; *Anafranil*® (Novartis); generic; (Rx)

## CLONAZEPAM

(kloe-na-ze-pam) Klonopin®

BENZODIAZEPINE

### Prescriber Highlights

- **Benzodiazepine anticonvulsant, used primarily as adjunctive therapy for short-term treatment of epilepsy in dogs & for longer-term adjunctive treatment of epilepsy in cats; may also be used as an anxiolytic**
- **Contraindications: Hypersensitivity to benzodiazepines, narrow angle glaucoma, significant liver disease**
- **May exacerbate myasthenia gravis**
- **If using for seizures, discontinue gradually**
- **Adverse Effects: Sedation & ataxia most prevalent; Cats: Possible hepatic necrosis, but thought less likely to occur than with diazepam**
- **Dogs: Tolerance to efficacy may occur (over a few weeks)**
- **Controlled substance (C-IV)**

---

## Uses/Indications

Clonazepam is used primarily as a short-term adjunctive anticonvulsant for the treatment of epilepsy in dogs. It has been considered as long-term adjunctive therapy in dogs not controlled with other, more standard therapies, but like diazepam, tolerance tends to develop in a few weeks of treatment. It can also be used as an anxiolytic agent.

Clonazepam has been used as an anxiolytic and in the treatment of epilepsy in cats.

## Pharmacology/Actions

The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by diazepam and other benzodiazepines thereby producing the anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

## Pharmacokinetics

In dogs, clonazepam's oral bioavailability is variable (20–60%) but absorption is rapid. Protein binding is about 82% and the drug rapidly crosses into the CNS. Clonazepam exhibits saturation kinetics in dogs as elimination rates are dose dependent.

In humans, the drug is well absorbed from the GI tract, crosses the blood-brain barrier and placenta and is metabolized in the liver to several metabolites that are excreted in the urine. Peak serum levels occur about 3 hours after oral dosing. Half-lives range from 19–40 hours.

### Contraindications/Precautions/Warnings

Clonazepam is contraindicated in patients who are hypersensitive to it or other benzodiazepines, have significant liver dysfunction, or acute narrow angle glaucoma. Benzodiazepines have been reported to exacerbate myasthenia gravis.

### Adverse Effects

There is very limited information on the adverse effect profile of this drug in domestic animals. Sedation (or excitement) and ataxia may occur. Clonazepam has been reported to cause a multitude of various adverse effects in humans. Some of the more significant effects include increased salivation, hypersecretion in upper respiratory passages, GI effects (vomiting, constipation, diarrhea, etc.), transient elevations of liver enzymes, and hematologic effects (anemia, leukopenia, thrombocytopenia, etc.). Tolerance (usually noted after several weeks) to the anticonvulsant effects has been reported in dogs.

In cats, clonazepam may cause sedation, ataxia and possibly, acute hepatic necrosis.

Patients discontinuing clonazepam, particularly those who have been on the drug chronically at high dosages, should be tapered off or status epilepticus may be precipitated. Vomiting and diarrhea may occur during this process.

### Reproductive/Nursing Safety

Safe use during pregnancy has not been established; adverse teratogenic effects have been seen in rabbits and rats. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known if clonazepam drug is excreted into milk, but several other benzodiazepines have been documented to enter milk. Theoretically, accumulation of the drug and its metabolites to toxic levels are possible; use with caution in nursing dams.

### Overdosage/Acute Toxicity

Overdoses commonly cause sedation, depression, and ataxia. Some animals will exhibit paradoxical signs, such as hyperactivity, disorientation, and vocalization. Emesis is generally not indicated. With mild to moderate overdoses, animals can often be monitored at home, as long as the animal is rousable and does not show paradoxical signs. Animals should be confined and stimulation kept to a minimum. Paradoxical excitation can be treated with a mild sedative, such as diphenhydramine.

There were 659 exposures to clonazepam reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 590 were dogs with 340 showing clinical signs, 66 were cats with 43 showing clinical signs, and 1 was a bird that showed clinical signs. The remaining 2 cases involved a rodent and a ferret that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, lethargy, hyperactivity, vomiting, disorientation, sedation, agitation, vocalization, and depression. Common findings in cats recorded in decreasing frequency included ataxia, sedation, lethargy, disorientation, agitation, and polyphagia.

Massive overdoses can lead to respiratory depression or hypotension. Flumazenil can be used to reverse respiratory depression or severe depression. The half-life of flumazenil is short and the animal may require multiple doses.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clonazepam and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (itraconazole, ketoconazole, etc.):** May increase clonazepam levels
- **CIMETIDINE:** May decrease metabolism of benzodiazepines
- **CNS DEPRESSANT DRUGS:** If clonazepam administered with other CNS depressant agents (barbiturates, narcotics, anesthetics, etc.) additive effects may occur
- **ERYTHROMYCIN:** May decrease the metabolism of benzodiazepines
- **PHENOBARBITAL:** May decrease clonazepam concentrations
- **PHENYTOIN:** May decrease clonazepam concentrations
- **PROPANTHELINE:** May decrease clonazepam concentrations
- **RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines

### Laboratory Considerations

- Benzodiazepines may decrease the thyroidal uptake of  $I^{123}$  or  $I^{131}$ .

### Doses

#### ■ DOGS:

As an adjunctive medication in the treatment of seizures:

- a) 1–2 mg/kg PO q12h (Dickinson 2010)
- b) 0.5 mg/kg PO two to three times a day; may need to lower phenobarbital dose by 10–20% (Neer 1994)

As an anxiolytic:

- a) 0.05–0.25 mg/kg PO q12–24h (Virga 2005)
- b) 0.1–1 mg/kg PO two to three times a day (Landsberg 2005)

#### ■ CATS:

As an anxiolytic:

- a) 0.05–0.25 mg/kg PO q12–24h (Virga 2005)

b) 0.02–0.2 mg/kg PO once to two times a day (Landsberg 2005)

c) 0.1–0.2 mg/kg PO as needed or up to two times a day. (Neilson 2009)

As an adjunctive medication in the treatment of seizures:

a) Starting dose is 0.5 mg (total dose) PO q12–24h (Podell 2006), (Podell 2008)

b) 1/8<sup>th</sup> to 1/4 of a 0.5 mg tablet PO two to three times daily; anecdotally more effective for maintenance and to decrease cluster seizures; acute hepatic necrosis possible (Pearce 2006)

## Monitoring

- Efficacy
- Adverse effects
- The therapeutic blood level has been reported as 0.015–0.07 micrograms/mL.
- Cats: Liver function tests

## Client Information

- A major factor in anticonvulsant therapy failure is lack of compliance with the prescribed therapy; it is very important to give doses regularly
- Cats: If patient develops lack of appetite, vomits, or yellowish whites of eyes, contact veterinarian immediately
- Do not stop therapy abruptly without veterinarian's guidance

## Chemistry/Synonyms

A benzodiazepine anticonvulsant, clonazepam occurs as an off-white to light yellow, crystalline powder having a faint odor. It is insoluble in water and slightly soluble in alcohol.

Clonazepam may also be known as: clonazepamum, Ro-5-4023, *Anteplepsin*®, *Clonagin*®, *Clonapam*®, *Clonax*®, *Clonex*®, *Diocam*®, *Epitril*®, *Iktorivil*®, *Kenoket*®, *Klonopin*®, *Kriadex*®, *Neuryl*®, *Paxam*®, *Rivatril*®, *Rivotril*®, or *Solfidin*®.

## Storage/Stability

Tablets should be stored in airtight, light resistant containers at room temperature. After manufacture, a 5-year expiration date is assigned.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Clonazepam oral suspension compounded from commercially available tablets has been published (Allen & Erickson 1996). Triturating six (6) clonazepam 2 mg tablets with 60 mL of *Ora-Plus*® and *qs ad* to 120 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 0.1 mg/mL suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of clonazepam should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Clonazepam Oral Tablets: 0.5 mg, 1 mg, & 2 mg; *Klonopin*® (Roche); generic; (Rx, C-IV)

Clonazepam Orally Disintegrating Tablets: 0.125 mg, 0.25 mg, 0.5 mg, 1 mg & 2 mg (with mannitol); *Klonopin*® *Wafers* (Roche); generic (Barr); (Rx, C-IV)

## CLONIDINE

(kloe-ni-deen) *Duraclon*®, *Catapres*®

CENTRAL ALPHA-2 AGONIST

### Prescriber Highlights

- Centrally acting alpha-adrenergic agonist used as a diagnostic for growth hormone deficiency or pheochromocytoma in dogs, adjunctive treatment for IBD, &, potentially, epidurally as an adjunct for pain &/or anesthesia or a premed prior to surgery
  - Limited experience in veterinary species for therapeutic purposes
  - Potential adverse effects include: Transient hyperglycemia, dry mouth, constipation, sedation, aggressive behavior, hypotension, collapse, & bradycardia
- 

## Uses/Indications

Clonidine is of interest in veterinary medicine as a diagnostic agent to determine growth hormone deficiency or pheochromocytoma in dogs, and as an adjunctive treatment for refractory inflammatory bowel disease, particularly in cats. It is being investigated as a premed in dogs and in a variety of species as an epidural adjunct with or without opiates in the treatment of severe pain or for surgical procedures using epidural anesthesia.

### Pharmacology/Actions

Clonidine acts centrally (brain stem), stimulating alpha-adrenoreceptors, thereby reducing sympathetic outflow from the CNS; decreased renal vascular resistance, peripheral resistance, cardiac rate, and blood pressure result. Renal blood flow and glomerular filtration rates are not affected. Clonidine stimulates growth hormone release by stimulating release of GHRH, but this effect does not persist with continued dosing. Clonidine possesses centrally acting analgesic effects probably at presynaptic and postjunctional alpha<sub>2</sub>-adrenoreceptors in the spinal cord thereby blocking pain signal transmission to the brain. It may also increase seizure threshold but the clinical significance for this effect is unclear.

### Pharmacokinetics

Limited information is available on the pharmacokinetics of clonidine in domestic animals. In cats, clonidine exhibits a two-compartment open model and penetrates into tissues rapidly.

In humans, the drug is well absorbed after oral administration. Peak plasma concentrations occur approximately 3–5 hours after oral administration. After epidural administration, maximal analgesia occurs within 30–60 minutes. Clonidine is apparently widely distributed into body tissues; tissue concentrations are higher than in plasma. Clonidine does enter into the CSF, but brain concentrations are low compared with other tissues. In humans with normal renal function, clonidine's half-life is 6–20 hours. Elimination may be prolonged with higher dosages (dose-dependent elimination kinetics) or in patients with renal dysfunction. Up to 60% of a dose is eliminated unchanged in the urine, but the remainder is metabolized in the liver; one active metabolite (p-hydroxyclonidine) has been identified.

### Contraindications/Precautions/Warnings

Clonidine is contraindicated in patients known to be hypersensitive to it. It should be used with caution in patients with severe cardiovascular disease, including conduction disturbances or heart failure; it should be used very cautiously in patients with renal failure.

### Adverse Effects

Reported adverse effects most likely to occur include: transient hyperglycemia, dry mouth, constipation, sedation, aggressive behavior, hypotension, collapse, and bradycardia (responsive to atropine). Tolerance to its therapeutic effects has been reported in humans.

### Reproductive/Nursing Safety

At reasonable dosages no significant teratogenic effects have been described in laboratory animals, but at very high dosages some effects (increased perinatal mortality, growth retardation, cleft palates) have been seen. In humans, the FDA categorizes clonidine as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

Clonidine does enter maternal milk at concentrations of about 20% of those found in plasma; clinical significance to nursing offspring is unknown, but clonidine was undetectable in plasma of an infant one hour after nursing from a mother taking clonidine.

### Overdosage/Acute Toxicity

Clonidine has a narrow margin of safety. Common signs include hypotension, bradycardia, vomiting, weakness, and depression. Rarely, seizures or respiratory depression is seen. The LD<sub>50</sub> values reported for oral clonidine in rats are 465 mg/kg and mice, 206 mg/kg.

There were 150 exposures to clonidine reported to the ASPCA Animal Poison Control Center (APCC) during 2008-2009. In these cases, 130 were dogs with 41 showing clinical signs and the remaining 20 cases were cats with 14 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, tachycardia, ataxia, and hypertension. Common findings in cats recorded in decreasing frequency included lethargy.

Fluids and dopamine can be used to treat hypotension.

Treatment for large overdoses includes gut evacuation using standard protocols. Use of emetics should be carefully considered, as level of consciousness may deteriorate rapidly. Treatment of systemic effects is primarily symptomatic and supportive. Hypotensive effects may be treated, if necessary, using fluids or pressors (*e.g.*, dopamine); bradycardia may be treated with IV atropine, if required. Atipamezole or yohimbine may also be used to help reverse the cardiovascular effects, but multiple doses may be required, as signs can last up to 48 hours, depending on clonidine dosage.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clonidine and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS, OTHER:** Possible additive hypotensive effects
- **BETA-ADRENERGIC BLOCKING AGENTS (*i.e.*, propranolol)** may enhance bradycardia when given with clonidine. In patients receiving clonidine and beta-adrenergic blocking agents together: if clonidine is to be discontinued, the beta-blocker should be discontinued prior to clonidine and clonidine gradually discontinued, otherwise rebound hypertension may occur.
- **CNS DEPRESSANT DRUGS (opiates, barbiturates, etc.):** Clonidine may exacerbate the actions of other CNS depressant drugs
- **DIGOXIN:** Possible additive bradycardia
- **PRAZOSIN:** May decrease the antihypertensive effects of clonidine
- **TRICYCLIC ANTIDEPRESSANTS (*e.g.*, amitriptyline):** May block the antihypertensive effects of clonidine

### Laboratory Considerations

- No specific laboratory interactions were noted for clonidine.

### Doses

#### ■ DOGS:

For diagnosing hyposomatotropism:

- a) Dosage may be variable depending on the laboratory's protocol. Contact lab prior to test to determine protocol and sample handling instructions. Usual dose is 10 micrograms/kg IV. Obtain plasma for growth hormone (GH) levels, prior to clonidine dosing and at 15, 30, 45, 60, and 120 minutes. Larger dosages may

cause a more pronounced and prolonged hyperglycemia and a higher incidence of other adverse reactions that may include sedation, aggressive behavior, hypotension, collapse, and bradycardia (responsive to atropine). Adverse effects may persist for 15–60 minutes post dose. Healthy dogs should demonstrate GH levels of 10 ng/mL after clonidine administration. (Feldman & Nelson 1996)

For adjunctive antidiarrheal therapy for refractory cases of inflammatory bowel disease:

a) 5–10 micrograms/kg PO or SC two to three times a day; can activate alpha2-receptors in the CRT and cause vomiting. (Washabau 2009)

#### ■CATS:

For adjunctive antidiarrheal therapy for refractory cases of inflammatory bowel disease:

a) As fourth line therapy after prostaglandin synthetase inhibitors (*i.e.*, sulfasalazine, bismuth subsalicylate), opioid agonists (*i.e.*, loperamide), and 5-HT<sub>3</sub> serotonergic antagonists (*i.e.*, ondansetron) are being used: clonidine 5–10 micrograms/kg two to three times a day, SC or PO. (Washabau 2000)

#### ■CATTLE:

For epidural analgesia/analgesia:

a) 2–3 micrograms/kg diluted to 8 mL with sterile normal saline epidurally; onset/duration of analgesia = 19 minutes/192 minutes with 2 micrograms/kg dose and = 9 minutes/311 minutes with 3 micrograms/kg dose; peak effects from 60–180 minutes (De Rossi *et al.* 2003)

### Monitoring

- Dependent upon purpose for use. When used for determining GH levels, adverse effects (noted in dosage section) should be evaluated.
- Blood pressure and cardiac rate are most likely to be affected, but effects usually only persist for an hour after dose.
- When used for ongoing diarrhea treatment, evaluation of efficacy and adverse effect profile should be monitored.

### Client Information

- When used for chronic therapy, have clients report signs that may indicate adverse effects (weakness, lethargy, behavioral changes, etc.); caution not to alter or discontinue treatment without veterinarian's advice.

### Chemistry/Synonyms

An imidazoline derivative centrally acting alpha-adrenergic agonist, clonidine HCl occurs as an odorless, bitter, white or almost white crystalline powder. It is soluble in water and alcohol. It is also considered highly lipid soluble. The commercially available injection for epidural use has its pH adjusted to between 5 to 7.

Clonidine may also be known as: ST-155, clonidini hydrochloridum, *Adesipress-TTS*®, *Arkamin*®, *Aruclonin*®, *Atensina*®, *Barclyd*®, *Cantanidin*®, *Caprysin*®, *Catanidin*®, *Catapresan*®, *Catapresan*®, *Catapres*®, *Catapressan*®, *Clonistada*®, *Clonnirit*®, *Dispaclonidin*®, *Dixarit*®, *Duraclon*®, *Epiclodina*®, *Glausine*®, *Haemiton*®, *Menograin*®, *Mirfat*®, *Normopresan*®, *Paracefan*®, or *Tenso-Timelets*®.

### Storage/Stability

Clonidine tablets should be stored in tight, light-resistant containers at room temperature; excursions permitted to 15–30°C (59–86°F). The preservative-free injection for epidural use should be stored at controlled room temperature (25°C). Because it contains no preservative, unused portions of the injection should be discarded.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

### **HUMAN-LABELED PRODUCTS:**

Clonidine HCl Injection for epidural use: 100 micrograms/mL, & 500 micrograms/mL preservative-free in 10 mL vials; *Duraclon*® (aiiPharma); (Rx)

Clonidine HCl Oral Tablets: 0.1 mg, 0.2 mg & 0.3 mg; *Catapres*® (Boehringer Ingelheim); generic; (Rx)

Clonidine HCl Oral Modified-release Tablets: 0.1 mg (equivalent to 0.087 mg of base); *Jenloga*® (UPM Inc); (Rx)

Clonidine HCl Transdermal: 0.1 mg/24hrs (2.5 mg total clonidine content), 0.2 mg/24hrs (5 mg total clonidine content), & 0.3 mg/24hrs (7.5 mg total clonidine content); *Catapres-TTS-1*®, 2® or 3® (Boehringer Ingelheim); (Rx)

---

## CLOPIDOGREL BISULFATE

(kloe-*pid*-oh-grel) *Plavix*®

PLATELET AGGREGATION INHIBITOR

### Prescriber Highlights

- Oral, once-daily platelet aggregation inhibitor that may be useful in preventing thromboembolic disease in cats and in hypercoagulable states in dogs
  - Limited clinical experience in feline medicine; but appears well tolerated
  - Potentially may cause vomiting or bleeding
-

## Uses/Indications

Clopidogrel, a platelet aggregation inhibitor, may be useful for preventing thrombi in susceptible cats. It may also improve pelvic limb circulation in cats after a cardiogenic embolic event via a vasomodulating effect secondary to inhibition of serotonin release from platelets. Research is ongoing. It may also prove to be of benefit in treating hypercoagulable states in dogs.

## Pharmacology/Actions

Clopidogrel is metabolized to an active, highly unstable compound (not yet identified) that is responsible for its inhibitory platelet-aggregation (both primary and secondary aggregation) activity. This compound binds selectively to platelet surface low-affinity ADP-receptors and inhibits ADP binding to the site. This inhibits activation of the platelet glycoprotein Ib/IIIa complex that is necessary for platelet-fibrinogen binding and inhibits the release from platelets other compounds that enhance platelet aggregation (*e.g.*, serotonin, calcium, fibrinogen, thrombospondin, ADP). Clopidogrel's active metabolite irreversibly alters the ADP receptor; the platelet is affected for its lifespan.

Clopidogrel's mechanism of action on platelet aggregation is different than aspirin's effects. Aspirin acetylates and inactivates COX-1 in platelets, thereby preventing formation of thromboxane A<sub>2</sub>.

## Pharmacokinetics

No specific information was located for the pharmacokinetics of clopidogrel in cats. In a pharmacodynamic study in cats (Hogan *et al.* 2004), doses as low as 18.75 mg were as effective as higher dosages in reducing platelet aggregation; maximal effects were seen after 3 days of therapy and platelet function returned to normal 7 days after stopping treatment. While lower dosages may be effective in cats, they have not been evaluated and are not practical to administer with the presently available 75 mg human-labeled dosage form (tablets).

In humans, clopidogrel is rapidly absorbed with a bioavailability of about 50%. Food does not alter its absorption. Clopidogrel is highly bound to plasma proteins in humans and is rapidly hydrolyzed to a carboxylic acid derivative inactive metabolite that is excreted via the urine and feces. The 2% of drug that is covalently bound to platelets has an approximate elimination half-life of 11 days.

## Contraindications/Precautions/Warnings

No specific information is available for cats. In humans, clopidogrel is contraindicated in patients with active pathologic bleeding or known hypersensitivity to the drug.

## Adverse Effects

Clopidogrel appears well tolerated by cats, but numbers treated have been relatively few. Some cats may vomit or develop anorexia; giving the drug with food may alleviate these effects.

In humans, the primary adverse effects reported have been bleeding related. In a major pre-clinical study, major bleeding occurred in approximately 2% of patients treated. Use of aspirin with clopidogrel may increase this incidence. Rashes and gastrointestinal effects (diarrhea) have also been reported. Rarely, thrombotic thrombocytopenic purpura (TTP) has been noted; onset can occur after a short period of treatment (<2 weeks).

## Reproductive/Nursing Safety

In pregnant rats and rabbits, dosages of approximately 65X and 78X respectively, of the human dose when compared on mg/m<sup>2</sup> basis, caused no teratogenic effects. In humans, the FDA categorizes clopidogrel as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

In rats, clopidogrel or its metabolites are distributed into milk. Although probably safe to use in nursing veterinary patients, weigh the potential risks to nursing offspring before allowing patients receiving the drug to nurse their young, or use a milk replacer.

## Overdosage/Acute Toxicity

Limited information is available. Reported lethal oral doses for mice and rats were 1500 mg/kg and 2000 mg/kg (460X human adult dose on a mg/m<sup>2</sup> basis), respectively. Acute toxic signs may include bleeding or vomiting. Platelet transfusions have been suggested if rapid reversal is required.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clopidogrel and may be of significance in veterinary patients:

- **ASPIRIN:** Increased risk for bleeding, however many human patients take both medications
- **HEPARIN; LOW MOLECULAR WEIGHT HEPARINS:** Clopidogrel appears safe to use with heparin (both unfractionated and LMW)
- **NSAIDS:** Increased risk for bleeding; clopidogrel may interfere with metabolism
- **PHENYTOIN:** Clopidogrel may interfere with metabolism
- **PROTON PUMP INHIBITORS (e.g., omeprazole):** Proton pump inhibitors may decrease the efficacy of clopidogrel. The clinical significance of this interaction is unclear and being intensely debated in human medicine.
- **TORSEMIDE:** Clopidogrel may interfere with metabolism
- **WARFARIN:** Increased risk for bleeding; clopidogrel may interfere with metabolism

## Laboratory Considerations

- None noted

## Doses

### ■ DOGS:

As an anti-platelet agent:

- a) 1–3 mg/kg PO once daily; if used with aspirin give lower doses (0.5–1 mg/kg PO once daily) (Brainard 2008)

## ■CATS:

To prevent thrombus formation:

- 18.75 mg (practically, 1/4 of a 75 mg tablet) PO once daily (Hogan 2006)
- 7 mg (total dose) PO once daily in combination with aspirin 40–81 mg (total dose) every 3 days. Clinical trials are needed to determine appropriate dosage and indications. (Moise 2007)
- 1–3 mg/kg PO once daily; if used with aspirin give lower doses (0.5–1 mg/kg PO once daily) (Brainard 2008)

## Monitoring

- Clinical efficacy
- Adverse effects (vomiting, bleeding)

## Client Information

- May be given without regard to feeding status
- Potential adverse effects include vomiting, lack of appetite or bleeding
- If vomiting occurs, give with food
- Report any bleeding or black, tarry stools to veterinarian

## Chemistry/Synonyms

Clopidogrel bisulfate, a thienopyridine, occurs as a white to off-white powder that is practically insoluble in water at a pH of 7, but freely soluble at a pH of 1.

Clopidogrel may also be known as: SR-259990C, PCR-4099, or clopedogreli. Internationally registered trade names for clopidogrel include: *Antiplaq*, *Clodian*, *Cloflow*, *Clopact*, *Clopivas*, *Clopod*, *Iscover*, *Iskimit*, *Nabratin*, *Noklot*, *Plavix*®, *Pleyar*, or *Troken*.

## Storage/Stability

Clopidogrel tablets should be stored at 25°C; excursions are permitted to 15–30°C.

## Compatibility/Compounding Considerations

**Compounded preparation stability:** Clopidogrel oral suspension compounded from commercially available tablets has been published (Skillman *et al.* 2010). Triturating four (4) clopidogrel 75 mg tablets with 30 mL of *Ora-Plus*® and *qs ad* to 60 mL with *Ora-Sweet*® (or *Ora-Sweet*® *SF*) yields a 5 mg/mL oral suspension that retains >90% potency for 60 days stored at both 5°C and 25°C. Compounded preparations of clopidogrel should be protected from light.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Clopidogrel Bisulfate Tablets: 75 mg & 300 mg; *Plavix*® (Bristol-Myers Squibb); (Rx)

## CLOPROSTENOL SODIUM

(*kloe-pros-te-nol*) Estrumate®

PROSTAGLANDIN (F-CLASS)

### Prescriber Highlights

- **Synthetic F-class prostaglandin used in cattle to induce luteolysis, induce abortion, treat pyometra, endometritis, etc.**
  - **Contraindications: Pregnancy (when abortion or induced parturition are not desired)**
  - **Can cause cholinergic-like adverse effects in dogs**
  - **Do not give IV**
  - **Pregnant women should not handle; caution handling in humans with asthma & women of childbearing age**
- 

## Uses/Indications

Cloprostenol is FDA-approved for use in beef or dairy cattle to induce luteolysis. It is recommended by the manufacturer for unobserved or undetected estrus in cows cycling normally, pyometra or chronic endometritis, expulsion of mummified fetus, luteal cysts, induced abortions after mismating, and to schedule estrus and ovulation for controlled breeding.

Cloprostenol has been used in dogs for pregnancy termination and treatment of open pyometra. The use of cloprostenol for pyometra is controversial as some believe dinoprost (PGF<sub>2</sub>α) is more effective and has fewer adverse effects than cloprostenol.

In horses, cloprostenol has been used for luteolysis, induce abortion, and stimulate uterine contractions.

## Pharmacology/Actions

Prostaglandin F<sub>2</sub>alpha and its analogues cloprostenol and fluprostenol are powerful luteolytic agents. They cause rapid regression of the corpus luteum and arrest its secretory activity. These prostaglandins also have direct stimulating effect on uterine smooth muscle causing contraction and a relaxant effect on the cervix.

In normally cycling animals, estrus will generally occur 2–5 days after treatment. In pregnant cattle treated between 10–150 days of gestation, abortion will usually occur 2–3 days after injection.

## Pharmacokinetics

No information was located on the pharmacokinetics of cloprostenol. It is reported to have a longer duration of action than dinoprost tromethamine.

## Contraindications/Precautions/Warnings

Should not be administered to pregnant animals when abortion is not desired.

Women of child-bearing age, persons with asthma or other respiratory diseases should use extreme caution when handling cloprostenol as the drug may induce abortion or acute bronchoconstriction. Cloprostenol is readily absorbed through the skin and must be washed off immediately with soap and water.

Do not administer IV.

## Adverse Effects

The manufacturer does not list any adverse effects for this product when used as labeled. If used after the 5th month of gestation, increased risk of dystocia and decreased efficacy occur.

In dogs, cloprostenol can cause increased salivation, tachycardia, increased urination and defecation, gagging, vomiting, ataxia, and mild depression. Pretreatment with an anticholinergic drug (such as atropine) may reduce the severity of these effects.

At higher doses in horses, cloprostenol can cause sweating, cramping and loose stools, but incidence of adverse effects is less than with dinoprost tromethamine. In horses, uterine contractions are stimulated for approximately 5 hours post-dose.

## Reproductive/Nursing Safety

Cloprostenol is contraindicated in pregnant animals when abortion or induced parturition is not desired.

## Overdosage/Acute Toxicity

The manufacturer states that at doses of 50 and 100 times those recommended, cattle may show signs of uneasiness, slight frothing, and milk let-down.

Overdoses of cloprostenol or other synthetic prostaglandin F<sub>2</sub>alpha analogs in small animals reportedly can result in shock and death.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cloprostenol and may be of significance in veterinary patients:

■**OXYTOCIC AGENTS, OTHER:** Activity may be enhanced by cloprostenol

## Doses

### ■DOGS:

For adjunctive treatment of open cervix pyometra:

- 1–5 micrograms/kg (0.001–0.005 mg/kg) (route not specified) once per day. May require up to 2–3 weeks of treatment. When starting treatment, start with one-half the normal dosage and gradually achieve the full dose within 2–3 days. (Romagnoli 2002)
- Cloprostenol at 1 microgram/kg SC (not during feeding) every 5 days for 15 days (if not cured earlier) with aglepristone at 10 mg/kg SC every 5 days until cured. Give *Clavamox*® (12.5 mg/kg PO twice daily and supportive hydration throughout protocol, if indicated. (Threlfall 2006)

For pregnancy termination:

- 1–2.5 micrograms/kg SC once daily for 4–7 days has been successful in terminating pregnancy in dogs after 30 days gestation (Davidson 2004)
- 1–2.5 micrograms/kg SC every 48 hours for three doses. At higher dose (2.5 mg/kg); appears very effective starting at 30 days of pregnancy. Anticholinergic drug administration (e.g., atropine) 15 minutes prior to dosing appears to lessen adverse effects. (Romagnoli 2006)

### ■CATTLE:

For treatment of pyometra:

- 500 micrograms IM (up to 97% efficacy) (McCormack 1986)

For pyometra or chronic endometritis, mummified fetus (manual assistance may be required to remove from vagina), luteal cysts:

- 500 micrograms IM (Package Insert; *Estrumate*®—Miles/Mobay)

For unobserved or undetected estrus in cows with continued ovarian cyclicity and a mature corpus luteum:

- 500 micrograms IM; estrus should commence in 2–5 days at which time the animal may be inseminated. If estrus detection is not possible or practical, animal may be inseminated twice at 72 and 96 hours post injection. (Package Insert; *Estrumate*®—Miles/Mobay)

For abortion, from one week after mating to approximately the 150th day of gestation:

- 500 micrograms IM; abortion generally takes place in 4–5 days after injection (Package Insert; *Estrumate*®—Miles/Mobay)

For controlled breeding:

- Single injection method:* Use only animals with mature corpus luteum. Examine rectally to determine corpus luteum maturity, anatomic normality, and lack of pregnancy. Give 500 micrograms cloprostenol IM. Estrus should occur in 2–5 days. Inseminate at usual time after detecting estrus, or inseminate once at 72 hours post injection, or twice at 72 and 96 hours post injection.

*Double injection method:* Examine rectally to determine if animal is anatomically normal, not pregnant, and cycling normally. Give 500 micrograms IM. Repeat dose 11 days later. Estrus should occur in 2–5 days after second injection. Inseminate at usual time after detecting estrus, or inseminate once at 72 hours post second injection, or twice at 72 and 96 hours post second injection.

Animals that come into estrus after first injection may be inseminated at the usual time after detecting estrus.

Any controlled breeding program should be completed by either observing animals and re-inseminating or hand mating after returning to estrus, or turning in clean-up bull(s) five to seven days after the last injection of cloprostenol to cover any animals returning to estrus. (Package Insert; *Estrumate*®—Miles/Mobay)

#### ■HORSES:

- To cause abortion prior to the twelfth day of gestation: 100 micrograms IM, most effective day 7 or 8 post estrus. Mare will usually return to estrus within 5 days. (Lofstedt 1986)
- For luteolysis and to stimulate uterine contractions: 250 micrograms (total dose) IM once. Research has shown that 1/10th of a dose can still cause luteolysis and if given on once or on two consecutive days can avoid side effects. (Dascanio 2009)
- For luteolysis: 25–250 micrograms (0.1–1 mL) IM once. As an ecboic: 250 micrograms (1 mL) IM q24h. Cloprostenol should not be used more than one day after ovulation because it can damage the corpus luteum and reduce progesterone. (Foss 2009)

#### ■SWINE:

To induce parturition in sows:

- 175 micrograms IM; give 2 days or less before anticipated date of farrowing. Farrowing generally occurs in approximately 36 hours after injection. (Pugh 1982)

#### ■SHEEP & GOATS:

- Goats:** To induce parturition in does: 62.5–125 micrograms IM at 144 days of gestation in early morning. Deliveries will peak at 30–35 hours after injection. Maintain goat in usual surroundings and minimize outside disturbances. (Williams 1986)
- Goats:** To treat pseudopregnancy (hydrometra/mucometra): 125 micrograms IM once. (Tibary 2009)

#### ■CAMELIDS:

- As a luteolytic: **Alpacas:** 100 micrograms IM once. **Llamas:** 250 micrograms IM once. Not to be given more than 4 days after ovulation. Luteolysis and abortion can be induced at any stage of pregnancy with 2-4 injections of cloprostenol. (Adams 2008)

### Client Information

- Cloprostenol should be used by individuals familiar with its use and precautions
- Pregnant women, asthmatics or other persons with bronchial diseases should handle this product with extreme caution
- Any accidental exposure to skin should be washed off immediately

### Chemistry/Synonyms

A synthetic prostaglandin of the F class, cloprostenol sodium occurs as a white or almost white, amorphous, hygroscopic powder. It is freely soluble in water and alcohol. Potency of the commercially available product is expressed in terms of cloprostenol.

Cloprostenol sodium may also be known as ICI-80996, *Estrumate*®, or *estroPLAN*®.

### Storage/Stability

Cloprostenol sodium should be stored at room temperature (15–30°C); protect from light.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Cloprostenol Sodium Injection equivalent to 250 micrograms/mL cloprostenol in 20 mL vials; *Estrumate*® (Schering-Plough); *estroPLAN*® Injection (Parnell); (Rx). FDA-approved for use in beef and dairy cattle. No preslaughter withdrawal or milk withdrawal is required; no specific tolerances for cloprostenol residues have been published.

**HUMAN-LABELED PRODUCTS:** None

## CLORAZEPATE DIPOTASSIUM

(klor-az-e-pate) Tranxene-SD®, Gen-Xene®

BENZODIAZEPINE

### Prescriber Highlights

- **Benzodiazepine anxiolytic, sedative-hypnotic, & anticonvulsant used in dogs & cats**
- **Contraindications:** Hypersensitivity to benzodiazepines, narrow angle glaucoma, or significant liver disease
- **Use extreme caution in aggressive animals (especially fear induced)**

- May exacerbate myasthenia gravis
  - Can interact with phenobarbital
  - Adverse Effects: Sedation & ataxia most prevalent
- 

## Uses/Indications

Clorazepate has been used in dogs both as an adjunctive anticonvulsant (usually in conjunction with phenobarbital) and in the treatment of behavior disorders, primarily those that are anxiety or phobia-related. In dogs, clorazepate has been reported to develop tolerance to its anticonvulsant effects less rapidly than clonazepam.

Clorazepate may be useful as an anxiolytic agent in cats.

## Pharmacology/Actions

The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by clorazepate and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung and heart. In all species studied, receptors are lacking in the white matter.

## Pharmacokinetics

In dogs, clorazepate peak serum levels generally occur within 1–2 hours. Volume of distribution is about 1.8 L/kg after multiple dosing. Clorazepate is metabolized to nordiazepam and other metabolites. Nordiazepam is active and has a very long half-life (in humans up to 100 hours). In dogs, the sustained release preparation apparently offers no pharmacokinetic advantage over the non-sustained preparations (Brown & Forrester 1989).

## Contraindications/Precautions/Warnings

Clorazepate is contraindicated in patients who are hypersensitive to it or other benzodiazepines, have significant liver dysfunction or have acute narrow angle glaucoma. Clorazepate should be used very cautiously, if at all, in aggressive patients as it may disinhibit the anxiety that may help prevent these animals from aggressive behavior. Benzodiazepines have been reported to exacerbate myasthenia gravis.

Use with caution in dogs displaying fear-induced aggression; these drugs may actually provoke dogs to attack.

## Adverse Effects

In dogs, the most likely adverse effects seen include sedation and ataxia. These effects apparently occur infrequently, are mild and usually transient. Physical dependence may occur and abrupt withdrawal of clorazepate may precipitate seizures.

In cats, clorazepate may cause sedation, ataxia and, potentially, acute hepatic necrosis.

## Reproductive/Nursing Safety

Safe use during pregnancy has not been established; teratogenic effects of similar benzodiazepines have been noted in rabbits and rats. In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Nordiazepam is distributed into milk and may affect nursing neonates.

## Overdosage/Acute Toxicity

When used alone, clorazepate overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Treatment of significant oral overdoses consists of standard protocols for removing and/or binding the drug in the gut and supportive systemic measures. The use of analeptic agents (CNS stimulants such as caffeine, amphetamines, etc.) is generally not recommended. Flumazenil may be considered for very serious overdoses.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving clorazepate and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE (itraconazole, ketoconazole, etc.):** May increase levels
- **CIMETIDINE:** May decrease metabolism of benzodiazepines
- **CNS DEPRESSANT DRUGS:** If clorazepate is administered with other CNS depressant agents (**barbiturates, narcotics, anesthetics, etc.**) additive effects may occur
- **ERYTHROMYCIN:** May decrease the metabolism of benzodiazepines
- **PHENOBARBITAL:** While used together in the treatment of seizures in dogs, can interact with one another. Clorazepate (especially high serum concentrations), may increase the serum levels of phenobarbital, particularly if added to patients who received phenobarbital long-term. In time, clorazepate levels may decrease, leading to decreased phenobarbital levels.
- **PHENYTOIN:** May decrease clorazepate concentrations
- **RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines

## Laboratory Considerations

- Benzodiazepines may decrease the thyroidal uptake of  $I^{123}$  or  $I^{131}$ .
- Clorazepate may increase **serum alkaline phosphatase** and **serum cholesterol** levels; clinical significance is unclear.

## Doses

## DOGS:

As an adjunctive medication in the treatment of seizures:

- In combination with phenobarbital: Clorazepate: 1–2 mg/kg PO q12h, but may need to divide q12h dose and give q8h to minimize adverse effects and maintain therapeutic levels (Boothe 1999)
- In combination with phenobarbital: Clorazepate: 0.5–1 mg/kg PO q8h. No advantage gained with using sustained release products over regular caps or tabs. May affect phenobarb levels; monitor 2 and 4 weeks later. (Thomas 2000)
- 1–2 mg/kg PO q12h (Podell 2006)
- 2–4 mg/kg PO twice daily, some dogs may require three times daily (Dowling 2003)
- As a third-line agent: 1–2 mg/kg PO q8–12h (Quesnel 2001)
- For management of cluster seizures: Immediately after first seizure give clorazepate at 0.5–2 mg/kg two to three times daily for the next 48–96 hours and then stop clorazepate. It may be used in addition to the existing anticonvulsant maintenance therapy, but it is used only during the time of seizure activity and not as maintenance therapy. (Hoskins 2005)

As adjunctive therapy for the treatment of fears and phobias:

- 11.25–22.5 mg per dog PO once to twice daily (recommends the sustained-delivery product (*Tranxene*®-SD). (Marder 1991)
- Using the sustained delivery product (*Tranxene*®-SD), initially give 22.5 mg for large dogs, 11.25 mg for medium dogs and 5.6 mg for small dogs PO; adjust dosage according dog's response (Shull-Selcer & Stagg 1991)
- 0.55–2.2 mg/kg PO as needed up to q8h; titrate to clinical sedation—dose may vary for individual dogs (Reisner & Houpt 2000), (Sherman & Mills 2008)
- 0.2–1 mg/kg PO q12–24h (Virga 2002)

## CATS:

- As an anxiolytic or for compulsive behaviors: 0.2–0.5 mg/kg PO q12–24h (Virga 2002)
- As an alternative drug to phenobarbital for seizures: 3.75–7.5 mg (total dose per cat) PO once to twice daily. Similar precautions are necessary as described for diazepam use in cats. (Podell 2008)

## Monitoring

- Efficacy
- Adverse effects

## Client Information

- A major factor in anticonvulsant therapy failure is lack of compliance with the prescribed therapy; it is very important to give doses regularly
- Do not stop giving this drug abruptly as convulsions may occur; contact veterinarian for guidance in stopping treatment
- Cats: If patient develops lack of appetite, vomits, or yellowish whites of eyes, contact veterinarian immediately

## Chemistry/Synonyms

A benzodiazepine anxiolytic, sedative-hypnotic, and anticonvulsant, clorazepate dipotassium occurs as a light yellow, fine powder that is very soluble in water and slightly soluble in alcohol.

Clorazepate dipotassium may also be known as Abbott-35616, AH-3232, 4306-CB, clorazepic acid, dipotassium clorazepate, dikalii clorazepas, or potassium clorazepate; many trade names are available.

## Storage/Stability

Clorazepate dipotassium is unstable in the presence of water. It has been recommended to keep the dessicant packets in with the original container of the capsules and tablets and to consider adding a dessicant packet to the prescription vial when dispensing large quantities of tablets or capsules to the client.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Clorazepate Dipotassium Tablets: 3.75 mg, 7.5 mg, & 15 mg; *Tranxene*® T-tab (Ovation); generic; (Rx, C-IV)

## CLORSULON

(*klor-su-lon*) Curatrem®, Ivomec Plus®

ANTIPARASITIC (FLUKICIDE)

## Prescriber Highlights

- **Adult flukicide (*Fasciola hepatica*)**
  - **Not for female dairy cattle**
  - **Slaughter withdrawal 8 days at labeled doses for *Curatrem*®, 49 days for *Ivomec Plus*®**
- 

### Uses/Indications

Clorsulon is FDA-approved for use in the treatment of immature and adult forms of *Fasciola hepatica* (Liver fluke) in cattle. It is not effective against immature flukes less than 8 weeks old. It also has activity against *Fasciola gigantica*. Although not FDA-approved, the drug has been used in practice in various other species (*e.g.* sheep, llamas). It has activity against *F. magna* in sheep, but is not completely effective in eradicating the organism after a single dose, thus severely limiting its clinical usefulness against this parasite. Clorsulon is also not effective against the rumen fluke (*Paramphistomum*).

### Pharmacology/Actions

In susceptible flukes, clorsulon inhibits the glycolytic enzymes 3-phosphoglycerate kinase and phosphoglyceromutase, thereby blocking the Emden-Myerhof glycolytic pathway; the fluke is deprived of its main metabolic energy source and dies. Clorsulon at 7 mg/kg is effective against migrating *F. hepatica* 8 weeks post-infection, but at 2 mg/kg is effective only against adult flukes (14 weeks post infection).

### Pharmacokinetics

After oral administration to cattle, the drug is absorbed rapidly with peak levels occurring in about 4 hours. Approximately 75% of the circulating drug is found in plasma and 25% in erythrocytes. At 8–12 hours after administration, clorsulon levels peak in the fluke.

### Contraindications/Precautions/Warnings

No milk withdrawal time has been determined, and the drug is labeled not for use in female dairy cattle of breeding age.

The combination injectable product (*Ivomec Plus*®) must be administered subcutaneously only; do not give IV or IM. The manufacturer warns to use in cattle only as severe reactions, including fatalities in dogs, may occur.

### Adverse Effects

When used as directed adverse effects are unlikely to occur with the oral suspension (*Curatrem*®). Local swelling may occur at injection sites with *Ivomec Plus*®.

### Reproductive/Nursing Safety

Clorsulon is considered safe to use in pregnant or breeding animals.

### Overdosage/Acute Toxicity

Clorsulon is very safe when administered orally to cattle or sheep. Doses of up to 400 mg/kg have not produced toxicity in sheep. A dose that is toxic in cattle has also not been determined.

### Drug Interactions/Laboratory Considerations

- None identified

### Doses

#### ■ CATTLE:

For *Fasciola hepatica* infections:

- a) 7 mg/kg PO; deposit suspension over the back of the tongue (Label directions; *Curatrem*®—Merial)

For *Fasciola hepatica* infections, round worms, lungworms, cattle grubs, sucking lice, mange mites (see Ivermectin monograph or product label for more information on species covered):

- a) Inject 1mL per 110 lb. body weight SC behind the shoulder (Label directions; *Ivomec Plus*®—Merial)

#### ■ SHEEP:

For *Fasciola hepatica* infections:

- a) 7 mg/kg PO (Roberson 1988)

#### ■ LLAMAS:

For *Fasciola hepatica* infections:

- a) 7 mg/kg PO (Fowler 1989)

### Monitoring

- Clinical efficacy

### Client Information

- Shake well before using (*Curatrem*®)
- Follow withdrawal times for slaughter (8 days for *Curatrem*®, 49 days for *Ivomec Plus*®)
- Do not use in female dairy cattle of breeding age

### Chemistry/Synonyms

A benzene-sulfonamide, clorsulon has a chemical name of 4-amino-6-trichloroethenyl-1,3-benzenedisulfonamide.

Clorsulon may also be known as MK-401, *Curatrem*®, or *Ivomec*®.

### Storage/Stability

Unless otherwise instructed by the manufacturer, clorsulon should be stored at room temperature (15–30°C).

### Dosage Forms/Regulatory Status

#### VETERINARY APPROVED PRODUCTS:

Clorsulon 8.5% (85 mg/mL) Oral Drench in quarts or gallons; *Curatrem*® (Merial); (OTC). FDA-approved for use in cattle. Slaughter withdrawal = 8 days (when used as labeled); Because a withdrawal time in milk has not been established, do not use in female dairy cattle of breeding age.

Clorsulon 10% (100 mg/mL) and Ivermectin 1% (10 mg/mL) Injection in 50 mL, 200 mL, 500 mL, & 1000 mL. *Ivomec*® Plus (Merial); *Normectin*® Plus (Norbrook); (OTC). FDA-approved for subcutaneous injection use in cattle. Do not use within 49 days of slaughter; do not use in female dairy cattle of breeding age.

**HUMAN APPROVED PRODUCTS:** None

## CLOXACILLIN SODIUM

## CLOXACILLIN BENZATHINE

(klox-a-sill-in) Orbenin-DC®, Dry-Clox®, Dariclox®

ANTI-STAPHYLOCOCCAL PENICILLIN

### Prescriber Highlights

- **Intramammary isoxazolyl (anti-staphylococcal) penicillin**
  - **Contraindicated: Hypersensitivity to penicillins**
  - **Oral dosage forms (human) no longer marketed in USA**
- 

### Uses/Indications

Cloxacillin is used via intramammary infusion in dry and lactating dairy cattle.

### Pharmacology/Actions

Cloxacillin, dicloxacillin and oxacillin have nearly identical spectrums of activity and can be considered therapeutically equivalent when comparing *in vitro* activity. These penicillinase-resistant penicillins have a narrower spectrum of activity than the natural penicillins. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly Staphylococcal species. They are sometimes called anti-staphylococcal penicillins. There are documented strains of Staphylococci that are resistant to these drugs (so-called methicillin-resistant Staph), but these strains have not yet become a major problem in veterinary species. While this class of penicillins does have activity against some other gram-positive and gram-negative aerobes and anaerobes, other antibiotics (penicillins and otherwise) are usually better choices. The penicillinase-resistant penicillins are inactive against *Rickettsia*, mycobacteria, fungi, Mycoplasma, and viruses.

### Pharmacokinetics

Cloxacillin is only available in intramammary dosage forms in the USA.

### Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (*e.g.*, cephalosporins, cefamycins, carbapenems).

### Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that 1–15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

### Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs. However, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

## Overdosage/Acute Toxicity

Overdosage of intramammary infusions is unlikely to pose much risk to the patient, but may prolong withdrawal times.

## Drug Interactions

- No significant interactions are likely when intramammary dosage forms are used as labeled.

## Laboratory Considerations

- No specific concerns noted

## Doses

**Note:** Oral dosage forms are no longer available commercially in the USA—see Dicloxacillin for oral use

### ■ DOGS:

For susceptible infections:

- a) 20–40 mg/kg PO q8h (Vaden & Papich 1995)
- b) For Staph. pyoderma, diskospondylitis, osteoarthritis or skin infections: 10–15 mg/kg PO q6h for 14–84 days
- c) For systemic infections, bacteremia: 10–40 mg/kg PO q6–8h for 7–14 days (Greene & Watson 1998)

### ■ CATS:

For susceptible infections:

- a) 20–40 mg/kg PO or IM q6–8h (Papich 1988)
- b) For Staph. pyoderma, diskospondylitis, osteoarthritis or skin infections: 10–15 mg/kg PO q6h for 14–84 days
- c) For systemic infections, bacteremia: 10–40 mg/kg PO q6–8h for 7–14 days (Greene & Watson 1998)

### ■ CATTLE:

For mastitis (treatment or prophylaxis) caused by susceptible organisms:

- a) Lactating cow (using lactating cow formula; *Dari-Clox*®): After milking out and disinfecting teat, instill contents of syringe; massage. Repeat q12h for 3 total doses.

Dry (non-lactating) cows (using dry cow formula; benzathine): After last milking (or early in the dry period), instill contents of syringe and massage into each quarter. (Package inserts; *Dari-Clox*®, *Orbenin-DC*®—Beecham; *Dri-Clox*®—Fort Dodge)

## Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

## Client Information

- Dry cow products (benzathine; *Orbenin-DC*®, *Dry-Clox*®) slaughter withdrawal = 28–30 days (depending on product used)
- Lactating cow product (*Dariclox*®) withdrawal times when used as labeled; milk withdrawal = 48 hours; slaughter withdrawal = 10 days

## Chemistry/Synonyms

An isoxazoly-penicillin, cloxacillin sodium is a semisynthetic, penicillinase-resistant penicillin. It is available commercially as the monohydrate sodium salt that occurs as an odorless, bitter-tasting, white, crystalline powder. It is freely soluble in water and soluble in alcohol and has a pKa of 2.7. One mg of cloxacillin sodium contains not less than 825 micrograms of cloxacillin.

Cloxacillin benzathine occurs as white or almost white powder that is slightly soluble in water and alcohol. A 1% (10 mg/mL) suspension has a pH from 3–6.5.

Cloxacillin sodium may also be known as: BRL-1621, sodium cloxacillin, chlorphenylmethyl isoxazoly penicillin sodium, methylchlorophenyl isoxazoly penicillin sodium, cloxacilina sodica, cloxacillinum natrium, or P-25; many trade names are available.

## Storage/Stability

Unless otherwise instructed by the manufacturer, cloxacillin benzathine or cloxacillin sodium mastitis syringes should be stored at temperatures less than 25°C in tight containers.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Cloxacillin Benzathine 500 mg (of cloxacillin) in a peanut-oil gel; 10 mL syringe for intramammary infusion: *Orbenin-DC*® (Schering-Plough), *Dry-Clox*® (BIVI), *Boviclox*® (Norbrook); (Rx). FDA-approved for use in dairy cows during the dry period (immediately after last milking or early in the dry period). Do not use *Dry-Clox*® or *Boviclox*® within 30 days prior to calving; (28 days for *Orbenin-DC*®). Slaughter withdrawal for *Dry-Clox*® = 30 days; *Orbenin-DC* = 28 days; *Boviclox*® = 72 hours for milk and meat. A tolerance of 0.01 ppm has been established for negligible residues in uncooked edible meat and milk from cattle.

Cloxacillin Sodium 200 mg (of cloxacillin) in vegetable oils; 10 mL syringe for intramammary infusion: *Dariclox*® (Schering-Plough); (Rx). FDA-approved for use in lactating dairy cows. When used as labeled, Milk withdrawal = 48 hours; Slaughter withdrawal = 10 days.

**HUMAN-LABELED PRODUCTS:** None

## CODEINE PHOSPHATE

## CODEINE SULFATE

(koe-deen)

OPIATE

### Prescriber Highlights

- Opiate used for analgesia, cough, & sometimes diarrhea in dogs & cats
  - **Contraindications:** Hypersensitivity to narcotics, receiving MAOI's (amitraz, selegiline?), or diarrhea caused by a toxic ingestion until the toxin is eliminated
  - **Conditions where narcotics must be used with caution:** Hypothyroidism, severe renal insufficiency, Addison's, head injuries or increased intracranial pressure, or acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions; in geriatric or severely debilitated patients; use extreme caution in patients with respiratory disease or acute respiratory dysfunction
  - **Adverse Effects most likely noted include:** Sedation, constipation, high doses may cause respiratory depression. Cats may also show CNS stimulation.
  - **Controlled Substance (Class-II when used as a sole agent)**
- 

### Uses/Indications

In small animal medicine, codeine is used principally as an oral analgesic when salicylates are not effective and parenteral opiates are not warranted. It may also be useful as an antitussive or an antidiarrheal.

### Pharmacology/Actions

Codeine possesses activity similar to other opiate agonists. It is an effective antitussive and a mild analgesic. It produces similar respiratory depression, as does morphine at equianalgesic dosages. For further information on opiate pharmacology, refer to: Opiate Agonists, Pharmacology.

### Pharmacokinetics

Very limited information is available for domestic animals. It has been stated that in dogs there is only limited evidence of oral absorption of codeine (Papich 2009). The following information is human data unless otherwise noted. After oral administration, codeine salts are rapidly absorbed. Codeine is about 2/3's as effective after oral administration when compared with parenteral administration. After oral dosing, onset of action is usually within 30 minutes and analgesic effects persist for 4–6 hours. Codeine is metabolized in the liver and then excreted into the urine.

### Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's disease), and in geriatric or severely debilitated patients. Codeine is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, or in patients taking monamine oxidase inhibitors (MAOIs). It is also contraindicated in patients with diarrhea caused by a toxic ingestion (until the toxin is eliminated from the GI tract) or when used repeatedly in patients with severe inflammatory bowel disease.

Codeine should be used with caution in patients with head injuries or increased intracranial pressure, and in those with acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. Use with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Opiate analgesics are contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus Ewing* and *C. gertschi Stahnke* as they may potentiate these venoms.

Do not use the combination product containing acetaminophen in cats.

### Adverse Effects

Codeine generally is well tolerated, but adverse effects are possible, particularly at higher dosages or with repeated use. Sedation is the most likely effect seen. Potential gastrointestinal effects include anorexia, vomiting, constipation, ileus, and biliary and pancreatic duct spasms. Respiratory depression is generally not noted unless the patient receives high doses or is at risk (see contraindications above).

In cats, opiates may cause CNS stimulation with hyperexcitability, tremors, and seizures are possible.

### Reproductive/Nursing Safety

Opiates cross the placenta. Very high doses in mice have caused delayed ossification. Use during pregnancy only when the benefits outweigh the risks, particularly with chronic use. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Although codeine enters maternal milk, no documented problems have been associated with its use in nursing mothers.

### Overdosage/Acute Toxicity

Opiate overdosage may produce profound respiratory and/or CNS depression in most species. Other effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Oral ingestions of codeine should be removed when possible using standard gut removal protocols. Because rapid changes in CNS status may occur, inducing vomiting should be attempted with caution. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated and animals should be closely observed because naloxone's effects may diminish before subtoxic levels of codeine are attained. Mechanical respiratory support should also be considered in cases of severe respiratory depression. Serious overdoses involving any of the opiates should be closely monitored; it is suggested to contact an animal poison control center for further information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving codeine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC DRUGS:** Use with codeine may increase the chances of constipation developing
- **ANTIDEPRESSANTS (tricyclic/monoamine oxidase inhibitors):** May potentiate CNS depressant effects
- **CNS DEPRESSANTS, OTHER (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.):** May cause increased CNS or respiratory depression when used with codeine
- **QUINIDINE:** May inhibit the transformation of codeine to morphine in the liver thereby decreasing its efficacy

## Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

## Doses

### ■ DOGS:

As an antitussive:

- 1–2 mg/kg PO q6–12h (Fenner 1994)
- Starting doses have been as low as 0.1–0.3 mg/kg PO q8–12h and as high as 1–2 mg/kg PO q6–12h. Whatever the starting point, the dose may need to be increased to achieve a satisfactory effective. (Church 2003)

As an analgesic:

- For mild to moderate acute pain: 0.5–2 mg/kg PO titrated to effect q6–12h. May use for chronic pain at lowest effective dose (Mathews 2000)
- In combination with acetaminophen: Using a 60 mg codeine and 300 mg acetaminophen fixed-dose tablet (e.g., *Tylenol*® #4), give 1–2 mg/kg (of the codeine) PO q6–8h. Using codeine alone: 1–4 mg/kg PO q1–6 hours (Hansen 1994); (Hardie 2000) **Note:** Do not use in cats.
- 0.5–1 mg/kg PO q4–6h (Gaynor 2008)

As an antidiarrheal:

- 0.25–0.5 mg/kg PO q6–8h (Sherding & Johnson 1994)

### ■ CATS:

**Note:** Do **NOT** use the combination product containing acetaminophen

As an analgesic:

- For mild to moderate acute pain: 0.5–2 mg/kg PO titrated to effect q6–12h. May use for chronic pain at lowest effective dose (Mathews 2000)
- 0.5–2 mg/kg PO q6–8h (Scherk 2003)
- 0.5 mg/kg PO q6h (Gaynor 2008)

### ■ RABBITS:

Using acetaminophen and codeine elixir:

- 1 mL in 10–20 mL of drinking water (add dextrose to enhance palatability) (Ivey & Morrisey 2000)

## Monitoring

- Efficacy
- Adverse effects (see above)

## Client Information

- Keep out of reach of children
- Do not use any product containing acetaminophen (e.g., *Tylenol* #3) in cats
- Report any significant changes in behavior or activity level, or GI effects (constipation, lack of appetite, vomiting) to veterinarian

## Chemistry/Synonyms

A phenanthrene-derivative opiate agonist, codeine is available as the base and three separate salts. Codeine base is slightly soluble in water and freely soluble in alcohol. Codeine phosphate occurs as fine, white, needle-like crystals or white, crystalline powder. It is freely soluble in water. Codeine sulfate's appearance resembles codeine phosphate, but it is soluble in water.

Codeine phosphate may also be known as: codeine phosphate hemihydrate, codeini phosphas; codeini phosphas hemihydricus, or codeinii phosphas; many trade names are available.

## Storage/Stability

Codeine phosphate and sulfate tablets should be stored in light-resistant, well-closed containers at room temperature. Codeine phosphate injection should be stored at room temperature (avoid freezing) and protected from light. Do not use the injection if it is discolored or contains a precipitate.

## Compatibility/Compounding Considerations

Codeine phosphate injection is reportedly **compatible** with glycopyrrolate or hydroxyzine HCl. It is reportedly **incompatible** with aminophylline, ammonium chloride, amobarbital sodium, chlorothiazide sodium, heparin sodium, methicillin sodium, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, secobarbital sodium, sodium bicarbonate, sodium iodide, and thiopental sodium.

## Dosage Forms/Regulatory Status

## TERMINARY-LABELED PRODUCTS: None.

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

There are many products available containing codeine. The following is a partial listing:

Codeine Phosphate Solution: 15 mg/5 mL in 500 mL & UD 5 mL; Codeine Phosphate (Roxane); (Rx, C-II)

Codeine Sulfate Tablets: 15 mg, 30 mg & 60 mg; generic; (Rx, C-II)

Codeine Phosphate Parenteral Injection: 15 mg/mL & 30 mg/mL in 2 mL *Carpject* syringe; generic; (Rx, C-II)

Codeine Phosphate Antitussives with expectorants: 10 mg codeine phosphate and 200 mg guaifenesin; 10 mg codeine phosphate and 100 mg guaifenesin; Many different trade names available; (C-V; C-III; certain states may restrict at a higher level; OTC or Rx)

Codeine Phosphate 7.5 mg (#1), 15 mg (#2), 30 mg (#3), 60 mg (#4) with Acetaminophen 300 mg tablets; *Tylenol® with Codeine #'s 1, 2, 3, 4* (McNeil); generic; (Rx, C-III) **Warning:** Do not use in cats.

Codeine Phosphate 15 mg (#2), 30 mg (#3), 60 mg (#4) with Aspirin 320 mg tablets; *Empirin® with Codeine #'s 2, 3, 4* (Glaxo Wellcome); generic; (Rx, C-III)

**Note:** Codeine-only products are Class-II controlled substances. Combination products with aspirin or acetaminophen are Class-III. Codeine containing cough syrups are either Class-V or Class-III, depending on the state.

## COLCHICINE

(kol-chi-seen)

ANTIINFLAMMATORY

Prescriber Highlights

- **Unique antiinflammatory occasionally used in dogs for hepatic cirrhosis/fibrosis; relatively experimental**
- **Contraindications: Serious renal, GI, or cardiac dysfunction**
- **Caution: Geriatric or debilitated patients**
- **Teratogenic, reduces spermatogenesis**
- **Most likely adverse effects are GI distress (may be an early sign of toxicity), but several serious effects are possible including bone marrow suppression**

---

## Uses/Indications

In veterinary medicine, colchicine has been proposed as a treatment in small animals for amyloidosis. For colchicine to be effective, however, it must be given early in the course of the disease and it will be ineffective once renal failure has occurred. At the time of writing, no conclusive evidence exists for its efficacy for this indication in dogs.

Colchicine has also been proposed for treating chronic hepatic fibrosis presumably by decreasing the formation and increasing the breakdown of collagen, but its efficacy is in question

A case report (Brown *et al.* 2008) using colchicine to treat endotracheal stent granulation stenosis in a dog has been published and the drug may find a place in therapy for this indication after further investigation.

## Pharmacology/Actions

Colchicine inhibits cell division during metaphase by interfering with sol-gel formation and the mitotic spindle. The mechanism for its antifibrotic activity is believed secondary to collagenases activity stimulation.

Colchicine apparently blocks the synthesis and secretion of serum amyloid A (SAA; an acute-phase reactant protein) by hepatocytes thereby preventing the formation of amyloid-enhancing factor and preventing amyloid disposition.

Colchicine is best known in human medicine for its antigout activity. The mechanism for this effect is not fully understood, but it probably is related to the drug's ability to reduce the inflammatory response to the disposition of monosodium urate crystals.

## Pharmacokinetics

No information was located specifically for domestic animals; the following information is human/lab animal data unless otherwise noted. After oral administration, colchicine is absorbed from the GI tract. Some of the absorbed drug is metabolized in the liver (first-pass effect). These metabolites and unchanged drug are re-secreted into the GI tract via biliary secretions where it is reabsorbed. This "recycling" phenomena may explain the intestinal manifestations noted with colchicine toxicity. Colchicine is distributed into several tissues, but is concentrated in leukocytes. Plasma half-life is about 20 minutes, but leukocyte half-life is approximately 60 hours. Colchicine is deacetylated in the liver and metabolized in other tissues. While most of a dose (as colchicine and metabolites) is excreted in the feces, some is excreted in the urine. More may be excreted in the urine in patients with hepatic disease. Patients with severe renal disease may have prolonged half-lives.

## Contraindications/Precautions/Warnings

Colchicine is contraindicated in patients with serious renal, GI, or cardiac dysfunction and should be used with caution in patients in early stages of these disorders. It should also be used with caution in geriatric or debilitated patients.

Colchicine use in veterinary medicine is somewhat controversial as safety and efficacy have not been well documented.

## Adverse Effects

There has been little experience with colchicine in domestic animals. There are reports that colchicine can cause nausea, vomiting, and diarrhea in dogs, but these are thought to occur infrequently at doses used. Neutropenia is a rare adverse effect.

In humans, GI effects have been noted (abdominal pain, anorexia, vomiting, diarrhea) and can be an early indication of toxicity; it is recommended to discontinue therapy (in humans) should these occur. Prolonged administration has caused bone marrow depression. Severe local irritation has been noted if extravasation occurs after intravenous administration; thrombophlebitis has also been reported.

## Reproductive/Nursing Safety

Because colchicine has been demonstrated to be teratogenic in laboratory animals (mice and hamsters) it should be used during pregnancy only when its potential benefits outweigh its risks. Colchicine may decrease spermatogenesis. In humans, the FDA categorizes this drug as category **C** (ORAL) for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In humans, the FDA categorizes this drug as category **D** (PARENTERAL) for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown if colchicine enters maternal milk; use cautiously in nursing mothers.

## Overdosage/Acute Toxicity

Colchicine can be a very toxic drug after relatively small overdoses. Deaths in humans have been reported with a single oral ingestion of as little as 7 mg, but 65 mg is considered the lethal dose in an adult human. GI manifestations are usually the presenting signs seen. These can range from anorexia and vomiting to bloody diarrhea or paralytic ileus. Renal failure, hepatotoxicity, pancytopenia, paralysis, shock, and vascular collapse may also occur.

There is no specific antidote to colchicine. Gut removal techniques should be employed when applicable. Because of the extensive GI “recycling” of the drug, repeated doses of activated charcoal and a saline cathartic may reduce systemic absorption. Other treatment is symptomatic and supportive. Dialysis (peritoneal) may be of benefit.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving colchicine and may be of significance in veterinary patients:

■ **BONE MARROW DEPRESSANT MEDICATIONS** (*e.g.*, antineoplastics, immunosuppressants, chloramphenicol, amphotericin B): May cause additive myelosuppression when used with colchicine

## Laboratory Considerations

- Colchicine may cause false-positive results when testing for **erythrocytes or hemoglobin in urine**.
- Colchicine may interfere with **17-hydroxycorticosteroid** determinations in urine if using the Reddy, Jenkins, and Thorn procedure.
- Colchicine may cause increased serum values of **alkaline phosphatase**.

## Doses

Colchicine may have some efficacy in the treatment of amyloidosis, but veterinary dosages are apparently unavailable at this time.

### ■ DOGS:

For the adjunctive treatment of hepatic cirrhosis/fibrosis:

- a) 0.03 mg/kg PO once daily (Leveille-Webster & Center 1995); (Twedt 1999); (Richter 2002); (Willard 2006)
- b) 0.025–0.03 mg/kg PO once daily (probenecid-free drug). Not recommended for initial use with azathioprine, chlorambucil or methotrexate due to similar side effects (GI toxicity, bone marrow suppression). Used in many dogs and fewer cats without problems. (Center 2002), (Center 2006)

For amyloidosis:

- a) For periodic fever syndrome in Shar Pei dogs: 0.03 mg/kg PO once daily. (Scherk & Center 2005)
- b) To reduce the frequency and severity of fever and prevent the development of amyloidosis in dogs with Shar Pei Fever: 0.025–0.03 mg/kg PO q24h; no evidence supports use of colchicine once amyloidosis has resulted in renal failure (Vaden 2006)

### ■ BIRDS:

As an antifibrotic for the adjunctive treatment of hepatic fibrosis:

- a) Psittacines: 0.2 mg/kg PO q12h. May potentiate gout in some cases. (Carpenter 2005), (Oglesbee 2009)

## Monitoring

- Efficacy
- Adverse effects (see above)
- CBC

## Client Information

- Clients should be informed of the “investigational” nature of colchicine use in dogs and should be informed of the potential adverse effects that may be seen
- Report changes in appetite or other GI effects immediately to veterinarian
- Keep well out of reach of children or pets

## Chemistry/Synonyms

An antigout drug possessing many other pharmacologic effects, colchicine occurs as a pale yellow, amorphous powder or scales. It is soluble in water and freely soluble in alcohol.

Colchicine may also be known as: colchicinum, *Artrex*®, *Colchily*®, *Colchicquim*®, *Colchis*®, *Colcine*®, *Colgout*®, *Goutichine*®, *Goutnil*®, *Reugot*®, *Ticolcin*®, or *Tolchicine*®.

## Storage/Stability

Colchicine tablets should be stored in tight, light resistant containers. The injection should be diluted only in 0.9% sodium chloride for injection or sterile water for injection. Do not use D5W or bacteriostatic sodium chloride for injection as precipitation may occur. Do not use solutions that have become turbid.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Colchicine Oral Tablets: 0.6 mg (1/100 gr); *Colcrys*® (AR Scientific); generic; (Rx);

A combination oral product (tablets) containing colchicine 0.5 mg and probenecid 500 mg is also available (not likely to be useful in veterinary patients)

---

## CORTICOTROPIN (ACTH)

(kor-ti-koe-troe-pin) Acthar®

HORMONAL DIAGNOSTIC AGENT

### Prescriber Highlights

- **Stimulates cortisol release; used primarily to test for hyper- or hypoadrenocorticism (ACTH-stimulation test); use as a screening test for naturally occurring “Cushing’s” is becoming less popular than in the past. Also used to test for iatrogenic Cushing’s and to monitor therapy when treating with anti-adrenal drugs.**
- **Adverse Effects: Unlikely unless using chronically**
- **Do not administer gel form IV**
- **Issues include availability & expense; may need to obtain via a compounding pharmacy. Many have switched to using cosyntropine.**

---

## Uses/Indications

Availability of corticotropin in FDA-approved products is an issue as no commercially products were commercially available for veterinary use at the time writing and either [cosyntropin](#) (see monograph) or compounded ACTH products are required.

In veterinary medicine, an ACTH product (*Adrenomone*®—Summit Hill) was FDA-approved for use in dogs, cats, and beef or dairy cattle for stimulation of the adrenal cortex when there is a deficiency of ACTH and as a therapeutic agent in primary bovine ketosis, but apparently is no longer commercially available. In practice, ACTH tends to be used most often in the diagnosis of hypoadrenocorticism (ACTH-stimulation test), iatrogenic Cushing’s syndrome, and to monitor the response to mitotane or trilostane therapy in Cushing’s syndrome. It is less often recommended as a screening test for naturally occurring “Cushing’s” syndrome in dogs as the test is relatively insensitive.

One reference (Behrend 2003) recommends using the ACTH stimulation test if the dog has non-adrenal illness, received any form of exogenous glucocorticoids (including topicals), or received phenobarbital. If the dog has no known non-adrenal illness and moderate to severe clinical signs of hyperadrenocorticism, use the low-dose dexamethasone suppression test. If using the ACTH-stim test, the author states that cosyntropin is the agent of choice (see that monograph). ACTH has been used for several purposes in human medicine for its corticosteroid stimulating properties, but as it must be injected, it is not commonly employed in veterinary patients.

## Pharmacology/Actions

ACTH stimulates the adrenal cortex (principally the zona fasciculata) to stimulate the production and release of glucocorticoids (primarily cortisol in mammals and corticosterone in birds). ACTH release is controlled by corticotropin-releasing factor (CRF) activated in the central nervous system and via a negative feedback pathway, whereby either endogenous or exogenous glucocorticoids suppresses ACTH release.

## Pharmacokinetics

Because it is rapidly degraded by proteolytic enzymes in the gut, ACTH cannot be administered PO. It is not effective if administered topically to the skin or eye.

After IM injection in humans, repository corticotropin injection is absorbed over 8–16 hours. The elimination half-life of circulating ACTH is about 15 minutes but because of the slow absorption after IM injection of the gel, effects may persist up to 24 hours.

### Contraindications/Precautions/Warnings

When used for diagnostic purposes, it is unlikely that increases in serum cortisol levels induced by ACTH will have significant deleterious effects on conditions where increased cortisol levels are contraindicated (*e.g.*, systemic fungal infections, osteoporosis, peptic ulcer disease, etc.). ACTH gel should not be used in patients hypersensitive to porcine proteins.

### Adverse Effects

Prolonged use may result in fluid and electrolyte disturbances and other adverse effects; if using on a chronic basis, refer to the human literature for an extensive listing of potential adverse reactions. The veterinary manufacturer suggests giving potassium supplementation with chronic therapy.

Do not administer the repository form (gel) IV.

### Reproductive/Nursing Safety

ACTH should only be used during pregnancy when the potential benefits outweigh the risks. It may be embryocidal. Neonates born from mothers receiving ACTH should be observed for signs of adrenocortical insufficiency. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

When used for diagnostic purposes, acute inadvertent overdoses are unlikely to cause any significant adverse effects. Monitor as required and treat symptomatically if necessary.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving corticotropin for diagnostic purposes and may be of significance in veterinary patients:

■ **ANTICHOLINESTERASES** (*e.g.*, **pyridostigmine**): ACTH may antagonize effects in patients with myasthenia gravis

■ **DIURETICS**: ACTH may increase electrolyte loss

### Laboratory Considerations

■ Patients should not receive **hydrocortisone** or **cortisone** on test day

■ ACTH may decrease **<sup>131</sup>I uptake** by the thyroid gland

■ ACTH may suppress **skin test reactions**

■ ACTH may interfere with **urinary estrogen** determinations

■ Obtain specific information from the laboratory on sample handling and laboratory normals for cortisol when doing ACTH stimulation tests

### Doses

**Note:** When using compounded ACTH products, it is recommended to get several post-ACTH samples, at a minimum one and two hours following injection. (Behrend 2005)

#### ■ DOGS:

ACTH Stimulation Test:

a) Draw baseline blood sample for cortisol determination and administer 2.2 Units/kg of ACTH gel IM. Draw sample 120 minutes after injection. (Feldman & Peterson 1984), (Kemppainen & Zerbe 1989)

b) Draw baseline blood sample for cortisol determination and administer 0.5 Units/kg of ACTH gel IM. Draw sample 120 minutes after injection.

Normals: Pre-ACTH 1.1–8 micrograms/dL; Post-ACTH 6.2–16.8 micrograms/dL. Hyperadrenocorticism: Pre-ACTH 4–10.8 micrograms/dL; Post-ACTH 11.7–50 micrograms/dL.

Hypoadrenocorticism: Pre-ACTH and Post-ACTH: ≤ 1 microgram/dL (Morgan 1988)

#### ■ CATS:

ACTH Stimulation Test:

a) Draw baseline blood sample for cortisol determination and administer 2.2 Units/kg of ACTH gel IM. Draw samples at 60 minutes and 120 minutes after injection. (Kemppainen & Zerbe 1989)

b) Draw baseline blood sample for cortisol determination and administer 0.5 Units/kg of ACTH gel IM. Draw sample 120 minutes after injection.

Normals: Pre-ACTH 0.33–2.6 micrograms/dL; Post-ACTH 4.8–7.6 micrograms/dL. Hyperadrenocorticism: Pre-ACTH 4–10.8 micrograms/dL; Post-ACTH 11.7–50 micrograms/dL.

Hypoadrenocorticism: Pre-ACTH and Post-ACTH: ≤ 1 microgram/dL (Morgan 1988)

#### ■ CATTLE:

For ACTH deficiency or for primary bovine ketosis:

a) 200–600 Units initially followed by daily or semi-daily dose of 200–300 Units (Package Insert; *Adrenomone*®—Summit Hill)

#### ■ HORSES:

ACTH Stimulation Test:

a) Draw baseline blood sample for cortisol determination and administer 1 Unit/kg IM of ACTH gel. Draw second sample 8 hours later. Normal stimulation will result in serum cortisol levels will increase 2–3 times. Horses with pituitary tumors will increase cortisol fourfold after ACTH. (Beech 1987)

b) Obtain pre-dose level. Administer 1 Unit/kg IM of ACTH gel between 8 and 10 AM; take post ACTH cortisol levels at 2 and 4 hours post dose. Horses with

functional adrenal gland should have a 2- to 3-fold increase in plasma cortisol when compared with baseline. (Toribio 2004)

## ■BIRDS:

ACTH Stimulation Test:

a) Draw baseline blood sample for corticosterone (not cortisol) determination and administer 16–25 Units IM. Draw second sample 1–2 hours later. Normal baseline corticosterone levels vary with regard to species, but generally range from 1.5–7 ng/mL. After ACTH, corticosterone levels generally increase by 5–10 times those of baseline. Specific values are listed in the reference. (Lothrop & Harrison 1986)

## Chemistry/Synonyms

A 39 amino acid polypeptide, corticotropin is secreted from the anterior pituitary. The first 24 amino acids (from the N-terminal end of the chain) define its biologic activity. While human, sheep, cattle and swine corticotropin have different structures, the first 24 amino acids are the same and, therefore, biologic activity is thought to be identical. Commercial sources of ACTH have generally been obtained from porcine pituitaries. One USP unit of corticotropin is equivalent to 1 mg of the international standard.

Corticotropin may also be known as: ACTH, adrenocorticotrophic hormone, adrenocorticotrophin, corticotrophin, corticotropinum, *Acethropan*®, *Acortan simplex*®, *Actharn*®, *Acthelea*®, *Acton prolongatum*®, *H.P. Acthar*® or *Cortrophin-Zinc*®.

## Storage/Stability

Corticotropin in the past has been available commercially as corticotropin for injection, repository corticotropin for injection, and corticotropin zinc hydroxide suspension. Corticotropin is commonly called ACTH (abbreviated from adrenocorticotrophic hormone). Repository corticotropin is often called ACTH gel and is the most commonly used ACTH product in veterinary medicine.

Corticotropin for injection (aqueous) can be stored at room temperature (15–30°C) before reconstitution. After reconstitution, it should be refrigerated and used within 24 hours. Repository corticotropin injection should be stored in the refrigerator (2–8°C). To allow ease in withdrawing the gel into a syringe, the vial may be warmed with warm water prior to use.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

Compounded ACTH products may be available from compounding pharmacies.

**HUMAN-LABELED PRODUCTS:**

Corticotropin Repository Injection: 80 Units/mL in 5 mL multi-dose vials; *H.P. Acthar*® *Gel* (Questcor); (Rx) **Note:** This product is only available through a specialty pharmacy distribution system and is not available via regular retail pharmacies or drug wholesalers.

## CORTISONE ACETATE

(kor-ti-zone ass-ah-tate)

ADRENAL CORTICOSTEROID

### Prescriber Highlights

- **Oral glucocorticoid with both glucocorticoid and mineralocorticoid effects; may be a lower drug cost way to manage Addison’s by reducing dosage requirements for mineralocorticoid drugs**
- **Not commonly used in veterinary medicine; whether it has any clinically significant benefit in dogs over oral prednis(ol)one is controversial**
- **Typical cautions and adverse effects associated with other corticosteroid drugs if used at supra-physiologic replacement doses; otherwise should be very well tolerated**
- **Relatively inexpensive**

---

## Uses/Indications

Cortisone acetate potentially could be an alternative to prednis(ol)one for the oral treatment of hypoadrenocorticism in dogs. *In vivo* it is rapidly converted to cortisol and thereby could serve as a total replacement for both glucocorticoid and mineralocorticoid effects. Whether cortisone acetate is any more effective than prednis(ol)one for long-term treatment in dogs is controversial as some believe that any benefit the increased mineralocorticoid activity cortisone acetate has is clinically insignificant.

## Pharmacology/Actions

Cortisone/cortisol has effects on practically every body system. For a more complete description refer to the Hydrocortisone monograph.

## Pharmacokinetics

Like other glucocorticoids, cortisone acetate’s pharmacokinetics do not correlate with its pharmacodynamic activity. Cortisol acetate is absorbed and converted to

cortisol *in vivo*. Oral bioavailability in humans ranges widely, but is approximately 50%.

### Contraindications/Precautions/Warnings

When used for physiologic replacement in dogs with hypoadrenocorticism, cortisone acetate is contraindicated if the patient is hypersensitive to it. If used at supra-physiologic dosages, the typical contraindications and warnings for drugs like prednisone should be followed. See that monograph for more information.

### Adverse Effects

When used for physiologic replacement in dogs with hypoadrenocorticism, cortisone acetate should be very well tolerated. Potentially, GI effects (vomiting, inappetence, diarrhea) could occur and hypersensitivity reactions are theoretically possible. If used at supra-physiologic dosages, the typical adverse effect profile for drugs like prednisone is possible. See the prednisone monograph for more information.

### Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreatic, and mammary development. However, excessive dosages early in pregnancy may lead to teratogenic effects. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

### Overdosage/Acute Toxicity

Acute ingestion is rarely a clinical problem and clinical effects are unlikely with acute overdose. However, neuropsychiatric effects can occur; cardiac arrhythmias and anaphylaxis are possible, but very rare.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrocortisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia; in humans, there have been cases of CHF and cardiac enlargement reported after using hydrocortisone to treat Amphotericin B adverse effects
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels and increase risk for GI ulceration/bleeding
- **DIURETICS, POTASSIUM-DEPLETING (e.g., spironolactone, triamterene):** Administered concomitantly with glucocorticoids may cause hypokalemia
- **ESTROGENS:** The effects of hydrocortisone and, possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN; ANTIDIABETIC AGENTS:** Insulin requirements may increase in patients receiving glucocorticoids
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **POTASSIUM-DEPLETING DRUGS (e.g., amphotericin B, furosemide, thiazides):** Administered concomitantly with glucocorticoids may cause hypokalemia
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids
- **WARFARIN:** Hydrocortisone may affect INR's; monitor

### Laboratory Considerations

- Cortisone can cross react with cortisol in ACTH response test. This test must be performed before cortisone is administered. (**Note:** Dexamethasone does not cross react)
- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of **thyroid stimulating hormone (TSH)** and reduce **T<sub>3</sub> & T<sub>4</sub>** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of **I131** by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

### Doses

#### ■ DOGS:

For long-term treatment of hypoadrenocorticism:

a) In the changeover period as animals recover from an acute crisis, start eating and drinking and are changed from parenteral to oral medication, traditionally a semi-selective mineralocorticoid (fludrocortisone) and a semi-selective glucocorticoid (cortisone acetate or prednisolone) are initially used together. The former is discontinued in a proportion of patients after one to two months. When using cortisone acetate most hypoadrenocorticoid dogs are started on a dose of 0.5–1 mg/kg PO q12-24h. Once stable, generally a dose of 0.5 mg/kg PO q12-24h provides adequate additional glucocorticoid supplementation. Some clinicians advocate prednisolone use as a glucocorticoid supplement in the long-term management of hypoadrenocorticism, but in the author's opinion cortisone acetate is a more effective alternative. (Church 2008), (Church 2009)

## Client Information

- Adherence to the prescribed dose and dosage schedule should be stressed and clients should not discontinue the drug abruptly without consulting with the veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with this drug.

## Monitoring

Monitoring of cortisone therapy is dependent on its reason for use, dosage, adjunctive mineralocorticoid therapy, dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

## Chemistry/Synonyms

Cortisone acetate is synthetic acetate ester of cortisone. It occurs as a white or practically white, odorless, crystalline powder. It is insoluble in water and slightly soluble in alcohol.

Cortisone acetate may also be known as acetato de cortisona, compound E acetate, acétate de cortisone, cortisoni acetas, or 11-dehydro-17-hydroxycorticosterone acetate.

## Storage/Stability

Cortisone acetate tablets should be stored in well-closed containers at a temperature less than 40°C, preferably at 15-30°C.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cortisone Acetate Oral Tablets; 25 mg; generic; (Rx)

## COSYNTROPIN

(koh-sin-troh-pin) Cortrosyn®, Synacthen®

HORMONAL DIAGNOSTIC AGENT

### Prescriber Highlights

- **Alternative to ACTH for adrenal function tests**
  - **Drug-lab interactions**
  - **Availability & expense have been issues**
- 

## Uses/Indications

Cosyntropin is used primarily as an alternative to ACTH to test for adrenocortical insufficiency (Addison's), or hyperadrenocorticism, particularly in animals who have reacted immunologically to corticotropin in the past or if ACTH gel is unavailable. In addition to its use to diagnose hypoadrenocorticism, the ACTH stimulation test is used to help diagnose iatrogenic Cushing's syndrome, and to monitor the response to mitotane or trilostane therapy in Cushing's syndrome. It is less often recommended as a screening test for naturally occurring "Cushing's" syndrome dogs as the test is relatively insensitive.

## Pharmacology/Actions

Like endogenous corticotropin, cosyntropin stimulates the adrenal cortex (in normal patients) to secrete cortisol, corticosterone, etc. Because of its structure, corticotropin is not as immunogenic as endogenous corticotropin. Apparently, the bulk of immunogenicity resides in the C-terminal portion of corticotropin (22–39 amino acids) and cosyntropin ends after amino acid #24.

## Pharmacokinetics

Cosyntropin must be given parenterally because it is inactivated by gut enzymes. It is rapidly absorbed after being given IM. After giving IM or rapid IV, plasma cortisol levels reach their peak within an hour. It is unknown how cosyntropin is inactivated or eliminated.

## Contraindications/Precautions/Warnings

Contraindicated in patients with known hypersensitivity to cosyntropin. Use caution in patients who have shown hypersensitive reactions to ACTH in the past; there is

Contraindicated in patients with known hypersensitivity to cosyntropin. Use caution in patients who have shown hypersensitive reactions to ACTH in the past, there is a distinct possibility that cross-reactivity could occur.

## Adverse Effects

When used short-term, the only real concern is hypersensitivity reactions.

## Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

Unlikely to be of clinical consequence if used one-time only.

## Laboratory Considerations

- Patients should not receive **hydrocortisone** or **cortisone** on test day; dexamethasone sodium phosphate does not interfere with cortisol assays
- If using a fluorometric analysis: Falsely high values may be observed if the patient is taking **spironolactone**
- Falsely high values may be observed in patients with high **bilirubin** or if free plasma hemoglobin present

## Doses

### ■ DOGS:

For testing (screening) adrenal function:

- a) For tentative diagnosis of Addison's disease: **1)** Draw blood for hemogram, serum biochemistry and basal cortisol; **2)** Begin IV fluids and give 2–5 mg/kg dexamethasone sodium phosphate; **3)** Immediately give 0.25 mg (250 micrograms) of cosyntropin IV or IM; **4)** Draw a second blood sample for plasma cortisol 45–60 minutes later. Blood levels of <1 micrograms/dL are typical for hypoadrenocorticism, while those stimulating to only 2–3 micrograms/dL are also suggestive. (Schaer 2006)
- b) For ACTH Stimulation test: Two different protocols: 1 microgram/kg or 250 micrograms/dog IV or IM with serum cortisol measured before and 1 hour post injection. 80–85% of dogs with pituitary-dependent hyperadrenocorticism (PD) and 60% of dogs with adrenal tumor/hyperplasia (AT) will have an exaggerated response. Unfortunately, just about any other extra-adrenal illness can cause an exaggerated post-ACTH level. (Reine 2006)
- c) Low dose ACTH stimulation test: 0.5 micrograms/kg IV; peak concentrations at 60 minutes after dose with a return to baseline at 240 minutes. (Martin *et al.* 2007)

### ■ CATS:

For testing (screening) adrenal function:

- a) For tentative diagnosis of Addison's disease: **1)** Draw blood for hemogram, serum biochemistry and basal cortisol; **2)** Begin IV fluids and give 2–5 mg/kg dexamethasone sodium phosphate; **3)** Immediately give 0.125 mg of cosyntropin IV or IM; **4)** Draw a second blood sample for plasma cortisol 45–60 minutes later. Blood levels of <1 microgram/dL are typical for hypoadrenocorticism, while those stimulating to only 2–3 micrograms/dL are also suggestive. (Schaer 2006)
- b) 0.125 mg (total dose—125 mcg) IM or IV. Begin test between 8–9 AM; obtain preinjection cortisol level and 30 minutes and 1 hour post. (Feldman 2000)
- c) For diagnosis of hyperadrenocorticism in cats: 125 micrograms/cat IM or IV with cortisol measurements before and at 30 and 60 minutes post. (Reine 2006)
- d) Low dose ACTH stimulation test: 5 micrograms/kg; cortisol concentrations peak at 60 minutes post-dose. (Martin *et al.* 2009)

### ■ HORSES:

For testing (screening) adrenal function:

- a) For relative adrenal insufficiency (RIA) evaluation in critically ill horses: Draw blood for baseline cortisol and give cosyntropin at 0.1 micrograms/kg; cortisol will peak after 30 minutes. (Stewart, A 2006)
- b) Obtain pre-dose level. Administer 1 mg IV of cosyntropin between 8 and 10 AM; take post ACTH cortisol levels at 2 hours post dose. Horses with a functional adrenal gland should have at least a two-fold increase in plasma cortisol when compared with baseline. (Toribio 2004)
- c) **Foals:** 0.5 micrograms/kg IV. Peak cortisol levels occur at 30 minutes post dose. (Stewart, AJ *et al.* 2007)

## Monitoring

- See specific protocols for test procedures

## Chemistry/Synonyms

A synthetic polypeptide that mimics the effects of corticotropin (ACTH), cosyntropin is commercially available as a lyophilized white to off-white powder containing mannitol. Cosyntropin's structure is identical to the first 24 (of 39) amino acids in natural corticotropin. 0.25 mg of cosyntropin is equivalent to 25 Units of corticotropin.

Cosyntropin may also be known as: tetracosactide, alpha(1–24)-corticotrophin, beta(1–24)-corticotrophin, tetracosactido, tetracosactidum, tetracosactrin, tetracosapeptide, *Cortrosina*®, *Cortrosyn*®, *Nuvacthen Depot*®, *Synacthen*®, *Synacthen Depot*®, *Synacthen Retard*®, or *Synacthene*®.

## Storage/Stability

After reconstituting with sterile normal saline, the solution is stable for 24 hours at room temperature; 21 days if refrigerated. Do not add the drug to blood or plasma infusions. One study (Frank and Oliver 1998) showed that cosyntropin can be reconstituted and stored frozen (-20°C) in plastic syringes for up to 6 months and still show biologic activity in the dog. It is recommended to freeze in small aliquots as it is unknown what effect thawing and refreezing has on potency.

## Dosage Forms/Regulatory Status

VETERINARY LABELED PRODUCTS: None

## VETERINARY-LABELED PRODUCTS: None

## HUMAN-LABELED PRODUCTS:

Cosyntropin Powder for Injection: 0.25 mg lyophilized (250 mcg) in single-dose vials with diluent; *Cortrosyn*<sup>®</sup> (Amphastar); (Rx)

Cosyntropin Solution for Injection: 0.25 mg/mL, preservative free in 1 mL single-dose vials; generic (Sandoz); (Rx)

---

## CROMOLYN SODIUM (SYSTEMIC)

(*kroh-mah-lin*) Disodium Cromoglycate, Sodium Cromoglicate, Intal<sup>®</sup>

MAST CELL STABILIZER

For ophthalmic use, see the monograph in the *Ophthalmic Drug Appendix*

### Prescriber Highlights

- **Inhaled mast cell stabilizer that may be useful adjunctive treatment in preventing airway hyper-reactivity in horses with type 2 (high mast cell count in BAL) IAD or with RAO (heaves)**
- **Not for treatment of acute bronchoconstriction; used as a preventative agent**
- **May take several days or weeks for efficacy**

---

## Uses/Indications

Cromolyn sodium is a mast cell stabilizer that may be useful in reducing airway hyper-reactivity in horses with type 2 (high mast cell count in bronchoalveolar lavage fluid; mast cells of >2% of the total cell count) inflammatory airway disease (IAD) or with recurrent airway obstruction (RAO; heaves). Use of this agent is somewhat controversial; studies have yielded conflicting efficacy results.

## Pharmacology/Actions

Cromolyn inhibits the release of histamine and leukotrienes from sensitized mast cells found in lung mucosa, nasal mucosa and eyes. Its exact mechanism of activity is not understood, but it is thought to be a result from blocking indirect entry of calcium ions into cells. Other effects of cromolyn include inhibiting neuronal reflexes in the lung, inhibiting bronchospasm secondary to tachykins, inhibiting the movement of other inflammatory cells (neutrophils, monocytes, eosinophils), and preventing the down-regulation of beta-2 adrenergic receptors on lymphocytes. Cromolyn does not possess antihistaminic, anticholinergic, antiserotonin, corticosteroid-like, or antiinflammatory actions.

## Pharmacokinetics

Limited information is available for horses. The amount of cromolyn reaching the distal airways is probably variable and dependent on the type of nebulizer used and the amount of concurrent bronchoconstriction present. Absorbed cromolyn is eliminated in the urine and via the bile into the feces.

In humans, less than 2% is absorbed from the GI tract after oral dosing. Approximately 8% is absorbed when inhaled into the lung. Absorbed drug is eliminated via the feces and urine as unchanged drug.

## Contraindications/Precautions/Warnings

Do not use in patients with documented hypersensitivity to cromolyn.

Unlikely to be of benefit in treating horses with types 1 and 3 IAD. Cromolyn has no efficacy in treating acute bronchospasm.

## Adverse Effects

Adverse effects associated with inhaled cromolyn use in horses are not well documented. Cough and treatment avoidance (secondary to bad taste?) have been reported. It has been proposed that pretreatment with albuterol may reduce the incidence of cough.

Humans can occasionally develop cough, throat irritation or complain of unpleasant taste. Rarely, bronchoconstriction and anaphylaxis (<0.0001%) have been reported.

## Reproductive/Nursing Safety

Laboratory animal studies have shown no effect on fertility. Teratogenicity studies in mice, rats and rabbits have not demonstrated any teratogenic effects and it is likely safe to use during pregnancy. Extremely low (or undetectable) levels have been detected in milk; cromolyn is most likely safe to use during nursing.

## Overdosage/Acute Toxicity

Because of the drug's low systemic bioavailability after inhalation or oral administration, acute overdoses are unlikely to cause significant morbidity.

## Drug Interactions

No notable drug interactions have been reported.

## Laboratory Considerations

No notable laboratory interactions or alterations have been reported.

## Doses

### ■HORSES:

- For type 2 inflammatory airway disease: Using a jet nebulizer: 200 mg (total dose) q12 hours; using an ultrasonic nebulizer 80 mg once daily (q24h). (Couetil 2002)
- For RAO/IAD (either as long-term therapy or before exposure to allergens): Using the aerosol (800 micrograms/puff) and a suitable delivery system: 8–12 mg (10–15 puffs) once to twice daily. (Mazan 2003)
- If inflammatory airway disease is mast cell rich: Albuterol, fluticasone and cromolyn are used. Albuterol inhaler: 10 puffs twice daily for 2 weeks then once daily for 1 week. Albuterol is used 20 minutes before giving corticosteroid (fluticasone 250 micrograms: 10 puffs twice daily for 2 weeks the once daily for 1 week.) Then give cromolyn: If using the *Intal*® 1 mg product: 10 puffs twice daily for 10 days then once daily for 10 days. If using the *Intal*® 5 mg product give 2 puffs twice daily for 10 days then once daily for 10 days. Instruct client to allow 20-30 seconds between each puff to maximize efficiency. (Lester & Secombe 2008)

## Monitoring

- Clinical efficacy
- For horses with type 2 IAD, reductions in mast cell counts in bronchoalveolar lavage fluid could help confirm efficacy

## Client Information

- This medication does not treat airway constriction but used to prevent airway constriction by reducing the release of substances from cells that can cause it; it should not be used to treat acute bronchoconstriction (difficulty breathing).
- This medicine must be dosed once to twice daily and it may take several days or weeks before it can be determined if it is working.
- Proper use of the drug delivery device is very important; if any questions arise regarding proper use, contact the veterinarian.

## Chemistry/Synonyms

Cromolyn sodium occurs as a white, odorless, hygroscopic, crystalline powder that is soluble in water and insoluble in alcohol.

Cromolyn sodium may also be known as cromoglicic acid, cromoglycic acid, sodium cromoglicate, disodium cromoglycate, sodium cromoglycate, DSCG, SCG, FPL-670, or DNSG; there are many international trade names.

## Storage/Stability/Compatibility

Cromolyn sodium solution for inhalation should be stored below 40°C (104°F); preferably between 15–30°C. Protect from freezing, light and humidity. Store in foil pouch until ready for use. Do not use solution if it is cloudy or contains a precipitate. Solution remaining in nebulizers after use should be discarded.

## Compatibility/Compounding Considerations

Cromolyn solution is reportedly **compatible** with acetylcysteine, albuterol, epinephrine, isoetherine, isoproterenol, metaproterenol, or terbutaline solutions for up to 60 minutes. It is **not compatible** with bitolterol.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None in the USA

### HUMAN-LABELED PRODUCTS:

Cromolyn Sodium Solution for Inhalation: 20 mg/2 mL vials or amps; generic; (Rx)

Cromolyn Sodium Aerosol for Inhalation: 800 micrograms/actuation in 8.1 g (approx. 112 sprays) and 14.2 g (approx. 200 sprays); *Intal*® (Aventis); (Rx)

There is also an OTC nasal solution (*Nasalcrom*®), and an oral concentrate (*Gastrocrom*®) indicated for mastocytosis available, but these dosage forms are unlikely to be of use in veterinary medicine.

## CYANOCOBALAMIN (VITAMIN B12)

(sye-an-oh-koe-bal-ah-min)

VITAMIN/NUTRITIONAL

### Prescriber Highlights

- Used for parenteral treatment of vitamin B12 deficiency
  - Very safe
- 

## Uses/Indications

Cyanocobalamin is used for treating deficiencies of vitamin B12. Malabsorption of the nutrient secondary to gastrointestinal tract disease, or dietary chromium

deficiencies (in ruminants) can be associated with dietary deficiencies of vitamin B12. As there appears to be a high percentage of cats with exocrine pancreatic insufficiency or gastrointestinal disease that are deficient in cobalamin, there is considerable interest in evaluating serum cobalamin (vitamin B12) in these patients. Giant schnauzers may have a genetic defect affecting the location of the cobalamin-intrinsic factor, causing cobalamin deficiency. Dogs with inflammatory bowel disease may also develop cobalamin deficiency.

### Pharmacology/Actions

Vitamin B12 (cobalamin), a cobalt-containing water-soluble vitamin, serves as an important cofactor for many enzymatic reactions in mammals that are required for normal cell growth, function and reproduction, nucleoprotein and myelin synthesis, amino acid metabolism, and erythropoiesis. Cobalamin is required for folate utilization; B12 deficiency can cause functional folate deficiency. Unlike humans, macrocytic anemias do not appear to be a significant component to cobalamin deficiency in dogs or cats.

Clinical signs associated with cobalamin deficiency in cats may include weight loss, poor haircoat, vomiting, or diarrhea. Increases in serum methionine and methylmalonic acid, and decreased serum cystathionine and cysteine values may be noted. Homocysteine levels do not appear to be affected.

In dogs, cobalamin deficiency may cause or contribute to inappetence, diarrhea, weight loss, leukopenia, or methylmalonylaciduria.

In ruminants, vitamin B12 appears to be synthesized by rumen microflora and requires dietary cobalt to be present for its formation. Clinical signs seen with cobalamin deficiency states associated with cobalt deficiency in cattle and sheep include inappetence, lassitude, poor haircoat/fleece, poor milk production, weight loss, or failure to grow.

### Pharmacokinetics

After food is consumed in monogastric mammals, cobalamin in food is bound to a protein (haptocorrin) in the stomach. Haptocorrin/cobalamin is degraded by pancreatic proteases in the duodenum, but cobalamin is then bound by Intrinsic factor (IF), a protein produced in the stomach and pancreas in dogs, in the pancreas (only) in cats, and in the stomach (only) in humans. The cobalamin-IF complex is absorbed in the small intestine where it binds to cubulin, which facilitates its entry into the portal circulation. A protein called transcobalamin 2 (TCII) then binds to cobalamin allowing its entry into target cells. Some cobalamin is rapidly excreted into the bile where entero-hepatic recirculation occurs. Dogs and cats, unlike humans, do not possess cobalamin-binding protein TC1. This means that dogs and cats with B12 dietary deficiency or malabsorption can rapidly deplete their stores of B12 in one to two months, whereas in humans it may require 1–2 years.

In normal cats, circulating half-life of cobalamin is approximately 13 days, but in two cats with inflammatory bowel disease, it was only 5 days (Simpson *et al.* 2001).

### Contraindications/Precautions/Warnings

For injectable use, no contraindications are documented for domestic animals. In humans, cyanocobalamin is contraindicated in patients hypersensitive to it or hydroxocobalamin.

### Adverse Effects

Cyanocobalamin appears very well tolerated when used parenterally in animals. In humans, anaphylaxis has been reported rarely after parenteral use. Some human patients complain of pain at the injection site, but this is uncommon.

### Reproductive/Nursing Safety

Studies documenting safety during pregnancy have apparently not been done in humans or animals, but it is likely safe to use. Vitamin B12 deficiency states are thought to cause teratogenic effects.

While vitamin B12 can be excreted into milk, it is safe to use while nursing.

### Overdosage/Acute Toxicity

No overdose information was located, but an inadvertent overdose of cyanocobalamin given via SC or IM injection is unlikely to cause significant morbidity.

### Drug Interactions

No significant drug interactions have been identified when cyanocobalamin is administered parenterally.

### Laboratory Considerations

- Serum samples to be analyzed for cobalamin and/or folate should be protected from bright light and excessive heat
- If a microbiologic method assay is used to determine cobalamin values, concurrent use of antibiotics can cause falsely low serum or red blood cell values

### Doses

#### ■ DOGS:

- a) Cobalamin deficiency in dogs with severe GI disease (protein losing enteropathies, inflammatory bowel disease): Injectable cyanocobalamin at 25 micrograms/kg once per week for 4–6 weeks, then once monthly thereafter to maintain normal serum levels. May take as long as 3–4 weeks to see a response and lifelong therapy may be required. (Zoran 2008)
- b) Cobalamin deficiency associated with GI disease: Based on body size, 250–1200 micrograms (total dose) SC once weekly for 6 weeks, then every 14 days for 6 weeks, then one dose 30 days later. Recheck serum cobalamin concentration one month after that. If the underlying disease process is resolved and cobalamin stores have been replenished, level should be supranormal. If levels are normal, continue treatment at least monthly. If subnormal, further workup is required and continue cobalamin treatment weekly or bi-weekly. (Steiner 2009)
- c) Cobalamin deficiency associated with exocrine pancreatic insufficiency: 250–500 mcg (total dose) parenterally; repeat treatment based upon serum levels. (Westermarck *et al.* 2005)

#### ■ CATS:

- a) Cobalamin deficiency in cats with IBD: 250–500 micrograms (total dose per cat) SC once per week for 6 weeks, then every 1–2 months. (Marks 2003). For adjunctive treatment of idiopathic hepatic lipidosis: 250 micrograms (total dose) SC once per week for 6 weeks. Recheck serum B12 level in one to two weeks after cessation of treatment as some cats may need repeated administration. (Marks 2009)
- b) Cobalamin deficiency associated with GI disease: Based on body size, 150–250 micrograms (total dose) SC once weekly for 6 weeks, then every 14 days for 6 weeks, then one dose 30 days later. Recheck serum cobalamin concentration one month after that. If the underlying disease process is resolved and cobalamin stores have been replenished, level should be supranormal. If levels are normal, continue treatment at least monthly. If subnormal, further workup is required and

stores are depleted, level should be supranormal. If levels are normal, continue treatment weekly or bi-weekly. (Steiner 2009)

c) Cobalamin deficiency associated with exocrine pancreatic insufficiency: 100–250 micrograms (total dose) SC once weekly; periodically assess cobalamin and folate levels. (Westermarck *et al.* 2005)

#### ■HORSES:

a) For vitamin B12 deficiency: 1–2 mL of a 1000 micrograms/mL injection (1000–2000 micrograms per horse) injected IM or SC; dosage may be repeated once or twice weekly, as indicated by condition or response. (Label information; Amtech Vitamin B12 1000 mcg—IVX)

#### ■CATTLE, SHEEP:

a) For treatment of vitamin B12 deficiency associated with cobalt deficiency: Lambs: 100 micrograms (total dose) injected once weekly. Adult sheep: 300 micrograms (total dose) injected once weekly. (Baxter 1986)

b) For treatment of vitamin B12 deficiency associated with cobalt deficiency: Cattle and sheep: 0.2–0.4 mL of a 5000 micrograms/mL injection (1000–2000 micrograms) injected IM or SC; dosage may be repeated in weekly intervals if necessary. (Label information; Vitamin B12 5000 micrograms—Butler)

#### ■SWINE:

a) For vitamin B12 deficiency: 0.1–0.4 mL of a 5000 micro-grams/mL injection (500–2000 micrograms) injected IM or SC; dosage may be repeated in weekly intervals if necessary. (Label information; Amtech Vitamin B12 5000 micrograms—IVX)

### Monitoring

- Cobalamin levels
- In small animals: folate status; both before and after treatment with cyanocobalamin
- Clinical signs associated with deficiency
- CBC, baseline and ongoing if abnormal

### Client Information

- Several weeks after starting B12 therapy may be required before improvement is seen
- Vitamin B12 deficiency in animals may require life-long treatment
- As cyanocobalamin may be administered SC, clients can be instructed to administer at home, but the importance of ongoing follow-up with the veterinarian must be stressed

### Chemistry/Synonyms

Cyanocobalamin occurs as dark red crystals or crystalline powder. It is sparingly soluble in water (1 in 80) and soluble in alcohol. When in the anhydrous form, it is very hygroscopic and can absorb substantial amounts of water from the air.

Vitamin B12 may also be known as cobalamins. Cyanocobalamin may also be known as: cyanocobalamine, cyanocobalaminum, cobamin, cianokobalaminas, cianocobalamina, or cymbemin; many internationally registered trade names.

### Storage/Stability

Cyanocobalamin injection should be stored below 40°C; protect from light and freezing.

### Compatibility/Compounding Considerations

Cyanocobalamin injection is reportedly **compatible** with all commonly used intravenous fluids.

### Dosage Forms

#### VETERINARY-LABELED PRODUCTS:

Cyanocobalamin (Vitamin B12) Injection 1000, 3000 and 5000 micrograms/mL in 100 mL, 250 mL and 500 mL multi-dose vials depending on source; generic; (Rx). Products may be labeled as cyanocobalamin or vitamin B12, and be labeled for use in cattle, horses, dogs, cats, sheep, or swine.

There are many combination products, both oral and injectable, containing cyanocobalamin as one of the ingredients. These are not recommended for use when cobalamin deficiency states exist.

#### HUMAN-LABELED PRODUCTS:

Cyanocobalamin (crystalline, Vitamin B12) Injection 100 micrograms (0.1 mg) per mL and 1000 (1 mg) per mL, vial sizes range from 1 mL single-use to 10 mL and 30 mL multi-dose; generic; (Rx). Besides generically labeled products, there are several products available with a variety of trade names, including *Cyanoject*®, *Rubisol*®, *Crysti*®, or *Crystamine*®.

Oral tablet dosage forms are also available, but have not been shown to be appropriate for therapy of cobalamin deficient states in small animal medicine. A nasally administered product is marketed, but there is no information on its use in dogs or cats.

### CYCLOPHOSPHAMIDE

(sye-kloe-foss-fa-mide) Cytoxan®, Neosar®

IMMUNOSUPPRESSIVE/ANTINEOPLASTIC

## Prescriber Highlights

- Antineoplastic/immunosuppressive used in dogs & cats for a variety of conditions
  - Low dose metronomic (continuous) therapy with piroxicam shows promise for preventing sarcoma recurrence in dogs with fewer adverse effects than high dose tx.
  - Contraindications: Prior anaphylaxis; caution in patients with leukopenia, thrombocytopenia, previous radiotherapy, impaired hepatic or renal function, or in those for whom immunosuppression may be dangerous (*e.g.*, infection)
  - Potentially teratogenic, fetotoxic
  - Primary adverse effects are myelosuppression, GI effects, alopecia (especially Poodles, Old English Sheepdogs, etc.), & hemorrhagic cystitis.
  - Adequate monitoring essential
- 

## Uses/Indications

In veterinary medicine, cyclophosphamide is used primarily in small animals (dogs and cats) in combination with other agents both as an antineoplastic agent (lymphomas, leukemias, carcinomas, and sarcomas) and as an immunosuppressant (SLE, ITP, IMHA, pemphigus, rheumatoid arthritis, proliferative urethritis, etc.). Its use in treating acute immune-mediated hemolytic anemia is controversial; there is some evidence that it does not add beneficial effects when used with prednisone.

Cyclophosphamide has been used historically as a chemical shearing agent in sheep.

## Pharmacology/Actions

While commonly categorized as an alkylating agent, the parent compound (cyclophosphamide) is a prodrug and cyclophosphamide's metabolites, such as phosphoramidate mustard, act as alkylating agents interfering with DNA replication, RNA transcription and replication, and ultimately disrupting nucleic acid function. The cytotoxic properties of cyclophosphamide are also enhanced by the phosphorylating activity the drug possesses.

Cyclophosphamide has marked immunosuppressive activity and both white cells and antibody production are decreased, but the exact mechanisms for this activity have not been fully elucidated.

## Pharmacokinetics

While the pharmacokinetics of cyclophosphamide apparently have not been detailed in dogs or cats, it is presumed that the drug is handled in a manner similar to humans. The drug is well absorbed after oral administration with peak levels occurring about 1 hour after dosing. Cyclophosphamide and its metabolites are distributed throughout the body, including the CSF (albeit in subtherapeutic levels). The drug is only minimally protein bound and is distributed into milk and presumed to cross the placenta.

Cyclophosphamide is metabolized in the liver to several metabolites. Which metabolites account for which portion of the cytotoxic properties of the drug is a source of controversy. After IV injection, the serum half-life of cyclophosphamide is approximately 4–12 hours, but drug/metabolites can be detected up to 72 hours after administration. The majority of the drug is excreted as metabolites and unchanged drug in the urine.

## Contraindications/Precautions/Warnings

Cyclophosphamide should not be used in patients with prior anaphylactic reactions to the drug otherwise, there are no absolute contraindications to the use of cyclophosphamide. It must be used with caution, however in patients with leukopenia, thrombocytopenia, previous radiotherapy, impaired hepatic or renal function, or in those for whom immunosuppression may be dangerous (*e.g.*, infected patients). Patients who develop myelosuppression should have subsequent doses delayed until adequate recovery occurs.

Because of the potential for development of serious adverse effects, cyclophosphamide should only be used in patients who can be adequately and regularly monitored.

## Adverse Effects

Primary adverse effects in animals associated with cyclophosphamide are myelosuppression, gastroenterocolitis (anorexia, nausea, vomiting, diarrhea), alopecia (especially in breeds where haircoat continually grows, *e.g.*, Poodles, Old English Sheepdogs), and hemorrhagic cystitis.

Cyclophosphamide's myelosuppressant effects primarily impact the white cells lines, but may also affect red cell and platelet production. The nadir for leukocytes generally occurs between 7–14 days after dosing and may require up to 4 weeks for recovery. When used with other drugs causing myelosuppression, toxic effects may be exacerbated.

Sterile hemorrhagic cystitis induced by cyclophosphamide is thought to be caused by the metabolite acrolein. Up to 30% of dogs receiving long-term (>2 months) cyclophosphamide can develop this problem. Furosemide administered with cyclophosphamide may reduce the occurrence of this adverse effect.

In cats, cyclophosphamide-induced-cystitis (CIC) is rare. Initial signs may present as hematuria and dysuria. Because bacterial cystitis is not uncommon in immunosuppressed patients, it must be ruled out by taking urine cultures. Diagnosis of CIC is made by a negative urine culture and inflammatory urine sediment found during urinalysis. Because bladder fibrosis and/or transitional cell carcinoma of the bladder is also associated with cyclophosphamide use, these may need to be ruled out by contrast radiography. It is believed that the incidence of CIC may be minimized by increasing urine production and frequent voiding. The drug should be given in the morning and animals should be encouraged to drink/urinate whenever possible. Recommendation for treatment of CIC includes discontinuing cyclophosphamide, furosemide, and corticosteroids. Refractory cases have been treated by surgical debridement, 1% formalin or 25% DMSO instillation in the bladder.

Other adverse effects that may be noted with CTX therapy include pulmonary infiltrates and fibrosis, depression, immune-suppression with hyponatremia, and leukemia.

In recovering dogs with immune-mediated hemolytic anemia, taper the withdrawal of the drug slowly over several months and monitor for early signs of relapse. Rapid withdrawal can lead to a rebound hyperimmune response.

## Reproductive/Nursing Safety

Cyclophosphamide's safe use in pregnancy has not been established and it is potentially teratogenic and embryotoxic. Cyclophosphamide may induce sterility (may be

Cyclophosphamide's safe use in pregnancy has not been established and it is potentially teratogenic and embryotoxic. Cyclophosphamide may induce sterility (may be temporary) in male animals. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Cyclophosphamide is distributed in milk and nursing is generally not recommended when dams are receiving the drug.

### Overdosage/Acute Toxicity

There is only limited information on acute overdoses of this drug. The lethal dose in the dogs has been reported as 40 mg/kg IV. If an oral overdose occurs, gut emptying should proceed if indicated and the animal should be hospitalized for supportive care.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cyclophosphamide and may be of significance in veterinary patients:

- **ALLOPURINOL**: May increase the myelosuppression caused by cyclophosphamide
- **CARDIOTOXIC DRUGS** (*e.g.*, doxorubicin): Use caution when using cyclophosphamide with other cardiotoxic agents as potentiation of cardiotoxicity may occur
- **CHLORAMPHENICOL**: May inhibit cyclophosphamide metabolism
- **IMIPRAMINE**: May inhibit cyclophosphamide metabolism
- **PHENOBARBITAL (or other barbiturates)** given chronically may increase the rate of metabolism of cyclophosphamide to active metabolites via microsomal enzyme induction and increase the likelihood of toxicity development
- **PHENOTHIAZINES**: May inhibit cyclophosphamide metabolism
- **POTASSIUM IODIDE**: May inhibit cyclophosphamide metabolism
- **SUCCINYLCHOLINE**: Metabolism may be slowed with resulting prolongation of effects, as cyclophosphamide may decrease the levels of circulating pseudocholinesterases
- **THIAZIDE DIURETICS**: May increase the myelosuppression caused by cyclophosphamide
- **VITAMIN A**: May inhibit cyclophosphamide metabolism

### Laboratory Considerations

- **Uric acid** levels (blood and urine) may be increased after cyclophosphamide use.
- The immunosuppressant properties of cyclophosphamide may cause false negative **antigenic skin test** results to a variety of antigens, including tuberculin, Candida, and Trichophyton.

### Doses

**Note:** In oral tablets, the active ingredient is contained within an inner tablet surrounded by an inert flecked outer tablet. Accurate dosing may be difficult if splitting or crushing tablets. When dosing in cats or very small dogs, or if using low-dose therapy, compounding pharmacies may be able to compound oral dosage forms containing less than 25 mg. Another method has been suggested (Mackin 2009) to allow use of whole 25 mg tablets when used as an immunosuppressant: Convert daily (or every other day) doses into a weekly total dose and then administer whole tablets at a suitable interval to allow using whole tablets.

#### ■ DOGS:

As an antineoplastic:

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

- a) To inhibit local recurrence in dogs with incompletely resected soft tissue sarcomas: 10 mg/m<sup>2</sup> (NOT mg/kg) PO once daily with piroxicam at 0.3 mg/kg PO once daily. If dog develops unacceptable adverse effects dosing interval increased to every other day. (Elmslie *et al.* 2008)
- b) 50 mg/m<sup>2</sup> (NOT mg/kg) PO 4 days/week or a single dose of 250 mg/m<sup>2</sup> (NOT mg/kg) PO once every 3 weeks; IV doses range from 100–300 mg/m<sup>2</sup> (NOT mg/kg) weekly, depending on the protocol used (Kitchell 2005)

As an immunosuppressant:

- a) For use with glucocorticoids in immune-mediated thrombocytopenia or acute immune-mediated hemolytic anemia (IMHA) in patients with marked anemia (PCV less than 10%), signs of marked clinical compromise (*e.g.*, weakness, stupor, collapse), disease severe enough to require transfusion, a strongly positive slide agglutination, or jaundice and/or hemoglobinemia or hemoglobinuria. Immunosuppressants may also be necessary within a few weeks of starting glucocorticoids therapy if patient fails to respond to steroids alone, or side effects (polydipsia, polyuria, polyphagia, tachypnea) become intolerable. May use azathioprine, cyclosporine or cyclophosphamide (personal choice as there is little concrete evidence to suggest one has clear benefits over the other two). If cyclophosphamide used: Start with 50 mg/m<sup>2</sup> (NOT mg/kg) PO every 2nd day; adjust dose to manage side effects. Because of adverse effects, prefer either cyclosporine or azathioprine for long-term therapy. (Mackin 2009)
- b) For use with glucocorticoids in acute immune-mediated hemolytic anemia (IMHA): Author starts all patients with IMHA with adjunctive immunosuppressants (usually azathioprine); if using cyclophosphamide: 50 mg/m<sup>2</sup> (NOT mg/kg) PO daily for 4 days on, 3 days off, as a pulse therapy. Alternatively some clinicians use 50 mg/m<sup>2</sup> PO every other day or high dose IV therapy at 200 mg/m<sup>2</sup> at the outset (author rarely uses the high dose IV therapy unless patient is on IV fluid support as hemorrhagic cystitis is more more likely to occur. (Noonan 2009)
- c) For polyarthritis: In most cases initial treatment is to attempt immunosuppression with high doses of corticosteroids (prednisolone at 2–4 mg/kg in a daily

divided dose for 2 weeks and then gradually reduced over the next 4–8 weeks); maintain therapy to help prevent relapses. If relapses occur or the response to prednisolone is poor, add cyclophosphamide given PO daily at a dose of 1.5 mg/kg for dogs over 30 kg, 2 mg/kg for dogs 15–30 kg, and 2.5 mg/kg for dogs for dogs under 15 kg. Give cyclophosphamide doses on 4 consecutive days each week as close to the above dosing regimen as possible, allowing that tablets cannot be split. Oral prednisolone also given each day at 0.25–0.5 mg/kg. Continue treatment for 2–4 months, but do not treat with cyclophosphamide longer than 4 months because of bladder toxicity. Test urine weekly for blood, stop if overt blood detected. Monitor CBC q7–14 days; if white count falls below 6,000/mm<sup>3</sup> or platelet count is <125,000/mm<sup>3</sup> reduce dosage by 1/4th; if white count falls below 4,000/mm<sup>3</sup> or platelet count is <100,000/mm<sup>3</sup> stop drug for 2 weeks and the resume at 1/2 prior dose. If relapses occur or response still poor, may add levamisole (5–7 mg/kg PO every other day; max dose of 150 mg). Goal is to stop therapy in 3–6 months. (Bennett 2005)

d) As an alternative immunosuppressive agent for glomerulonephritis: 2.2 mg/kg PO q24h for 4 days, discontinue for 3 days and then repeat. (Labato 2006)

#### ■CATS:

As an antineoplastic: Cyclophosphamide has been used a sole agent and in a COP protocol to treat lymphomas in cats. Collaboration with a veterinary oncologist is highly recommended.

As an immunosuppressant:

a) For ITP or IMHA: Most cats respond to oral steroids alone (oral prednisolone starting dose 4 mg/kg/day) and other immunosuppressants are rarely needed. If cyclophosphamide is to be added, dose as in dogs (see Mackin dose above), but author prefers to use either cyclosporine or chlorambucil in cats. (Mackin 2009)

b) To slow progression of FIP: 2–4 mg/kg PO four times a week. (Foley 2005)

#### ■HORSES:

For neoplastic diseases; consultation with a veterinary oncologist is encouraged before use:

a) Usual doses used in horses are: 200 mg/m<sup>2</sup> (usually 1 gram per horse per dose) IV every 1–2 weeks. For generalized lymphoma the CAP protocol was used at the time of publication by one of the authors. See the reference or the vincristine monograph for more information. (Mair & Couto 2006)

#### ■RABBITS:

As an antineoplastic (lymphoma) agent:

a) 50 mg/m<sup>2</sup> (NOT mg/kg) PO daily for 3 days each week or 100–200 mg/m<sup>2</sup> IV (cephalic or saphenous veins) every 7 days. Consider using a fully implantable vascular access device for multiple IV chemo administration. (Bryan 2009)

### Monitoring

- Efficacy; See the Protocol section or refer to the references from the Dosage section above for more information
- Toxicity, see Adverse Effects above. Regular hemograms and urinalyses are mandatory.

### Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality.
- After dosing in dogs, frequent walks to encourage urination is suggested to attempt to lessen the risk for bladder toxicity.
- Clients should contact veterinarian should the animal exhibit any signs of abnormal bleeding and/or bruising.
- Although no special precautions are necessary when handling intact tablets, direct exposure should be avoided with crushed tablets, oral elixir, or the animal's urine or feces. Should exposure occur, wash the area thoroughly with soap and water.

### Chemistry/Synonyms

A nitrogen-mustard derivative, cyclophosphamide occurs as a white, crystalline powder that is soluble in water and alcohol. The commercially available injection has pH of 3 to 7.5.

Cyclophosphamide may also be known as: CPM, CTX, CYT, B-518, ciclofosfamida, cyclophosphamidum, cyclophosphanum, NSC-26271, WR-138719, *Alkyloxan*®, *Carloxan*®, *Ciclosmida*®, *Cicloaxal*®, *Cyclan*®, *Cyclo-cell*®, *Cycloblastin*®, *Cycloblastine*®, *Cyclostin*®, *Cycloxan*®, *Cytophosphan*®, *Cytoxan*®, *Endoxan*®, *Endoxana*®, *Enduxan*®, *Fosfaseron*®, *Genoxal*®, *Genuxal*®, *Ledoxina*®, *Neosar*®, *Procytox*®, or *Sendoxan*®.

### Storage/Stability

Cyclophosphamide tablets and powder for injection should be stored at temperatures less than 25°C. They may be exposed to temperatures up to 30°C for brief periods, but should not be exposed to temperatures above 30°C. Tablets should be stored in tight containers. The commercially available tablets (*Cytoxan*®) are manufactured in a bi-level manner with a white tablet containing the cyclophosphamide found within a surrounding flecked outer tablet. Therefore, the person administering the drug need not protect their hands from cyclophosphamide exposure unless the tablets are crushed. Because of their construction, accurately splitting tablets is problematic and cannot be recommended.

Cyclophosphamide injection may be dissolved in aromatic elixir to be used as an oral solution. When refrigerated, it is stable for 14 days.

After reconstituting the powder for injection with either sterile water for injection or bacteriostatic water for injection, the product should be used within 24 hours if stored at room temperature; 6 days if refrigerated.

### Compatibility/Compounding Considerations

Commercially available cyclophosphamide tablets may not have the active ingredient dispersed evenly throughout the tablet. To assure accurate oral dosing, it is recommended to obtain dosing forms from an experienced compounding pharmacist.

Cyclophosphamide is reportedly **compatible** with the following intravenous solutions and drugs: Amino acids 4.25%/dextrose 25%, D5 in normal saline, D5W, sodium chloride 0.9%. It is also **compatible** in syringes or at Y-sites for brief periods with the following: bleomycin sulfate, cefazolin, cisplatin, doxorubicin HCl, droperidol, fluorouracil, furosemide, heparin sodium, leucovorin calcium, methotrexate sodium, metoclopramide HCl, mitomycin, vinblastine sulfate, and vincristine sulfate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

## HUMAN-LABELED PRODUCTS:

Cyclophosphamide Tablets: 25 mg & 50 mg; generic (Gensia Sicor); (Rx)

Cyclophosphamide Powder for Solution for Injection: 500 mg, 1 g and 2 g in vials; generic (Rx)

## CYCLOSPORINE (SYSTEMIC)

(sye-kloe-spor-een) Atopica®, Neoral®, Sandimmune®

### IMMUNOSUPPRESSIVE

**Note:** Cyclosporine topical ophthalmic information is found in the ophthalmology section in the appendix.

### Prescriber Highlights

- **Immunosuppressant (primarily cellular immunity)**
  - **Adverse Effects: Primarily GI related, but uncommon at usual dosages**
  - **If using human-labeled products, don't confuse Sandimmune® with Atopica®/Neoral®/Gengraf® dosages; they are not bioequivalent. When using generically labeled products, determine with which product they are bioequivalent & dose appropriately.**
  - **Serum levels should be measured to assure efficacy & minimize adverse effect potential**
  - **Cost may be an issue**
  - **Drug-drug interactions**
- 

## Uses/Indications

Cyclosporine may be useful as an immunosuppressant for immune-mediated diseases (see dosage section) and as part of a protocol to reduce the rejection of allografts in transplant medicine in dogs and cats. It has been postulated that cyclosporine may have beneficial effects in keratinization disorders.

## Pharmacology/Actions

Cyclosporine is an immunosuppressant that focuses on cell-mediated immune responses (but it has some humoral immunosuppressive action). While cyclosporine's exact mechanism of action is not known, it is believed that it acts by a specific, reversible inhibition of immunocompetent lymphocytes in the G0- or G1-phase of the cell cycle. T-helper lymphocytes are the primary target, but T-suppressor cells are also affected. Lymphokine production and release (including interleukin-2, T-Cell Growth factor) are also inhibited by cyclosporine.

## Pharmacokinetics

Cyclosporine is poorly absorbed after oral administration and bioavailability can vary widely between patients. The emulsion form oral product (Neoral®) reportedly achieves much higher blood levels in dogs and cats for a given dose and dosage recommendations change accordingly. **Note:** Neoral®/Atopica® and Sandimmune® are NOT bioequivalent.

In dogs, the veterinary-labeled oral product (Atopica®) is rapidly absorbed, but bioavailability is variable and can range from 23–45%. Food in the GI increases variability of bioavailability and reduces it by about 20%.

Cyclosporine is distributed in high levels into the liver, fat and blood cells (RBC's lymphocytes). It does not appreciably enter the CNS.

The drug is primarily metabolized in the liver via the cytochrome P450 system and excreted into the bile. Less than 1% of a dose is excreted unchanged into the urine. Elimination half-life in the dog is approximately 5–12 hours.

There is some controversy regarding dosing cyclosporine in overweight animals. It has been stated that since the drug is hydrophobic, it lends support to dosing based upon the patient's ideal weight rather than its actual weight (Diesel & Moriello 2008). However in humans, obesity does not significantly impact cyclosporine pharmacokinetics (Lindholm 1991) and no published studies were found for dogs comparing pharmacokinetics in non-obese and obese animals.

## Contraindications/Precautions/Warnings

Cyclosporine is contraindicated in patients hypersensitive to it or any component (e.g., polyoxyethylated castor oil) in the injectable micro-emulsion products. It is labeled as being contraindicated in dogs with a history of malignant neoplasia. Cyclosporine should be used with caution in patients with hepatic or renal disease.

Because of its immunosuppressant effects it has been recommended to check cats' FeLV and FIP status before using cyclosporine.

Cyclosporine is pumped by P-glycoprotein, but the Washington State University Clinical Pharmacology Lab reports that it has not seen any increased sensitivity to cyclosporine and does not recommend any dose reductions in dogs with MDR1 mutations. They do however, recommend therapeutic drug monitoring. (WSU-VetClinPharmLab 2009)

## Adverse Effects

In dogs, vomiting, anorexia, and diarrhea are most commonly seen; gingival hyperplasia, hypertrichosis, excessive shedding, and papillomatosis have been reported. Quite commonly dogs will vomit when starting therapy, but this generally abates with time.

In order to reduce the incidence of vomiting in dogs when starting therapy, some clinicians will start at a low dose, give with food and gradually increase oral doses over the first week or so. One protocol (Bloom 2006) is: 1–2 mg/kg PO once daily for 2 days, 2–3 mg/kg PO once daily for 2 days, 3–4 mg/kg PO once daily for 3 days, and then 5 mg/kg PO once daily for 30 days. For the first 10 days metoclopramide is given 30 minutes prior to cyclosporine. For the first 14 days cyclosporine is given with a meal and after that, 2 hours prior to a meal.

Cats with high blood levels (1,000 ng/mL) may develop anorexia. Gastrointestinal upset may be seen in cats especially during the first month of therapy. Increased hair growth, gingival hyperplasia, flare of latent viral infections have also been noted in feline patients on cyclosporine. A case of a cat developing fatal systemic toxoplasmosis while on cyclosporin therapy has been reported.

While nephrotoxicity and hepatotoxicity are potentially an issue in dogs and cats, it appears that extremely high blood levels (>3,000 ng/mL) are necessary before this is a significant problem.

Animals who have levels greater than 1,000 ng/mL that persist for weeks or months may be more susceptible to bacterial or fungal infections. Long-term use, particularly in combination with other immunosuppressants (steroids), may predispose the patient to develop neoplastic diseases.

Because the drug has an unpleasant taste, it has been suggested that compounded dosages be placed in gelatin capsules or used with taste-masking flavoring agents.

## Reproductive/Nursing Safety

Cyclosporine has been shown to be fetotoxic and embryotoxic in rats in rabbits at dosages 2–5 times normal. Use during pregnancy only when the risks outweigh the benefits. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Cyclosporine is distributed into milk and safety cannot be assured for nursing offspring. In humans, it is not recommended that women nurse while taking cyclosporine.

## Overdosage/Acute Toxicity

Acute overdoses may cause transient renal- or hepato-toxicity. Overdoses may be treated with gut evacuation (emesis is apparently effective in humans if used within 2 hours of ingestion); otherwise, treat supportively and symptomatically.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cyclosporine and may be of significance in veterinary patients:

The following drugs may **increase** cyclosporine blood levels and increase the risk for cyclosporine toxicity:

■ **ACETAZOLAMIDE**

■ **ALLOPURINOL**

■ **AMIODARONE**

■ **AMLODIPINE**

■ **AZITHROMYCIN**

■ **AZOLE ANTIFUNGALS** (*e.g.*, ketoconazole, itraconazole, fluconazole) Both ketoconazole and fluconazole have been used to therapeutic advantage to reduce the dose (and cost) required of cyclosporine in dogs.

■ **BROMOCRIPTINE**

■ **CALCIUM CHANNEL BLOCKERS** (*e.g.*, verapamil, diltiazem)

■ **CARVEDILOL**

■ **CIMETIDINE**

■ **CHLORAMPHENICOL**

■ **CIPROFLOXACIN/ENROFLOXACIN**

■ **CISAPRIDE**

■ **COLCHICINE** (colchicine levels may also increase)

■ **CORTICOSTEROIDS**

■ **DANAZOL**

■ **DIGOXIN**

■ **ESTROGENS**

■ **FLUVOXAMINE**

■ **GLIPIZIDE/GLYBURIDE**

■ **GRAPEFRUIT JUICE/GRAPEFRUIT JUICE POWDER**

■ **IMIPENEM**

■ **LOSARTAN, VALSARTAN**

■ **MACROLIDE ANTIBIOTICS** (*e.g.*, erythromycin, clarithromycin)

■ **MEDROXYPROGESTERONE**

■ **METOCLOPRAMIDE**

■ **METRONIDAZOLE**

## ■ OMEPRAZOLE

## ■ SERTRALINE

## ■ TINIDAZOLE

■ The following drugs may **decrease** the blood levels of cyclosporine:

## ■ AZATHIOPRINE

## ■ CARBAMAZEPINE

■ CLINDAMYCIN (may decrease cyclosporine bioavailability)

## ■ CYCLOPHOSPHAMIDE

## ■ FAMOTIDINE

## ■ GRISEOFULVIN

## ■ NAFCILLIN

## ■ OCTREOTIDE

## ■ RIFAMPIN

## ■ PHENOBARBITAL

## ■ PHENYTOIN

## ■ ST. JOHN'S WORT

## ■ SULFADIAZINE/SULFAMETHOXAZOLE

## ■ SULFASALAZINE

## ■ TERBINAFINE

■ TRIMETHOPRIM (may also increase risk for nephrotoxicity)

■ WARFARIN (may also reduce efficacy of warfarin)

Additional interactions/notes:

■ ACE INHIBITORS (**benazepril, enalapril**, etc): Have been case reports in humans where renal function declined

■ DIGOXIN: Cyclosporine can cause increased digoxin levels with possible toxicity

■ DOXORUBUCIN: Cyclosporine can increase doxorubicin and doxorubicinol (active metabolite) levels

■ KETOCONAZOLE and other **azole antifungals**: Have been shown that they can substantially reduce the metabolism of cyclosporine in dogs or cats and many clinicians are using this interaction to reduce the dose and resultant cost of cyclosporine treatment. Attempt this with caution only, and with the realization that monitoring of cyclosporine levels may be required.

■ MELPHALAN: Increased risk for renal failure

■ METHOTREXATE: Cyclosporine may increase MTX levels

■ MYCOPHENOLATE: Reduced levels of mycophenolate

■ NEPHROTOXIC DRUGS, OTHER (*e.g.*, **acyclovir, amphotericin B, aminoglycosides, colchicine, vancomycin, NSAIDs, tacrolimus**): Possible additive nephrotoxicity

■ SPIRONOLACTONE and other **potassium sparing diuretics**: Increased risk for hyperkalemia

■ VACCINATIONS: May be less effective while patients are receiving cyclosporine; avoid the use of live attenuated vaccines

## Doses

**Note:** Dosages are for *Sandimmune*® unless otherwise noted. *Atopica*® or *Neoral*® are not interchangeable with *Sandimmune*® dosages.

## ■ DOGS:

For control of atopic dermatitis using *Atopica*® in dogs weighing at least 1.8 kg:

a) 5 mg/kg (3.3–6.7 mg/kg) PO once daily for 30 days. Following this initial treatment period, dosage may be tapered to every other day, and then 2 times per week, until a minimum frequency is reached that will maintain the desired therapeutic effect. Give at least one hour before, or two hours after meals. (Label information; *Atopica*®—Novartis)

b) 5–7 mg/kg/day or less. Ideally should be given on an empty stomach, but if causes GI upset, administration with food may help. In large dogs, administration of cyclosporine at 2.5 mg/kg/day with ketoconazole (5 mg/kg/day) may give good results and reduce expenses. (White 2007)

c) The standard dosage for atopic dermatitis is 5 mg/kg per day. Dosages of *Atopica*® of 2.5–3 mg/kg per day may be as effective as 5 mg/kg per day when given with generic ketoconazole at 5 mg/kg per day. After control of pruritus is achieved, the clinician may be able to reduce the daily dosage or switch to every second or third day therapy. (Ihrke 2009)

For inflammatory bowel disease using *Neoral*® or modified cyclosporine (*Atopica*®):

a) In dogs refractory to immunosuppressive doses of steroids: 5 mg/kg PO once daily. (Allenspach *et al.* 2006)

b) For inflammatory bowel disease refractory to azathioprine and prednisone: 5 mg/kg PO once daily (Marks 2007)

c) 2–5 mg/kg PO q12h; dose can be very individual, so it is recommended to monitor trough levels (aim for 500 ng/mL) (Moore 2004)

As an immunosuppressant (usually as part of an immunosuppressive protocol):

a) *Sandimmune*®: 10–25 mg/kg/day PO divided q12h. *Neoral*®: 5–10 mg/kg/day PO divided q12h. Trough level of approximately 500 ng/mL is goal (values are dependent on methodology used); may check level 24–48 hours after starting therapy. To reduce the cost of treatment in large dogs, may give ketoconazole at

10 mg/kg/day divided q12h with cyclosporine. (Gregory 2000)

b) For pemphigus: Using *Atopica*® or *Neoral*®: 5–10 mg/kg PO q24h with ketoconazole (5 mg/kg PO q24h). May be used as a sole agent or in combination with glucocorticoids. (Rosenkrantz 2004)

c) As an alternative immunosuppressive agent for refractory IMHA, especially those that are non-regenerative: 5–10 mg/kg PO divided twice daily to achieve plasma trough levels of >200 ng/mL (**Note:** *reference states >200 mg/mL, but it is believed this is a typo*). Large breed dogs can be dosed concurrently with ketoconazole (10 mg/kg/day) to allow reduction of cyclosporine dose. (Macintire 2006)

For perianal fistulas (anal furunculosis):

a) Induce remission of clinical signs by using cyclosporine alone (5 mg/kg orally twice daily) or combined with ketoconazole (cyclosporine: 5 mg/kg orally once daily; ketoconazole: 8 mg/kg orally once daily). Monitor the dog for signs of clinical improvement. Most dogs show some benefit within 2–4 weeks, but complete remission of clinical signs can take 16–20 weeks. Once clinical remission has been established, treat for an additional 4 weeks and then discontinue therapy. If a relapse occurs, repeat the above treatment protocol and then establish a maintenance dose that keeps the lesions in clinical remission. Some dogs have needed a dose as low as 25 mg daily or every other day. Univ. of Wisconsin School of Veterinary Medicine Protocol from: (Diesel & Moriello 2008)

b) Week 1: Tuesday: Hospitalization. Clip perineum to monitor healing and improve hygiene. Wednesday: Start treatment with: Cyclosporine (CyA) 10 mg/kg/day (*Neoral*®, 100 mg capsules) and Ketoconazole (KC) 5 mg/kg/day (*Nizoral*®, 200 mg tablets); Thursday: Maintain CyA dose; Friday: Check CyA plasma concentration, Maintain CyA dose; Saturday: Adjust CyA dose to obtain a trough plasma concentration of 240–400 ng/mL; Maintain KC dose during the entire period of treatment; Sunday: Maintain CyA dose

Week 2: Monday: Check CyA plasma concentration, Maintain CyA dose; Tuesday: Adjust CyA dose if needed; Wednesday: Maintain CyA dose; Thursday: Check CyA plasma concentration; Maintain CyA dose; Friday: Adjust CyA dose if needed; Discharge from hospital.

Week 3–Week 8: Check CyA plasma concentration every Tuesday. Check for possible side effects: Hair loss and hypertrichosis (CyA), pruritus (KC), gingival hyperplasia (CyA), vomiting (CyA, KC), diarrhea (CyA), kidney (CyA) and liver (CyA, KC) damage, cholestasis (KC), cutaneous papillomatosis (CyA), and viral and fungal infections (CyA).

CyA dose is adjusted if needed, KC dose is maintained.

Discontinue treatment after 8 weeks. Serious cases that are not healed but show substantial improvement may be treated for another 4 weeks. (van Sluijs 1999)

## ■CATS:

As an immunosuppressant (usually as part of an immunosuppressive protocol):

a) *Sandimmune*®: 4–15 mg/kg/day PO divided q12h. *Neoral*®: 1–5 mg/kg/day PO divided q12h. Trough level of approximately 250–500 ng/mL is goal; may check level 24–48 hours after starting therapy. (Gregory 2000)

For feline asthma (in chronic severe cases where patients either require large doses of steroids or are steroid resistant):

a) *Sandimmune*®: Initial dose of 10 mg/kg PO q12h. Check blood levels at least weekly until a stable dose achieves trough blood levels of 500–1,000 ng/mL. (Padrid 2000)

For inflammatory bowel disease using *Neoral*® or modified cyclosporine (*Atopica*®):

a) 1–4 mg/kg PO q12–24h; dose can be very individual, so it is recommended to monitor trough levels (aim for 500 ng/mL). (Moore 2004)

b) As an alternative to prednisolone: 1–4 mg/kg PO twice a day (Gruffyd-Jones 2009)

For dermatologic conditions:

a) For atopic dermatitis 5 mg/kg PO q24h; (**Note:** Actual product used not identified in study; but drug was provided by Novartis-Pharma, makers of *Atopica*®) (Wisselink & Willemsse 2009)

b) For atopic dermatitis or eosinophilic granuloma complex: 5–10 mg/kg PO daily (eosinophilic granuloma lesions may require up to 12.5 mg/day). When symptoms are controlled decrease frequency of administration. In cats difficult to dose orally, one colleague uses *Sandimmune*® at 2.5–5 mg/kg SC daily with decreased dosing frequency once controlled. (Ashley 2009)

## Monitoring

- Therapeutic efficacy
- Adverse effects
- Consider therapeutic drug monitoring, particularly when response is poor or adverse effects occur; ideally after 24–48 hours after starting therapy and then every 2–4 weeks; target trough levels (12 hours after last dose) have been suggested as 100–500 ng/mL in dogs and 250–1,000 ng/mL for cats (see dosage references) for immunosuppression. Because different methodologies may yield different results; contact the laboratory for recommendations on the evaluation of levels
- CBC and biochem profile: baseline and then monthly to every 3 months has been suggested; others believe this is not warranted

## Client Information

- Clients should be briefed on the expense of this medication before prescribing.
- Give to an animal with an empty stomach (one hour before or two hours after meals). Importance of regular dosing must be stressed. If a dose is missed, the next dose should be administered (without doubling) as soon as possible, but dosing should be no more frequent than once daily.
- There may be a lag time of up to 6 weeks before the drug demonstrates clinical benefit.
- While the drug's label states that the dose may be tapered after 30 days of therapy, your veterinarian may wish to extend this time, as it has been shown that many animals benefit from getting the higher dosage for a longer period.

## Chemistry/Synonyms

Also known as Cyclosporin A, cyclosporine is a naturally produced immunosuppressant agent. It is a non-polar, cyclic, polypeptide antibiotic consisting of 11 amino acids and occurs as a white, fine crystalline powder. It is relatively insoluble in water, but generally soluble in organic solvents and oils.

Commercially cyclosporine is available in several dosage forms, including an oral liquid, capsules, and a concentrate for injection. To increase oral absorption, a micro emulsion forming preparation (*Neoral*®) is also available in capsules and oral liquid. The veterinary product, *Atopica*®, is a micro-emulsion product equivalent

to *Neoral*®.

Cyclosporine may also be known as: ciclosporin, 27-400, ciclosporinum, cyclosporine, cyclosporine A, OL-27-400, *Atopica*® , *Gengraf*® , *Neoral*®, *Sandimmune*®, or *Sigmatasporin*®.

## Storage/Stability

The veterinary product (*Atopica*®), should be stored and dispensed in the original unit-dose container at controlled room temperature (15–35°C; 59–77°C).

The oral liquid and oral capsules (*Sandimmune*®) should be stored in their original containers at temperatures less than 30°C; protect from freezing and do not refrigerate. After opening the oral liquid, use within 2 months.

The oral liquid and capsules for emulsion (*Neoral*®) should be stored in their original containers at 25°C. Temperatures below 20°C may cause the solution to gel or flocculate. Rewarming to 25° can reverse this process without harm.

The injection should be stored at temperatures less than 30°C and be protected from light. After diluting to a concentration of approximately 2 mg/mL, the resultant solution is stable for 24 hours in D5W or normal saline; if diluting with normal saline it would be wise to use the solution within 12 hours. It does not need to be protected from light after diluting.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Cyclosporine (Modified) Capsules: 10 mg, 25 mg, 50 mg, & 100 mg; *Atopica*® (Novartis); (Rx). FDA-approved for use in dogs.

See the appendix for more information on the topical ophthalmic preparation.

### HUMAN-LABELED PRODUCTS:

**Note:** Determining bioequivalence between cyclosporine products is complicated; for the latest information see the FDA's Orange Book Website <http://www.fda.gov/cder/ob/> and search on cyclosporine.

Cyclosporine Oral Capsules (Soft-gelatin): 25 mg, 50 mg & 100 mg; *Sandimmune*® (Novartis); generic; (Rx)

Cyclosporine (Microemulsion) Oral Capsules (Soft-gelatin): 25 mg, & 100 mg; *Neoral*® (Novartis); *Gengraf*® (Abbott); generic; (Eon Labs), (Pliva); (Rx)

Cyclosporine Oral Solution: 100 mg/mL in 50 mL btl's with syringe; *Sandimmune*® (Novartis); (Rx)

Cyclosporine Oral Solution Microemulsion: 100 mg/mL in 50 mL btl's; *Neoral*® (Novartis); generic, (Abbott; Pliva); (Rx)

Cyclosporine Concentrated Solution for Injection: 50 mg/mL in 5 mL single-use vials & amps; *Sandimmune*® (Novartis); generic (Bedford Labs); (Rx)

## CYPROHEPTADINE HCL

(*sip-roe-hep-ta-deen*) *Periactin*®

ANTIHISTAMINE

### Prescriber Highlights

- **Serotonin antagonist antihistamine used as an appetite stimulant in cats & as an antipruritic/antihistamine in dogs & cats; used in horses for photic head shaking or treatment of equine Cushing's; may be useful for treating serotonin-syndrome in small animals**
- **Caution: Urinary or GI obstruction, severe CHF, narrow angle glaucoma**
- **Adverse Effects: Sedation (cats may demonstrate paradoxical hyperexcitability) & anticholinergic effects; some reports of hemolytic anemia in cats**

---

## Uses/Indications

Cyproheptadine may be useful in cats as an appetite stimulant. It potentially may be of benefit in the treatment of feline asthma or pruritus in cats, but clinical efficacy is marginal for these indications. Cyproheptadine use as monotherapy for eosinophilic airway inflammation in cats is not recommended (Schooley *et al.* 2007).

Cyproheptadine is an antihistamine but its efficacy is questionable for this indication in dogs. The drug may be useful as adjunctive therapy for Cushing's syndrome probably as result of its antiserotonin activity, however one study demonstrated efficacy in less than 10% of dogs treated for pituitary dependent hyperadrenocorticism.

Cyproheptadine may be useful as adjunctive treatment in dogs or cats with serotonin syndrome.

In horses, cyproheptadine has been used for treating photic head shaking and pituitary pars intermedia dysfunction (PPID, Equine Cushing's Disease). Pergolide is generally considered to be superior to cyproheptadine for treating PPID.

## Pharmacology/Actions

Like other H1-receptor antihistamines, cyproheptadine acts by competing with histamine for sites on H1-receptor sites on effector cells. Antihistamines do not block

histamine release, but can antagonize its effects. Cyproheptadine also possesses potent antiserotonin activity and, reportedly, has calcium channel blocking action as well.

### Pharmacokinetics

Limited data is available. Cyproheptadine is well absorbed after oral administration. Its distribution characteristics are not well described. Cyproheptadine is apparently nearly completely metabolized in the liver and these metabolites are then excreted in the urine; elimination is reduced in renal failure. Elimination half-life in cats averages about 13 hours, but there is wide interpatient variability.

### Contraindications/Precautions/Warnings

Cyproheptadine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyeloduodenal obstruction.

### Adverse Effects

The most likely adverse effects seen with cyproheptadine are related to its CNS depressant (sedation) and anticholinergic effects (dryness of mucous membranes, etc.). Cats can develop a paradoxical agitated state that resolves upon dose reduction or discontinuation. There have been reports of cyproheptadine-induced hemolytic anemia in cats. Horses may show mild depression, anorexia, or lethargy.

At higher dosages, cyproheptadine has caused significant polyphagia in dogs.

### Reproductive/Nursing Safety

Cyproheptadine has been tested in pregnant lab animals in doses up to 32X labeled dose without evidence of harm to fetuses. Nevertheless, because safety has not been established in other species, its use during pregnancy should be weighed carefully. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known if cyproheptadine is distributed into milk.

### Overdosage/Acute Toxicity

There are no specific antidotes available. Significant overdoses should be handled using standard gut emptying protocols when appropriate and supportive therapy when required. The adverse effects seen with overdoses are an extension of the drug's side effects, principally CNS depression (although CNS stimulation may be seen), anticholinergic effects (severe drying of mucous membranes, tachycardia, urinary retention, hyperthermia, etc.) and possibly hypotension. Physostigmine may be considered to treat serious CNS anticholinergic effects, and diazepam employed to treat seizures, if necessary.

Horses that have received doses 2 times greater than recommended apparently showed no untoward effects.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cyproheptadine and may be of significance in veterinary patients:

- **CNS DEPRESSANT MEDICATIONS:** Additive CNS depression may be seen if combining cyproheptadine with other CNS depressant medications, such as barbiturates, tranquilizers, etc.
- **SSRIs (including sertraline, fluoxetine, paroxetine, etc.):** Cyproheptadine may decrease the efficacy of the SSRI

### Laboratory Considerations

- Because antihistamines can decrease the wheal and flair response to **skin allergen testing**, antihistamines should be discontinued from 3–7 days (depending on the antihistamine used and the reference) before intradermal skin tests.
- Cyproheptadine may increase amylase and prolactin serum levels when administered with **thyrotropin-releasing hormone**.

### Doses

#### ■ DOGS:

As an antihistamine:

a) 0.3–2 mg/kg PO twice daily (Bevier 1990), (MacDonald 2002)

As an appetite stimulant:

a) 0.2 mg/kg PO q12h. May be dosed less frequently if inappetence is mild. (Moore 2005)

For adjunctive treatment of serotonin syndrome:

a) 1.1 mg/kg PO; doses may be repeated q4–6h as needed until signs have resolved. In cases where PO dosing not possible (severe vomiting), may crush tablets and mix with saline and give rectally. (Wisner 2006)

#### ■ CATS:

As an appetite stimulant:

a) 2–4 mg per cat PO once or twice daily (Davenport 1994), (Ogilvie 2003)

b) 1–4 mg/cat PO, or 0.35–1 mg/kg PO once or twice a day (Frimberger 2000)

c) 2 mg per cat PO q12h (Smith 2003)

d) 0.35–1 mg/kg PO q12h. May be dosed less frequently if inappetence is mild. (Moore 2005)

e) In cats with renal insufficiency: 1 mg per cat PO q12h (Scherk 2008)

As an antihistamine/antipruritic:

a) 2 mg per cat PO q12h (Messinger 2000)

b) 0.2 mg per cat PO q12h (Hilli 2002)

b) 2 mg per cat or 1.1 mg/kg PO q12h (Hnilica 2003)

c) For feline asthma (particularly when cats are maxed out on dosages of corticosteroids and terbutaline): 2 mg PO q12h. Therapeutic response may not be seen for 4–7 days, but CNS depression can occur in 24 hours. (Padrid 2000)

For adjunctive treatment of serotonin syndrome:

a) 2–4 mg (total dose) PO; doses may be repeated q4–6h as needed until signs have resolved. In cases where PO dosing not possible (severe vomiting), may crush tablets and mix with saline and give rectally. (Wisner 2006)

#### ■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

For photic head shaking:

a) 0.3–0.6 mg/kg PO q12h (Dowling 1999)

b) 0.3 mg/kg PO twice daily (Mealey 2004)

For treatment of equine Cushing's:

a) 0.25 mg/kg PO once a day for 4–8 weeks; if no response (clinical signs and plasma ACTH), increase dosage frequency to twice daily. Approximately 1/3 of horses may benefit, non-responders should be switched to pergolide. (Toribio 2004)

b) 65–125 mg (total dose) PO once daily. Pergolide is the drug of choice as it is much more effective than cyproheptadine. (Young 2009)

c) If only a limited response to a pergolide dose of 0.006 mg/kg (3 mg a day for a 500 kg horse) and endocrinologic tests remain abnormal, typically add cyproheptadine at 0.5 mg/kg PO q12h. Clinical improvement may occur even if endocrinologic tests remain abnormal so continue to monitor blood glucose and endrinologic tests. (Schott II 2009)

## Monitoring

- Efficacy (weight if used for anorexia)
- Adverse effects, if any
- With long-term use, should occasionally monitor serum BUN in cats

## Client Information

- Possible side effects include sedation/lethargy and mucous membrane dryness
- Cats may respond with agitation; contact veterinarian if this occurs; if cat becomes very lethargic, weak or develops pale mucous membranes contact veterinarian immediately
- Horses may show mild depression, anorexia, or lethargy

## Chemistry/Synonyms

An antihistamine that also possesses serotonin antagonist properties, cyproheptadine HCl occurs as a white to slightly yellow crystalline powder. Approximately 3.64 mg are soluble in one mL of water and 28.6 mg in one mL of alcohol.

Cyproheptadine HCl may also be known as: cyproheptadini hydrochloridum, *Ciplactin*®, *Cyheptine*®, *Cyprogin*®, *Cyprono*®, *Cyrosian*®, *Klarivitina*®, *Nuran*®, *Periactine*®, *Periactinol*®, *Periatin*®, *Peritol*®, *Polytab*®, *Practin*®, *Preptin*®, *Supersan*®, or *Trimetabol*®.

## Storage/Stability

Cyproheptadine HCl tablets and oral solution should be stored at room temperature and freezing should be avoided.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Cyproheptadine HCl Oral Tablets: 4 mg; generic; (Rx)

Cyproheptadine HCl Oral Syrup: 2 mg/5 mL in 473 mL; generic; (Rx)

## CYTARABINE

(*syeh-tare-a-bean*)

Cytosine arabinoside, Cytosar-U®

ANTINEOPLASTIC

Prescriber Highlights

- **Parenteral antineoplastic (lymphoreticular neoplasms, leukemias) for dogs & cats**
  - **Contraindications: Hypersensitivity; potentially, embryotoxic & teratogenic**
  - **Adverse Effects: Primarily myelosuppression, but GI & other toxicities can occur**
  - **Adequate monitoring essential**
- 

### Uses/Indications

In veterinary medicine, cytarabine is used primarily in small animals as an antineoplastic agent for lymphoreticular neoplasms, myeloproliferative disease (leukemias), and CNS lymphoma.

### Pharmacology/Actions

Cytarabine is converted intracellularly into cytarabine triphosphate that apparently competes with deoxycytidine triphosphate, thereby inhibiting DNA polymerase with resulting inhibition of DNA synthesis. Cytarabine is cell phase specific, and acts principally during the S-phase (DNA synthesis). It may also, under certain conditions, block cells from the G1 phase to the S phase.

### Pharmacokinetics

Cytarabine has very poor systemic availability after oral administration and is only used parenterally. Following IM or SC injections, the drug peaks in plasma within 20–60 minutes, but levels attained are much lower than with an equivalent IV dose.

Cytarabine is distributed widely throughout the body, but crosses into the CNS in only a limited manner. If given via continuous IV infusion, CSF levels are higher than with IV bolus injection and can reach 20–60% of those levels found in plasma. Elimination half-life in the CSF is significantly longer than that of serum. In humans, cytarabine is only about 13% bound to plasma proteins. The drug apparently crosses the placenta, but it is not known if it enters milk.

Circulating cytarabine is rapidly metabolized by the enzyme cytidine deaminase, principally in the liver but also in the kidneys, intestinal mucosa, and granulocytes, to the inactive metabolite ara-U (uracil arabinoside). About 80% of a dose is excreted in the urine within 24 hours as both ara-U ( $\approx 90\%$ ) and unchanged cytarabine ( $\approx 10\%$ ).

### Contraindications/Precautions/Warnings

Cytarabine is contraindicated in patients hypersensitive to it. Because of the potential for development of serious adverse reactions, cytarabine should only be used in patients who can be adequately and regularly monitored.

The person preparing or administering cytarabine for injection, need not observe any special handling precautions other than wearing gloves, however, should any contamination occur, thoroughly wash off the drug from skin or mucous membranes.

### Adverse Effects

The principal adverse effect of cytarabine is myelosuppression (with leukopenia being most prevalent), but anemia and thrombocytopenia can also be seen. Myelosuppressive effects are more pronounced with IV administration and reach a nadir at 5–7 days, and generally recover at 7–14 days.

GI disturbances (anorexia, nausea, vomiting, diarrhea), conjunctivitis, oral ulceration, neurotoxicity, hepatotoxicity and fever may also be noted with cytarabine therapy, but occur rarely in veterinary patients. Anaphylaxis has been reported, but is believed to occur very rarely.

Cytarabine is a mutagenic and, potentially, carcinogenic agent.

### Reproductive/Nursing Safety

Cytarabine's safe use in pregnancy has not been established and it is potentially teratogenic and embryotoxic. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown if cytarabine enters milk; safe use during nursing cannot be assured.

### Overdosage/Acute Toxicity

Cytarabine efficacy and toxicity (see Adverse Effects) are dependent not only on the dose, but also the rate the drug is given. In dogs, the IV LD<sub>50</sub> is 384 mg/kg when given over 12 hours and 48 mg/kg when infused IV over 120 hours. Should an inadvertent overdose occur, supportive therapy should be instituted.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving cytarabine and may be of significance in veterinary patients:

- **DIGOXIN:** Presumably due to causing alterations in the intestinal mucosa, cytarabine may decrease the amount of digoxin (tablets only) absorbed after oral dosing; this effect may persist for several days after cytarabine has been discontinued
- **FLUCYTOSINE (5-FC):** Limited studies have indicated that cytarabine may antagonize the anti-infective activity of fluorocytosine; monitor for decreased efficacy
- **GENTAMICIN:** Limited studies have indicated that cytarabine may antagonize the anti-infective activity of gentamicin; monitor for decreased efficacy

### Laboratory Considerations

- None reported

### Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

## ■DOGS:

For susceptible neoplastic diseases:

The following is a usual dosage or dose range for cytarabine in dogs and should be used only as a general guide: Usually, cytarabine is dosed at 100 mg/m<sup>2</sup> (NOT mg/kg) IV either as a continuous infusion over 2–3 days or divided and given IV or SC for 2–4 days.

## ■CATS:

For susceptible neoplastic diseases:

The following is a usual dosage or dose range for cytarabine in cats and should be used only as a general guide: Usually, cytarabine is dosed at 100 mg/m<sup>2</sup> (NOT mg/kg) IV either as a continuous infusion over 2–3 days or divided and given IV or SC for 2–4 days. Cats are generally dosed similarly as dogs.

## ■HORSES:

For neoplastic diseases; consultation with a veterinary oncologist is encouraged before use:

a) Usual doses used in horses are: 200–300 mg/m<sup>2</sup> (usually 1–1.5 grams per horse per dose) SC, IM or IV every 1–2 weeks. For generalized lymphoma the CAP protocol was used at the time of publication by one of the authors. See the reference or the vincristine monograph for more information. (Mair & Couto 2006)

## Monitoring

- Efficacy; see the Protocol section or refer to the references from the Dosage section above for more information
- Toxicity; see Adverse Effects above. Regular hemograms are mandatory. Periodic liver and kidney function tests are suggested.

## Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality
- Clients should contact the veterinarian should the patient exhibit any signs of profound depression, abnormal bleeding and/or bruising

## Chemistry/Synonyms

A synthetic pyrimidine nucleoside antimetabolite, cytarabine occurs as an odorless, white to off-white, crystalline powder with a pKa of 4.35. It is freely soluble in water and slightly soluble in alcohol.

Cytarabine may also be known as: 1-beta-D-arabinofuranosylcytosine, arabinosylcytosine, ara-C, cytarabine liposome, cytarabinum, cytosine arabinoside, liposomal cytarabine, NSC-63878, U-19920, U-19920A, WR-28453, ARA-cell®, *Alexan*®, *Arabine*®, *Aracytin*®, *Aracytine*®, *Ciab*®, *Citagenin*®, *Citaloxan*®, *Cylocide*®, *Cytarbel*®, *Cytarine*®, *DepoCyt*®, *DepoCyte*®, *Erpalfa*®, *Ifarab*®, *Laracit*®, *Medsara*®, *Novutrax*®, *Serotabir*®, *Starasid*®, *Tabine*®, *Tarabine*® or *Udicol*®.

## Storage/Stability

Cytarabine sterile powder for injection should be stored at room temperature (15–30°C). After reconstituting with bacteriostatic water for injection, solutions are stable for at least 48 hours when stored at room temperature. One study, however, demonstrated that the reconstituted solution retains 90% of its potency for up to 17 days when stored at room temperature. If the solution develops a slight haze, the drug should be discarded.

## Compatibility/Compounding Considerations

Cytarabine is reportedly **compatible** with the following intravenous solutions and drugs: amino acids 4.25%/dextrose 25%, dextrose containing solutions, dextrose-saline combinations, dextrose-lactated Ringer's injection combinations, Ringer's injection, lactated Ringer's injection, sodium chloride 0.9%, sodium lactate 1/6 M, corticotropin, lincomycin HCl, methotrexate sodium, metoclopramide HCl, potassium chloride, prednisolone sodium phosphate, sodium bicarbonate, and vincristine sulfate.

Cytarabine **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: cephalothin sodium, gentamicin sulfate, hydrocortisone sodium succinate, and methylprednisolone sodium succinate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Cytarabine is reportedly **incompatible** with the following solutions or drugs: carbenicillin disodium, fluorouracil, regular insulin, nafcillin sodium, oxacillin sodium, and penicillin G sodium.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Cytarabine Powder for Injection: 100 mg, 500 mg, 1 g & 2 g in vials; generic; (Rx)

Cytarabine Injection: 10 mg/mL (liposomal) preservative free in 5 mL vials; *DepoCyt*® (Enzon); (Rx);

Cytarabine Injection: 20 mg/mL in 5 mL single- & multi-dose vials & preservative free 50 mL bulk package vials, & 100 mg/mL in 20 mL single-dose vials; *Tarabine*® PFS (Adria); generic (Mayne); (Rx)

## DTIC

(da-kar-ba-zeen)

ANTINEOPLASTIC

### Prescriber Highlights

- Parenteral antineoplastic used in dogs for relapsed lymphomas, soft tissue sarcomas, & melanoma
  - Not recommended for use in cats
  - Contraindications: Hypersensitivity; potentially teratogenic.
  - Primary adverse effects are GI (can be severe & dose limiting) & bone marrow suppression; adequate monitoring essential
  - Must give diluted IV; extravasation injuries can be serious
- 

### Uses/Indications

Dacarbazine has been used to treat relapsed canine lymphoma, soft tissue sarcomas and melanoma in dogs. In combination with doxorubicin, dacarbazine has been evaluated to treat dogs with relapsed lymphosarcoma. Ongoing studies evaluating various protocols are ongoing for this indication.

### Pharmacology/Actions

The mechanism for dacarbazine's antineoplastic activity has not been precisely determined, but it is believed the drug acts as an alkylating agent through the formation of reactive carbonium ions. Dacarbazine also possesses antimetabolic activity by inhibiting DNA's of purine nucleoside. It possesses minimal immunosuppressant activity and is probably not a cell cycle-phase specific drug.

### Pharmacokinetics

Dacarbazine (DTIC) is poorly absorbed from the GI tract and is administered intravenously. It is converted into an active form of the drug in the liver. The drug's distribution characteristics are not well known, but it is only slightly bound to plasma proteins and probably concentrates in the liver. Only limited amounts cross the blood-brain barrier; it probably crosses the placenta, but it is unknown if it is distributed into milk. Dacarbazine is extensively metabolized in the liver and is excreted in the urine via tubular secretion. Elimination half-life is about 5 hours.

### Contraindications/Precautions/Warnings

Dacarbazine is not recommended for use in cats as it is unknown whether the feline liver can adequately metabolize it.

Dacarbazine (DTIC) is contraindicated in patients who are hypersensitive to it. DTIC can cause life-threatening toxicity. It should only be used where adequate monitoring and support can be administered. It should be used with caution in patients with preexisting bone marrow depression, hepatic or renal dysfunction, or infection.

### Adverse Effects

Gastrointestinal toxicity (including vomiting, anorexia, diarrhea) can commonly be seen after administration and is dose limiting. Pretreatment with an antiemetic (*e.g.*, dolasetron, ondansetron) is used by some oncologists.

Bone marrow toxicity is usually asymptomatic with leukocyte and platelet nadirs seen several weeks after therapy. Occasionally severe hematopoietic toxicity can occur with fatal consequences. Other delayed toxic effects can include, alopecia, severe hepatotoxicity, renal impairment, and photosensitivity reactions. These delayed reactions appear rarely.

Because DTIC can cause extensive pain and tissue damage, avoid extravasation injuries. Venous spasm and phlebitis may occur during IV administration. Severe pain at the injection site can occur if giving the concentrated drug; dilution and administration by IV infusion is recommended. Pretreatment with dexamethasone and/or butorphanol has been suggested to reduce vasospasm, phlebitis and pain.

There is increasing evidence that chronic exposure by health care givers to antineoplastic drugs increases the mutagenic, teratogenic, and carcinogenic risks associated with these agents. Proper precautions in the handling, preparation, administration, and disposal of these drugs and supplies associated with their use are strongly recommended.

### Reproductive/Nursing Safety

DTIC is teratogenic in rats at higher than clinically used dosages. It should be used during pregnancy only when the potential benefits outweigh its risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

While it is unknown if DTIC enters milk, the potential carcinogenicity of the drug warrants using extreme caution in allowing the mother to continue nursing while receiving DTIC.

### Overdosage/Acute Toxicity

Because of the toxic potential of this agent, iatrogenic overdoses must be avoided. Recheck dosage calculations. See Adverse Effects above for additional information on toxicity.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dacarbazine and may be of significance in veterinary patients:

- **MYELOSUPPRESSIVE DRUGS, OTHER** (*e.g.*, other antineoplastics, immunosuppressives, chloramphenicol, flucytosine, colchicine, etc.): May cause additive myelosuppression when used with DTIC
- **RIFAMPIN**: May increase the metabolism of DTIC
- **PHENOBARBITAL**: May increase the metabolism of DTIC

■ **PHENYTOIN:** May increase the metabolism of DTIC

## Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [*e.g.*, (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is **strongly recommended**.

## ■ DOGS:

Usual doses for DTIC in dogs (depending on the protocol used) are 800–1000 mg/m<sup>2</sup> (NOT mg/kg) IV over 5–8 hours every 2–3 weeks.

## Monitoring

- Efficacy
- Toxicity, including CBC with differential and platelets; renal and hepatic function tests

## Client Information

- Inform clients of the potential toxicities and risks associated with this therapy and report immediately any signs associated with serious toxicity (*e.g.*, bloody vomiting or diarrhea, abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.).

## Chemistry/Synonyms

An antineoplastic agent, dacarbazine occurs as a colorless to ivory colored crystalline solid. It is slightly soluble in water or alcohol. After reconstituting with sterile water, the injection has a pH of 3–4.

Dacarbazine may also be known as: dacarbazinum, DIC, DTIC, imidazole carboxamide, diemthyl triazeno imadazol carboxamide, NSC-45388, WR-139007, *Asercit*®, *DTI*®, *DTIC-Dome*®, *Dacarb*®, *Dacarbaziba*®, *Dacatic*®, *Deticene*®, *Detilem*®, *Detimedac*®, *Fauldetic*®, *Ifadac*®, or *Oncocarbil*®.

## Storage/Stability

The powder for injection should be protected from light and kept refrigerated. If exposed to heat, the powder may change color from ivory to pink indicating some decomposition.

After reconstituting with sterile water for injection the resultant solution is stable for up to 72 hours if kept refrigerated; up to 8 hours at room temperature. If further diluted (up to 500 mL) with either D5W or normal saline, the solution is stable for at least 24 hours when refrigerated; 8 hours at room temperature under normal room lighting.

## Compatibility/Compounding Considerations

Drug additives that are reported to be **compatible** with dacarbazine include: bleomycin, cyclophosphamide, cytarabine, dactinomycin, doxorubicin, ondansetron and vinblastine. **Y-site compatibility** includes: doxorubicin liposome, granisetron, and ondansetron.

Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dacarbazine Powder for Injection: 100 mg & 200 mg (may contain mannitol) vials; *DTIC-Dome*® (Bayer); generic; (Rx)

## DACTINOMYCIN

### ACTINOMYCIN D

(dak-ti-noe-mye-sin) Cosmegen®

ANTINEOPLASTIC

### Prescriber Highlights

- Parenteral antibiotic antineoplastic used in dogs & cats
  - Contraindications: Hypersensitivity. Caution: Preexisting bone marrow depression, hepatic dysfunction, or infection
  - Teratogenic
  - Primary adverse effects are GI & bone marrow depression (may be life threatening); adequate monitoring essential
  - Specific administration techniques required, avoid extravasation injuries
-

## Uses/Indications

Dactinomycin has been used as adjunctive treatment of lymphoreticular neoplasms, bone and soft tissue sarcomas, and carcinomas in small animals. It appears to have low efficacy against most carcinomas and sarcomas. It is being investigated as a part of protocols for rescue therapy for canine lymphomas.

## Pharmacology/Actions

Dactinomycin is an antibiotic antineoplastic. While it has activity against gram-positive bacteria, the drug's toxicity precludes its use for this purpose. Dactinomycin's exact mechanism of action for its antineoplastic activity has not been determined, but it apparently inhibits DNA-dependent RNA synthesis. Dactinomycin forms a complex with DNA and interferes with DNA's template activity. Dactinomycin also possesses immunosuppressing and some hypocalcemic activity.

## Pharmacokinetics

Because dactinomycin is poorly absorbed it must be given IV. It is rapidly distributed and high concentrations may be found in bone marrow and nucleated cells. Dactinomycin crosses the placenta, but it is unknown whether it enters maternal milk. The majority of the drug is excreted unchanged in the bile and urine.

## Contraindications/Precautions/Warnings

Dactinomycin can cause life-threatening toxicity. It should only be used where adequate monitoring and support can be administered. Dactinomycin is contraindicated in patients who are hypersensitive to it. It should be used with caution in patients with preexisting bone marrow depression, hepatic dysfunction, or infection.

Dactinomycin is actively transported by the p-glycoprotein pump and certain breeds susceptible to MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet) are at higher risk for toxicity. It is suggested to test susceptible breeds prior to treating (test available at Washington State Univ. Vet. School).

## Adverse Effects

Adverse effects that may be seen more frequently include: anemia, leukopenia, thrombocytopenia (or other signs of bone marrow depression), diarrhea, and ulcerative stomatitis or other GI ulceration. Because dactinomycin may cause increased serum uric acid levels, allopurinol may be required to prevent urate stone formation in susceptible patients. Hepatotoxicity is potentially possible with this agent.

Because dactinomycin can cause extensive pain and tissue damage, avoid extravasation injuries. Dilution and administration by IV infusion is recommended or to administer slowly into a running IV line; use the "two-needle" technique.

There is increasing evidence that chronic exposure by health care givers to antineoplastic drugs increases the mutagenic, teratogenic and carcinogenic risks associated with these agents. Proper precautions in the handling, preparation, administration, and disposal of these drugs and supplies associated with their use are strongly recommended.

## Reproductive/Nursing Safety

Dactinomycin has been demonstrated to be embryotoxic and teratogenic in rats, rabbits, and hamsters at higher than clinically used dosages. It should be used during pregnancy only when the potential benefits outweigh its risks. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

While it is unknown if dactinomycin enters maternal milk, the potential mutagenicity and carcinogenicity of the drug warrants using extreme caution in allowing the mother to continue nursing while receiving dactinomycin.

## Overdosage/Acute Toxicity

Because of the toxic potential of this agent, iatrogenic overdoses must be avoided; recheck dosage calculations. See Adverse Effects above for additional information on toxicity.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dactinomycin and may be of significance in veterinary patients:

- **DOXORUBICIN:** Additive cardiotoxicity may occur if used concurrently or sequentially with doxorubicin
- **MYELOSUPPRESSIVE DRUGS, OTHER (e.g., other antineoplastics, chloramphenicol, flucytosine, colchicine, etc.):** May cause additive myelosuppression when used with dactinomycin
- **VITAMIN K:** Patients requiring vitamin K may require higher dosages when receiving dactinomycin

## Laboratory Considerations

- Dactinomycin may interfere with determination of antibacterial **drug levels** if using bioassay techniques.

## Doses

**Note:** Because of the potential toxicity of this drug to patients, veterinary personnel and clients, and since chemotherapy indications, treatment protocols, monitoring and safety guidelines often change, the following dosages should be used only as a general guide. Consultation with a veterinary oncologist and referral to current veterinary oncology references [e.g., (Henry & Higginbotham 2009); (Argyle *et al.* 2008); (Withrow & Vail 2007); (Villalobos 2007); (Ogilvie & Moore 2006); (Ogilvie & Moore 2001)] is *strongly recommended*.

### ■ DOGS:

Depending on the protocol, usual doses for dactinomycin in dogs range from 0.5–1 mg/m<sup>2</sup> (NOT mg/kg) IV over 20 minutes; doses may be repeated (depending on the protocol) at 1–3 week intervals.

## Monitoring

- Efficacy
- Toxicity: including CBC with differential and platelets; hepatic function tests; check inside patient's mouth for ulceration

## Client Information

■ Inform clients of the potential toxicities and risks associated with this therapy and to report immediately any signs associated with serious toxicity (e.g., bloody vomiting or diarrhea, abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.).

## Chemistry/Synonyms

An antibiotic antineoplastic agent, dactinomycin (also known as actinomycin D) occurs as a bright red, crystalline powder. It is somewhat hygroscopic and soluble in water at 10°C and slightly soluble at 37°C. The commercially available preparation is a yellow lyophilized mixture of dactinomycin and mannitol.

Dactinomycin may also be known as: DTIC, ACT, actinomycin C(1), actinomycin D, meractinomycin, NSC-3053, *Ac-De*®, *Bioact-D*®, or *Dacmozen*®.

## Storage/Stability

The commercially available powder should be stored at room temperature and protected from light. When reconstituting, sterile water for injection without preservatives must be used as preservatives may cause precipitation. After reconstituting, the manufacturer recommends using the solution immediately and discarding any unused portion (no preservatives). When stored in the refrigerator, reconstituted solution loses 2–3% potency over 6 hours. The reconstituted solution may be added to D5W or normal saline IV infusions. IV fluid sterilizing filters (cellulose ester membrane) may partially remove dactinomycin.

## Compatibility/Compounding Considerations

A precipitate may form when dactinomycin is added to sterile water that contains preservatives.

Drugs that reported to be **compatible with dactinomycin when injected at a Y-site** include: granisetron and ondansetron. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dactinomycin Powder for Injection, lyophilized: 500 micrograms with mannitol 20 mg in vials; *Cosmegen*® (Merck); (Rx)

## DALTEPARIN SODIUM

(*dahl-tep-ah-rin*) Fragmin®

ANTICOAGULANT

### Prescriber Highlights

- **Low molecular weight (fractionated) heparin that may be useful for treatment or prophylaxis of thromboembolic disease**
- **Preferentially inhibits factor Xa & usually only minimally impacts thrombin & clotting time (TT or aPTT)**
- **Hemorrhage unlikely, but possible**
- **Must be given subcutaneously**
- **Cats & dogs may require very frequent dosing making outpatient administration impractical**
- **Expense may be an issue, particularly in large dogs/horses**

---

## Uses/Indications

Dalteparin may be useful for prophylaxis or treatment of deep vein thrombosis or pulmonary embolus. Recent pharmacokinetic work in dogs and cats, raises questions whether the drug can be effectively and practically administered long-term. In humans, it is also indicated for prevention of ischemic complications associated with unstable angina/non Q-wave MI.

## Pharmacology/Actions

By binding to and accelerating antithrombin III, low molecular weight heparins (LMWHs) enhance the inhibition of factor Xa and thrombin. The potential advantage to using these products over standard (unfractionated) heparin is that they preferentially inhibit factor Xa and only minimally impact thrombin and clotting time (TT or aPTT).

## Pharmacokinetics

In dogs, dalteparin is completely absorbed after SC injection. It has a volume of distribution of 50–70 mL/kg and a half-life of about 2 hours. Dalteparin half-life in dogs is shorter than in humans.

Cats appear to have a much shorter duration of activity (anti-Xa) associated with LMWHs than do humans and to maintain a therapeutic target of anti-XA activity of 0.5–1 IU/mL requires 150 Units/kg SC q4h dosing of dalteparin. (Alwood, A. *et al.* 2007)

In horses, dalteparin's pharmacokinetics are similar to humans.

In humans, after subcutaneous injection, dalteparin is absorbed rapidly with a bioavailability of about 87%; peak plasma levels (activity) occur in about 4 hours. Anti-factor Xa activity persists for up to 24 hours and doses are usually given once to twice a day. Dalteparin is excreted via the kidneys in the urine; elimination half-

life is about 3–5 hours. Half-life may be prolonged in patients with renal dysfunction.

### Contraindications/Precautions/Warnings

Dalteparin is contraindicated in patients who are hypersensitive to it, heparin, or pork products. It is also contraindicated in patients with major bleeding, or thrombocytopenia associated with positive *in vitro* tests for anti-platelet in the presence of dalteparin. Use dalteparin cautiously in patients with significant renal dysfunction as drug accumulation could result. It should be used with extreme caution in patients with heparin-induced thrombocytopenia or increased risk of hemorrhage.

### Adverse Effects

In humans adverse effects do not routinely occur, but hemorrhage is a possibility. Injection site hematomas or pain, allergic reactions, and neurologic sequelae secondary to epidural or spinal hematomas have been reported.

Do not administer via IM or IV routes; dalteparin must be given via subcutaneous injection only. Dalteparin cannot be used interchangeably with other LMWHs or heparin sodium, as dosages differ for each.

### Reproductive/Nursing Safety

In humans, dalteparin is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Dalteparin is likely safe to use during nursing.

### Overdosage/Acute Toxicity

Overdosage may lead to hemorrhagic complications. If treatment is necessary, protamine sulfate via slow IV may be administered. 1 mg of protamine sulfate can inhibit the effects of 100 units of administered anti-Xa dalteparin. Avoid overdoses of protamine.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dalteparin and may be of significance in veterinary patients:

- **ANTICOAGULANTS, ORAL (Warfarin):** Increased risk for hemorrhage
- **PLATELET-AGGREGATION INHIBITORS (aspirin, clopidogrel):** Increased risk for hemorrhage
- **THROMBOLYTIC AGENTS:** Increased risk for hemorrhage

### Laboratory Considerations

- Low molecular weight heparins may cause asymptomatic, fully-reversible increases in **AST** or **ALT**; **bilirubin** is only rarely increased in these patients, therefore, interpret these tests with caution, as increases do not necessarily indicate hepatic damage or dysfunction.

### Doses

#### ■ DOGS:

- a) 150 Units/kg SC three times daily; twice daily dosing may be effective. Studies are ongoing to clarify efficacy and dosages. (Dunn 2006)
- b) Initial dose 150 Units/kg SC q8h. (Alwood, A.J. 2008)

#### ■ CATS:

- a) Cats appear to have a much shorter duration of activity (anti-Xa) associated with LMWHs than do humans and to maintain a therapeutic target of anti-XA activity of 0.5–1 IU/mL requires 150 Units/kg SC q4h dosing of dalteparin. Current clinical dose recommendation is 180 Units/kg SC q4-6h (Alwood, A. *et al.* 2007), (Alwood, A.J. 2008)

#### ■ HORSES:

- a) For prophylaxis of coagulation disorders in colic patients: 50 Units/kg SC once daily (q24h) (Feige *et al.* 2003)

### Monitoring

- Baseline and ongoing during therapy CBC (with platelet count)
- Urinalysis
- Stool occult blood test
- Routine coagulation tests (aPTT, PT) are usually insensitive measures of activity and normally not warranted
- Factor Xa activity (available at Cornell Coagulation Laboratory) may be useful, particularly if bleeding occurs or patient has renal dysfunction. **Note:** To measure peak anti-Xa activity in cats, sample at 2 hours post-dose

### Client Information

- If this drug is to be used on an outpatient basis, clients must be instructed in proper injection technique for subcutaneous injection and to immediately report any signs associated with bleeding or pulmonary thrombosis. If not using the pre-filled syringes, use a very small gauge insulin or tuberculin syringe and needle (*e.g.*, 27 gauge).
- Clients must understand that if they do not use the drug regularly (as prescribed), clots may form.

### Chemistry/Synonyms

A low molecular weight heparin (LMWH), dalteparin sodium is obtained by nitrous acid depolymerization of heparin derived from pork intestinal mucosa. The average molecular weight is about 5000 and 90% ranges from 2000–9000 daltons (heparin sodium has a molecular weight around 12000). 1 mg of dalteparin is equivalent to not less than 110 Units and not more than 210 Units of anti-factor Xa.

Dalteparin sodium may also be known by as: Daltaparinum natricum, Kabi-2165, *Boxol*®, *Fragmine*®, *Ligofragmin*®, or *Low Liquevine*®.

## Storage/Stability

The manufacturer of the commercially available injection states the product should be stored at controlled room temperature (20–25°C, 68–77°F). Do not use if particulate matter or discoloration occur. Once the multi-dose vial is punctured, store at room temperature; discard any unused solution after 2 weeks.

A study showed that commercially available dalteparin solution was stable when drawn into syringes for up to 30 days when stored at room temperature or refrigerated. (Laposata & Johnson 2003)

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dalteparin Sodium Injection (Anti-factor Xa International Units): Available in a variety of preservative-free single dose syringes that range from 2500 Units (16 mg/0.2 mL) to 18,000 Units per 0.72 mL (115.2 mg/0.72 mL); these are less likely to be of clinical use in veterinary medicine. Multi-dose vials include: 95,000 Units per 9.5 mL (64 mg/mL), contains benzyl alcohol 14 mg/mL in 9.5 mL multidose vials; *Fragmin*® (Pfizer); (Rx)

---

## DANAZOL

(*da-na-zole*) Danocrine®

ANDROGEN

### Prescriber Highlights

- **Synthetic androgen; suppresses the pituitary-ovarian axis. Used primarily for adjunctive treatment of autoimmune hemolytic anemia/thrombocytopenia in dogs & cats. Efficacy is unpredictable and slow.**
- **Caution: Severe cardiac, renal or hepatic function impairment, or undiagnosed abnormal vaginal bleeding**
- **Teratogenic**
- **Rare hepatotoxicity in dogs**
- **Expense may be an issue**

---

## Uses/Indications

Because of expense and unpredictable efficacy, danazol is not commonly used in veterinary medicine, but has been used as adjunctive therapy (with corticosteroids) in the treatment of canine immune-mediated thrombocytopenia and hemolytic anemia, particularly if the patient becomes refractory to glucocorticoids and other immunosuppressive therapy. There is apparently synergism when danazol is combined with corticosteroids for these indications. Once remission is attained, some dogs may have their dosage reduced or other medications may be eliminated and be controlled with danazol alone. In humans, danazol has been used for the treatment of endometriosis, fibrocystic breast disease, idiopathic thrombocytopenic purpura and a variety of other conditions.

## Pharmacology/Actions

Danazol is a synthetic androgen with weak androgenic effects. It suppresses the pituitary-ovarian axis. Danazol probably directly inhibits the synthesis of sex steroids and binds to sex steroid receptors in tissues where it may express anabolic, weak androgenic, and antiestrogenic effects. Danazol appears to reduce affinity of antibody with the mononuclear phagocytic system Fc receptor. It also may compete with glucocorticoids on steroid-binding globulin, thereby allowing greater free glucocorticoid to act.

## Pharmacokinetics

There is very limited data available. Danazol is absorbed from the GI tract, but appears to be a rate limited process as increasing the dosage does not yield a corresponding increase in serum level. Distribution information is practically nonexistent; the drug apparently crosses the placenta. Danazol is believed to be principally metabolized in the liver. In humans, half-lives average about 4–5 hours.

## Contraindications/Precautions/Warnings

Danazol should be used in patients with severe cardiac, renal, or hepatic function impairment, or undiagnosed abnormal vaginal bleeding only when its benefits outweigh its risks.

## Adverse Effects

Hepatotoxicity (incidence is rare) is the most significant of the adverse effects that have been reported thus far in dogs. Otherwise virilization in females is the most likely other effect that may be seen. Rarely, danazol may cause weight gain or lethargy. Human patients have developed vaginitis. Other potential adverse effects include edema, testicular atrophy, hirsutism, or alopecia.

## Reproductive/Nursing Safety

Because of documented teratogenic effects, danazol is contraindicated during pregnancy. In humans, the FDA categorizes this drug as category **X** for use during pregnancy. (See also [Contraindications/Precautions/Warnings](#).)

pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

While it is unknown if danazol enters milk, the potential adverse effects associated with androgens in young animals warrants caution. In humans, breastfeeding is contraindicated in patients taking danazol.

### Overdosage/Acute Toxicity

No information was located. Significant overdoses should initially be handled by contacting an animal poison control center and initiate gut emptying protocols when applicable.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving danazol and may be of significance in veterinary patients:

- **CYCLOSPORINE:** May significantly increase cyclosporine levels
- **INSULIN:** By affecting carbohydrate metabolism, danazol may affect insulin requirements (doses may need to be increased) in diabetic patients
- **WARFARIN:** Concomitant use of danazol with anticoagulants may enhance the anticoagulant effect as danazol may decrease the synthesis of procoagulant factors in the liver

### Laboratory Considerations

- Danazol may decrease **total serum thyroxine** (T<sub>4</sub>) and increase T<sub>3</sub> uptake; because thyroid-binding globulin is decreased, free T<sub>4</sub> and TSH remain normal.
- **ALT** (SGPT) and **AST** (SGOT) may increase early in therapy but decrease towards baseline later in therapy. After discontinuation of danazol, levels usually return to baseline.

### Doses

#### ■ DOGS:

For adjunctive treatment of immune-mediated hemolytic anemia or thrombocytopenia:

- a) As adjunctive therapy with glucocorticoids in non-regenerative forms of IMHA: 5 mg/kg PO three times daily. Used to reduce the dose of glucocorticoids needed for long-term therapy. (Chabanne 2006)
- b) 5 mg/kg PO 2–3 times per day; rarely helpful. Costly and has limited effectiveness. (Noonan 2009)
- c) Initially, (in addition to prednis(ol)one) danazol may be given at 10 mg/kg/day PO. Once anemia improves, corticosteroids may be slowly tapered and eventually DC'd. When remission maintained by danazol alone, may lower to 5 mg/kg/day. Slowly taper after 2–3 months of normal hemograms with frequent monitoring of hemograms. (Bucheler & Cotter 1995)

#### ■ CATS:

For adjunctive treatment of immune-mediated hemolytic anemia:

- a) 5 mg/kg PO twice daily (Loar 1994)

### Monitoring

For autoimmune hematologic disorders:

- Efficacy (CBC, platelets, etc.)
- Hepatic function, baseline and at regular intervals while on therapy

### Client Information

- Clients should be informed that it may take several (2–3) months to see a positive response with this drug
- Clients should monitor for hepatotoxicity (jaundice) or changes in hematologic status (bleeding, tarry stools, etc.)

### Chemistry/Synonyms

A synthetic derivative of ethisterone (ethinyl testosterone), danazol occurs as a white to pale yellow, crystalline powder. It is practically insoluble in water and sparingly soluble in alcohol.

Danazol may also be known as: Win-17757, *Anargil*®, *Azol*®, *Cyclomen*®, *D-Zol*®, *Danalem*®, *Danatrol*®, *Danazant*®, *Danogen*®, *Danocrine*®, *Danokrin*®, *Danol*®, *Ectopal*®, *Gonablok*®, *Kendazol*®, *Ladazol*®, *Ladogal*®, *Lisigon*®, *Mastodanazol*®, *Norciden*®, *Vabon*®, *Winobanin*®, *Zendol*®, or *Zoldan-A*®.

### Storage/Stability

Danazol capsules should be stored in well-closed containers at room temperature.

### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:**

Danazol Capsules: 50 mg, 100 mg, & 200 mg; generic; (Rx)

## DANOFLOXACIN MESYLATE

(dan-oh-floks-a-sin) A180®, Advocin®

INJECTABLE FLUOROQUINOLONE

### Prescriber Highlights

- Parenteral fluoroquinolone antibiotic labeled for use in cattle (not dairy or veal) to treat BRD associated with *Mannheimia* (*Pasturella*) *hemolytica* & *P. multocida*; may also be of benefit in treating fluoroquinolone-susceptible infections in non-food producing species (horses, camelids, exotics)
  - Labeled in cattle for two SC injections 48 hours apart
  - FDA prohibits extra-label use in food animals
- 

### Uses/Indications

Danofloxacin mesylate injection is indicated for the treatment of Bovine Respiratory Disease (BRD) associated with *Mannheimia* (*Pasturella*) *hemolytica* and *P. multocida* in cattle (not dairy or veal). Because of the drug's spectrum of activity, it may also be of benefit in the treatment of infections caused by *Histophilus somni* (*Haemophilus somnus*) or *M. bovis*, but the drug is not labeled (at the time of writing) for treating these pathogens. In other countries, danofloxacin may be labeled for use in swine and chickens (non-laying), but in the USA it is illegal to use the drug in an extra-label manner in food-producing species.

Danofloxacin may be of benefit in treating susceptible infections in adult horses, camelids and other non-food producing species.

### Pharmacology/Actions

Danofloxacin is a fluoroquinolone bactericidal antibiotic that inhibits bacterial DNA-gyrase, preventing DNA supercoiling and DNA synthesis. Fluoroquinolones have good activity against many gram-negative bacilli and some gram-positive cocci (*Staphylococcus aureus* and *Staphylococcus intermedius*). In general, fluoroquinolones have a dose or concentration dependant effect rather than a time-dependant bactericidal effect.

MIC90 values for *Mannheimia* (*Pasturella*) *hemolytica* and *Pasturella multocida* average 0.06 micrograms/mL and 0.015 micrograms/mL, respectively.

### Pharmacokinetics

After subcutaneous injection in the neck in cattle, danofloxacin is reportedly rapidly absorbed with high bioavailability ( $\approx 90\%$ ). Peak serum levels occur about 2–3 hours after dosing. Steady-state volume of distribution is approximately 2.7 L/kg; lung levels exceed those in plasma. Terminal elimination half-life ranges from 3–6 hours. In cattle, elimination is primarily unchanged drug into the urine. Other species may metabolize greater percentages of the drug into a desmethyl metabolite (desmethyldanofloxacin).

In horses, a research study on the pharmacokinetics of IM, IV and IG (intra-gastric) administration of danofloxacin at 1.25 mg/kg to healthy mature horses revealed favorable bioavailability with the IM route at 89% and poor bioavailability of the IG route at 22%. The authors reported good tolerability of the IG route (Fernandez-Varon *et al.* 2006).

In sheep, the drug quickly reaches high tissue concentrations. One hour after IM administration, the concentration peaks in lung tissue and interdigital skin. A study dosing sheep at 1.25 mg/kg IV and IM resulted in similar levels for serum, exudates and transudates (Aliabadi, Landoni *et al.* 2003).

In goats, a study of danofloxacin administered at 1.25 mg/kg IV or IM, revealed similar half-lives of 4.67 and 4.41 hours after IV and IM, respectively. Volume of distribution was high via either route with 100% bioavailability reported after IM administration. The drug's penetration into both exudates and transudates were slightly slower after IM administration (Aliabadi & Lees 2001). Another study found that goats challenged with *E. coli* endotoxin receiving danofloxacin at 1.25 mg/kg IV or IM had an altered clearance of the drug with significant increases in plasma concentrations and AUC (Ismail 2006).

In camels, IV administration of the drug at 1.25mg/kg results in a high volume of distribution, a half-life of 5.37 hours and rapid clearance. The IM administration of the drug at the same dose resulted in rapid and near complete absorption, with a half life of 5.71 hours (Aliabadi, Badrelin *et al.* 2003).

In pigs, the drug has been shown to reach a high concentration in lung tissue and gastrointestinal tissue, including mucosa. In the first 24-hours after an intramuscular dose of 2 mg/kg, 43% of the dose is eliminated in the urine. Elimination half-life in swine is about 7 hours.

### Contraindications/Precautions/Warnings

The FDA prohibits extra-label usage of this drug in food animals. The manufacturer cautions use of danofloxacin in animals with known or suspected CNS disorders as quinolones have rarely caused CNS stimulation.

### Adverse Effects

Hypersensitivity reactions and lameness have been reported after administration to calves at labeled dosages. Incidence rates are not known, but they are believed to occur uncommonly. In cattle, subcutaneous injections can cause a local tissue reaction that may result in trim loss.

### Reproductive/Nursing Safety

Studies documenting safety during pregnancy in cattle are not available. In studies performed in rats (100 mg/kg/day), mice (50 mg/kg/day) and rabbits (15 mg/kg/day), no teratogenic effects were observed.

Danofloxacin safety during nursing is not known, but it is prohibited from use in lactating dairy cattle where the milk is for human consumption.

### Overdosage/Acute Toxicity

Limited information is available for cattle. High dosages, 18–60 mg/kg for 3–6 days in feeder calves reportedly can cause arthropathies/lameness (consistent with other fluoroquinolones), CNS stimulation (ataxia, nystagmus, tremors), inappetence, recumbency, depression, and exophthalmos. Some (3/6) 21-day-old calves receiving 18 mg/kg twice 48 hours apart developed nasal pad erythema.

Studies performed in adult dogs given 2.4 mg/kg/day PO for 90 days developed no observable effects.

### Drug Interactions

No specific interactions have been reported when danofloxacin is used in cattle. In humans:

**-THEOPHYLLINE (aminophylline):** Some injectable fluoroquinolones (e.g., ciprofloxacin) can potentially increase serum concentrations; increased monitoring of

**DANTROLENE (aminophylline):** Some injectable fluoroquinolones (e.g., ciprofloxacin) can potentially increase serum concentrations; increased monitoring of theophylline concentrations is recommended

## Laboratory Considerations

- No issues identified

## Doses

### ■ CATTLE:

For labeled indications:

- a) 6 mg/kg (1.5 mL per 100 lb body weight) SC. Repeat once in approximately 48 hours. Administered dosage volume should not exceed 15 mL. (Label directions; *A180*®—Pfizer)

## Monitoring

- Clinical efficacy

## Client Information

- If clients are to administer this product to food animals, they should be advised on proper injection technique and the importance of using the product per the label only

## Chemistry/Synonyms

Danofloxacin mesylate is a synthetic fluoroquinolone that occurs as a white to off-white crystalline powder. Approximately 180 grams are soluble in 1 liter of water.

Danofloxacin may also be known by the following synonyms: CP-76136-27, danofloxacin or danofloxacin. Internationally registered trade names include: *Advocin*®, *Advocine*®, *Danocin*®, *Advocid*®, and *Advover*®.

## Storage/Stability

Danofloxacin mesylate for injection should be stored at or below 30° C and protected from light and freezing. The color of the injectable solution is yellow to amber and does not affect potency.

Danofloxacin injection for SC use should not be mixed with other medications or diluents. Fluoroquinolone injectable products can be very sensitive to pH changes or chelation with cationic substances (calcium, magnesium, zinc, etc.).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Danofloxacin Mesylate 180 mg/mL (of danofloxacin) in 100 mL & 250 mL multi-dose vials; *A180*® (Pfizer); (Rx). FDA-approved for use in cattle only. Not for use in cattle intended for dairy product or calves to be processed for veal. When administered per the label directions, slaughter withdrawal is 4 days from the time of the last treatment.

### HUMAN-LABELED PRODUCTS: None

## DANTROLENE SODIUM

(*dan-troe-leen*) *Dantrium*®

SKELETAL MUSCLE RELAXANT

### Prescriber Highlights

- **Direct acting muscle relaxant**
- **Primary indications:** **Horses:** post-anesthesia myositis/acute rhabdomyolysis; **Dogs & Cats:** functional urethral obstruction, potentially rhabdomyolysis; **Swine:** malignant hyperthermia
- **Extreme caution:** Hepatic dysfunction
- **Caution:** Severe cardiac dysfunction or pulmonary disease
- **Adverse Effects:** Weakness, sedation, increased urinary frequency, GI effects; hepatotoxicity possible especially with chronic use.
- **Injectable is very expensive**

---

## Uses/Indications

In humans, oral dantrolene is indicated primarily for the treatment associated with upper motor neuron disorders (e.g., multiple sclerosis, cerebral palsy, spinal cord injuries, etc.). In veterinary medicine, its proposed indications include: the prevention and treatment of malignant hyperthermia syndrome in various species, the treatment of functional urethral obstruction due to increased external urethral tone in dogs and cats, the prevention and treatment of equine post-anesthetic myositis

(PAM), and equine exertional rhabdomyolysis. It has also been recommended for use in the treatment of bites from Black Widow Spiders in small animals and the treatment of porcine stress syndrome.

## Pharmacology/Actions

Dantrolene exhibits muscle relaxation activity by direct action on muscle. While the exact mechanism is not well understood, it probably acts on skeletal muscle by interfering with the release of calcium from the sarcoplasmic reticulum. It has no discernible effects on the respiratory or cardiovascular systems, but can cause drowsiness and dizziness. The reasons for these CNS effects are not known.

## Pharmacokinetics

The bioavailability of dantrolene after oral administration in humans is only about 35% and after intragastric administration to horses, approximately 39%. The drug is fairly slowly absorbed, with peak levels occurring about 5 hours after oral administration (humans) and 1.5 hours in horses. The drug is substantially bound to plasma proteins (principally albumin), but many drugs may displace it from such (see Drug Interactions).

Dantrolene is rapidly eliminated from the horse (half-life≈130 minutes). The elimination half-life in humans is approximately 8 hours. Dantrolene is metabolized in the liver and the metabolites are excreted in the urine. Only about 1% of the parent drug is excreted unchanged in the urine and bile.

In horses, oral dantrolene absorption is affected by food and must be given to fasted horse orally to achieve therapeutic levels.

## Contraindications/Precautions/Warnings

Because dantrolene can cause hepatotoxicity, it should be used with extreme caution in patients with preexisting liver disease. It should be used with caution in patients with severe cardiac dysfunction or pulmonary disease.

## Adverse Effects

The most significant adverse reaction with dantrolene therapy is hepatotoxicity. In humans, it is most commonly associated with high dose chronic therapy, but may also be seen after short high dose therapy. The incidence of this reaction is unknown in veterinary medicine, but monitor for its occurrence.

More common, but less significant are the CNS associated signs of weakness, sedation, dizziness, headache, and GI effects (nausea, vomiting, constipation). Also seen are increased urinary frequency and, possibly, hypotension.

## Reproductive/Nursing Safety

The safe use of dantrolene during pregnancy has not been determined. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Dantrolene is distributed into milk; safe use cannot be assured during nursing.

## Overdosage/Acute Toxicity

There is no specific antidotal therapy to dantrolene overdoses, therefore, remove the drug from the gut if possible and treat supportively.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dantrolene and may be of significance in veterinary patients:

- **BENZODIAZEPINES & OTHER CNS DEPRESSANTS:** Increased sedation may be seen if tranquilizing agents are used concomitantly with dantrolene
- **CALCIUM-CHANNEL BLOCKERS:** Rare reports of cardiovascular collapse in humans; concomitant use with dantrolene during malignant hyperthermia crises not recommended
- **ESTROGENS:** Increased risks of hepatotoxicity from dantrolene have been seen in women >35 years of age who are also receiving estrogen therapy; veterinary significance is unknown
- **WARFARIN:** Dantrolene may be displaced from plasma proteins by warfarin with increased effects or adverse reactions resulting

## Doses

### ■ DOGS:

For treatment of functional urethral obstruction due to increased external urethral tone:

- a) 1–5 mg/kg PO q8–12h (Lane 2000), (Coates 2004)
- b) 1 mg/kg PO q8h (Lulich 2004)

For canine stress syndrome (CSS)/Malignant Hyperthermia (MH):

- a) To treat an acute attack: 0.2–3 mg/kg IV (Axlund 2004)
- b) For MH-like syndrome associated with hops (*Humulus lupulus*) ingestion: 2–3 mg/kg IV or 3.5 mg/kg PO as soon as possible after ingestion. (Wisner 2004)

For adjunctive treatment of rhabdomyolysis:

- a) 1.5 mg/kg PO q8h (from a case report; very intensive drug and supportive therapy used in this case). (Wells *et al.* 2009)

For adjunctive treatment of Black Widow Spider bite:

- a) 1 mg/kg IV; followed by 1 mg/kg PO q4h (Bailey 1986)

### ■ CATS:

For treatment of functional urethral obstruction due to increased external urethral tone:

- a) 0.5–2 mg/kg PO q12h OR 0.5–1 mg/kg IV (IV product very expensive) (Gunn-Moore 2008)
- b) 0.5–2 mg/kg PO three times daily (Coates 2004)
- c) 2–10 mg (total dose) PO three times daily with either prazosin (0.5 mg/cat once to twice daily) or phenoxybenzamine (2.5–7.5 mg/cat once to twice daily)

(Sparkes 2006)

d) 0.5–1 mg/kg PO q12h (Bartges 2009)

## ■HORSES:

For treatment of acute rhabdomyolysis:

a) 15–25 mg/kg slow IV four times daily (Robinson 1987)

b) 2–4 mg/kg PO via nasogastric tube once daily (Hanson 1999)

For prevention of rhabdomyolysis:

a) For prevention of recurrent exertional rhabdomyolysis in Thoroughbreds: 4 mg/kg PO in horses fasted (12-hour fast in study) prior to administration. (McKenzie *et al.* 2003)

b) Several dosage regimens have been recommended, but take care as use and efficacy are uncertain: 2 mg/kg PO once daily for 3–5 days and then every 3rd day for a month has been recommended. Drug is diluted in normal saline and given via stomach tube. Another dosage recommendation is 300 mg (total dose) PO once daily (may be preferable because the drug is hepatotoxic). Another recommendation is 500 mg (total dose) PO for 3–5 days and then 300 mg PO every third day. Monitor hepatic function and status. (MacLeay 2004)

c) 800 mg (total dose); within 30 minutes prior to administration contents of capsules mixed with 9 mL tap water to make a suspension and given PO one hour before exercise. (Edwards *et al.* 2003)

For prevention of post-anesthetic myositis (PAM):

a) To prevent muscle damage in horses undergoing hypotensive anesthesia: 6 mg/kg enterally (given via NG tube in study) 60 minutes prior to general anesthesia. Does not appear to prolong recovery time. (McKenzie & Mosley 2009)

b) 10 mg/kg PO (intra-gastric) 1.5 hours before surgery. This should give peak levels at the time surgery begins and maintain postulated therapeutic levels for an additional 2 hours. The intra-gastric preparation was made by dissolving/suspending the contents of oral capsules into 500 mL of normal saline. Should further doses be warranted, additional doses of 2.5 mg/kg PO (intra-gastric) q60 minutes can be given. Alternatively, IV doses of 1.9 mg/kg loading will give therapeutic levels but will only persist for about 20 minutes. An IV dose of 4 mg/kg will maintain therapeutic levels for about 2 hours, but peak levels will be quite high. (Court *et al.* 1987)

## ■SWINE:

Prevention or treatment of malignant hyperthermia:

a) 3.5 mg/kg IV (Booth 1988)

## Monitoring

Depending on the reason for use:

- Baseline and periodic liver function tests (ALT, AST, Alk Phos, etc.) if projecting to be used chronically or using high dosages
- Body temperature (malignant hyperthermia)
- Urine volume, frequency, continence

## Client Information

- Dantrolene can cause GI upset (vomiting, lack of appetite), increased urinary frequency, and sedation (drowsiness)
- Rarely, dantrolene can cause liver toxicity; contact veterinarian if patient develops persistent vomiting, lack of appetite, unexplained profound lethargy, or yellowish whites of eyes or mucous membranes
- Intravenous use of this drug should only be used by professionals familiar with its use

## Chemistry/Synonyms

A hydantoin derivative that is dissimilar structurally and pharmacologically from other skeletal muscle relaxant drugs, dantrolene sodium is a weak acid with a pKa of 7.5. It occurs as an odorless, tasteless, orange, fine powder that is slightly soluble in water. It rapidly hydrolyzes in aqueous solutions to the free acid form that precipitates out of solution.

Dantrolene Sodium may also be known by the following synonyms and internationally registered trade names: F-440, F-368, *Danlene*®, *Dantamacrin*®, *Dantralen*®, or *Dantrolen*®.

## Storage/Stability

Dantrolene capsules should be stored in well-closed containers at room temperature. Dantrolene powder for injection should be stored at temperatures less than 30°C and protected from prolonged exposure to light. After reconstitution, the powder for injection should be used within 6 hours when stored at room temperature and should be protected from direct light. It is **not compatible** with either normal saline or D5W injection.

## Compatibility/Compounding Considerations

To dose in small dogs or cats, it has been suggested to re-encapsulate 1/8th–1/4th of the contents of a 25 mg capsule and place into a size 2 or 4 gelatin capsule (Gunn-Moore 2008).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dantrolene Sodium Oral Capsules: 25 mg, 50 mg, & 100 mg; *Dantrium*® (JHP Pharm); generic; (Rx)

Dantrolene Sodium Powder for Injection Solution: 20 mg/vial (approx. 0.32 mg/mL dantrolene after reconstitution; with mannitol 3 g/vial) in 70 mL vials; *Dantrium*® *Intravenous* (JHP Pharm); (Rx). **Note:** Because of the expense, minimum order quantity, and non-returnable nature of the commercially available intravenous product, it may not be practical for veterinary use.

## DAPSONE

(*dap-son-e*) DDS

ANTIMYCOBACTERIAL ANTIBIOTIC

### Prescriber Highlights

- **Potentially useful for treating mycobacterial & some protozoal (Pneumocystis) infections; may be used to treat Brown Recluse spider bites & cutaneous vasculitis**
- **Rarely used due to potential for severe adverse effects**
- **Relatively contraindicated in cats**
- **Adverse effects: hepatotoxicity, methemoglobinemia, anemia, thrombocytopenia, neutropenias, gastrointestinal effects, neuropathies, & cutaneous drug eruptions; photosensitivity reactions are possible**

---

## Uses/Indications

Dapsone may be useful as a second-line agent in the treatment of mycobacterial diseases in dogs and, possibly, cats. It potentially may be a useful treatment for *Pneumocystis jiroveci* (formerly *Pneumocystis carinii*) infections.

Because of its leukocyte inhibitory characteristics, dapsone may be useful for adjunctive treatment of Brown recluse spider (*Loxosceles reclusa reclusa*) bites, or when an underlying etiology causing cutaneous vasculitis cannot be determined.

## Pharmacology/Actions

The exact mechanism for dapsone's actions are not known. It probably has similar actions to that of the sulfonamides, primarily affecting folic acid synthesis in susceptible organisms. Dapsone also decreases neutrophil chemotaxis, complement activation, antibody production and lysosomal enzyme synthesis. The mechanisms for these actions are not well understood.

## Pharmacokinetics

After oral administration to dogs, dapsone is rapidly and completely absorbed. Elimination half-life ranges from about 6–10 hours. In humans, the monoacetyl metabolite is almost completely bound to plasma proteins, but in dogs, it is only about 60% bound. Dapsone is primarily eliminated via the kidneys as conjugates and unidentified metabolites. Half-life in humans is widely variable and ranges from about 10–50 hours.

## Contraindications/Precautions/Warnings

Because of increased incidences of neurotoxicity and hemolytic anemia, dapsone is generally not recommended for use in cats. Dapsone is contraindicated in patients hypersensitive to it or other sulfone drugs. It should not be used in patients with severe anemias or other preexisting blood dyscrasias. Because of its potential for causing hepatic toxicity, dapsone should be used with caution in animals with preexisting hepatic dysfunction.

## Adverse Effects

Adverse effects include hepatotoxicity, dose-dependent methemoglobinemia, hemolytic anemia, thrombocytopenia, neutropenias, gastrointestinal effects, neuropathies, and cutaneous drug eruptions. Photosensitivity is possible. Dapsone is a potential carcinogen.

## Reproductive/Nursing Safety

In pregnant animals, dapsone should be used with caution. In humans, the FDA categorizes dapsone as a category *C* drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). Animal studies have apparently not been performed with dapsone to determine its effects in pregnancy.

Dapsone is excreted into milk in concentrations equivalent to those found in plasma; and hemolytic reactions have been seen in human neonates. Consider switching to milk replacer if dapsone is required in a nursing dam.

## Overdosage/Acute Toxicity

Because of its toxicity potential, specific species differences in sensitivity, and pharmacokinetics, it is recommended to contact an animal poison control center in cases of dapsone overdoses. In humans, dapsone overdoses generally cause nausea, vomiting, and hyperexcitability which can occur within minutes of an overdose. Methemoglobinemia with associated depression, seizures, and cyanosis can occur. Hemolysis may be delayed, occurring from 7–14 days after the overdose. Treatment in humans includes removal of drug from the gut, methylene blue for methemoglobinemia and, sometimes, hemodialysis to enhance removal of the drug and the

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dapsone and may be of significance in veterinary patients:

- **PROBENECID:** May decrease the renal excretion of active metabolites of dapsone
- **PYRIMETHAMINE:** May increase risk of hematologic reactions occurring with dapsone
- **RIFAMPIN:** May decrease plasma dapsone concentrations (7–10 fold)
- **TRIMETHOPRIM:** May increase plasma dapsone concentrations (and vice versa) and potentially increase each other's toxicity

## Laboratory Considerations

- No specific laboratory interactions or considerations noted

## Doses

### ■ DOGS:

- As an alternative treatment for pemphigus: Dapsone at 1 mg/kg PO q8h; with sulfasalazine at 10–40 mg/kg q8h. (Rosenkrantz 2004)
- For post-vaccination alopecia/vasculitis resistant to prednisone therapy: 1 mg/kg PO q8h (Lemarie 2003b)
- For treating mycobacteriosis: 1.1 mg/kg PO q6h until remission, then 0.3 mg/kg q8–12h after recovery (Greene & Watson 1998)
- For adjunctive therapy of vasculitis: 1 mg/kg PO q8h (Hillier 2006)
- For adjunctive treatment of Brown Recluse spider (*Loxosceles* spp.) bite: 1 mg/kg PO three times daily for 10 days (Peterson 2006)

### ■ CATS:

**Caution:** Dapsone can potentially cause serious side effects in cats (*e.g.*, blood dyscrasias, and hepatic or neuro toxicities); many consider its use relatively contraindicated in cats. If this drug is to be used, clients must accept the risks associated with its use; intensive monitoring for adverse effects must be performed.

- As an alternative to clofazimine for treating feline leprosy (see caution above): 1 mg/kg once daily PO. (Lemarie 2003a)
- For treating mycobacteriosis: 8 mg/kg PO once daily for 6 weeks (Greene & Watson 1998)
- For aural chondritis: 1 mg/kg PO q24h (Griffin 2006)

### ■ HORSES:

- As an alternative treatment for *Pneumocystis carinii* pneumonia: 3 mg/kg PO once daily (q24h). **Note:** From one case report of treatment of a foal; treatment period was 56 days. (Clark-Price *et al.* 2004)

## Monitoring

- CBC with platelets every 2–3 weeks during first 4 months of treatment and then every 3–4 months
- Liver function tests
- Other adverse effects (GI, drug eruptions, neurotoxicity, etc.)
- Efficacy

## Client Information

- Clients should understand that limited experience has occurred with dapsone in domestic animals and that toxicity may occur.
- Because photosensitivity can occur, exposed skin should be protected from prolonged exposure to sunlight.

## Chemistry/Synonyms

A sulfone antimycobacterial/antiprotozoan, dapsone occurs as a white or creamy-white, odorless, crystalline powder. It is very slightly soluble in water, freely soluble in alcohol, and insoluble in fixed or vegetable oils.

Dapsone may also be known as: DADPS, dapsonum, DDS, diaminodiphenylsulfone, NSC-6091, diphenylsulfone, disulone, sulfonyldianiline, *Avlosulfone*®, *Daps*®, *Dapsoderm-X*®, *Dopsan*®, *Novasulfone*®, *Servidapsone*®, and *Sulfona*®.

## Storage/Stability

Dapsone tablets should be stored protected from light at controlled room temperature (20–25°C, 68–77°F).

## Compatibility/Compounding Considerations

Dapsone tablets may be compounded into a stable liquid dosage form. The simplest method is to use a 1:1 ratio of *Ora-Plus*®: *Ora-Sweet*® and use crushed tablets to make a concentration of 2 mg/mL. This preparation is stable either stored refrigerated or at room temperature for 90 days (Nahata *et al.* 2000).

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dapsone Oral Tablets: 25 mg & 100 mg (scored); generic (Jacobus); (Rx)

## DARBEPOETIN ALFA

(dar-beh-poe-eh-tin al-fah) Aranesp®

ERYTHROPOIETIC AGENT

### Prescriber Highlights

- **Biosynthetic erythropoietic agent potentially useful for treating anemia of chronic kidney disease in dogs & cats**
  - **May be less immunogenic (not proven) in dogs or cats than epoetin alfa (rHuEPO)**
  - **Longer duration of effect, initially only dosed once per week**
  - **Treatment expense may be formidable**
- 

### Uses/Indications

Darbepoetin may potentially be useful in treating anemia of chronic kidney disease in dogs and cats. It may be less immunogenic than epoetin, but this is only theoretical and has not been documented. Another advantage is that doses may be administered less often to maintain PCV. Treatment costs may be higher than using epoetin, however.

### Pharmacology/Actions

Darbepoetin is a recombinant DNA-produced protein related to erythropoietin. It stimulates erythropoiesis using the same mechanism as endogenous erythropoietin by interacting with progenitor stem cells to increase RBC production. Darbepoetin may be less immunogenic in animals than epoetin secondary to its formulation utilizing carbohydrates as part of its structure. Theoretically, carbohydrates may “shield” the sites on the drug of greatest antigenic potential from immune cell detection. Carbohydrates also increase the solubility and stability of the compound, causing less aggregate formation and, therefore, potentially less immunogenicity.

### Pharmacokinetics

No information was located on the pharmacokinetics in dogs or cats. In humans with chronic renal failure after subcutaneous injection, bioavailability is about 37% and the drug is absorbed slowly with a distribution half-life of about 1.4 hours. It is extensively metabolized and terminal elimination half-life averages 21 hours. Terminal half-life is about 3 times greater than that of epoetin alfa.

### Contraindications/Precautions/Warnings

Darbepoetin should not be used in dogs or cats with documented anti-rHuEPO antibodies. Antibody formation diagnosis is based upon high myeloid:erythroid ratio on bone marrow cytology and exclusion of other causes of anemia. In humans, darbepoetin is contraindicated in patients hypersensitive to it or excipients in the formulation and in those with uncontrolled hypertension.

### Adverse Effects

The adverse effect profile for darbepoetin is unknown, but adverse effects reported with rHuEPO (epoetin) therapy in animals include: anti-rHuEPO antibody formation with resultant pure red blood cell aplasia (PRCA), hypertension, seizures, or iron deficiency.

### Reproductive/Nursing Safety

Studies performed in pregnant rats and rabbits demonstrated no overt teratogenicity at IV dosages of up to 20 mg/kg/day. Decreased body weights were noted in some rat pups.

It is unknown if darbepoetin is distributed into milk, but it is unlikely to pose much risk to animals nursing.

### Overdosage/Acute Toxicity

Little information is available. Humans have received therapeutic dosages of up to 8 micrograms/kg every week for 12 weeks. Polycythemia is possible and therapeutic phlebotomy may be required.

### Drug Interactions

None have been identified. For epoetin (a related compound):

- **ANDROGENS:** May increase the sensitivity of erythroid progenitors and this interaction has been used for therapeutic effect
- **DESMOPRESSIN:** With EPO can decrease bleeding times

### Laboratory Considerations

- No specific lab issues were identified; see Contraindications and Monitoring for more information.

### Doses

#### ■ DOGS/CATS:

Doses and dosing intervals for darbepoetin in dogs and cats have not been well established. Anecdotally it has been suggested to use the initial human dose of 0.45 micrograms/kg of darbepoetin in dogs and cats and adjust using clinical judgment and careful monitoring. Alternatively, animals that have received epoetin alfa (RHuEPO) can have their total weekly dosages converted using the following guidelines: Total weekly dose of epoetin in Units divided by 200 = once weekly dose in micrograms darbepoetin. Example: animal gets 400 Units of epoetin 3 times weekly = 1200 Units. Divide by 200 = 6 micrograms of darbepoetin once weekly.

### Monitoring

## Monitoring

- Before re-dosing check PCV each time
- Monitor patient's iron stores or supplement with iron
- Blood pressure

## Client Information

- Clients must be committed to the expense and associated monitoring required for this treatment
- Therapeutic effects may not be noted for several weeks after starting treatment

## Chemistry/Synonyms

Darbepoetin is a 165-amino acid protein that is produced using recombinant DNA technology in Chinese hamster ovary cells. Two additional N-linked oligosaccharide chains are added to human erythropoietin yielding a glycoprotein with an approximate molecular weight of 37,000 daltons.

Darbepoetin may also be known by the following synonyms: NESP, novel erythropoiesis stimulating protein, darbepoetina or darbepoetinum. Internationally registered trade names include: *Aranesp*® and *Nespo*®.

## Storage/Stability

The commercially available injection solutions (polysorbate or albumin-based) should be stored at 2–8°C and protected from light. Do not freeze or shake.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. It is also prohibited on the premises of a racing facility.

## HUMAN-LABELED PRODUCTS:

Darbepoetin Alfa Solution for Injection (preservative free); *Aranesp*® (Amgen); (Rx)

Each size is available in polysorbate or albumin-based solutions:

- 25 micrograms/0.42 mL preservative free in single-dose prefilled syringes
- 25 micrograms/mL preservative free, in single-dose vials
- 40 micrograms/0.4 mL preservative free in single-dose prefilled syringes
- 40 micrograms/mL preservative free in single-dose vials
- 60 micrograms/0.3 mL preservative free in single-dose prefilled syringes
- 60 micrograms/mL in single-dose vials
- 100 micrograms/0.5 mL preservative free in single-dose prefilled syringes
- 100 micrograms/mL in single-dose vials
- 150 micrograms/0.3 mL preservative free in single-dose prefilled syringes
- 150 micrograms/0.75 mL in single-dose vials
- 200 micrograms/0.4 mL preservative free in single-dose prefilled syringes
- 200 micrograms/mL in single-dose vials
- 300 micrograms/0.6 mL preservative free in single-dose prefilled syringes
- 300 micrograms/mL in single-dose vials
- 500 micrograms/mL preservative free in single-dose vials and prefilled syringes

---

## DECOQUINATE

(de-koe-kwin-ate) Deccox®

ANTIPROTOZOAL/COCCIDIOSTAT

### Prescriber Highlights

- **Coccidiostat**
  - **Not FDA-approved for lactating dairy animals, laying chickens**
  - **Not effective against adult coccidia; no effect on clinical coccidiosis; results in treating calves with cryptosporidiosis have been disappointing**
- 

## Uses/Indications

Decoquinatate is labeled for use in cattle for the prevention of coccidiosis in either ruminating or non-ruminating calves, cattle or young goats caused by the species *E. christensenii* or *E. ninakohlyakimoviae*. It is used for prevention of coccidiosis in broilers caused by *E. tenella*, *E. necatrix*, *E. acervulina*, *E. mivati*, *E. maxima* or *E. burnetti*.

It may be useful in dogs as prophylactic treatment and hepatozoonosis relapse.

## Pharmacology/Actions

Decoquinatate is 4-hydroxy quinolone agent that has anticoccidial activity. Decoquinatate acts on the sporozoite stage of the life cycle. The sporozoite apparently can still penetrate the host intestinal cell, but further development is prevented. The mechanism of action for decoquinatate is to disrupt electron transport in the mitochondrial cytochrome system of coccidia.

## Pharmacokinetics

No information was located.

## Contraindications/Precautions/Warnings

Decoquinatate is not effective for treating clinical coccidiosis and has no efficacy against adult coccidia. Decoquinatate is not FDA-approved for use in animals producing milk for food or in laying chickens.

## Adverse Effects

No adverse effects listed when given as directed.

## Overdosage/Acute Toxicity

No specific information located. Decoquinatate is considered to have a wide safety margin.

## Drug Interactions/Laboratory Considerations

- None noted

## Doses

### ■ DOGS:

For coccidiosis prophylaxis:

- a) 50 mg/kg PO once daily (Matz 1995)

For canine hepatozoonosis (*Hepatozoon americanum*): **Note:** When using decoquinatate for this indication, obtain the decoquinatate 6% (27.2 gram/lb.) powder. An approximate conversion is ¼ teaspoonful is equivalent to approximately 45 mg decoquinatate and 1 teaspoonful (5 mL) is equivalent to approximately 180 mg decoquinatate.

- a) For 14 days: Use TMP/Sulfa 15 mg/kg PO q12h; Clindamycin 10 mg/kg PO q8h; Pyrimethamine 0.25 mg/kg PO once daily);

Then to prevent relapse after TCP therapy: Decoquinatate at 20 mg/kg PO q12h long-term. Recommend treating for 2 years and then performing muscle biopsy. If negative, may discontinue. When using the 27.2 gram/lb (6%) feed additive (*Deccox*®) the decoquinatate powder can be administered at a rate of 1 teaspoon per 10 kg (22 lb) of body weight and fed twice daily. (Macintire *et al.* 2006), (Macintire 2007)

- b) TMP/Sulfa 15 mg/kg PO daily for 14 days; Clindamycin 10 mg/kg PO q8h For 14 days; Pyrimethamine 0.25 mg/kg PO once daily For 14 days; then give Decoquinatate: 10–20 mg/kg PO q12h for 24 months. (Blagburn 2005)

### ■ CATTLE:

- a) For prophylaxis of coccidiosis: Using the 6% premix: 0.5 mg/kg per day in feed for at least 28 days (Penzhorn and Swan 1993) (McDougald & Roberson 1988)

### ■ GOATS:

For prophylaxis of coccidiosis:

- a) 0.5 mg/kg per day in feed during periods of exposure (Bretzlaff 1993)
- b) 0.5–1 mg/kg of body weight PO (de la Concha 2002)

### ■ LLAMAS:

- a) For prophylaxis of coccidiosis: Using the 6% premix: 0.5 mg/kg per day in feed for at least 28 days (Johnson 1993)

## Client Information

- Decoquinatate should be used for at least 4 weeks when used for preventing coccidiosis outbreaks
- When used in dogs for Hepatozoonosis treatment may be for up to two years
- Mix well into food

## Chemistry/Synonyms

A coccidiostat, decoquinatate occurs as a cream to buff-colored fine amorphous powder having a slight odor. It is insoluble in water.

Decoquinatate may also be known as HC-1528, M&B-15497, or *Deccox*®.

## Storage/Stability

Decoquinatate is reportedly **incompatible** with strong bases or oxidizing material. Follow label storage directions; store in a cool, dry place, preferably in airtight containers.

*Deccox*® is labeled as being **compatible** (and cleared for use) with bacitracin zinc (with or without roxarsone), chlortetracycline, and lincomycin.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Decoquinatate 6% (27.2 gram/lb.) Feed Additive (with corn meal, soybean oil, lecithin and silicon dioxide) in 50 lb bags; *Deccox*® (Alpharma); (OTC). FDA-approved for use in cattle, sheep, goats (**DO NOT** feed to cows, goats or sheep producing milk for food), and chickens (not laying chickens).

Decoquinatate 0.5% (2.271 grams/lb) Feed Additive in 50 lb bags; *Deccox®-L* (Alpharma), (OTC). FDA-approved for use in ruminating and non-ruminating calves and cattle. **DO NOT** feed to cows producing milk for food.

Decoquinatate 0.8% (3.632 grams/lb) in 5 lb and 50 lb bags. *Deccox®M* (Alpharma) (OTC). FDA-approved for use in ruminating and non-ruminating calves including veal calves.

Also available are calf milk replacers that contain 22.7 mg decoquinatate per pound. For the prevention of coccidiosis in non-ruminating and calves and cattle. *Advance® Calvita® Supreme 20/21* (and *18/21*) *Medicated with Decoquinatate* (MS Specialty Nutrition); (OTC)

**HUMAN-LABELED PRODUCTS:** None

---

## DEFEROXAMINE MESYLATE

(de-fer-ox-a-meen) Desferal®, DFO

### Prescriber Highlights

- **Parental iron chelating agent used primarily for treatment of iron or aluminum intoxication in dogs/cats; has been used as a ferric ion chelator in cardiac arrest/GDV**
- **Contraindications: Severe renal failure unless dialysis used**
- **Caution: Pregnancy**
- **Adverse Effects: Allergic reactions, auditory neurotoxicity, pain or swelling at injection sites, GI distress**
- **When used IV, must be given slowly**

---

## Uses/Indications

Deferoxamine is used for the treatment of either acute or chronic iron toxicity. It is being evaluated as an iron chelator for adjunctive treatment of acute cardiac ischemia and as a chelator for aluminum toxicity. Its efficacy in treating reperfusion injuries has been disappointing.

## Pharmacology/Actions

Deferoxamine (DFO) binds ferric (Fe<sup>+++</sup>) ions to its three hydroxamic groups forming ferrioxamine. This forms a stable, water-soluble compound that is readily excreted by the kidneys. DFO does not appear to chelate other trace metals (except aluminum) or electrolytes in clinically significant quantities.

## Pharmacokinetics

DFO is poorly absorbed from the GI and is usually given parenterally. The drug is widely distributed in the body. DFO and ferrioxamine are excreted primarily in the urine. Ferrioxamine will give the urine a reddish color ("vin rosé") that indicates iron removal.

## Contraindications/Precautions/Warnings

DFO is contraindicated in patients with severe renal failure, unless dialysis is used to remove ferrioxamine.

## Adverse Effects

There is little veterinary experience with this drug. Potential adverse effects include, allergic reactions, auditory neurotoxicity (particularly with chronic, high-dose therapy), pain or swelling at injection sites, and GI distress. Too rapid IV injection may cause rapid heart rates, convulsions, hypotension, hives, and wheezing.

Oral administration of DFO is controversial. Some have recommended oral administration after oral iron ingestions, but DFO may actually increase the amount of iron absorbed from the gut. At present, oral sodium bicarbonate solution 5% given as a gastric lavage is probably a better treatment in reducing oral absorption of iron.

## Reproductive/Nursing Safety

Because deferoxamine has caused skeletal abnormalities in animals at dosages just above those recommended for iron toxicity, it should be used during pregnancy only when its benefits outweigh its risks. In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

See Adverse Effects above. Chronic high dose use may also lead to hypocalcemia and thrombocytopenia.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving deferoxamine and may be of significance in veterinary patients:

■ **PROCHLORPERAZINE:** Use with deferoxamine may cause temporary impairment of consciousness

■ **VITAMIN C:** May be synergistic with deferoxamine in removing iron, but could lead to increased tissue iron toxicity especially in cardiac muscle; it should be used

with caution, particularly in patients with preexisting cardiac disease

## Laboratory Considerations

- DFO may interfere (falsely low values) with colorimetric **iron** assays
- DFO may cause falsely high total iron binding capacity (**TIBC**) measurements

## Doses

### ■ DOGS & CATS:

In dogs at risk for, or exhibiting signs of severe iron toxicosis; cat dosages not well established:

- a) Most effective within the first 24 hours. Extrapolated animal dose is 40 mg/kg IM q4–8 hours. IM route is preferred as too rapid IV administration can cause hypotension and pulmonary edema. Efficacy can be increased by giving ascorbic acid **after** the gut has been cleared of iron. Deferoxamine-iron complex gives a salmon pink (“vin rose”) color to urine. Continue to chelate until urine clears or serum iron levels return to normal. (Wisner 2004)
- b) Initiate ASAP or at least within 12 hours of ingestion; give as a constant rate infusion at 15 mg/kg/hour. More rapid infusion may precipitate arrhythmias or aggravate hypotension. If constant rate infusion is not possible or are unable to monitor patient during infusion, give 40 mg/kg IM q4–8h, depending on clinical status. Continue therapy until serum iron levels are below 300 microliters/dL or decrease below the TIBC, whichever is lower. Chelation therapy may require 2–3 days of therapy. Following recovery, monitor for signs of GI obstruction, which may develop 4–6 weeks post-ingestion. (Greentree & Hall 1995)
- c) 10 mg/kg IM or IV q8h for 24 hours (Firth 2000)

Experimentally, as a ferric ion chelator during treatment of cardiac arrest:

- a) 5–15 mg/kg IV, IM or SC (Muir 1994)
- b) 10 mg/kg IV, IM q2h twice, then three times daily for 24 hours (Hackett & Van pelt 1995)

## Monitoring

For iron overload:

- Efficacy (serum ferritin, serum iron, TIBC are recommended to monitor iron overload)
- Treatment is continued until serum iron levels decrease below total iron-binding capacity or until urine loses its “vin rosé” color
- Adverse effects (see above); additionally, if chronic iron overload: eye examinations (iron toxicity and its subsequent removal may adversely affect vision)

## Chemistry/Synonyms

An iron-chelating agent, deferoxamine mesylate occurs as a white to off-white powder that is freely soluble in alcohol or water.

Deferoxamine mesylate may also be known as: desferoxamine mesylate, DFO, Ba-33112, Ba-29837, deferoxamini mesilas, desferrioxamine mesylate, desferrioxamine methanesulphonate, NSC-527604, *Desferal*® or *Desferin*®.

## Storage/Stability

Store at room temperature. After aseptic reconstitution (2–5 mL for 500 mg vial; 8–20 mL for 2 gram vial) with sterile water for injection, the solution may be stored for up 24 hours at room temperature and protected from light. It is recommended not to mix this agent with other drugs; do not use if solution is turbid. Dilution in normal saline, lactated Ringer’s or dextrose 5% has been recommended when administering as an intravenous infusion.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Deferoxamine Mesylate Powder for Injection (lyophilized): 500 mg & 2 g in vials; *Desferal*® (Novartis); generic; (Hospira); (Rx)

## DERACOXIB

(*dare-a-cox-ib*) Deramaxx®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

### Prescriber Highlights

- Coxib-class NSAID FDA-approved for use in dogs for treatment of post-operative pain (higher dose, 7 day maximum) & for treatment of pain & inflammation associated with osteoarthritis (lower dose, ongoing dosing)
  - May be useful alternative to piroxicam in adjunctive treatment of transitional cell carcinoma of bladder
  - At lower doses, appears to cause predominantly COX-2 inhibition
  - Adverse effect profile still being fully determined, but GI & renal effects are possible
-

## Uses/Indications

Deracoxib is indicated for the treatment of post-operative pain (higher dose, 7 day maximum), and for the treatment of pain and inflammation associated with osteoarthritis (lower dose, ongoing dosing) in dogs.

Like piroxicam, deracoxib is of interest in adjunctive treatment of transitional cell carcinoma of the bladder; investigations into this use are ongoing.

## Pharmacology/Actions

Deracoxib is a coxib-class, nonsteroidal antiinflammatory drug (NSAID). It is believed to predominantly inhibit cyclooxygenase-2 (COX-2) and spare COX-1 at therapeutic dosages. This, theoretically, would inhibit production of the prostaglandins that contribute to pain and inflammation (COX-2) and spare those that maintain normal gastrointestinal and renal function (COX-1). However, COX-1 and COX-2 inhibition studies are done *in vitro* and do not necessarily correlate perfectly with clinical effects seen in actual patients.

## Pharmacokinetics

After oral administration to dogs, bioavailability is greater than 90%; the time to peak serum concentration occurs at approximately 2 hours. The presence of food in the gut can enhance bioavailability. The drug has an apparent volume of distribution of 1.5 L/kg in dogs and is at least 90% bound to canine plasma proteins. Deracoxib is hepatically metabolized to four primary metabolites. These metabolites and unchanged drug are principally eliminated in the feces. Some excretion of metabolites occurs via renal mechanisms. Terminal elimination half-life in the dog is dependent upon dose. In dosages up to approximately 8 mg/kg, half-life is about 3 hours (clearance  $\approx$  5 mL/min/kg). Half-life at a dose of 20 mg/kg is approximately 19 hours (clearance  $\approx$  1.7 mL/min/kg). Drug accumulation can occur with higher dosages, leading to increased toxic effects as increased COX-1 inhibition can occur at higher concentrations. Serum half-life is not necessarily a good predictor of duration of efficacy, possibly due to the drug's high protein binding.

In cats, after 1 mg oral doses of deracoxib, peak levels (0.28 micrograms/mL) occurred about 3.6 hours after administration. Elimination half-life was about 8 hours (Gassel *et al.* 2006).

## Contraindications/Precautions/Warnings

Deracoxib is contraindicated in patients known to be hypersensitive to it. It should be used with caution in patients with concurrent GI ulcerative diseases, renal or hepatic dysfunction, those in hypoproteinemic states, or with conditions that may predispose them to hypercoagulability.

## Adverse Effects

In the majority of dogs treated, deracoxib appears to be well tolerated, particularly when dosed as labeled and not in conjunction with other NSAIDs or corticosteroids. However, like other NSAIDs used in dogs, many adverse effects associated with deracoxib have been reported and include: gastrointestinal (vomiting, anorexia/weight loss, diarrhea, melena, hematemesis, hematochezia, GI ulceration/perforation); urinary (azotemia, polydipsia, polyuria, UTI, hematuria, incontinence, renal failure); hematologic (anemia, thrombocytopenia); hepatic (increased hepatic enzymes, changes in total protein, etc.); neurologic (lethargy/weakness, seizures, etc.); cardiovascular/respiratory (tachypnea, bradycardia, cough); and dermatologic/immunologic (fever, facial/muzzle edema, urticaria, dermatitis). Rare occurrences of death associated with these effects are possible. As additional clinical experience is gained with this agent, relative instances of these effects and the potential risk for them to occur in a given patient population should be clarified.

## Reproductive/Nursing Safety

No information on the drug's safety in pregnancy or in nursing pups was located. Use with caution in these animals.

## Overdosage/Acute Toxicity

There is little data available regarding this drug's acute toxicity. A 14-day study in dogs demonstrated no clinically observable adverse effects in the dogs that received 10 mg/kg. Dogs who received 25 mg/kg, 50 mg/kg or 100 mg/kg per day for 10–11 days survived, but showed vomiting and melena; no hepatic or renal lesions were demonstrated in these dogs.

In safety studies performed by the drug manufacturer (Roberts *et al.* 2009), oral deracoxib was well tolerated by dogs when administered for up to six months at a variety of doses. Some dogs receiving  $\leq$  6 mg/kg/day (1.5–5X) showed signs of focal tubular degeneration/regeneration on histopathology. Focal tubular necrosis was seen in 4 dogs (of a total of 20) when dosed at 8 mg/kg/day (1 of 10 dogs) or 10 mg/kg/day (3 of 10 dogs) in the 6 month safety study.

There were 979 exposures to deracoxib reported to the ASPCA Animal Poison Control Center (APCC) during 2008–2009. In these cases 948 were dogs with 96 showing clinical signs and the remaining 31 cases were cats with 1 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, diarrhea, lethargy, and elevated creatinine.

Because non-linear elimination occurs in dogs at dosages of 10 mg/kg and above, dogs acutely ingesting dosages above this amount should be observed for gastrointestinal erosion or ulceration and treated symptomatically for vomiting and GI bleeding.

This medication is a NSAID. As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. The ASPCA APCC recommends GI protectants at acute dosages of 15 mg/kg and above and IV fluid diuresis at dosages of 30 mg/kg and above in healthy dogs.

## Drug Interactions

No specific drug interactions were noted, but the manufacturer warns that use in conjunction with other **NSAIDs** or **corticosteroids** be avoided, or monitored carefully. While some advocate a multi-day washout period when switching from one NSAID to another (not aspirin—see below), there does not appear to be any credible evidence that this is required. Until so, consider starting the new NSAID when the next dose would be due for the old one.

It is also possible deracoxib may cause increased renal dysfunction if used with other drugs that can cause or contribute to **renal dysfunction** (*e.g.*, **diuretics**, **aminoglycosides**), but the clinical significance of this potential interaction is unclear.

The following drug interactions have either been reported or are theoretical in humans or animals receiving coxib-class NSAIDs and may be of significance in veterinary patients:

■ **ACE INHIBITORS** (*e.g.*, **enalapril**, **benazepril**): Some NSAIDs can reduce effects on blood pressure. Because ACE inhibitors potentially can reduce renal blood flow, use with NSAIDs could increase the risk for renal injury. However, one study in dogs receiving tepoxalin did not show any adverse effect. It is unknown what effects, if any, occur if other NSAIDs and ACE inhibitors are used together in dogs.

■ **ASPIRIN**: May increase the risk of gastrointestinal toxicity (*e.g.*, ulceration, bleeding, vomiting, diarrhea). Washout periods several days long are probably warranted when switching from an NSAID to aspirin therapy in dogs.

■ **CORTICOSTEROIDS (e.g., prednisone):** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

■ **DIGOXIN:** NSAIDs may increase serum levels

■ **FLUCONAZOLE:** Administration has increased plasma levels of celecoxib in humans and potentially could also affect deracoxib levels in dogs

■ **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects

■ **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution

■ **NEPHROTOXIC DRUGS (e.g., furosemide, aminoglycosides, amphotericin B, etc.):** May enhance the risk of nephrotoxicity development

■ **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

### Laboratory Considerations

■ No specific laboratory interactions were noted for deracoxib. Deracoxib does not appear to affect thyroid function tests in dogs.

### Doses

#### ■ DOGS:

a) For the control of pain and inflammation associated with osteoarthritis: 1–2 mg/kg PO once a day as needed.

For treatment of post-operative pain: 3–4 mg/kg PO once a day as needed, not to exceed 7 days of therapy at this dosage. (Package insert; *Deramaxx*®)

### Monitoring

■ Baseline and periodic CBC and serum chemistry (including BUN/serum creatinine, and liver function assessment)

■ Baseline history and physical

■ Efficacy of therapy

■ Adverse effect monitoring via client

### Client Information

**Note:** The manufacturer provides a client information sheet they recommend be given with every prescription for this medication.

■ Since dogs may find the chewable tablets' taste desirable, the drug should be stored out of reach of animals and children

■ Owners should immediately report to the veterinarian if any of the following adverse effects occur: bloody stool/diarrhea or vomit, or allergic reaction (facial swelling face, hives, red, itchy skin)

■ Owners should contact the veterinarian if any of the following adverse effects persist or are severe: loss of appetite, vomiting, change in bowel movements (e.g., stool color), change in behavior, decrease in water consumption, or urination

■ The manufacturer recommends that although the drug can be given on an empty stomach, it is preferable to be given with food; water should be available at all times to avoid dehydration

■ Other drugs for pain or inflammation should not be used with this medication without the approval of the veterinarian

■ Do not increase or alter the dose of this medication without the approval of the veterinarian.

### Chemistry/Synonyms

Deracoxib is a diaryl-substituted pyrazole that is chemically related to other coxib-class NSAIDs such as celecoxib. Its molecular weight is 397.38.

Deracoxib's chemical name is: 4-[3-(difluoromethyl)-5-(3-fluoro-4-methoxyphenyl)-1H-pyrazole-1-yl] benzenesulfonamide.

### Storage/Stability

The commercially available chewable tablets for dogs should be stored at room temperature between 15–30°C (59–86°F).

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Deracoxib Chewable (scored) Tablets: 25 mg, 50 mg, 75 mg, & 100 mg in bottles of 7, 30 and 90 tablets; *Deramaxx*® (Novartis) (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS: None

### DESFLURANE

(*dez-floor-ane*) *Suprane*®

INHALANT ANESTHETIC

[Prescriber Highlights](#)

- **Primary benefit is when very rapid recoveries are desired**
  - **Similar effects on CNS, respiratory and cardiovascular systems as isoflurane**
  - **Requires desflurane-specific vaporizer (electric, heated, pressurized, expensive)**
- 

### Uses/Indications

Desflurane is a volatile anesthetic with a chemical structure identical to isoflurane except for substitution of a fluorine atom for chlorine at the alpha-ethyl carbon. Desflurane may be of particular use when rapid recoveries are desired.

### Pharmacology/Actions

Desflurane is a halogenated inhalant anesthetic. It is structurally related to isoflurane (has a fluorine atom substituted for chlorine at the alpha-ethyl carbon). While the precise mechanism that inhalant anesthetics exert their general anesthetic effect is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Like sevoflurane, desflurane has a very low blood/gas partition coefficient (0.42). Minimal Alveolar Concentration (MAC; %) in oxygen reported for desflurane: dogs = 7; cats = 9.8; horse = 7.23; rabbit = 8.9, alpacas/llamas = 7.8-8.

Some key pharmacologic effects noted with desflurane include: rapid inductions and recoveries; rapid recoveries may be a benefit, but could also be detrimental particularly if perioperative analgesics are not used. It is relatively resistant to biodegradation that may minimize risk for nephrotoxicity.

Like sevoflurane, desflurane does not potentiate catecholamine-induced arrhythmias, and like all the inhalant anesthetics it does decrease arterial blood pressure and depress ventilation in a dose-dependent manner. Unlike sevoflurane, it is a respiratory irritant, has a pungent odor and is not well suited for mask inductions.

### Pharmacokinetics

Onset of action is very rapid after inhalation; some have described as "one breath" induction. At body temperature (37°C) desflurane has a blood/gas coefficient (predicts rate of recovery) of 0.47, an oil/gas coefficient (indicates potency) of 19 and a brain/blood coefficient of 1.3.

Very little of desflurane is eliminated via hepatic routes as only 0.02% is recovered as metabolites. In humans, elimination half-life is 2.5 minutes (isoflurane about 9.5 minutes).

### Contraindications/Precautions/Warnings

Desflurane is contraindicated in patients that are hypersensitive to it or other halogenated agents or that have a history or predilection towards malignant hyperthermia. It should be used with caution (benefits vs. risks) in patients with increased CSF pressure or head injury.

Because of its rapid action, use caution not to overdose during the induction phase. Because of the rapid recovery associated with desflurane, use caution (and appropriate analgesia and sedation during the recovery phase) particularly with large animals.

Geriatric or critically ill animals may require less inhalation anesthetic.

The National Institute for Occupational Safety and Health Administration has recommended that no worker should be exposed at ceiling concentrations greater than 2 ppm of any halogenated anesthetic agent over a sampling period not to exceed 1 hour.

### Adverse Effects

Desflurane is usually very well tolerated. Hypotension and respiratory depression may occur and are considered dose-dependent. Like all halogenated anesthetics, desflurane can cause malignant hyperthermia in susceptible individuals (usually humans or pigs). Desflurane may have a lower incidence rate of this effect than other halogenated anesthetics.

When used for mask inductions, desflurane can cause respiratory irritation and cause salivation in dogs and cats. Rapid changes in desflurane concentrations may result in a sympathetic response and temporarily increase cardiac work.

### Reproductive/Nursing Safety

Desflurane appears to be relatively safe to use during pregnancy, but data are limited. Because of its low blood solubility, desflurane may be one of the safest inhalant anesthetics for use during pregnancy. In rats and rabbits, no overt teratogenic effects were observed when exposed at 1 MAC-hour/day during organogenesis (10-13 days exposure). For humans, desflurane is categorized by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Desflurane is likely compatible with nursing as levels are low in milk and rapidly washout within 24 hours of use. However, safety during nursing has not been established.

### Overdosage/Acute Toxicity

In the event of an overdosage, discontinue desflurane; maintain airway and support respiratory and cardiac function as necessary.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving desflurane and may be of significance in veterinary patients:

■ **ACE INHIBITORS OR OTHER HYPOTENSIVE AGENTS:** Concomitant use may increase risks for hypotension. Enalapril caused significant decreases in systolic blood pressure in cats and dogs undergoing isoflurane anesthesia (Ishikawa *et al.* 2007). Similar effects may be expected with desflurane.

■ **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS:** Additive neuromuscular blockade may occur

■ **SUCCINYLCHOLINE:** With inhalation anesthetics, may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia

### Laboratory Considerations

■ Like other halogenated anesthetics, desflurane can cause transient increases in glucose and white blood cell count.

- Clinically useful concentrations: Induction = 8–15%; Maintenance = 5–9% (Grubb 2004)
- Approximate MAC for emergency patients: 6% (Gaynor 2010)
- Following intravenous induction: the author usually starts with a vaporiser setting of about 8% (around MAC in most animals), increasing the concentration as required. (Clarke 2008)

## Monitoring

- Respiratory, ventilatory status
- Cardiac rate/rhythm; blood pressure
- Level of anesthesia
- Body temperature,
- Neuromuscular function

## Chemistry/Synonyms

Desflurane has the chemical name: (±)-2-Difluoromethyl 1,2,2,2-tetrafluoroethyl ether and has molecular weight of 168. It is a clear, colorless, heavy liquid. It is non-flammable and non-explosive. At one atmosphere it has a boiling point of 22-23°C, a vapor pressure of 669mm Hg at 20°C, specific gravity is 1.465 at 20°C. Desflurane is practically insoluble in water, but miscible with anhydrous alcohol. Desflurane has a very low blood:gas solubility ratio of 0.42 (at 37°C).

Desflurane may also be known as I-653, desfluraani, desflurano, or desfluranum. A common trade name is *Suprane*®.

## Storage/Stability

Desflurane solution should be stored in its original container at 15° to 30°C (59° to 86°F). Secure cap on bottle tightly after use. Protect from light.

Before opening, the contents of the bottle should be cooled to below 10°C (48°F). Desflurane is relatively stable in soda lime at room temperature, but can produce carbon monoxide and formaldehyde. At 80°C, rate of degradation per hour is 0.44%.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Desflurane Solution for Inhalation Anesthesia in 240 mL btl; *Suprane*® (Baxter); (Rx)

---

## DESLORELIN ACETATE

(*dess-lor-a-lin*) SucroMate®, Ovuplant®

HORMONAL AGENT

### Prescriber Highlights

- **Synthetic GnRH analog for estrual mares to induce & time ovulation; implants may also be effective to control reproduction in the bitch or as a contraceptive in male dogs**
  - **No labeled contraindications**
  - **Adverse Effects: May cause some local swelling, pain, etc; interovulatory period may be prolonged if implant not removed**
- 

## Uses/Indications

Deslorelin is FDA-approved for inducing ovulation in estrual mares. There is also interest in developing dosages and dosage forms as a long-term, reversible contraceptive in a variety of animal species, as a treatment for prostatic disease in male dogs, and incontinence in ovariectomized dogs.

In humans, deslorelin has been investigated for treating children with precocious puberty, and in adults for prostate carcinoma, dysmenorrhea, fibroids, and endometriosis.

## Pharmacology/Actions

Deslorelin increases the levels of endogenous luteinizing hormone (LH), thereby inducing ovulation. When developing follicles are greater than 30 mm in diameter, deslorelin induces ovulation in approximately 78% of mares within 48 hours of administration.

## Pharmacokinetics

In horses after implantation of a 2.1 mg pellet, concentrations of LH and FSH peak about 12 hours after implant and return to pretreatment levels approximately 3–4 days after implantation. Oral dosing of 100 micrograms/kg to Beagles, demonstrated no increase in LH or FSH.

## Contraindications/Precautions/Warnings

Deslorelin acetate is contraindicated in horses known to be hypersensitive to it. Do not use in horses intended for human consumption. Do not administer IV.

## Adverse Effects

The IM gel can cause swelling at the site of injection. Swelling generally subsides with 5 days. With the implants, minor local swelling, sensitivity to touch, and elevated skin temperature at injection site may occur; these effects should resolve within 5 days of implantation.

There is some evidence that deslorelin implants can suppress pituitary FSH secretion and decrease follicular development in subsequent diestrus, leading to a prolonged interovulatory period. Some clinicians (see the dose recommendation by McCue 2003, below), recommend removing the implant to negate this possibility.

## Reproductive/Nursing Safety

Abnormalities in foal viability or behavior related to the use of deslorelin have not been observed in foals born to treated mares.

## Overdosage/Acute Toxicity

In 8 mares that received a single IM injection at 10X the recommended of 1.8 mg dose, one exhibited moderate tremors and hives 6 hours after injection. If inadvertent administration of additional implant is done, it should be removed upon detection if within 96 hours of implant.

## Drug Interactions

- No specific interactions noted

## Laboratory Considerations

- None noted

## Doses

### ■ DOGS:

As a contraceptive in male dogs: Using the 4.7 mg implant (*Suprelorin-6*®—Virbac/Peptech): Implant SC every 6 months. Using the 9.4 mg implant (*Suprelorin-12*®—Peptech): Implant SC every 12 months. Implant in loose skin between lower neck and lumbar area; avoid implanting into fat. Pregnant women should not administer the implant. (Adapted from label information; see full label for further dosing instructions, precautions and adverse effects)

### ■ HORSES:

For induction of ovulation:

- For inducing ovulation within 48 hours in cyclic estrous mares with an ovarian follicle between 30 and 40 mL in diameter: Shake vial well before drawing into syringe. Administer 1.8 mg (1 mL) by intramuscular injection in the neck. (Label Information—*SucroMate*® Equine)
- If follicle is greater than 30 mm in diameter (as determined by rectal palpation or ultrasound), and breeding is to take place within 48 hours, place one implant subcutaneously in the neck. Implant site should be midway between head and shoulder over the muscle mass of the neck and away for subcutaneous nerves and vessels. Thoroughly disinfect site of implant. Insert the entire length of needle SC and fully depress the implanter plunger. Slowly withdraw needle while pressing skin at injection site. Examine implanter to assure that implant has been administered. Do not reuse implanter. Implant will be absorbed with time. (Package insert; *Ovuplant*®)
- As above, but because interovulatory interval may be prolonged if implant is left in the mare, remove after approximately 48 hours.

Alternative dosing/removal method: Restrain mare and briefly wash vulva with soap and water and then dry. One mL of lidocaine is infused into the edge of the vulva. The implant is inserted just beneath the epithelium in the blocked area. When the lidocaine is absorbed, the implant can be palpated. After ovulation, the implant can be gently “squeezed” out of the original opening created by the implant device. No treatment is required at the site after removal of the implant. (McCue 2003)

## Monitoring

- None required

## Chemistry/Synonyms

Deslorelin acetate is a synthetic gonadotropin-releasing hormone (GnRH, gonadorelin) analog. It is a nonapeptide and has chemical modifications in the amino acid composition at positions 6 and 9/10.

## Storage/Stability

Deslorelin implants or injectable suspension should be stored refrigerated (2–8°C, 36–46°F).

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Deslorelin Suspension for Injection 1.8 mg/mL in 10 mL multi-dose vials; *SucroMate*® Equine (Thorn/Bioniche; NADA 141-319); (Rx). FDA-approved for horses (not intended for food).

Deslorelin 2.1 mg cylindrical implant with implanter; 5 per box *Ovuplant*® (Peptech) (Rx). FDA-approved for ovulation induction in mares. Not for use in horses intended for food. This product is FDA-approved in the USA (per the FDA’s Green Book), but it may not be currently marketed.

In Australia, New Zealand (6 month only) and several EU countries: Deslorelin Implants 4.7 mg (6 month) and 9.4 mg (12 month) are available for contraceptive use in male dogs. Trade name is *Suprelorin*®-6 or *Suprelorin*®-12 (Peptech)

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

**HUMAN-LABELED PRODUCTS:** None

## DESMOPRESSIN ACETATE

(des-moe-press-in) Stimate®, DDAVP®

HORMONAL AGENT

### Prescriber Highlights

- **Synthetic vasopressin analogue used to treat diabetes insipidus & Von Willebrand's disease (limited usefulness)**
  - **Contraindications: Hypersensitivity to desmopressin, type IIB or platelet-type (pseudo) Von Willebrand's (German shorthair pointers?)**
  - **Use caution in patients susceptible to thrombosis**
  - **Adverse Effects: Eye irritation after conjunctival administration; hypersensitivity possible**
  - **Overdoses can cause fluid retention/hyponatremia**
- 

### Uses/Indications

Desmopressin has been found to be useful in the treatment of central diabetes insipidus in small animals. It may be useful in treating Von Willebrand's disease, but its short duration of activity (2–4 hours) in this condition, resistance development, and expense limit its usefulness for this disorder. Desmopressin may be useful perioperatively to reduce lymph node involvement and metastatic disease in canine mammary gland cancer.

### Pharmacology/Actions

Desmopressin is related structurally to arginine vasopressin, but it has more antidiuretic activity and less vasopressor properties on a per weight basis. Desmopressin increases water reabsorption by the collecting ducts in the kidneys, thereby increasing urine osmolality and decreasing net urine production. Therapeutic doses do not directly affect either urinary sodium or potassium excretion.

Desmopressin causes a dose-dependent increase in plasma factor VIII and plasminogen factor and also causes smaller increases in factor VIII-related antigen and ristocetin cofactor activities.

### Pharmacokinetics

Because desmopressin is destroyed in the GI tract, it usually is given parenterally or topically. Oral tablets have been used in those dogs that cannot tolerate ophthalmic administration, but bioavailability is very low. In humans, intranasal administration is commonly used, while in veterinary medicine topical administration to the conjunctiva is preferred. The onset of antidiuretic action in dogs usually occurs within one hour of administration, peaks in 2–8 hours, and may persist for up to 24 hours. Distribution characteristics of desmopressin are not well described, but it does enter maternal milk. The metabolic fate is also not well understood. Terminal half lives in humans after IV administration are from 0.4–4 hours.

### Contraindications/Precautions/Warnings

Desmopressin is contraindicated in patients hypersensitive to it. It should not be used for treatment of type IIB or platelet-type (pseudo) Von Willebrand's disease as platelet-aggregation and thrombocytopenia may occur. German shorthair pointers apparently can have this type of vWD. Desmopressin should be used with caution in patients susceptible to thrombotic events.

When desmopressin is used to stimulate von Willebrand factor, with repeated administration tachyphylaxis (increasing lack of efficacy) will occur to a variable extent within 24 hours.

### Adverse Effects

Side effects in small animals apparently are uncommon. Occasionally eye irritation may occur after conjunctival administration. Hypersensitivity reactions are possible. Humans using the drug have complained about increased headache frequency.

### Reproductive/Nursing Safety

Safe use during pregnancy has not been established; however safe doses of up to 125 times the average human antidiuretic dose have been given to rats and rabbits without demonstration of fetal harm. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Desmopressin is likely safe to use during nursing.

### Overdosage/Acute Toxicity

Oral doses of 0.2 mg/kg/day have been administered to dogs for 6 months without any significant drug-related toxicities reported. Dosages that are too high may lead to fluid retention and hyponatremia; dosage reduction and fluid restriction may be employed to treat. Adequate monitoring should be performed.

### Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving desmopressin and may be of significance in veterinary patients:

■ **CHLORPROPAMIDE, FLUDROCORTISONE, UREA:** May enhance the antidiuretic effects of desmopressin

### Laboratory Considerations

■ See Monitoring Parameters

### Doses

**Note:** When doses listed below use “drops” of the nasal solution they are referencing the 0.1 mg/mL product and NOT the 1.5 mg/mL product (*Stimate*®). Do not confuse the two.

#### ■ DOGS:

- One drop placed twice daily in the conjunctival sac sufficiently controls polyuria in most dogs with central DI. Using one drop three times a day usually returns urine production to normal. (Rijnberk 2005)
- For treatment of diabetes insipidus (central): 1–4 drops of the intranasal solution in the conjunctival sac once to twice daily; may use intranasal solution parenterally at 2–5 micrograms SC once to twice daily (Nichols 2000)
- For treatment of complete and partial central diabetes insipidus: 1–4 drops of the intranasal solution in the conjunctival sac once a day to twice a day (Behrend 2003)
- 1–2 drops into the conjunctival sac or 0.01–0.05 mL SC once a day to twice a day (Bruyette, D 2002)
- As a trial in place of water deprivation test: one-half to one 0.1 or 0.2 mg DDAVP tablet PO q8h or 1–4 drops of nasal spray from an eye dropper into the conjunctival sac every 12 hours for 5–7 days. If central DI, owners should notice a decrease in PU/PD by the end of treatment period. Increase in urine specific gravity by 50% or more, compared with pre-treatment values, also support diagnosis of central DI. (Nelson 2002)

For treatment of Von Willebrand’s disease:

- For preoperative prophylaxis: 1 microgram/kg SC one-half hour before surgery. Close monitoring needed to determine extent and duration of response. Transfusion should be readily available. Desmopressin not effective for treatment or preoperative prophylaxis of severe Types 2 and 3 vWD. (Brooks 2003)
- May be particularly useful to help prevent or control bleeding in association with surgery. Intranasal product is given subcutaneously at 1–4 micrograms/kg. Onset of activity occurs in 30 minutes and duration of effect is approximately 2 hours. (Carr & Panciera 2000)

#### ■ CATS:

- To help differentiate central diabetes insipidus from the nephrogenic form: 1 drop into the conjunctival sac twice daily for 2–3 days; a dramatic reduction in water intake or a 50% or greater increase in urine concentration gives strong evidence for a deficit in ADH production. For treatment of central DI: 1–2 drops into the conjunctival sac once or twice a day; duration of activity is 8–24 hours. (Bruyette, DS 1991)
- For treatment of diabetes insipidus (central): 1–4 drops of the intranasal solution in the conjunctival sac once to twice daily; may use intranasal solution parenterally at 2–5 micrograms SC once to twice daily (Nichols 2000)
- For treatment of diabetes insipidus in cats whose owners find the intranasal or conjunctival application of desmopressin inconvenient: 25–50 micrograms (total dose; ¼th to ½ of a 100 microgram tablet) PO q12h. Dose and response may be variable. (Aroch *et al.* 2005)

#### ■ HORSES:

For diagnosis of diabetes insipidus:

- 20 micrograms IV (Barnes *et al.* 2002)
- Dilute the nasal spray formulation (0.1 mg/ml) in sterile water and administer 0.05 micrograms/kg IV. Urine specific gravity (SG) should be measured every 2 hours. An increase in SG to 1.025 or greater within 2 to 7 hours is consistent with central DI. No change in urine SG is consistent with nephrogenic DI if medullary washout has been accounted for. (McKenzie 2009)

#### Monitoring

For Central DI:

- Serum electrolytes
- Urine osmolality and/or urine volume
- For Von Willebrand’s disease:
- Bleeding times

#### Client Information

- Keep solutions refrigerated whenever possible.
- Instruct clients on the importance of compliance with administering this drug as directed. It is a treatment, not a cure for the condition.
- Clients should be counseled on the expense associated with using this drug long-term.

#### Chemistry/Synonyms

A synthetic polypeptide related to arginine vasopressin (antidiuretic hormone), desmopressin acetate occurs as a fluffy white powder with a bitter taste. The commercially available nasal solution has HCl added and the pH is approximately 4. This preparation also contains chlorobutanol 0.5% as a preservative.

Desmopressin Acetate may also be known as: 1-Deamino-8-D-Arginine Vasopressin, *DDAVP*®, *Concentraid*®, *D-Void*®, *Defirin*®, *Desmogalen*®, *Desmospray*®, *Desmotabs*®, *Emosint*®, *Minirin*®, *Minirin/DDAVP*®, *Minrin*®, *Minurin*®, *Nocutil*®, *Octim*®, *Octostim*®, *Presinex*®, or *Stimate*®.

#### Storage/Stability

The nasal solution should be refrigerated (2–8°C). It has an expiration date of one year after manufacture. While the nasal solution should be stored in the refrigerator, it is stable at room temperature for 3 weeks in the unopened bottle. The product for injection should be stored refrigerated (4°C); do not freeze.

#### Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

#### HUMAN-LABELED PRODUCTS:

Desmopressin Acetate Intranasal Spray Solution: 0.1 mg/mL (0.01%; 10 micrograms/spray) in 5 mL bottle or 2.5 mL rhinal tube delivery system; *DDAVP*® (Sanofi-Aventis); generic; (Rx)

Desmopressin Acetate Intranasal Spray Solution: 1.5 mg/mL (0.15%; 150 micrograms/spray) in 2.5 mL bottle; *Stimate*® (ZI B Behring); (Rx)

Desmopressin Acetate Injection Solution: 4 micrograms/mL in 1 mL single-dose amps & 10 mL multiple dose vials; *DDAVP*® (Sanofi-Aventis); generic; (Rx)

Desmopressin Acetate Oral Tablets: 0.1 mg & 0.2 mg; *DDAVP*® (Sanofi-Aventis); generic; (Rx)

## DESOXYCORTICOSTERONE PIVALATE; DOCP

(de-sox-ee-kor-ti-kost-er-ohn *pih*-vah-late) Percorten-V®

MINERALOCORTICOID

### Prescriber Highlights

- Parenteral mineralocorticoid used to treat Addison's in dogs/cats
- Relative contraindications: congestive heart failure, severe renal disease, or edema; Caution: pregnancy
- Addison's patients must receive glucocorticoid supplementation in periods of high stress/illness
- May cause irritation at injection site
- Adjust dosage based upon monitoring parameters

---

## Uses/Indications

DOCP is indicated for the parenteral treatment of adrenocortical insufficiency in dogs. It is also used in an extra-label manner in cats.

## Pharmacology/Actions

Desoxycorticosterone pivalate (DOCP) is a long-acting mineralocorticoid agent. The site of action of mineralocorticoids is at the renal distal tubule where it increases the absorption of sodium. Mineralocorticoids also enhance potassium and hydrogen ion excretion. To be effective, mineralocorticoids require a functioning kidney.

## Pharmacokinetics

Little information is available. It is injected IM (or subcutaneously) as a microcrystalline depot for slow dissolution into the circulation. DOCP usually has a duration of action in dogs for 21–30 days after injection.

## Contraindications/Precautions/Warnings

The drug is contraindicated in dogs suffering from congestive heart failure, severe renal disease, or edema.

Because some animals may be more (or less) sensitive to the effects of the drug, “cookbook” dosing without ongoing monitoring is inappropriate. Some animals may require additional supplementation with a glucocorticoid agent on an ongoing basis that may cause polydipsia, polyuria, or polyphagia if doses are too high. All animals with hypoadrenocorticism should receive additional glucocorticoids (2–10 times basal) during periods of stress or acute illness.

Do not administer DOCP IV; acute collapse and shock may result. If given IV, treat immediately for shock with IV fluids and glucocorticoids.

## Adverse Effects

Occasionally, irritation at the site of injection may occur. Adverse effects of DOCP are generally a result of excessive dosage (see Overdosage below).

## Reproductive/Nursing Safety

The manufacturer states that the drug should not be used in pregnant dogs as safe use during pregnancy has not been established. Use in pregnant animals only when the potential benefits outweigh the risks.

DOCP should be safe for offspring when administered to nursing dams.

## Overdosage/Acute Toxicity

Overdosage may cause polyuria, polydipsia, hypernatremia, hypertension, edema, and hypokalemia. Cardiac enlargement is possible with prolonged overdoses. Excessive weight gain may be indicative of fluid retention secondary to sodium retention. Electrolytes should be aggressively monitored and potassium may need to be supplemented. Discontinue the drug in patients until clinical signs associated with overdosage have resolved and then restart the drug at a lower dosage.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving DOCP and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Patients may develop hypokalemia if mineralocorticoids are administered concomitantly with amphotericin B
- **ASPIRIN:** DOCP may reduce salicylate levels
- **DIGOXIN:** Because DOCP may cause hypokalemia, it should be used with caution and increased monitoring when used in patients receiving digitalis glycosides
- **INSULIN:** Potentially, DOCP could increase the insulin requirements of diabetic patients

■ **POTASSIUM-DEPLETING DIURETICS (e.g., furosemide, thiazides):** Patients may develop hypokalemia if mineralocorticoids are administered concomitantly with potassium-depleting diuretics; as diuretics can cause a loss of sodium, they may counteract the effects DOCP

## Doses

### ■ DOGS:

**Note:** Dosage requirements are variable and should be individualized to the patient.

For hypoadrenocorticism:

a) 2.2 mg/kg IM every 25 days (Label information; *Percorten®-V*)

b) Initially, inject 2.2 mg/kg IM or SC every 25 days. Reevaluate at 12 and 25 days after initial injection. If hyponatremia and/or hyperkalemia are noted at 12 days, increase dose by 10%. If they are noted at 25 days (but not on day 12), shorten dosing interval by 2 days. (Reusch 2000)

c) 1.5–2.2 mg/kg IM q20–30 days (Lorenz & Melendez 2002)

d) Initially, 2.2 mg/kg IM q25 days. If electrolytes remain in normal range at 30 days, reduce dose by 10% a month. In our clinic, we have used a dose of DOCP as low as 1 mg/kg q30 days with good control of hypoadrenocorticism. (Scott-Moncrieff 2006)

### ■ CATS:

For maintenance therapy of hypoadrenocorticism:

a) 2.2 mg/kg IM every 25 days plus prednisolone (0.25–1 mg/cat PO twice daily; if daily oral dosing not feasible, may give 10 mg of methylprednisolone acetate once a month IM) (Reusch 2000)

b) 10–12.5 mg (total dose) IM per month. Adjust dose based-upon follow-up serum electrolyte concentrations monitored every 1–2 weeks during initial maintenance period. Normal electrolyte values 2 weeks following injection, suggests adequate dosing, but does not provide information regarding duration of action. Prednisone at 1.25 mg PO once a day or IM methylprednisolone acetate 10 mg once a month can provide long-term glucocorticoid supplementation. (Bruyette 2002)

## Monitoring

■ Serum electrolytes, BUN, creatinine; initially every 1–2 weeks, then once stabilized, every 3–4 months

■ Weight, PE for edema

## Client Information

■ Clients should be familiar with the symptoms associated with both hypoadrenocorticism (e.g., weakness, depression, anorexia, vomiting, diarrhea, etc.) and DOCP overdosage (e.g., edema) and report these to the veterinarian immediately.

■ If client is injecting the drug at home, instruct in proper technique for IM administration. Vial should be shaken vigorously to suspend the macrocrystals.

## Chemistry/Synonyms

A mineralocorticoid, desoxycorticosterone pivalate (DOCP) occurs as a white or creamy white powder that is odorless and stable in air. It is practically insoluble in water, slightly soluble in alcohol and vegetable oils. The injectable product is a white aqueous suspension and has a pH between 5–8.5.

Desoxycorticosterone pivalate may also be known as: desoxycorticosterone pivalate, desoxycorticosterone trimethyl-acetate, deoxycortone pivalate, deoxycortone trimethylacetate, desoxycorticosterone pivalate, desoxycorticosterone trimethyl-acetate, *Cortiron®*, or *Percorten-V®*.

## Storage/Stability

Store the injectable suspension at room temperature and protect from light or freezing. Do not mix with any other agent.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Desoxycorticosterone Pivalate Injectable Suspension: 25 mg/mL in 4 mL vials; *Percorten-V®* (Novartis); (Rx). FDA-approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

## DETOMIDINE HCL

(*de-toe-ma-deen*) Dormosedan®

### Prescriber Highlights

- **Alpha2 sedative analgesic used primarily in horses**
- **Contraindications: Heart block, severe coronary, cerebrovascular, or respiratory disease, chronic renal failure**
- **Caution: Horses with endotoxic or traumatic shock or approaching shock, advanced hepatic or renal disease; stress due to temperature extremes, fatigue, or high altitude; patients treated for intestinal impactions; with suspected colic as it may mask abdominal pain or changes in respiratory & cardiac rates**

- May respond (*i.e.*, kick) to external stimuli even after fully sedated; use caution, opioids may temper
  - Adverse Effects: Initial blood pressure increase, then bradycardia/heart block, piloerection
- 

## Uses/Indications

At present, detomidine is only FDA-approved for use as a sedative analgesic in horses, but it has been used clinically in other species.

## Pharmacology/Actions

Detomidine, like xylazine, is an alpha<sub>2</sub>-adrenergic agonist that produces a dose-dependent sedative and analgesic effect, but it also has cardiac and respiratory effects. For more information, refer to the xylazine monograph or the adverse effects section below. Detomidine is approximately 50–100 times as potent as xylazine.

## Pharmacokinetics

Detomidine is well absorbed after oral administration, but is used only parenterally currently. The drug is apparently rapidly distributed into tissues, including the brain after parenteral administration and is extensively metabolized and then excreted primarily into the urine. Peak sedative actions can range from 5–20 minutes post injection in horses.

Published mean or median pharmacokinetic values for detomidine in horses include: Volume of distribution: 0.47-0.59 L/kg (at rest), 1.3 L/kg (after exercise). Time to reach maximum blood level concentration: Approximately 2 minutes (IV), 77 minutes (IM). Clearance: 12-16 mL/min/kg. Elimination half-life: 24–26 minutes (IV, at rest), 46 minutes (IV, after exercise), 51 minutes (IM, at rest) (Hubbell, J.A.E. *et al.* 2009), (Mama *et al.* 2009). The oromucosal gel product (available in some countries) bioavailability is lower than IM (22% vs. 38%) (Kaukinen *et al.* 2009).

After exercise, the volume of distribution of detomidine is higher than at rest. Initial dose requirements may be higher and subsequent doses lower after exercise (Hubbell, J.A.E. *et al.* 2009).

## Contraindications/Precautions/Warnings

Detomidine is contraindicated in horses with preexisting AV or SA heart block, severe coronary insufficiency, cerebrovascular disease, respiratory disease or chronic renal failure. Use cautiously in animals with endotoxic or traumatic shock or approaching shock, and advanced hepatic or renal disease. Horses who are stressed due to temperature extremes, fatigue, or high altitude should be given the drug carefully. Because this drug may inhibit gastrointestinal motility, use with prudence in patients treated for intestinal impactions. In horses with suspected colic, the use of detomidine analgesia should be used cautiously as it may mask abdominal pain and conceal changes in respiratory and cardiac rates, thereby making diagnosis more difficult.

Although animals may appear to be deeply sedated, some may respond (kick, etc.) to external stimuli; use appropriate caution. The addition of opioids (*e.g.*, butorphanol) may help temper this effect. The manufacturer recommends allowing the horse to stand quietly for 5 minutes prior to injection and for 10–15 minutes after injection to improve the effect of the drug. After administering detomidine, protect the animal from temperature extremes.

During times of ambient temperature extremes, especially summer heat, consider using dosages in the lower range to reduce chances for toxicity.

When using the gel, wear impermeable gloves during drug administration or doing procedures that require contact with the horse's mouth.

## Adverse Effects

Detomidine can cause an initial rise in blood pressure that is then followed by bradycardia and heart block. Atropine at 0.02 mg/kg IV has been successfully used to prevent or correct the bradycardia that may be seen when the detomidine is used at labeled dosages. In addition, piloerection, sweating, ataxia, salivation, slight muscle tremors, and penile prolapse may all be noted after injection.

When compared to xylazine, detomidine causes more pronounced bradycardia and bradyarrhythmias. Because the sedative and muscle-relaxing effects of detomidine in horses can persist for up to 90 minutes, it may influence the quality of recovery and contribute to post-anesthesia ataxia.

## Reproductive/Nursing Safety

The manufacturer states that "Information on the possible effects of detomidine HCl in breeding horses is limited to uncontrolled clinical reports; therefore, this drug is not recommended for use in breeding animals." No other information was located.

## Overdosage/Acute Toxicity

The manufacturer states that detomidine is tolerated by horses at doses 5X (0.2 mg/kg) the high dose level (0.04 mg/kg). Doses of 0.4 mg/kg given daily for 3 consecutive days produced microscopic foci of myocardial necrosis in 1 of 8 horses tested. Doses of 10–40X recommended can cause severe respiratory and cardiovascular changes that can become irreversible and cause death. Yohimbine or atipamezole could be used to reverse some or all of the effects of the drug. Atipamezole, at a dose of 50–100 micrograms/kg has been successfully used to treat inadvertent overdoses of detomidine in horses.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving detomidine and may be of significance in veterinary patients:

- **ALPHA-2 AGONISTS, OTHER** (*e.g.*, xylazine, medetomidine, romifidine, clonidine and including epinephrine): Not recommended to be used together with detomidine as effects may be additive
- **ANESTHETICS, OPIATES, SEDATIVE/HYPNOTICS**: Effects may be additive; dosage reduction of one or both agents may be required; potential for increased risk for arrhythmias when used in combination with thiopental, ketamine or halothane
- **EPINEPHRINE**: As epinephrine possesses alpha agonist effects, do not use to treat cardiac effects caused by detomidine
- **PHENOTHIAZINES** (*e.g.*, acepromazine): Severe hypotension can result
- **SEDATIVES OR ANALGESICS, OTHER**: The manufacturer warns to use with extreme caution in combination with other sedative or analgesic drugs
- **SULFONAMIDES, POTENTIATED** (*e.g.*, trimethoprim/sulfa): The manufacturer warns against using this agent with intravenous potentiated sulfonamides (*e.g.*, trimethoprim/sulfa) as fatal dysrhythmias may occur

## Doses

## ■HORSES: (Note: ARCI Class 3 Drug)

For sedation/analgesia (**CAUTION:** Do not confuse micrograms/kg with mg/kg doses):

a) Injection: 20–40 micrograms/kg (0.02–0.04 mg/kg) IV or IM (IV only for analgesia). Effects generally occur within 2–5 minutes. Lower dose will generally provide 30–90 minutes of sedation and 30–45 minutes of analgesia. The higher dose will generally provide 90–120 minutes of sedation and 45–75 minutes of analgesia. Allow animal to rest quietly prior to and after injection.

Sublingual Gel: 0.04 mg/kg (0.018 mg/lb) (0.040 mg/kg) placed beneath the tongue of the horse; not meant to be swallowed. The dosing syringe delivers the product in 0.25 mL increments. The package insert provides a dosing table to determine correct amount of gel to administer for the weight of the horse. (Package inserts; *Dormosedan*®; *Dormosedan Gel*®—Pfizer)

b) For horses with marked abdominal pain that are either not candidates for exploratory surgery or must be transported long distances for surgery: 0.01–0.02 mg/kg (10–20 micrograms/kg) IV or IM (Moore 1999)

c) Detomidine at 0.01–0.02 mg/kg IV or IM with or without butorphanol (0.02–0.03 mg/kg) (Taylor 1999)

d) For adjunctive treatment of moderate pain: 0.03–0.04 mg/kg IV;

For caudal epidural analgesia: 0.06 mg/kg, given between S4–S5; duration of analgesia is 2–3 hours *or* detomidine 0.03 mg/kg with morphine (0.2 mg mg/kg) given between S1–L6; duration of analgesia is >6 hours (Muir 2004)

e) For oral administration when horse is not amenable to injections: 0.06 mg/kg PO; profound sedation occurs in about 45 minutes (Hubbell, J. 2006)

f) As a CRI for standing chemical restraint and analgesia: Two protocols have been described:

1) Loading dose of 7.5 micrograms/kg IV bolus, followed by a CRI rate of 0.6 micrograms/kg/minute for the first 15 minutes; after this CRI rate is halved every 15 minutes. In many cases did not provide adequate analgesia alone and needed to be supplemented by local anesthetics, epidural analgesia, or supplemental detomidine and/or butorphanol. Average duration of procedures was 40 minutes.

2) Loading dose of 8.4 micrograms/kg IV bolus, then 0.5 micrograms/kg/minute for 15 minutes, then 0.3 micrograms/kg/minute for 15 minutes, then 0.15 micrograms/kg/minute thereafter. A butorphanol CRI was used if additional sedation and analgesia was required. (Mogg 2006)

## ■CATTLE:

a) For sedation/analgesia: 30–60 micrograms/kg (0.03–0.06 mg/kg) IV or IM (Not FDA-approved) (Alitalo 1986)

b) For analgesia: 0.01 mg/kg IV; short (½ hour) duration of action. Appropriate withdrawal times are: Milk = 72 hours; Slaughter = 7 days. (Walz 2006)

## ■SHEEP, GOATS:

a) For anesthesia: Detomidine at 0.01 mg/kg IM, followed by propofol at 3–5 mg/kg IV.

For analgesia: 0.005–0.05 mg/kg IV or IM q3–6 hours (once) (Haskell 2005)

## ■LLAMAS, ALPACAS:

a) For analgesia: 0.005–0.05 mg/kg IV or IM q3–6 hours (once) (Haskell 2005)

## ■BIRDS:

a) For sedation/analgesia: 0.3 mg/kg IM; limited data available on duration of effect, adverse effects, etc. (Clyde & Paul-Murphy 2000)

## Monitoring

■ Level of sedation, analgesia

■ Cardiac rate/rhythm; blood pressure if indicated

## Client Information

■ This drug should be used in a professionally supervised setting by individuals familiar with its properties.

## Chemistry/Synonyms

An imidazoline derivative alpha2-adrenergic agonist, detomidine HCl occurs as a white crystalline substance that is soluble in water.

Detomidine HCl may also be known as: demotidini hydrochloridum, MPV-253-AII, or *Dormosedan*®.

## Storage/Stability

Detomidine HCl for injection should be stored at room temperature (59–85°F; 15–30°C) and protected from light.

Detomidine Gel for SL Administration should be stored at controlled room temperature (68–77°F; 20–25°C); excursions are permitted to 59–85°F (15–30°C).

## Dosage Forms/Regulatory Status

## VETERINARY-LABELED PRODUCTS:

Detomidine HCl for Injection: 10 mg/mL in 5 mL and 20 mL vials; *Dormosedan*® (Pfizer); (Rx). FDA-approved for use in mature horses and yearlings.

Detomidine HCl Oromucosal Gel for Sublingual Administration: 7.8 mg/mL in 3 mL graduated dosing syringes; *Dormosedan Gel*® (Pfizer); (Rx). FDA-approved for use in horses not intended for human consumption.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

**HUMAN-LABELED PRODUCTS:** None

## DEXAMETHASONE

### DEXAMETHASONE SODIUM PHOSPHATE

(dex-a-meth-a-zone) Azium®, Dexasone®

#### GLUCOCORTICOID

#### Prescriber Highlights

- **Injectable, oral & ophthalmic glucocorticoid**
  - **Long acting; 30X more potent than hydrocortisone; no mineralocorticoid activity**
  - **If using for therapy, goal is to use as much as is required & as little as possible for as short an amount of time as possible**
  - **Primary adverse effects are “Cushingoid” in nature with sustained use, but acute effects (primarily GI, colon perforation in dogs after high doses) can be seen**
  - **Many potential drug & lab interactions**
- 

#### Uses/Indications

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (*e.g.*, adrenal insufficiency), rheumatic diseases (*e.g.*, rheumatoid arthritis), collagen diseases (*e.g.*, systemic lupus), allergic states, respiratory diseases (*e.g.*, asthma), dermatologic diseases (*e.g.*, pemphigus, allergic dermatoses), hematologic disorders (*e.g.*, thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (*e.g.*, ulcerative colitis exacerbations), and renal diseases (*e.g.*, nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete. High dose fast-acting corticosteroids use for shock or CNS trauma is controversial; recent studies have not demonstrated significant benefit and it actually may cause increased deleterious effects.

#### Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

**Cardiovascular System:** Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs’ vasoconstrictive properties and increased blood volume that may be produced.

**Cells:** Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

**CNS/Autonomic Nervous System:** Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

**Endocrine System:** When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (*e.g.*, renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T<sub>4</sub>) to triiodothyronine (T<sub>3</sub>) may be reduced by glucocorticoids; plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

**Hematopoietic System:** Glucocorticoids can increase the numbers of circulating platelets, neutrophils and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.

**GI Tract and Hepatic System:** Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulphophthalein) retention time.

**Immune System** (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

**Metabolic effects:** Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (*e.g.*, abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

**Musculoskeletal:** Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

**Ophthalmic:** Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and

**Pharmacokinetics:** Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

**Renal, Fluid, & Electrolytes:** Glucocorticoids can increase potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

**Skin:** Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

## Pharmacokinetics

Pharmacokinetics of dexamethasone do not translate into pharmacologic effect. The half-life of dexamethasone in dogs is about 2–5 hours, but biologic activity can persist for 48 hours or more.

## Contraindications/Precautions/Warnings

Because dexamethasone has negligible mineralocorticoid effect, it should generally not be used alone in the treatment of adrenal insufficiency.

Do not administer the propylene glycol base injectable product rapidly intravenously; hypotension, collapse, and hemolytic anemia can occur. Many clinicians only use dexamethasone sodium phosphate when giving the drug intravenously.

In dogs, dexamethasone can cause more gastrointestinal complications and bleeding than does prednisone, so careful attention to the minimum dosing necessary is required. There is a high incidence of gastrointestinal bleeding and colonic perforation in canine neurosurgical patients treated with dexamethasone (also seen with methylprednisolone sodium succinate); the dose and duration of therapy should be limited to as short a time as possible, and prednisone or prednisolone used when possible instead of dexamethasone (Wilson 2011).

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Animals, particularly cats, at risk for diabetes mellitus or with concurrent cardiovascular disease should receive glucocorticoids with caution due to these agents' potent hyperglycemic effect.

## Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. Glucocorticoids can retard growth in young animals. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP) and polyuria (PU), may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when giving the drug. Very high doses in dogs with spinal chord injuries have caused fatal colon perforations. Other adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting, and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and, potentially, more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Glucocorticoids appear to have a greater hyperglycemic effect in cats than other species. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to "Cushingoid" effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

## Reproductive/Nursing Safety

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

## Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause significant harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dexamethasone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine, neostigmine, etc.**): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES:** May increase the metabolism of glucocorticoids and decrease dexamethasone blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIAZEPAM:** Dexamethasone may decrease diazepam levels

- **DIURETICS, POTASSIUM-DEPLETING (e.g., spironolactone, triamterene):** Administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May reduce dexamethasone blood levels and interfere with dexamethasone suppression tests
- **INDOMETHACIN:** Can cause false negative test results in the dexamethasone suppression test
- **INSULIN:** Insulin requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE AND OTHER AZOLE ANTIFUNGALS:** May decrease the metabolism of glucocorticoids and increase dexamethasone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis
- **MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin):** May decrease the metabolism of glucocorticoids and increase dexamethasone blood levels
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **PHENYTOIN:** May increase the metabolism of glucocorticoids and decrease dexamethasone blood levels
- **RIFAMPIN:** May increase the metabolism of glucocorticoids and decrease dexamethasone blood levels
- **DEXAMETHASONE:** In dogs, dexamethasone increased quinidine volume of distribution (49-78%) and elimination half-life (1.5-2.3X). (Zhang *et al.* 2006)
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

### Laboratory Considerations

- While dexamethasone does not interfere with the cortisol assay, over a few days it will suppress the HPA axis and suppress endogenous release of cortisol, so if using it to diagnose hypoadrenocorticism, **ACTH stimulation tests** should be performed as soon as possible.
- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T<sub>3</sub> & T<sub>4</sub>** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I<sup>131</sup> by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** in dogs which can persist for weeks after drug discontinuation

### Doses

#### ■ DOGS:

For labeled indications (antiinflammatory; glucocorticoid agent):

a) Injection: 0.5–1 mg IV or IM; may be repeated for 3–5 days; Tablets: 0.25–1.25 mg PO daily in single or two divided doses (Package Insert; *Azium*®—Schering)

As an antiinflammatory agent or immunosuppressive:

a) Generally, most veterinarians use prednisone or prednisolone when a glucocorticoid is administered orally to dogs. Despite a short circulating half-life, dexamethasone has a long biologic duration of effect (thought to be >48 hours, whereas the biologic duration of effect of prednisone is 12–36 hours). Thus, it is difficult to spare normal adrenal function, even when dexamethasone is given every other day. (Wilson 2011)

Replacement of glucocorticoid activity in patients with adrenal insufficiency (Note: Dexamethasone has no mineralocorticoid activity):

a) For Addisonian crises: give 0.1–0.2 mg/kg dexamethasone sodium phosphate IV as the initial dose. Dexamethasone is not measured on the cortisol assay, so the ACTH stimulation test will be valid after dexamethasone is used. If the dog is vomiting/inappetent, dexamethasone may be continued at a dose of 0.05–0.1 mg/kg q12h until able to switch to oral prednisone as the glucocorticoid replacement (see Prednisone monograph for more information) (Wilson 2011).

b) For Addisonian crisis: Dexamethasone sodium phosphate at 0.2–0.5 mg/kg IV once; maintenance therapy with prednisone. Dexamethasone, unlike prednisone will not interfere with cortisol assays. (Jutkowitz 2009)

c) For adjunctive acute treatment (including correction of hypotension/hypovolemia, electrolyte imbalances, acidosis, hypoglycemia, and hypercalcemia: Immediately place IV catheter in cephalic or jugular vein, and collect a blood sample for measurement of electrolytes and cortisol. Cosyntropin (synthetic ACTH) is then administered IV, and a second blood sample for measurement of cortisol collected 1 hour later. Fluid therapy (0.9% saline IV, 30–80 mL/kg/24 hours plus correction for dehydration) should be started immediately. After the second blood sample is collected, give prednisolone sodium succinate (4–20 mg/kg IV), or hydrocortisone hemisuccinate or hydrocortisone phosphate (2–4 mg/kg IV) or dexamethasone sodium phosphate at 0.5–2 mg/kg as an initial dose. Then add dexamethasone at a dose of 0.05–0.1 mg/kg q12 hours into fluids until able to switch to oral glucocorticoids. If animal is in shock, administration of steroids should be at shock doses and this should take precedence over establishing an immediate diagnosis. For dogs with hyperkalemia consider IV glucose and insulin to rapidly lower serum potassium, and calcium gluconate to protect the heart from the cardiopressive effects of hyperkalemia. (Scott-Moncrieff 2010)

For use a diagnostic agent:

Low-Dose Dexamethasone Suppression (LDDS) Test:

a) Obtain plasma samples for cortisol before and 4 and 8 hours after IV administration of 0.01 mg/kg dexamethasone. The 8-hour plasma cortisol is used as a screening test for hyperadrenocorticism, with concentrations >1.4 micrograms/dL being consistent with (not confirming) the diagnosis of Cushing's syndrome. Test is relatively sensitive and specific, but not perfect. Approximately 90% of dogs with Cushing's syndrome have an 8 hour post-dexamethasone plasma cortisol concentration >1.4 micrograms/dL and another 6 to 8% have values of 0.9-1.3 micrograms/dL. The results of a low dose test can also aid in discriminating pituitary-dependent hyperadrenocorticism (PDH) from adrenocortical tumor (ACT), using 3 criteria: **1)** an 8 hour plasma cortisol >1.4

micrograms/dL but <50% of the basal value; **2**) a 4 hour plasma cortisol concentration <1.0 micrograms/dl; and **3**) a 4 hour plasma cortisol concentration <50% of the basal value. If a dog has Cushing's and it meets any of these 3 criteria, it most likely has PDH. Approximately 65% of dogs with naturally occurring PDH demonstrate suppression, as defined by these 3 criteria. A dog with Cushing's that fails to meet any of these 3 criteria could have either PDH or ACT. However, if two relatively equal sized adrenals on abdominal ultrasonography, it most likely has PDH. (Feldman 2009)

High-Dose Dexamethasone Suppression (HDDS) Test:

a) Relatively easy to perform (plasma obtained before and 4 or 8 hours after IV administration of 0.1 mg/kg dexamethasone), readily available and inexpensive. If a dog has Cushing's syndrome and the plasma cortisol, 8 hours post-dexamethasone, is <50% of the basal value, the dog has pituitary-dependent hyperadrenocorticism (PDH). However, our experience with the LDDS and abdominal ultrasonography has limited the need and use of HDDS. Approximately 75% of dogs with PDH demonstrate suppression with the HDDS. Realizing that approximately 65% of PDH dogs demonstrate "suppression" consistent with PDH on the LDDS limits the value of this test by only identifying an additional 10% of afflicted dogs. (Feldman 2009)

#### ■CATS:

For labeled indications (antiinflammatory; glucocorticoid agent): Injection: 0.125–0.5 mg IV or IM; may be repeated for 3–5 days; Tablets: 0.125–0.5 mg daily in single or divided doses (Package Insert; *Azium*®— Schering)

As an antiinflammatory agent or immunosuppressive:

Generally, most veterinarians use prednisolone when a glucocorticoid is administered orally to cats. If using dexamethasone, figure the dose for prednisolone and administer 10-20% of that dose as dexamethasone. Approximately 0.75 mg of dexamethasone is equivalent to 5 mg prednisone.

Low-Dose Dexamethasone Suppression (LDDS) Test:

a) Test of choice for diagnosis of feline hyperadrenocorticism; uses a higher dose of dexamethasone (0.1 mg/kg IV) than in dogs. A base-line blood sample is collected, and additional samples are collected at 4 and 8 hours after dexamethasone administration. Cortisol concentration will be suppressed (<1.5 micrograms/dL) at 8 hours in normal cats but not in cats with hyperadrenocorticism. A few cats with HAC will suppress normally on the LDDS. If the index of suspicion for hyperadrenocorticism is high, a second test using the lower dose of dexamethasone (0.01 mg/kg) can be performed, but some normal cats will fail to suppress at this dose. (Scott-Moncrieff 2010)

#### ■RABBITS/RODENTS/SMALL MAMMALS:

a) **Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas:** 0.6 mg/kg IM (as an antiinflammatory) (Adamcak & Otten 2000)

#### ■CATTLE:

For adjunctive therapy of insect bites or stings:

a) 2 mg/kg IM or IV q4h (use epinephrine if anaphylaxis develops) (Fowler 1993)

For primary bovine ketosis:

a) 5–20 mg IV or IM (Package Insert; *Azium*®— Schering)

#### ■HORSES: (Note: ARCI UCGFS Class 4 Drug)

For labeled indications (antiinflammatory; glucocorticoid agent):

a) Dexamethasone Injection: 2.5–5 mg IV or IM (Package Insert; *Azium*®— Schering)

Dexamethasone sodium phosphate injection: 2.5–5 mg IV (Package Insert; *Azium*® SP— Schering)

For recurrent airway obstruction (heaves):

a) For a 500 kg horse give 40 mg IM once every other day for 3 treatments, followed by 35 mg IM once every other day for 3 treatments, followed by 30 mg IM once every other day for 3 treatments, etc., until horse is weaned off dexamethasone. Corticosteroid use may be contraindicated in horses predisposed to laminitis or exhibiting endocrinopathies. (Ainsworth & Hackett 2004)

b) For short term treatment with environmental control: In the study, dexamethasone sodium phosphate was dosed at 0.1 mg/kg IM once daily for 4 days, 0.075 mg/kg IM once daily for 4 days, and 0.05 mg/kg IM for 4 days. Except for bronchoalveolar lavage cytology, oral prednisolone (1 mg/kg PO X 4d, 0.75 mg/kg PO x 4d, 0.5 mg/kg PO x 4d) was as effective as IM dexamethasone. (Courouce-Malblanc *et al.* 2008)

c) In this study, horses were under continuous antigen exposure: Dexamethasone was given at 0.05 mg/kg PO once daily for 7 days or prednisolone (2 mg/kg PO once daily for 7 days). Both were effective, but dexamethasone more so. (Leclere *et al.* 2010)

Dexamethasone suppression test:

a) 20 mg IM. Normal values: Cortisol levels decrease 50% in 2 hours, 70% in 4 hours, and 80% at 6 hours. At 24 hours, levels are still depressed about 30% of original value. (Beech 1987)

#### ■SWINE:

For glucocorticoid therapy:

a) 1–10 mg IV or IM (Howard 1986)

#### ■LLAMAS:

For adjunctive therapy of anaphylaxis:

a) 2 mg/kg IV (Smith 1989)

#### ■BIRDS:

For shock, trauma, gram-negative endotoxemia:

a) Dexamethasone 2 mg/mL injection: 2–4 mg/kg IM or IV once, twice or three times daily. Taper off drug when using long-term. (Clubb 1986)

#### ■REPTILES:

For septic shock in most species:

a) Using Dexamethasone Sodium Phosphate: 0.1–0.25 mg/kg IV or IM (Gauvin 1993)

#### Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

### Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

### Chemistry/Synonyms

A synthetic glucocorticoid, dexamethasone occurs as an odorless, white to practically white, crystalline powder that melts with some decomposition at about 250°C. It is practically insoluble in water and sparingly soluble in alcohol. Dexamethasone sodium phosphate occurs as an odorless or having a slight odor, white to slightly yellow, hygroscopic powder. One gram is soluble in about 2 mL of water; it is slightly soluble in alcohol

1.3 mg of dexamethasone sodium phosphate is equivalent to 1 mg of dexamethasone; 4 mg/mL of dexamethasone sodium phosphate injection is approximately equivalent to 3 mg/mL of dexamethasone.

Dexamethasone may also be known as: desamethasone, dexametason, dexamethasonum, 9alpha-Fluoro-16alpha-methylprednisolone; hexadecadrol; many trade names are available.

### Storage/Stability

Dexamethasone is heat labile and should be stored at room temperature (15–30°C) unless otherwise directed by the manufacturer. Dexamethasone sodium phosphate injection should be protected from light. Dexamethasone tablets should be stored in well-closed containers.

### Compatibility/Compounding Considerations

Dexamethasone sodium phosphate for injection is reportedly **compatible** with the following drugs: amikacin sulfate, aminophylline, bleomycin sulfate, cimetidine HCl, glycopyrrolate, lidocaine HCl, nafcillin sodium, netilmicin sulfate, prochlorperazine edisylate and verapamil.

Dexamethasone sodium phosphate is reportedly **incompatible** with: daunorubicin HCl, doxorubicin HCl, metaraminol bitartrate, and vancomycin. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

### Dosage Forms/Regulatory Status

#### VETERINARY-LABELED PRODUCTS:

Dexamethasone Injection: 2 mg/mL; *Azium® Solution* (Schering-Plough), generic; (Rx). FDA-approved for use in dogs, cats, horses (those not intended for food) and cattle. There are no withdrawal times required when used in cattle. A withdrawal period has not been established for this product in preruminal calves; do not use in veal calves.

Dexamethasone Oral Powder: 10 mg crystalline in 10 mg packets. FDA-approved for use in cattle and horses (not horses intended for food). *Azium® Powder* (Schering-Plough); (Rx)

Dexamethasone Sodium Phosphate Injection: 4 mg/mL (equivalent to 3 mg/mL dexamethasone); generic; (Rx). FDA-approved for use in horses.

Dexamethasone 5 mg and trichlormethiazide 200 mg oral bolus: in boxes of 30 and 100 boluses; *Naquasone® Bolus* (Schering-Plough); (Rx). FDA-approved for use in cattle. Milk withdrawal = 72 hours.

The ARCI (Racing Commissioners International) has designated dexamethasone as a class 4 substance. See the appendix for more information.

#### HUMAN-LABELED PRODUCTS:

Dexamethasone Oral Tablets: 0.25 mg, 0.5 mg, 0.75 mg, 1 mg, 1.5 mg, 2 mg, 4 mg, & 6 mg; *Decadron®* (Merck); *DexPak® Day TaperPak* (ECR); *Zema-Pak® 10 & 13 Day* (Macoven); generic; (Rx)

Dexamethasone Oral Elixir/Solution: 0.5 mg/5 mL in 100 mL, 237 mL, 500 mL and UD 5 & UD 20 mL; 1 mg/mL (concentrate) in 30 mL with dropper; *Dexamethasone Intensol®* (Roxane); generic; (Rx)

Dexamethasone Sodium Phosphate Injection: 4 mg/mL (as sodium phosphate solution) in 1 mL, 5 mL, 10 mL & 30 mL vials, 1 mL syringe & 1 mL fill in 2 mL vials; generic; (Rx); 10 mg/mL (as sodium phosphate solution) in 1 mL and 10 mL vials & 1 mL syringes; generic; (Rx); 20 mg/mL (as sodium phosphate solution) in 5 mL vials (IV); *Hexadrol® Phosphate* (Organon), (Rx)

Dexamethasone is also available in topical ophthalmic (see ophthalmic products in the appendix) and inhaled aerosol dosage forms.

## DEXMEDETOMIDINE

(deks-mee-deh-toe-mih-deen) Dexdomitor®

ALPHA-2 ADRENERGIC AGONIST

### Prescriber Highlights

- **Alpha-2 agonist similar to medetomidine used as a preanesthetic & for sedation, analgesia in dogs & cats**
  - **Contraindications: cardiac disease, liver or kidney diseases, shock, severe debilitation, or animals stressed due to heat, cold or fatigue; caution in very old or young animals, animals with seizure disorders, respiratory, renal or kidney disorders**
  - **Adverse Effects: Bradycardia, occasional AV blocks, decreased respiration, hypothermia, urination, vomiting, hyperglycemia, & pain on injection (IM). Rarely: prolonged sedation, paradoxical excitation, hypersensitivity, apnea & death from circulatory failure**
  - **Dosed in dogs based upon body surface area, not weight**
  - **Effects may be reversed with atipamezole**
- 

### Uses/Indications

In the USA, dexmedetomidine for dogs and cats is FDA-approved for use as a sedative and analgesic to facilitate clinical examinations, clinical procedures, minor surgical procedures, and minor dental procedures, and in dogs only as a preanesthetic to general anesthesia. In Europe, there is an additional indication in cats as a premed for use prior to ketamine general anesthesia.

### Pharmacology/Actions

Dexmedetomidine is the dextrorotatory enantiomer of the alpha<sub>2</sub> adrenergic agonist, medetomidine. The other enantiomer, levomedetomidine is thought to be pharmacologically inactive so dexmedetomidine is about two times more potent than medetomidine.

Dexmedetomidine is much more specific than xylazine for alpha<sub>2</sub> receptors versus alpha<sub>1</sub> receptors. The pharmacologic effects of dexmedetomidine include: depression of CNS (sedation, anxiolysis), analgesia, GI (decreased secretions, varying affects on intestinal muscle tone) and endocrine functions, peripheral and cardiac vasoconstriction, bradycardia, respiratory depression, diuresis, hypothermia, analgesia (somatic and visceral), muscle relaxation (but not enough for intubation), and blanched or cyanotic mucous membranes. Effects on blood pressure are variable, but dexmedetomidine can cause hypertension longer than does xylazine.

### Pharmacokinetics

In dogs after IM administration, dexmedetomidine is absorbed (bioavailability 60%) and reaches peak plasma levels in about 35 minutes. Volume of distribution is 0.9 L/kg and elimination half-life is approximately 40–50 minutes. The drug is primarily metabolized in the liver via glucuronidation and N-methylation. No metabolites are active and they are eliminated primarily in the urine and to lesser extent in the feces.

In cats after IM administration, dexmedetomidine is absorbed and reaches peak plasma levels of about 17 ng/mL occur in about 15 minutes. Oral transmucosal (OTM, buccal) administration of dexmedetomidine (40 micrograms/kg) appears to give similar levels (extrapolated from clinical effects) as IM administration in cats (Slingsby *et al.* 2009). But in comparing OTM versus IM dexmedetomidine (20 micrograms/kg combined with buprenorphine 20 micrograms/kg, another report found that cats in the IM group were more sedated than in the OTM group, but that OTM administration allowed placement of an IV catheter in 75% of the cats (Santos *et al.* 2009). Volume of distribution is 2.2 L/kg and elimination half-life is approximately 1 hour. Metabolites are eliminated primarily in the urine and to lesser extent in the feces.

In humans after IV administration, dexmedetomidine is rapidly distributed, undergoes almost complete biotransformation via both glucuronidation and CY-450 enzymes systems and has a terminal elimination half-life of about 2 hours. Metabolites are eliminated in the urine and feces.

### Contraindications/Precautions/Warnings

The US labeling states not to use in dogs or cats with cardiovascular disease, respiratory disorders, liver or kidney diseases, or in conditions of shock, severe debilitation, or stress due to extreme heat, cold or fatigue. It is not recommended in cats with respiratory disease. Due to the pronounced cardiovascular effects of dexmedetomidine, only clinically healthy dogs and cats should be treated. While not contraindicated in pediatric or geriatric dogs or cats in the US label, it states that the drug has not been evaluated in dogs younger than 16 weeks of age or in cats younger than 12 weeks of age, or in geriatric dogs and cats.

The UK labeling states not to use in puppies less than 6 months old or in kittens less than 5 months old; in animals with cardiovascular disorders; in animals with severe systemic disease or that are moribund; or in animals known to be hypersensitive to the active substance or any of the excipients.

Use with caution in animals with, or prone to developing, seizures. Dexmedetomidine lowered the seizure threshold in cats undergoing anesthesia with enflurane.

Because blinking may be impaired in cats during sedation and dexmedetomidine/butorphanol has been shown to reduce tear production in dogs (Jalomaki & Eskelinen 2007), eye lubricants should be used when using dexmedetomidine.

### Adverse Effects

The adverse effects reported with medetomidine or dexmedetomidine are essentially extensions of their pharmacologic effects including bradycardia, vasoconstriction, muscle tremors, transient hypertension, reduced tear production, occasional AV blocks, decreased respiration, hypothermia, urination, vomiting, hyperglycemia, and pain on injection (IM). Rare effects that have been reported include: prolonged sedation, paradoxical excitation, hypersensitivity, pulmonary edema, apnea, and death from circulatory failure.

### Reproductive/Nursing Safety

The drug is not recommended for use in pregnant dogs or those used for breeding purposes because safety data for use during pregnancy is insufficient; therefore use only when the benefits clearly outweigh the drug's risks. However, no teratogenic effects were observed when rats were given up to 200 micrograms/kg SC from days

3–16 of gestation or when rabbits were given up to 96 micrograms/kg IV from days 6–18 of gestation. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Dexmedetomidine is distributed into the milk of lactating rats; safe use during nursing has not been established.

### Overdosage/Acute Toxicity

Single doses of up to 5X (IV) and 10X (IM) were tolerated in dogs, but adverse effects can occur (see above). Because of the potential of additional adverse effects occurring (heart block, PVC's, or tachycardia), treatment of dexmedetomidine-induced bradycardia with anticholinergic agents (atropine or glycopyrrolate) is usually not recommended. Atipamezole is probably a safer choice to treat any dexmedetomidine-induced effect.

### Drug Interactions

**Note:** Before attempting combination therapy with dexmedetomidine, it is strongly advised to access references from veterinary anesthesiologists familiar with the use of this drug. The following drug interactions have either been reported or are theoretical in humans or animals receiving dexmedetomidine or medetomidine (a related compound) and may be of significance in veterinary patients:

■ **ANESTHETICS, OPIATES, SEDATIVE/HYPNOTICS:** Effects may be additive; dosage reduction of one or both agents may be required. General anesthetic requirements may be reduced between 30-60%.

■ **ATROPINE, GLYCOPYRROLATE:** The use of atropine (or glycopyrrolate) with dexmedetomidine can significantly increase arterial blood pressure and heart rate; use together is not recommended in dogs (and probably other species) (Congdon *et al.* 2009).

■ **EPINEPHRINE:** As epinephrine possesses alpha agonist effects, do not use to treat cardiac effects caused by dexmedetomidine

■ **YOHIMBINE:** May reverse the effects of medetomidine; but atipamezole is preferred for clinical use to reverse the drug's effects

### Laboratory Considerations

■ Medetomidine (and presumably dexmedetomidine) can inhibit ADP-induced **platelet aggregation** in cats.

### Doses

#### ■ DOGS:

a) For sedation and analgesia: 375 micrograms/m<sup>2</sup> body surface area (BSA) IV; 500 micrograms/m<sup>2</sup> BSA IM. The microgram/kg dosage decreases as body weight increases.

As a preanesthetic: Depending on duration and severity of the procedure and anesthetic regimen: 125–375 micrograms/m<sup>2</sup> IM. The microgram/kg dosage decreases as body weight increases. Accurate dosing is not possible with dogs weighing less than 2 kg. An extensive dosing table using patient weights is available in the package insert. It is recommended that patients be fasted for 12 hours prior to use. After injection allow animal to rest quietly for 15 minutes, sedation/analgesia occur within 5-15 minutes, with peak effects at 30 minutes post dose. (Label Information; *Dexdomitor*®—Pfizer)

b) For use in combination with an opioid and ketamine (so-called “doggie magic”) to provide anesthesia and pain management (**Note:** reference has dosing tables for conversion of patient weight to various microgram/m<sup>2</sup> doses of dexmedetomidine; opioid concentrations used in the reference are: Butorphanol 10 mg/mL, Hydromorphone 2 mg/mL, Morphine 15 mg/mL, & Buprenorphine 0.3 mg/mL. Ketamine concentration is 100 mg/mL. As these drugs may be available in other concentrations, only use those products with the above concentrations if using this protocol.)

For geriatric dogs, dogs with renal or liver dysfunction as a premed prior to propofol or face mask induction, followed by maintenance on isoflurane or sevoflurane: dexmedetomidine at 62.5 micrograms/m<sup>2</sup>. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.

For slightly heavier sedation in ASA class II or II dogs requiring sedation for radiographic procedures: Dexmedetomidine at 125 micrograms/m<sup>2</sup>. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.

For dogs undergoing minor surgery, Penn hip or OFA-types of radiographic procedures that require significant muscle relaxation: Dexmedetomidine at 250 micrograms/m<sup>2</sup>. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV.

To induce a surgical plane of anesthesia for OHE, castration, or other abdominal surgery: Dexmedetomidine at 375 micrograms/m<sup>2</sup>. Combine with equal volumes of one of the opioids noted above and ketamine. May administer IM or IV. Provides rapid immobilization; lateral recumbency in 5-8 minutes. Dogs can be intubated and maintained on oxygen. Supplemental low doses of isoflurane (0.5%) or sevoflurane (1%) can be used.

For immobilizing extremely fractious dogs and wolf-hybrid dogs: Dexmedetomidine at 500 micrograms/m<sup>2</sup>. Combine with equal volumes of one of the opioids noted above and ketamine. Administer IM. This dose is rarely required.

To reverse above, atipamezole IM at the same volume as the dexmedetomidine. (Ko 2009)

c) As a constant rate infusion for post-operative pain management in critically ill dogs: After surgery a loading dose of 25 micrograms/m<sup>2</sup> IV, followed by a constant rate infusion for 24 hours at 25 micrograms/m<sup>2</sup>/hr. In study, morphine at 0.2 mg/kg IV was used when rescue analgesia required (about half the dogs in the study). In this study, dexmedetomidine was as effective as morphine CRI (2.5 mg/m<sup>2</sup> load, and 2.5 mg/m<sup>2</sup>/hr CRI). Authors concluded that CRI's of dexmedetomidine have potential to provide postoperative analgesia in critically ill patients, but additional studies required to determine appropriate doses and/or use with other analgesics to provide maximal and safe post-surgical analgesia. (Valtolina *et al.* 2009)

#### ■ CATS:

a) For sedation and analgesia: 40 micrograms/kg IM. A dosing table is available in the package insert. Recommended that patients be fasted for 12 hours prior to use. Apply an eye lubricant. After injection allow animal to rest quietly for 15 minutes, sedation/analgesia occurs within 5-15 minutes, with peak effects at 30 minutes post dose. (Label Information; *Dexdomitor*®—Pfizer)

b) For use in combination with an opioid and ketamine (so-called “kitty magic”, “DKT” or “Triple Combination”) to provide sedation and analgesia (**Note:** Opioid concentrations used in the reference are: Butorphanol 10 mg/mL, Hydromorphone 2 mg/mL, Morphine 15 mg/mL, & Buprenorphine 0.3 mg/mL. Ketamine concentration is 100 mg/mL. Dexmedetomidine concentration is 0.5 mg/mL. As these drugs may be available in other concentrations, only use those products with the above concentrations if using this protocol.)

products with the above concentrations. If using any procedure)  
For the chart below: MILD = For sedation or as a premed prior to propofol or face mask induction; MODERATE = For castration or minor surgical procedures; PROFOUND = Invasive surgical procedures including OHE and declaws. Cats can be reversed immediately with an equal volume (of the dexmedetomidine dose) of atipamezole.

Cat Weight		Volume (of each) of: Dexmedetomidine- Opioid-Ketamine			IM Route
Lbs	Kg	MILD	MODERATE	PROFOUND	
4-7	2-3	0.025 mL	0.05 mL	0.1-0.15 mL	
7-9	3-4	0.05 mL	0.1 mL	0.2-0.25 mL	
9-13	4-6	0.1 mL	0.2 mL	0.3-0.35 mL	
14-15	6-7	0.2 mL	0.3 mL	0.4-0.45 mL	
15-18	7-8	0.3 mL	0.4 mL	0.5-0.55 mL	

(Ko 2009)

(Ko 2009)

## Monitoring

- Level of sedation and analgesia; heart rate; body temperature
- Heart rhythm, blood pressure, respiration rate, and pulse oximetry should be considered, particularly in higher risk patients

## Client Information

- This drug should be administered and monitored by veterinary professionals only
- Clients should be made aware of the potential adverse effects associated with its use, particularly in dogs at risk (older, preexisting conditions)

## Chemistry/Synonyms

Dexmedetomidine is the dextrorotatory enantiomer of medetomidine.

Dexmedetomidine HCl may also be known as (S)-medetomidine, (+)-medetomidine, MPV 1440, MPV 295, or MPV 785. Trade names include: *Precedex*® or *Dexdomitor*®.

## Storage/Stability

Store the injection at room temperature (15–30°C); do not freeze.

## Compatibility/Compounding Considerations

Information “on file” with the manufacturer states that dexmedetomidine 0.5 mg/mL solution for injection can be mixed with butorphanol 2 mg/mL or with ketamine 50 mg/ml solution, or with butorphanol 2 mg/mL solution and ketamine 50 mg/mL solution, in the same syringe and possesses no pharmacological risk. Anecdotal comments have been noted that buprenorphine, hydromorphone, morphine can also be mixed with dexmedetomidine.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Dexmedetomidine HCl 0.5 mg/mL (500 micrograms/mL) in 10 mL multidose vials; *Dexdomitor*® (Pfizer); (Rx).

### HUMAN-LABELED PRODUCTS:

Dexmedetomidine HCl Concentrated Solution for Injection: 100 micrograms/mL (equiv. to dexmedetomidine hydrochloride 118 mcg), preservative free, sodium chloride 9 mg in 2 mL vials; *Precedex*® (Hospira); (Rx)

---

## DEXPANTHENOL

### D-PANTHENOL

(dex-pan-the-nole) Ilopan®

### Prescriber Highlights

- Precursor to Coenzyme A that ostensibly aids in production of acetylcholine
  - Potentially may be useful in the prevention of post-surgical ileus, but efficacy is in doubt
  - Contraindications: Ileus secondary to mechanical obstruction or in cases of colic caused by the treatment of cholinergic anthelmintics
- 

## Uses/Indications

Dexpantnenol has been suggested for use in intestinal atony or distension, postoperative retention of flatus and feces, prophylaxis and treatment of paralytic ileus after abdominal surgery or traumatic injuries, equine colic (not due to mechanical obstruction) and any other condition when there is an impairment of smooth muscle function. Controlled studies are lacking with regard to proving the efficacy of the drug for any of these indications.

## Pharmacology/Actions

## Pharmacology/Actions

A precursor to pantothenic acid, dexpanthenol acts as a precursor to coenzyme A that is necessary for acetylation reactions to occur during gluconeogenesis and in the production of acetylcholine. It has been postulated that post-surgical ileus can be prevented by giving high doses of dexpanthenol, thereby assuring adequate levels of acetylcholine. However, one study in normal horses (Adams, Lamar, and Masty 1984) failed to demonstrate any effect of dexpanthenol on peristalsis.

## Pharmacokinetics

Dexpanthenol is rapidly converted to pantothenic acid *in vivo*, which is widely distributed throughout the body, primarily as coenzyme A.

## Contraindications/Precautions/Warnings

Dexpanthenol is contraindicated in ileus secondary to mechanical obstruction, or in cases of colic caused by the treatment of cholinergic anthelmintics. It is also contraindicated in humans with hemophilia as it may exacerbate bleeding.

## Adverse Effects

Adverse reactions are reportedly rare. Hypersensitivity reactions have been reported in humans, but may have been due to the preservative agents found in the injectable product. Potentially, GI cramping and diarrhea are possible.

## Reproductive/Nursing Safety

Safety in use during pregnancy has not been established. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

## Overdosage/Acute Toxicity

The drug is considered non-toxic even when administered in high doses.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving dexpanthenol and may be of significance in veterinary patients:

■ **NEOSTIGMINE; SUCCINYLCHOLINE:** The manufacturers have recommended that dexpanthenol not be administered within 12 hours of neostigmine or other parasympathomimetic agents or within 1 hour of patients receiving succinylcholine. The clinical significance of these potential interactions has not been documented, however.

## Doses

### ■ DOGS & CATS:

- a) 11 mg/kg IM; repeat if indicated at 4–6 hour intervals (Rossoff 1974)
- b) 11 mg/kg IM; may be repeated in 2 hours after initial injection and followed every 6–8 hours until condition is alleviated. The time interval and duration of therapy will depend upon the degree of severity that the animal is exhibiting from the clinical standpoint. (Label Instructions; *d-Panthenol® Injectable*—Vedco)

### ■ HORSES:

- a) 2.5 grams IV or IM; repeat if indicated at 4–6 hour intervals (Rossoff 1974), (Label Instructions; *d-Panthenol® Injectable*—Vedco)

## Monitoring

Clinical efficacy

## Client Information

■ Should be used in a professionally monitored situation where gastrointestinal motility can be monitored.

## Chemistry/Synonyms

The alcohol of D-pantothenic acid, dexpanthenol occurs as a slightly bitter-tasting, clear, viscous, somewhat hygroscopic liquid. It is freely soluble in water or alcohol. Dexpanthenol may also be known as: D-panthenol, dexpanthenolum, dextro-pantothenyl alcohol, pantothenol; many trade names are available.

## Storage/Stability

Dexpanthenol should be protected from both freezing and excessive heat. It is incompatible with strong acids and alkalis.

## Dosage Forms/Regulatory Status

### VETERINARY-LABELED PRODUCTS:

Dexpanthenol Injection: 250 mg/mL in 100 mL vials; *D-Panthenol® Injectable* (Vedco), generic (Butler, Phoenix Pharmaceutical); (Rx). Labeled for use in dogs, cats, and horses.

### HUMAN-LABELED PRODUCTS:

Dexpanthenol Injection: 250 mg/mL in 2 mL & 10 mL vials, UD *Stat-Pak* 2 mL disp syringes; *Ilopan®* (Adria); generic; (Rx)

**Dextrose—see the Tables of Parenteral Fluids in the Appendix**

---

## DEXRAZOXANE

(dex-ra-t-ane) Zinecard®

ANTIDOTE

## Prescriber Highlights

- May be useful in attenuating the cardiotoxic effects of doxorubicin in patients (dogs) showing signs of anthracycline cardiotoxicity, have cardiac disease, or are at maximum cumulative dosages of doxorubicin; also used to treat extravasation injuries associated with doxorubicin
  - Potentially may reduce efficacy of doxorubicin & increase myelosuppression
  - For extravasation treatment, must be administered within hours of injury
  - Very expensive
- 

## Uses/Indications

Dexrazoxane may be useful to attenuate the cardiotoxic effects of doxorubicin in patients who are showing signs of anthracycline cardiotoxicity, have cardiac disease, or are at maximum cumulative dosages of doxorubicin. It is also used to treat extravasation injuries associated with doxorubicin.

While dexrazoxane has been shown to be cardioprotective when given at dosages of 10 times the doxorubicin dose, there is evidence that it may also partially protect the cancer cells being treated.

## Pharmacology/Actions

Dexrazoxane is hydrolyzed to an active metabolite that chelates intracellular iron that is believed to prevent the formation of an anthracycline-iron complex thought to be the primary cause of anthracycline-induced cardiomyopathy.

## Pharmacokinetics

In dogs, dexrazoxane's pharmacokinetics fit a two compartment open model. Steady-state volume of distribution is 0.67 L/kg, terminal half life is about 1.2 hours, and clearance about 11 mL/min/kg. Clearance was dose-independent and the drug showed low tissue and protein binding. Dexrazoxane is primarily excreted in the urine as unchanged drug and metabolites.

## Contraindications/Precautions/Warnings

Dexrazoxane should not be used unless an anthracycline antineoplastic agent is being used.

Efficacy and safety for use in cats is not known.

## Adverse Effects

Dexrazoxane may cause additive myelosuppression when used with other myelosuppressive agents. There is some evidence in humans, that dexrazoxane may reduce the efficacy of anthracycline antitumor agents. Clinical significance in veterinary patients is unknown.

Wear gloves when handling and use normal procedures for handling and disposal of anti-cancer medications. If unconstituted powder contacts skin or mucous membranes, wash off thoroughly with soap and water.

## Reproductive/Nursing Safety

Dexrazoxane has been shown to cause testicular atrophy in dogs when administered at usual doses for 13 weeks. In humans, the FDA categorizes dexrazoxane as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). In rats and rabbits, dexrazoxane was teratogenic at doses lower than those administered to humans.

It is unknown if dexrazoxane enters maternal milk; human mothers are advised to discontinue nursing if given the drug.

## Overdosage/Acute Toxicity

Because of the method of administration and drug expense, overdoses are unlikely in veterinary medicine. As there is no known antidote, treatment would be supportive. Potentially, the drug could be removed via hemodialysis.

## Drug Interactions

Dexrazoxane does not influence the pharmacokinetics of doxorubicin.

The following drug interactions have either been reported or are theoretical in humans or animals receiving dexrazoxane and may be of significance in veterinary patients:

- **MYELOSUPPRESSIVE AGENTS, OTHER:** Additive myelo-suppression may occur when used with other myelosuppressive agents.

## Laboratory Considerations

- No specific laboratory interactions or considerations were noted.

## Doses

### ■ DOGS:

For treatment of anthracycline (doxorubicin, epirubicin, etc.) extravasation:

- a) Terminate doxorubicin infusion immediately, and infuse intravenously 1000 mg/m<sup>2</sup> of dexrazoxane in a separate infusion within 6 hours and again on day 2. Infuse 500 mg/m<sup>2</sup> on day 3. Acute surgical evaluation is performed. **Note:** Dosage recommendations are for human patients, but may apply to veterinary patients. (Langer *et al.* 2000)

- b) Anecdotally; IV administration of dexrazoxane at 10 times the doxorubicin dose with 3 hours and again at 24 and 48 hours after extravasation significantly reduces local tissue injury. (Vail 2006)

For prevention of doxorubicin-induced cardiomyopathy:

- a) Dexrazoxane to doxorubicin dose ratio is 10:1 (*e.g.*, 300 mg/m<sup>2</sup> of dexrazoxane to 30 mg/m<sup>2</sup> doxorubicin) given as slow IV bolus, starting 30 minutes of, and

prior to the doxorubicin dose (as a short, IV bolus.) (Selting 2005)

b) Use can be considered in breeds at risk (Shelties, Collies, Australian Shepherds, etc.), dogs that are exceeding the usual cumulative dose cut-off, and in cases where there is preexisting cardiac disease and no effective chemo options exist: Dexrazoxane to doxorubicin dose ratio is 10:1 (e.g., 300 mg/m<sup>2</sup> of dexrazoxane to 30 mg/m<sup>2</sup> doxorubicin) given as slow IV bolus, starting 30 minutes before doxorubicin is administered. (Vail 2006)

## Monitoring

- CBC
- If used for cardioprotection: echocardiogram, ECG, etc.

## Client Information

- Clients should understand and accept the potential costs associated with this drug and that when used for extravasation injuries, may not be fully effective.

## Chemistry/Synonyms

A derivative of EDTA, dexrazoxane occurs as a white crystalline powder that is soluble in water and slightly soluble in ethanol and practically insoluble in nonpolar organic solvents. It has a pKa of 2.1 and degrades rapidly at pH's above 7.

Dexrazoxane may also be known as: 2,6-Piperazinedione, ADR-529, ICRF-187, NSC-169780, *Zinecard*®, *Cardioxane*® or *Eucardion*®.

## Storage/Stability

Unreconstituted dexrazoxane vials should be stored at 25°C (77°F); excursions permitted to 15–30°C (59–86°F). Once reconstituted with the supplied diluent, it is stable for 6 hours at room temperature or refrigerated. Unused solutions after that time should be discarded. After reconstitution, the resulting solution may be diluted with either 0.9% sodium chloride injection or D5W in concentrations of 1.3–5 mg/mL. Inspect visually for particulate matter and discoloration prior to administering.

## Compatibility/Compounding Considerations

The manufacturer states that dexrazoxane should not be mixed with any other drug.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

## HUMAN-LABELED PRODUCTS:

Dexrazoxane Lyophilized Powder for Injection Solution: 250 mg in single-use vials with 25 mL vial of sodium lactate injection; and 500 mg regular & preservative free (equiv to dexrazoxane hydrochloride 589 mg) in single-use vials with 50 mL vial of sodium lactate injection; *Zinecard*® (Pfizer); *Totect*® (Topo Target); generic; (Rx)

## DEXTRAN 70

(*dex-tran*)

PLASMA VOLUME EXPANDER

**Note:** *Dextran* is also available as *Dextran 40* and *Dextran 75*. As *Dextran 70* is the most commonly used version in veterinary medicine, the following monograph is limited to it alone.

### Prescriber Highlights

- **Branched polysaccharide plasma volume expander**
- **Contraindications: Preexisting coagulopathies**
- **Caution: Patients susceptible to circulatory overload (severe heart or renal failure), thrombocytopenia**
- **Adverse Effects: Quite rare in dogs. Increased bleeding times, acute renal failure & anaphylaxis possible (but very rare)**
- **Must monitor for fluid overload**

---

## Uses/Indications

Dextran 70 is a relatively low cost colloid for the adjunctive treatment of hypovolemic shock. Hetastarch is the more commonly employed synthetic colloid used today.

## Pharmacology/Actions

Dextran 70 has osmotic effects similarly to albumin. Dextran's colloidal osmotic effect draws fluid into the vascular system from the interstitial spaces, resulting in increased circulating blood volume.

## Pharmacokinetics

After IV infusion, circulating blood volume is increased maximally within one hour and effects can persist for 24 hours or more. Approximately 20–30% of a given dose remains in the intravascular compartment at 24 hours and it may be detected in the blood 4–6 weeks after dosing. Dextran 70 is slowly degraded to glucose by

dextranase in the spleen and then metabolized to carbon dioxide and water. A small amount may be excreted directly into the gut and eliminated in the feces.

### Contraindications/Precautions/Warnings

Patients overly susceptible to circulatory overload (severe heart or renal failure) should receive dextran 70 with great caution. Dextran 70 is contraindicated in patients with severe coagulopathies and should be used with caution in patients with thrombocytopenia as it can interfere with platelet function. Do not give dextran IM. Patients on strict sodium restriction should receive dextran cautiously as a 500 mL bag contains 77 mEq of sodium.

### Adverse Effects

Dextran 70 may increase bleeding time and decrease von Willebrand's factor antigen and factor VIII activity. This does not usually cause clinical bleeding in dogs.

While anaphylactoid reactions are not rare in humans, they do occur rarely in dogs, but at a higher rate than with hetastarch. Unlike dextran 40, dextran 70 has rarely been associated with acute renal failure. In humans, GI effects (abdominal pain, nausea/vomiting) have been reported with use of dextran 70.

### Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

### Overdosage/Acute Toxicity

The drug should be dosed and monitored carefully as volume overload may result.

### Drug Interactions

Dextran reportedly has no drug interactions that are clinically significant.

### Laboratory Considerations

- Dextran 70 may interfere with **blood cross-matching** as it can cross-link with red blood cells and appear as rouleaux formation. Isotonic saline may be used to negate this effect.
- **Blood glucose** levels may be increased as dextran is degraded.
- Falsely elevated **bilirubin** levels may be noted; reason unknown.

### Doses

#### ■ DOGS:

- a) Small volume resuscitation techniques are recommended in any dog with closed cavity hemorrhage, head injury, pulmonary contusions or edema, cardiogenic shock, or oliguric renal failure. An initial dose of balanced isotonic crystalloids (10–15 mL/kg) for dogs is given. Either hetastarch or dextran-70 is then administered (5 mL/kg in dogs) over 1-5 minutes. The perfusion parameters are reassessed and the initial mL/kg bolus repeated as needed until the end-point of resuscitation is reached. (Kirby 2008)
- b) 20 mL/kg/day; when acute resuscitation is required, may be given as a slow bolus over 30 minutes to an hour. May also be given as a constant rate infusion over a longer period to augment colloid oncotic pressure or decrease the volume of crystalloids infused, thereby reducing hemodilution. (Martin 2004)

#### ■ CATS:

- a) Small volume resuscitation techniques are recommended in the hypovolemic cat with closed cavity hemorrhage, head injury, pulmonary contusions or edema, cardiogenic shock, or oliguric renal failure. An initial dose of balanced isotonic crystalloids (5–10 mL/kg for cats) is given. Either hetastarch or dextran-70 is then administered (2–5 mL/kg in cats) over 1-5 minutes. The perfusion parameters are reassessed and the initial mL/kg bolus repeated as needed until the end-point of resuscitation is reached. (Kirby 2008)
- b) 10 mL/kg/day; when acute resuscitation is required. May be given as a slow bolus over 30 minutes to an hour. May also be given as a constant rate infusion over a longer period to augment colloid oncotic pressure or decrease the volume of crystalloids infused, thereby reducing hemodilution. (Martin 2004)

#### ■ CATTLE:

- a) For dehydrated (secondary to diarrhea) calves given as 6% Dextran 70 in 7.2% sodium chloride: To prepare solution, add 31.6 g sodium chloride into the barrel of a 60 mL syringe. Draw 60 mL of 6% dextran 70 in 0.9% NaCl from the bag/bottle to dilute the NaCl crystals. Re-inject the dissolved solution into the bag/bottle through a 0.22 micron filter giving a 6% dextran 70 in 7.2% NaCl solution. Resultant solution may be refrigerated for up to 3 months. Inject IV 4–5 mL/kg of this solution over 4–5 minutes, followed immediately by oral administration of isotonic electrolyte solution. Give dextran 70 solution one time only or hypernatremia may result and follow-up with isotonic fluids (oral or IV) are critical. (Sweeney 2003)

### Monitoring

- Other than the regular monitoring performed in patients that would require volume expansion therapy, there is no inordinate monitoring required specific to dextran therapy.

### Chemistry/Synonyms

A branched polysaccharide used intravenously as a plasma volume expander, dextran 70 occurs as a white to light yellow amorphous powder. It is freely soluble in water and insoluble in alcohol. Dextran 70 contains (on average) molecules of 70,000 daltons. Each 500 mL of the commercially available 6% dextran 70 in normal saline provides 77 mEq of sodium. Dextran 70 in normal saline has a viscosity of 3.68 centipose (blood is 3 centipose) and a colloid osmotic pressure of 62 mmHg (canine plasma is approximately 20 mmHg).

Dextran 70 may also be known as: dextranum 70, polyglucin, *Dextran 70*®, *Fisiodex 70*®, *Gentran 70*®, *Hyskon*®, *Lomodex 70*®, *Longasteril 70*®, *Macrodex*®, *Macrohorn 70*®, *Neodextril 70*®, *Plander*®, *RescueFlow*®, or *Solplex 70*®.

### Storage/Stability

Dextran 70 injection should be stored at room temperature; preferably in an area with little temperature variability. While only clear solutions should be used, dextran flakes can form but may be resolubilized by heating the solution in a boiling water bath until clear, or autoclaving at 110°C for 15 minutes.

## Compatibility/Compounding Considerations

Dextran 70 is **compatible** with many other solutions and drugs; refer to specialized references or a hospital pharmacist for more information.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

**HUMAN-LABELED PRODUCTS:**

Dextran High Molecular Weight Injection: 6% dextran 70 in 0.9% sodium chloride in 500 mL; *Dextran 70*<sup>®</sup> (McGaw); (Rx), *Gentran70*<sup>®</sup> (Baxter); (Rx), *Macrodex*<sup>®</sup> (Medisan); (Rx)

Dextran High Molecular Weight Injection: 6% dextran 70 in 5% dextrose in 500 mL; *Macrodex*<sup>®</sup> (Medisan); (Rx)

## DIAZEPAM

(dye-az-e-pam) Valium<sup>®</sup>, Diastat<sup>®</sup>

BENZODIAZEPINE

### Prescriber Highlights

- **Benzodiazepine used for a variety of indications (anxiolytic, muscle relaxant, hypnotic, appetite stimulant, & anticonvulsant) in several species; use in cats is controversial**
- **In dogs, tolerance to anticonvulsant effects occurs with long-term use and make it less useful to treat status epilepticus**
- **Contraindications: Hypersensitivity to benzodiazepines, cats exposed to chlorpyrifos, significant liver disease (especially in cats)**
- **Caution: hepatic or renal disease, aggressive, debilitated or geriatric patients; patients in coma, shock or with significant respiratory depression**
- **Adverse Effects: Sedation & ataxia most prevalent. Dogs: CNS excitement, increased appetite; Cats: Hepatic failure or behavior changes; Horses: Muscle fasciculations**
- **Inject IV slowly**
- **May be teratogenic**
- **Drug interactions**
- **Controlled substance (C-IV)**

---

## Uses/Indications

Diazepam is used clinically for its anxiolytic, muscle relaxant, hypnotic, appetite stimulant, and anticonvulsant activities. It is also used in preanesthesia protocols for neuroleptanalgesia.

While diazepam is a drug of choice for treating status epilepticus and cluster seizures in dogs, it, and the other benzodiazepines are not very useful as maintenance anticonvulsants in dogs. They have short durations of action and long-term administration usually causes tolerance to their anticonvulsant effects. Additionally, long-term use in dogs may prevent effective use of diazepam for the emergency treatment of seizures. In cats, diazepam has a longer elimination half-life and tolerance does not appear to be a major concern, but many neurologists avoid its use in cats because of the risk for serious hepatotoxicity.

## Pharmacology/Actions

The subcortical levels (primarily limbic, thalamic, and hypothalamic), of the CNS are depressed by diazepam and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

## Pharmacokinetics

Diazepam is rapidly absorbed following oral administration. Peak plasma levels occur within 30 minutes to 2 hours after oral dosing. The drug is slowly (slower than oral) and incompletely absorbed following IM administration. In dogs, rectally administered diazepam has a bioavailability of <10%, but when factoring in diazepam plus the active (20-50% of the anticonvulsant activity of diazepam) metabolites desmethyldiazepam and oxazepam, bioavailability is closer to 80%. When administered intranasally to dogs, bioavailability is about 80%.

Diazepam is highly lipid soluble and is widely distributed throughout the body. It readily crosses the blood-brain barrier and is fairly highly bound to plasma proteins. In the horse at a serum concentration of 75 ng/mL, 87% of the drug is bound to plasma proteins. In humans, this value has been reported to be 98-99%.

Diazepam is metabolized in the liver to several metabolites, including desmethyldiazepam (nordiazepam), temazepam, and oxazepam, all of which are pharmacologically active. These are eventually conjugated with glucuronide and eliminated primarily in the urine. Because of the active metabolites, serum values of diazepam are not useful in predicting efficacy. Serum half-lives (approximated) have been reported for diazepam and metabolites in dogs, cats, and horses:

	Dogs	Cats	Horses	Humans
--	------	------	--------	--------

Diazepam	2.5–3.2 hrs	5.5 hrs	7–22 hrs	20–50 hrs
Nordiazepam	3 hrs	21.3 hrs		30–200 hrs

## Contraindications/Precautions/Warnings

Inject intravenously slowly. This is particularly true when using a small vein for access or in small animals; diazepam may cause significant thrombophlebitis. Rapid injection of intravenous diazepam in small animals or neonates may cause hypotension/cardiotoxicity secondary to the propylene glycol in the formulation. Intra-carotid artery injections must be avoided.

Use of diazepam in cats is controversial, primarily because of case reports of serious hepatotoxicity. Some are of the opinion that the drug should not be used chronically in cats.

Use cautiously in patients with hepatic or renal disease and in debilitated or geriatric patients. The drug should be administered to patients in coma, shock, or with significant respiratory depression very cautiously. It is contraindicated in patients with known hypersensitivity to the drug. Diazepam should be used very cautiously, if at all, in aggressive patients, as it may disinhibit the anxiety that may help prevent these animals from aggressive behavior. Benzodiazepines may impair the abilities of working animals. If administering the drug IV, be prepared to administer cardiovascular or respiratory support.

It is recommended not to use diazepam for seizure control in cats exposed to chlorpyrifos as organophosphate toxicity may be potentiated.

Animals who have toxicity from ingesting human sleep aids such as zolpidem (*Ambien*®) or eszopiclone (*Lunesta*®) should not receive benzodiazepines to treat paradoxical CNS stimulation as these drugs also increase GABA activity; IV phenothiazines such as acepromazine or chlorpromazine, or phenobarbital are recommended instead.

Rapid IV bolus administration can potentially cause hypotension; administer over 1–3 minutes depending on dose and patient size.

## Adverse Effects

Rapid IV administration of diazepam can potentially cause hypotension; give IV slowly and flush IV catheter with fluids after administration to help prevent phlebitis.

Adverse effects reported in dogs include sedation, increased appetite, agitation, ataxia, and aggression. Additionally, dogs may exhibit a contradictory response (CNS excitement) following administration of diazepam. Doses of 0.8 mg/kg or higher are more likely to cause this effect. Diazepam's effects with regard to sedation and tranquilization in dogs can be variable and some feel that this makes it less than an ideal inpatient sedating agent, particularly when used alone.

Cats may exhibit changes in behavior (irritability, depression, aberrant demeanor) after receiving diazepam. There have been reports of cats developing hepatic failure after receiving oral diazepam (not dose dependent) for several days. Clinical signs (anorexia, lethargy, increased ALT/AST, hyperbilirubinemia) have been reported to occur 5–11 days after beginning oral therapy. Cats that receive diazepam should have baseline liver function tests. These should be repeated and the drug discontinued if emesis, lethargy, inappetence or ataxia develops.

In horses, diazepam may cause muscle fasciculations, weakness and ataxia at doses sufficient to cause sedation. Doses greater than 0.2 mg/kg may induce recumbency as a result of its muscle relaxant properties and general CNS depressant effects.

## Reproductive/Nursing Safety

Diazepam has been implicated in causing congenital abnormalities in humans if administered during the first trimester of pregnancy. Infants born of mothers receiving large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, hypotonia, etc. Withdrawal symptoms have occurred in infants whose mothers chronically took benzodiazepines during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Benzodiazepines and their metabolites are distributed into milk and may cause CNS effects in nursing neonates.

## Overdosage/Acute Toxicity

When administered alone, diazepam overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Hypotension, respiratory depression, and cardiac arrest have been reported in human patients, but apparently are quite rare.

Treatment of acute toxicity consists of standard protocols for removing and/or binding the drug in the gut if taken orally, and supportive systemic measures. The use of analeptic agents (CNS stimulants such as caffeine) is generally not recommended. Flumazenil may be considered for adjunctive treatment of overdoses of benzodiazepines.

## Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving diazepam and may be of significance in veterinary patients:

- **AMITRIPTYLINE:** Diazepam may increase levels
- **ANTACIDS:** May decrease oral diazepam absorption
- **ANTIFUNGALS, AZOLE (itraconazole, ketoconazole, etc.):** May increase diazepam levels
- **CIMETIDINE:** May decrease metabolism of benzodiazepines
- **CNS DEPRESSANT DRUGS (barbiturates, narcotics, anesthetics, etc.):** If diazepam administered with other CNS depressant agents additive effects may occur
- **DEXAMETHASONE:** May decrease diazepam levels
- **DIGOXIN:** Diazepam may increase digoxin levels
- **ERYTHROMYCIN:** May decrease the metabolism of benzodiazepines
- **MINERAL OIL:** May decrease oral diazepam absorption
- **OMEPRAZOLE:** May inhibit the metabolism of diazepam and increase levels
- **PHENOBARBITAL:** May decrease diazepam concentrations
- **PHENYTOIN:** May decrease diazepam concentrations
- **QUINIDINE:** May increase diazepam levels

■**RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines

## Laboratory Considerations

■ Patients receiving diazepam, may show false negative **urine glucose** results if using *Diastix*® or *Clinistix*® tests.

## Doses

### ■**DOGS:**

For treatment of seizures:

- For cluster seizures or status epilepticus (for client treatment at home): 0.5 mg/kg rectally; if on phenobarbital, use diazepam at 2 mg/kg (using diazepam parenteral solution) per rectum. Administer at the onset of seizure and up to 3 times in a 24-hour period, but should not be given within 10 minutes of the prior dose. Owners should stay with dog for one hour after administration. (Podell 2000), (Podell 2006), (Podell 2009)
- For cluster seizures (for client treatment at home): 1 mg/kg administered rectally at the onset of seizures; can be given up to 3 times over a 24 hour period. Dogs receiving phenobarbital should receive 2 mg/kg. Because diazepam is inactivated by light and adheres to plastic, it is best to dispense the drug in the original glass vial and instruct the owner to draw the required amount into a syringe when needed. A rubber catheter or teat cannula is then placed on the syringe for rectal administration. (Munana 2010)
- For refractory status epilepticus using constant rate IV infusion: 0.1–0.5 mg/kg diluted in D5W. Rate administered per hour should be equal to the maintenance fluid requirement for the patient. Use with caution as diazepam can crystallize in solution and adsorb to PVC tubing. For status or cluster seizure treatment at home: 0.5–2 mg/kg per rectum (Platt & McDonnell 2000)
- For status epilepticus: Rule out hypoglycemia, electrolyte abnormalities as primary cause. Stop seizure with diazepam or midazolam 0.5–1 mg/kg IV, 1–2 mg/kg rectally or IV if patient on phenobarbital. Place IV catheter and initiate active cooling if necessary. If another seizure occurs, repeat IV diazepam or midazolam. Administer a long-acting anticonvulsant (*e.g.*, phenobarbital at 5–8 mg/kg IV every 4–6h until seizures are under control regardless of additional therapy). If patient still has seizure activity, consider one or more of the following: **1)** continuous rate infusion of diazepam or midazolam, **2)** propofol or other means of anesthesia. (Knipe 2006), (Knipe 2009)
- For status epilepticus: 0.5 mg/kg IV, intranasally or rectally. Dose may be repeated twice, if necessary. Anticonvulsant activity lasts only 15–30 minutes so a longer acting therapy is required if seizures stop. For at home therapy for cluster seizures, diazepam may be given rectally or intranasally at 0.5 mg/kg. Dogs who are on chronic phenobarbital therapy, may require higher doses (1–2 mg/kg). (Mariani 2010b)

Functional urethral obstruction/urethral sphincter hypertonus:

- 2–10 mg q8h (Polzin and Osborne 1985); (Lane 2000)
- 2–10 mg PO three times a day; 0.5 mg/kg IV (Chew *et al.* 1986)
- 0.2 mg/kg PO q8h or 2–10 mg (total dose) PO q8h (Bartges 2003)

As a psychotherapeutic agent (*e.g.*, situational anxiety):

- 0.55–2.2 mg/kg PO q8–12h (Haug 2008)
- 0.5–2.2 mg/kg prn for storms (Sherman & Mills 2008)
- As a fast-acting anxiolytic: 0.5–2 mg/kg PO prn (Neilson 2009)

For adjunctive treatment of metronidazole toxicity (CNS):

- Doses of diazepam averaged 0.43 mg/kg in the study and were given as an IV bolus once, and then PO q8h for 3 days. (Evans *et al.* 2002)

### ■**CATS:**

As a psychotherapeutic agent:

- Urine marking and anxiety: 0.2–0.4 mg/kg PO q12–24h (start at 0.2 mg/kg PO q12h) (Overall 2000)
- For spraying: 1–2.5 mg per cat PO q8–12h; sedation and ataxia should abate within several days (Reisner & Houpt 2000)
- As a fast-acting anxiolytic: 0.2–0.5 mg/kg PO prn (Neilson 2009)

For treatment of seizure disorders:

- 0.25–0.5 mg/kg PO q8–12h. To halt an ongoing seizure, diazepam may be administered at 0.5–1 mg/kg IV. If cat has a history of receiving insulin, glucose may be more beneficial. Do not use if cat has been exposed to chlorpyrifos as organophosphate toxicity may be potentiated. (Shell 2000)
- For maintenance therapy: 0.2–1 mg/kg PO q12h. Use with caution; associated with fatal hepatic necrosis. Phenobarbital is preferred as a maintenance drug in cats. (Mariani 2010a)

Functional urethral obstruction/urethral sphincter hypertonus:

- 1–2.5 mg (total dose) PO q8h (Osborne *et al.* 2000)
- 2.5–5 mg (total dose) PO q8h or as needed, or 0.5 mg/kg IV (Bartges 2003)

### ■**FERRETS:**

For premedication/sedation:

- 1–2 mg/kg IM; may be given with ketamine (10–20 mg/kg) (Morrisey & Carpenter 2004)
- For sedation anesthesia: 0.5 mg/kg IM or IV (IV preferred); 0.2 mg/kg if using with ketamine (2–5 mg/kg) (Kaiser-Klingler 2009)

### ■**RABBITS/RODENTS/SMALL MAMMALS:**

- Rabbits:** Pre-anesthetic: 2–10 mg/kg IM; 1–5 mg/kg IM or IV. Give IV to effect for seizures. (Ivey & Morrisey 2000)
- Rabbits:** For sedation: 0.5–2 mg/kg IV or IM (IV preferred).

For anesthesia: Diazepam 0.5–1 mg/kg with ketamine (20–35 mg/kg) IM or IV.

**Hedgehogs:** For long anesthesia: Diazepam at 0.5–2 mg/kg with ketamine at 5–20 mg/kg IM (Kaiser-Klingler 2009)

c) **Hamsters, Gerbils, Mice, Rats:** 3–5 mg/kg IM.

**Guinea pigs:** 0.5–3 mg/kg IM (Adamcak & Otten 2000)

#### ■ **CATTLE:**

a) Sedative in calves: 0.4 mg/kg IV (Booth 1988)

b) As a tranquilizer: 0.55–1.1 mg/kg IM (Lumb & Jones 1984)

c) Treatment of CNS hyperactivity and seizures: 0.5–1.5 mg/kg IM or IV (Bailey 1986)

#### ■ **HORSES: (Note: ARCI UCGFS Class 2 Drug)**

For field anesthesia:

a) Sedate with xylazine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures).

If adequate sedation does not occur, either **1)** Redose xylazine: up to half the original dose; **2)** Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (*e.g.*, high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes; **3)** Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes; **4)** Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)

For seizures:

a) **Foals:** 0.05–0.4 mg/kg IV; repeat in 30 minutes if necessary

b) **Adults:** 25–50 mg IV; repeat in 30 minutes if necessary (Sweeney & Hansen 1987)

Treatment of seizures secondary to intra-arterial injection of xylazine or other similar agents:

a) 0.10–0.15 mg/kg IV (Thurmon & Benson 1987)

As an appetite stimulant:

a) 0.02 mg/kg IV; immediately after dosing, offer animal food. Keep loud noises and distractions to a minimum. If effective, usually only 2–3 treatments in a 24–48 hour period are required. (Ralston 1987)

#### ■ **SWINE:**

For tranquilization:

a) 5.5 mg/kg IM (will develop posterior ataxia in 5 minutes and then recumbency within 10 minutes) (Booth 1988)

b) 0.55–1.1 mg/kg IM (Lumb & Jones 1984)

c) For sedation prior to pentobarbital anesthesia: 8.5 mg/kg IM (maximized at 30 minutes; reduces pentobarbital dose by 50%) (Booth 1988)

For treatment of CNS hyperactivity and seizures:

a) 0.5–1.5 mg/kg IM or IV (Howard 1986)

#### ■ **SHEEP:**

As a tranquilizer:

a) 0.55–1.1 mg/kg IM (Lumb & Jones 1984)

#### ■ **GOATS:**

For Bermuda grass induced toxicosis and tremors:

a) 0.8 mg/kg IV (Booth 1988)

To stimulate appetite:

a) 0.04 mg/kg IV; offer food immediately, duration of effect may last up to 45 minutes (Booth 1988)

#### ■ **BIRDS:**

a) For adjunctive therapy of pain control (with analgesics): 0.5–2 mg/kg IV or IM (Clyde & Paul-Murphy 2000)

b) For sedation/induction: 0.5–2 mg/kg IV or IM. Doses apply to pet birds to the medium parrots. Adjustments would need to be made for large parrots or wild species such as raptors. (Kaiser-Klingler 2009)

#### ■ **ZOO, EXOTIC, WILDLIFE SPECIES:**

For use of diazepam in zoo, exotic and wildlife medicine refer to specific references, including:

a) *Zoo Animal and Wildlife Immobilization and Anesthesia*. West, G, Heard, D, Caulkett, N. (eds.). Blackwell Publishing, 2007.

b) *Handbook of Wildlife Chemical Immobilization, 3rd Ed.* Kreeger, T.J. and J.M. Arnemo. 2007.

c) *Restraint and Handling of Wild and Domestic Animals*. Fowler, M (ed.), Iowa State University Press, 1995

d) *Exotic Animal Formulary, 3rd Ed.* Carpenter, J.W., Saunders. 2005

e) The 2009 American Association of Zoo Veterinarian Proceedings by D. K. Fontenot also has several dosages listed for restraint, anesthesia, and analgesia for a variety of drugs for carnivores and primates. VIN members can access them at: <http://goo.gl/BHRih> or <http://goo.gl/9UJse>

#### **Monitoring**

■ Horses should be observed carefully after receiving this drug.

■ Cats receiving diazepam should have baseline liver function tests. Repeat and discontinue drug if emesis, lethargy, inappetence, or ataxia develop. When used for seizure control in cats, one author (Quesnel 2000) recommends obtaining serum level 5 days after beginning therapy. Therapeutic serum concentration goals for seizure control in cats ranges from 2500–700 nmol/L. (200–700 ng/mL). depending on the source.

## Client Information

- Keep out of reach of children and in tightly closed containers
- Cats: If patient develops lack of appetite, vomits, or yellowish whites of eyes contact veterinarian immediately

## Chemistry/Synonyms

A benzodiazepine, diazepam is a white to yellow, practically odorless crystalline powder with a melting point between 131°–135°C and pKa of 3.4. Diazepam is tasteless initially, but develops a bitter after-taste. One g is soluble in 333 mL of water, 25 mL of alcohol, and it is sparingly soluble in propylene glycol. The pH of the commercially prepared injectable solution is adjusted with benzoic acid/sodium benzoate to 6.2–6.9. It consists of a 5 mg/mL solution with 40% propylene glycol, 10% ethanol, 5% sodium benzoate/benzoic acid buffer, and 1.5% benzyl alcohol as a preservative.

Diazepam may also be known as: diazepamum, LA-III, NSC-77518, or Ro-5-2807; many trade names are available.

## Storage/Stability

All diazepam products should be stored at room temperature (15°–30°C). The injection should be kept from freezing and protected from light. The oral dosage forms (tablets/capsules) should be stored in tight containers and protected from light.

Because diazepam may adsorb to plastic, it should not be stored drawn up into plastic syringes. The drug may also significantly adsorb to IV solution plastic (PVC) bags and to the infusion tubing. This adsorption appears to be dependent on several factors (temperature, concentration, flow rates, line length, etc.).

## Compatibility/Compounding Considerations

The manufacturers of injectable diazepam do not recommend the drug be mixed with any other medication or IV diluent and diluting for infusion cannot be recommended. However, some studies have shown that dilution in some IV solutions at low concentrations do not exhibit visible precipitates; but microcrystal formation could not be ruled out

Mixing ketamine with diazepam in the same syringe or IV bag is not recommended as precipitation may occur. Although there are many anecdotal reports of mixing ketamine with diazepam in the same syringe just prior to injection there does not appear to be any published information documenting the stability of the drugs after mixing. Do not use if a visible precipitate forms.

## Dosage Forms/Regulatory Status

**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

## HUMAN-LABELED PRODUCTS:

Diazepam Oral Tablets: 2 mg, 5 mg, & 10 mg; *Valium*® (Roche); generic; (Rx, C-IV)

Diazepam Oral Solution: 1 mg/mL in 500 mL, and 5 mg & 10 mg patient cups; generic (Roxane); (Rx, C-IV); Concentrated oral solution: 5 mg/mL in 30 mL with dropper; *Diazepam Intensol*® (Roxane); (Rx, C-IV)

Diazepam Injection: 5 mg/mL in 2 mL *Carpject* cartridges; generic; (Rx, C-IV)

Diazepam Rectal Gel: 2.5 mg, 10 mg, & 20 mg; *Diastat*® (Xcel); (Rx, C-IV)

## DIAZOXIDE, ORAL

(di-az-ok-side) Proglycem®, Hyperstat IV®

DIRECT VASODILATOR/HYPERGLYCEMIC

## Prescriber Highlights

- Orally administered drug used to treat insulinomas in small animals
- Contraindications/Cautions: Functional hypoglycemia or hypoglycemia secondary to insulin overdosage (diabetics); hypersensitive to thiazide diuretics; CHF or renal disease

• Adverse Effects: Most likely are anorexia, vomiting, &/or diarrhea (may be reduced by giving with food). Less likely tachycardia, hematology

**Adverse Effects:** Most likely are anorexia, vomiting &/or diarrhea (may be reduced by giving with food). Less likely: tachycardia, hematologic abnormalities, diabetes mellitus, cataracts, & sodium & water retention. Adverse effects are more likely in dogs with hepatic disease.

---

## Uses/Indications

Oral diazoxide has been used in canine and ferret medicine for the treatment of hypoglycemia secondary to hyperinsulin secretion (*e.g.*, insulinoma). Insulinomas are apparently very rare in the cat; there is little experience with this drug in that species.

## Pharmacology/Actions

Although related structurally to the thiazide diuretics, diazoxide does not possess any appreciable diuretic activity. By directly causing a vasodilatory effect on the smooth muscle in peripheral arterioles, diazoxide reduces peripheral resistance and blood pressure. To treat malignant hypertension, intravenous diazoxide is generally required for maximal response.

Diazoxide exhibits hyperglycemic activity by directly inhibiting pancreatic insulin secretion. This action may be a result of the drug's capability to decrease the intracellular release of ionized calcium, thereby preventing the release of insulin from the insulin granules. Diazoxide does not apparently affect the synthesis of insulin, nor does it possess any antineoplastic activity. Diazoxide also enhances hyperglycemia by stimulating the beta-adrenergic system thereby stimulating epinephrine release and inhibiting the uptake of glucose by cells.

## Pharmacokinetics
